The light blue bars represent 20 GW, 5 GW, and 33 GW of peak demand savings that result from the assumed improvements in building envelopes (i.e., reduced heating loads), the conversion of 75% of homes heated with electric resistance to heat pumps, and the assumed improvement in heat pump performance, respectively. These savings are concentrated in warmer provinces, as the peak day temperatures in colder provinces continue to force dependence on back-up resistance heating in 2050, despite the rapid technology improvement.

Scenario 4 on the right includes **heat pumps with natural gas backup heating**. On the coldest days of the year, when heat pumps operate less efficiently, all of the heating load will be met by natural gas (or other fossil fuels).

In provinces with high portions of existing electric space heating (Quebec and New Brunswick) the coldest day of the year remains the peak day, and the new heat pumps do not add to electric peak demand.

In the other provinces, the broad adoption of heat pumps that are assumed to operate until the temperature drops below -10°C, results in the peak electric day becoming that -10°C day, instead of the coldest day of the year. Benefits of this approach include increased heat pump efficiency at this more moderate peak temperature (reduced peak load) and better utilization of the capacity, since there will be numerous winter days around the -10°C level, as opposed to very few -40°C days.

7
POWER GENERATION REQUIRED FOR NEW LOADS

In **scenarios 1-3**, where electricity is the only heating fuel customers use, meeting peak period demand will require significant investments in new generation, transmission, and distribution infrastructure to serve the additional space heating load. Due to the nature of the demand this infrastructure would be essential for reliability purposes but would be called on to deliver energy only on a rare basis, driving up the cost of energy considerably.

Figure 9 shows the expansion of generating capacity required in each scenario to meet new peak load – growing from 141 GW of generating capacity to between 278 GW and 422 GW over the thirty year period. For comparison, the Site C hydro-electric dam in British Columbia is rated at 1.1 GW, hence this level of growth in peak load would require the equivalent of between 125 and 255 additional Site C projects, as well as the additional transmission and distribution system expansions needed to deliver the power to end-users.

In addition to the peak load levels, the amount of new capacity shown here depends on the types of power generation deployed to meet demand in the scenario. In **scenario 1**, which requires all fossil fuel to be retired by 2050, more capacity is required to ensure reliability – since the intermittent nature of renewable wind and solar generation limits their capacity and availability without significant investment in battery storage and system control. **Scenario 3** requires less capacity – because, in this scenario, natural gas generation can be relied upon during peak periods – but will produce more GHG emissions. **Scenario 4** requires less capacity growth because the peak load served here has been greatly reduced by allowing for natural gas/fossil fuels to remain as back-up in customer space heating, and natural gas fired generation is available to meet peak load reliability requirements – but this scenario also relies on significant amounts of renewable capacity to ensure the scenario achieves significant GHG reductions.

***Figure 9:** Growth in Total Electric Power Generation Capacity*

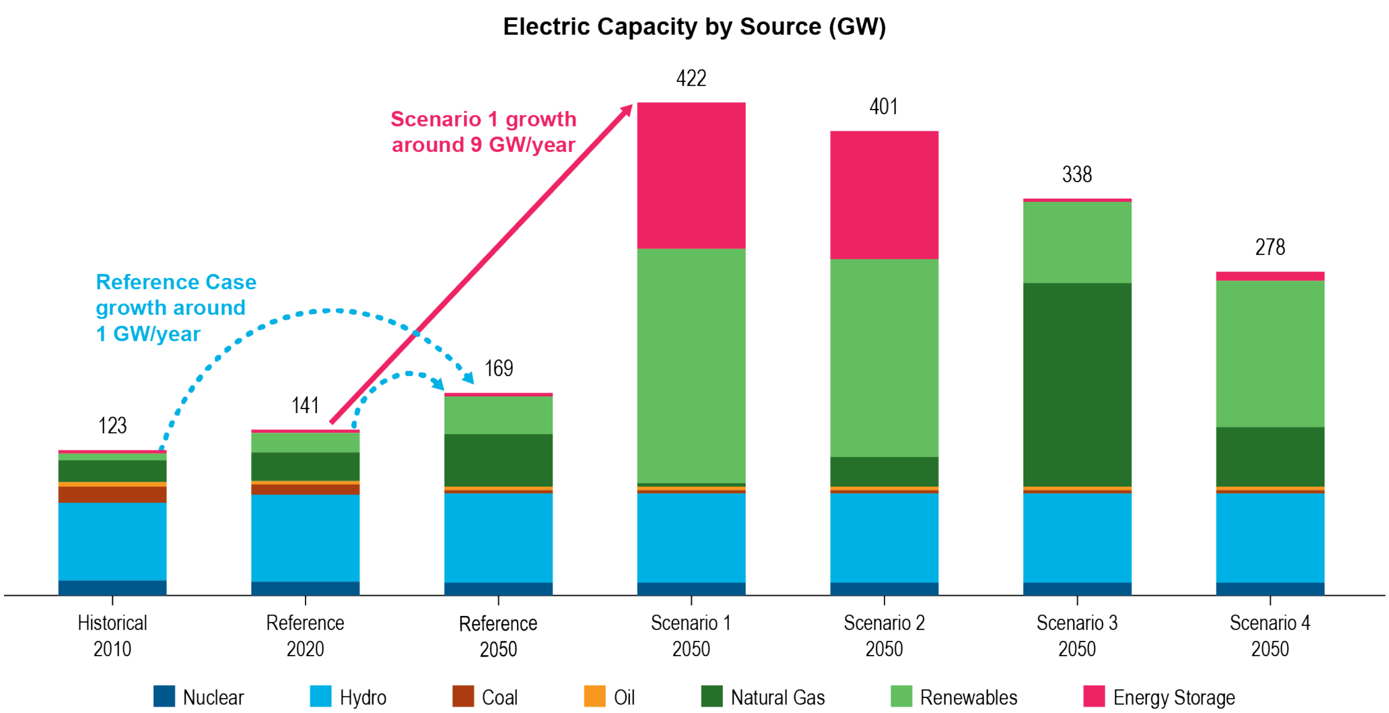

Figure 10 provides more detail on the expansion of generation capacity out to 2050 required in each scenario. In all scenarios, there are 10 GW of retirements for coal and oil units, and a net 1.4 GW of retirements for nuclear between 2020 and 2050.[8] Beyond these common changes, the additions and retirements of natural gas generation, renewables, and battery storage differ between the reference case and each of the scenarios.

***Figure 10:** Changes in Generation Capacity from 2020 to 2050 by Resource Type*

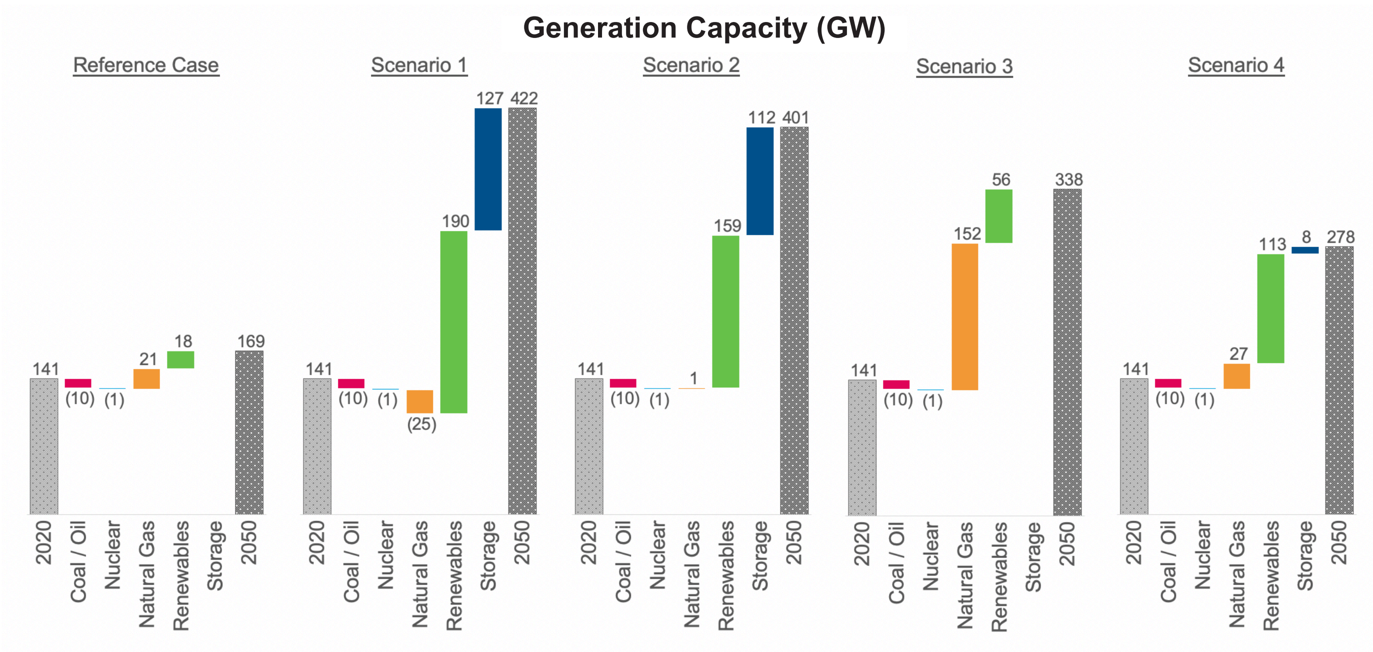

Figure 11 shows the changes in annual electricity generation for 2050 between the scenarios – indicating how the generation capacity shown above is used. All scenarios use essentially the same amount of baseload nuclear and hydro. The primary difference between how scenarios generate the required energy demand comes down to how much they use renewable (wind and solar) versus natural gas generation. It is noteworthy that **scenario 4** builds significant amounts of natural gas generation capacity, but uses this capacity infrequently in order to stay under an emissions cap. Most of this scenario's natural gas is built to be used only during peak periods, minimizing the need for battery capacity to complement intermittent renewables.

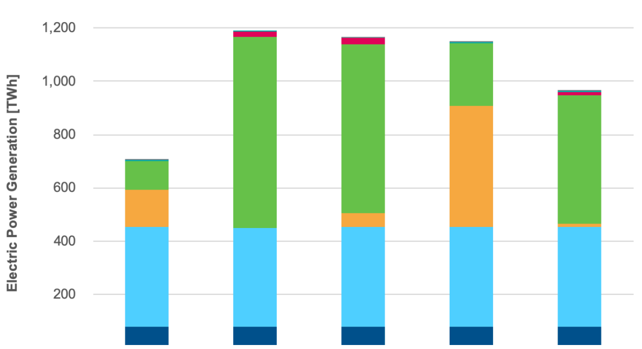
***Figure 11:** Total Electric Power Generation (TWh) in 2050 by Resource Type*



-	Reference Case	Scenario 1	Scenario 2	Scenario 3	Scenario 4
Coal	1	-	1	1	1
Other	3	3	3	3	3
Storage	0	22	23	-	10
Renewables	107	715	633	235	484
Natural Gas	140	-	52	454	12
Hydro	375	374	375	375	375
Nuclear	77	77	78	78	78

[8]The modeled 2020 capacity is lower than the total installed capacity, as it excludes about 1.5 GW of nuclear units that are undergoing planned refurbishment. From a total capacity perspective (operating and under refurbishment), about 3 GW of nuclear units are retired between 2020 and 2050.

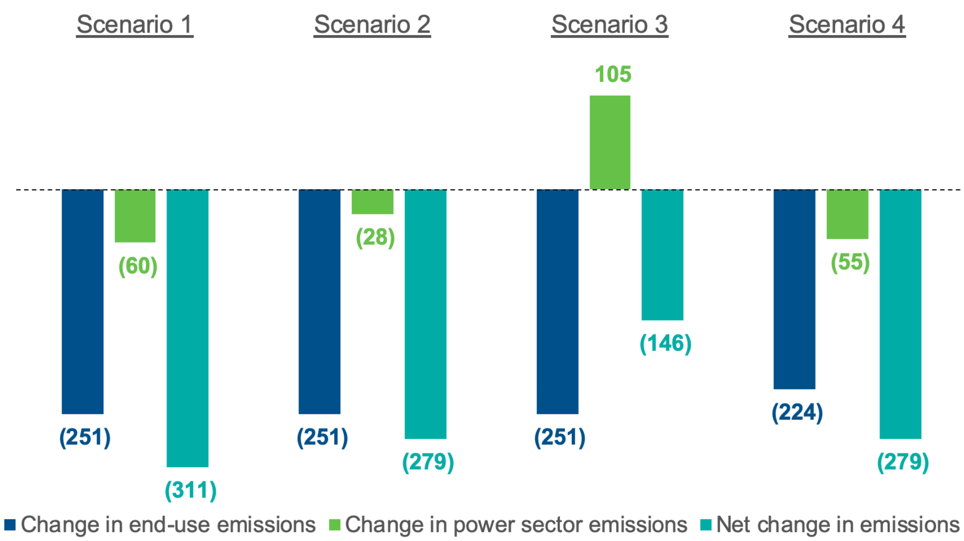
8
GHG EMISSION IMPACTS

Figure 12 illustrates the 2050 emissions associated with each scenario, relative to the reference case. The figure shows the annual emissions impact of:

1. The change in end-use (residential, commercial, industrial, transportation) CO_2 emissions[9],
2. The change in power sector CO_2 emissions, and
3. The net change in emissions.

All the scenarios see major reductions in end-use emissions through widespread electrification. **Scenario 1** (all renewables) achieves the greatest overall emissions reduction, with power sector emissions decreasing to zero. **Scenario 3** (market-based) achieves the smallest emissions reduction, as there are no limits on natural gas generation and this option is selected as the least-cost approach to meet much of the increased electrical demand. By design, **scenario 2** and **scenario 4** achieve the same net emission reductions, with **scenario 4's** power sector emissions capped to achieve the same level.[10]

Figure 12: 2050 Scenario Emissions Relative to the Reference Case (million metric tonnes of CO_2 / year)



9
TOTAL COSTS FOR ELECTRIFICATION SCENARIOS

The cost of this expansion of the power sector, as well as other aspects of the policy scenarios, are illustrated in **Figure 13**. The cumulative cost impacts from 2020 to 2050 in these scenarios range from $580 billion to $1.37 trillion, and are incremental to any energy cost increases resulting from the reference case growth. The cost categories included in the analysis are explained below, with more details available in **Appendix D**.

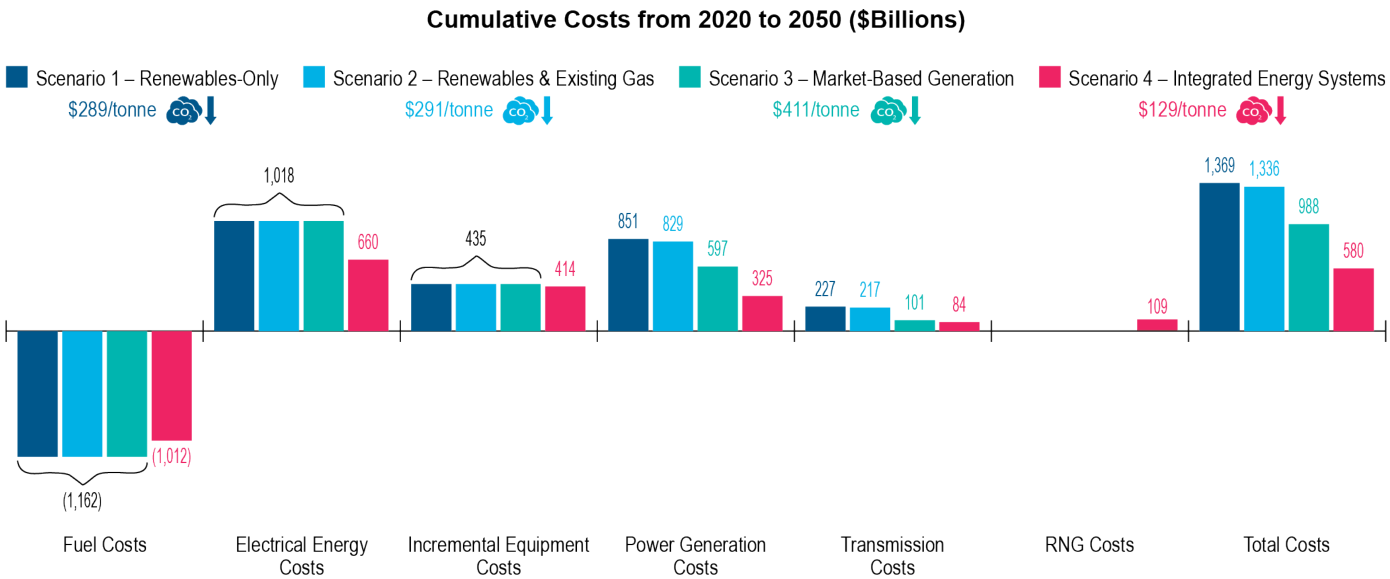
- Avoided **fuel costs** represents the monies not spent by energy consumers on the natural gas and refined petroleum products they are no longer assumed to be using. The energy prices used are those set out in the reference case forecast – the savings shown here include the avoided expenditures from passenger vehicles not needing gasoline or diesel, and fuel oil and natural gas replaced for space heating, water heating, and industrial processes.

[9] End-use emissions do not include any GHGs from electricity consumption, as the CO_2 emissions from electricity production are captured within the power sector emissions.

[10] Before accounting for CO_2 emissions from electricity generation, scenario 4 resulted in 27 million metric tonnes of CO_2 emissions more than scenario 2, from demand-side changes to energy consumption. To match scenario 2's overall emissions, scenario 4 power generation emissions were thus capped at a level 27 million metric tonnes of CO_2 below scenario 2 power generation emissions.

- Incremental **electrical energy costs** represent the increase in costs to energy consumers based on the increase in electricity consumption and based on the energy price levels set out in the reference case forecast. The cost increases shown here are the aggregate for residential, commercial, industrial, and transportation customers.
- Incremental **equipment upgrade costs** represent the additional upfront investment residential, commercial, transportation, and industrial end-users would need to make to purchase and install electric equipment and invest in energy efficiency, as compared to purchasing the traditional fossil fuel option.
- Incremental **power generation costs** (additional to the electrical energy costs) represent over half the overall cost impact in each scenario, and include the capital, fuel, operating, and maintenance costs necessary to deploy the additional electricity generation capacity and any required battery storage.
- Incremental **transmission costs** represent the wires required to connect electricity from new generating capacity to the customers that need this power, and are estimated as a ratio to incremental generation capital costs.
- **Renewable natural gas costs** represent the assumed incremental cost to supply the gas distribution system with RNG in **scenario 4**.
- **Total costs** represent the combined incremental energy cost changes that the Canadian economy will need to cover between 2020 and 2050, above and beyond 'business as usual' reference case energy costs.

Figure 13: *Cumulative Incremental Costs from 2020 to 2050*



The costs shown here are incremental to the reference case, so these would be in addition to any energy cost increases expected under 'business as usual'. The study also does not include the unique distribution system level investment required to enhance infrastructure to deliver incremental power load.

Even with optimistic 'cost-conservative' assumptions in terms of energy efficiency and electric technology improvement, the costs in these aggressive electrification scenarios are substantial. The integrated energy approach, using both natural gas and electricity, represents a significantly lower cost pathway. This emphasizes the need to be selective about which electrification opportunities are pursued and consider a broad range of technology options in pursuit of GHG emission reductions.

10 SUMMARY & CONCLUSIONS

The overall impacts of the policy-driven scenarios across the provinces considered in this study are highlighted in **Table 3**, which presents cumulative total impacts between 2020 and 2050, except where otherwise specified.

Table 3: *Summary of Overall Impacts of Electrification*

	Scenario 1	Scenario 2	Scenario 3	Scenario 4
Power Sector Impacts	252 GW of incremental generation capacity required at a cost of \$851 billion \$227 billion of associated transmission system upgrades	232 GW of incremental generation capacity required at a cost of \$829 billion \$217 billion of associated transmission system upgrades	169 GW of incremental generation capacity required at a cost of \$597 billion \$101 billion of associated transmission system upgrades	108 GW of incremental generation capacity required at a cost of \$325 billion \$84 billion of associated transmission system pgrades
Equipment and Energy Costs	16 million households, 23 million passenger vehicles, 25% of medium & heavy duty vehicles, 11 billion square feet of commercial space, and 50% of industrial fossil energy are converted to electric equipment \$291 billion in net energy & equipment costs over the 30-year period			Similar scope, with different equipment, only 25% industrial, and 10-15% RNG \$170 billion in net energy, equipment, and RNG costs
Total Cost of Policy-Driven Electrification	Total energy costs increase by \$1.37 trillion \$95,000 average per Canadian household[11] \$3,200 per year per Canadian household increase in energy costs	Total energy costs increase by \$1.33 trillion \$93,000 average per Canadian household[11] \$3,100 per year per Canadian household increase in energy costs	Total energy costs increase by \$988 billion \$69,000 average per Canadian household[11] \$2,300 per year per Canadian household increase in energy costs	Total energy costs increase by \$580 billion \$40,000 average per Canadian household[11] \$1,300 per year per Canadian household increase in energy costs
GHG Emission Impacts	Annual GHG emissions reduced by 311 million tonnes of CO_2 by 2050 compared to 2050 reference (52 percent)	Annual GHG emissions reduced by 279 million tonnes of CO_2 by 2050 compared to 2050 reference (47 percent)	Annual GHG emissions reduced by 146 million tonnes of CO_2 by 2050 compared to 2050 reference (25 percent)	Annual GHG emissions reduced by 279 million tonnes of CO_2 by 2050 compared to 2050 reference (47 percent)
Cost of Emissions Reductions	\$289 per tonne of CO_2 reduction (\$331 discounted[12])	\$291 per tonne of CO_2 reduction (\$334 discounted[12])	\$411 per tonne of CO_2 reduction (\$483 discounted[12])	\$129 per tonne of CO_2 reduction (\$164 discounted[12])

The analysis conducted for this study highlights both the role electrification can play in reducing GHG emissions and the need to be selective in its application to minimize impacts on peak demand. What is clear is that widespread electrification should not be considered as a stand-alone solution. Without significant levels of energy efficiency improvement embodied in the reference case, and the additional improvements assumed in the scenarios, peak load and the associated costs of electrification would be significantly higher. Without the use of natural gas to meet peak period space heating

[11]Cumulative costs from all sectors for 2020 to 2050 divided by 14.34 million total households (using all heating types) forecast for the provinces considered in this study in 2020.

[12] Discounted costs are Real 2019 \$, with both emissions and costs from the study period discounted to 2019 using a 5 percent discount rate.

requirements and to provide peaking capacity for the power generation grid, the costs of GHG emissions reductions increase dramatically.

In the results above, policies that rely on electrification and renewable power cost more than twice as much per tonne of carbon dioxide reduced ($289 / tCO_2) than the approach which allows for an integrated energy system to achieve GHG emission reductions ($129 / tCO_2). Canada's existing natural gas and electricity distribution infrastructure are good at serving different roles and together can be optimized for a lower cost solution. Allowing natural gas to continue being used for heating on very cold days (when the efficiency of electric options drop), and allowing some natural gas in the power generation sector to continue providing peak capacity, drastically lowers the electric infrastructure requirements and costs from the scenario where natural gas is completely eliminated – while still allowing for significant (90% of **scenario 1**) GHG emission reductions to be achieved.

These scenarios rely on wind and solar generation to achieve GHG emission reductions through electrification, even in **scenario 4** where natural gas continues to be built to meet peak capacity. There are questions about whether a grid can operate reliably running entirely on renewables and the scale of renewable capacity that could be feasibly deployed. While such concerns were not factored into this assessment, it stands that enabling renewables on the necessary scale for these scenarios will require improvements in battery storage, grid integration, smart appliances, and electric vehicle charging infrastructure.

In terms of system optimization, while it was not studied here, advanced control strategies for hybrid gas-electric heat pumps could allow even cheaper integration of renewables – a smart control system would be able to switch more hybrid heat pumps to electric-mode if renewables (e.g. wind turbines) are producing excess energy, or shift more heating load to natural gas if renewables are producing less than required on a given day, reducing the amount of battery storage required to accommodate intermittent renewables.

The widespread level of electrification studied here would not only require expansion of electric generation and transmission capacity, but also significant investments in local electricity distribution system upgrades, costs which are not assessed in this study. Such costs are very region-specific, but the transformation of widespread electrification considered here would likely require significant distribution infrastructure upgrades.

The costs and benefits of electrification vary considerably by province, and even by region within a province, making one-size fits all solutions ineffective and more expensive. Key regional factors that must be considered when assessing the potential costs and benefits of electrification and determining the investments in infrastructure needed to ensure a reliable, affordable, and lower emitting energy system include weather and climate, energy prices, differences in the housing stock, the amount and age of capacity in existing electric generation, transmission, and distribution infrastructure, the GHG intensity of the electric grid, and the resource potential for non-emitting generation capacity.

APPENDICES

Appendix A Scenario Details for Demand-Side Analysis

On the demand-side, this study included a detailed analysis of electrification in the residential and commercial sectors, alongside a simplified assessment of the industrial and transportation sectors. **Table 4** outlines the key assumptions used in each of the demand-side scenarios modeled in this study and is followed by a series of figures which highlight the scale of the transition assumed in the different sectors.

Table 4: Summary of Demand-Side Scenario Assumptions

<table>
<tr><th>Sector</th><th>Scenarios 1, 2, 3</th><th>Scenario 4</th></tr>
<tr><td rowspan="2">Residential & Commercial Electricity Demand</td><td>• All fossil fuel use is converted to electricity by 2050
• All new construction projects install electric equipment, starting in 2020
• Most provinces adopt CC-ASHPs, but BC uses ASHPs
• 75% of existing buildings heated with electric resistance are converted to CC-ASHPs by 2050</td><td>• All fossil fuel use for space heating is converted to hybrid systems by 2050 (ASHP with fossil fuel backup)
• All fossil fuel use for water heating is converted to electricity by 2050 (heat pump water heaters)
• Heating systems switch from an ASHP to the fossil fuel backup system when outdoor temperatures fall below -10°C. At a national level, this strategy reduces annual fossil fuel consumption is by ~80% while peak day requirements for gas remain unchanged.
• 75% of existing buildings heated with electric resistance are converted to ASHPs by 2050</td></tr>
<tr><td colspan="2">• All equipment conversions occur when existing fossil fuel equipment reaches the end of its useful life
• Energy efficiency improvements reduce average space and water heating loads (GJ/home or GJ/ft²) by 10% by 2050. This improvement is incremental to the 1.4% per year reduction in building energy use intensity assumed by the CER reference case.
• NREL's 'Rapid Advancement' curves are used to model the improvement of heat pumps over the study period (2020-2050)</td></tr>
<tr><td>Industrial Electricity Demand</td><td>• Partial electrification, with ~50% of fossil fuel energy consumption converted to electricity by 2050
• More specifically the following end uses are electrified:
    • 100% space heating
    • 100% steam boilers
    • 50% process heating
    • 0% non-energy use
    • 0% cogeneration
• Energy efficiency improvements are captured as part of the conversion to electric equipment</td><td>• Partial electrification, with ~25% of fossil fuel energy consumption converted to electricity by 2050
• More specifically the following end-uses are electrified:
    • 100% space heating
    • 50% steam boilers
    • 25% process heating
    • 0% non-energy use
    • 0% cogeneration
• Energy efficiency improvements are captured as part of the conversion to electric equipment, and a 10% energy efficiency improvement applied to fuel use that was electrified in scenarios 1-3 but not electrified in scenario 4</td></tr>
<tr><td rowspan="2">Transportation Electricity Demand</td><td colspan="2">• As per the Federal Government's target, light-duty EVs make up 10% of sales by 2025, 30% by 2030, and 100% by 2040
• Medium and heavy-duty vehicles: 25% electric by 2050
• Commuter trains and off-road vehicles: 25% electric by 2050</td></tr>
<tr><td></td><td>• An additional 25% of medium and heavy-duty vehicles, commuter trains, and off-road vehicles convert to CNG/LNG by 2050</td></tr>
<tr><td>Other Measures</td><td>• Nothing beyond CER Energy Futures 2018 Reference Case</td><td>• RNG is used to decarbonize natural gas supply. RNG as a percent of 2018 natural gas demand from the reference case:
    • QC 5% by 2025, 10% 2050
    • BC 15% by 2030, then flat
    • Other provinces all 5% by 2030, 10% by 2050</td></tr>
</table>

Figure 14 compares the types of residential heating systems used in the 'business as usual' reference case to the transition modeled in the electrification scenarios. The type of heat pumps used will vary between electrification scenarios, but the expanding light green band shows how heat pumps are assumed to replace natural gas and electric resistance heating on a massive scale – with around 15 million households converting to heat pumps by 2050 and close to complete elimination of natural gas and refined petroleum usage for residential heat.

Figure 14: Residential Sector Primary Heating Fuel Option

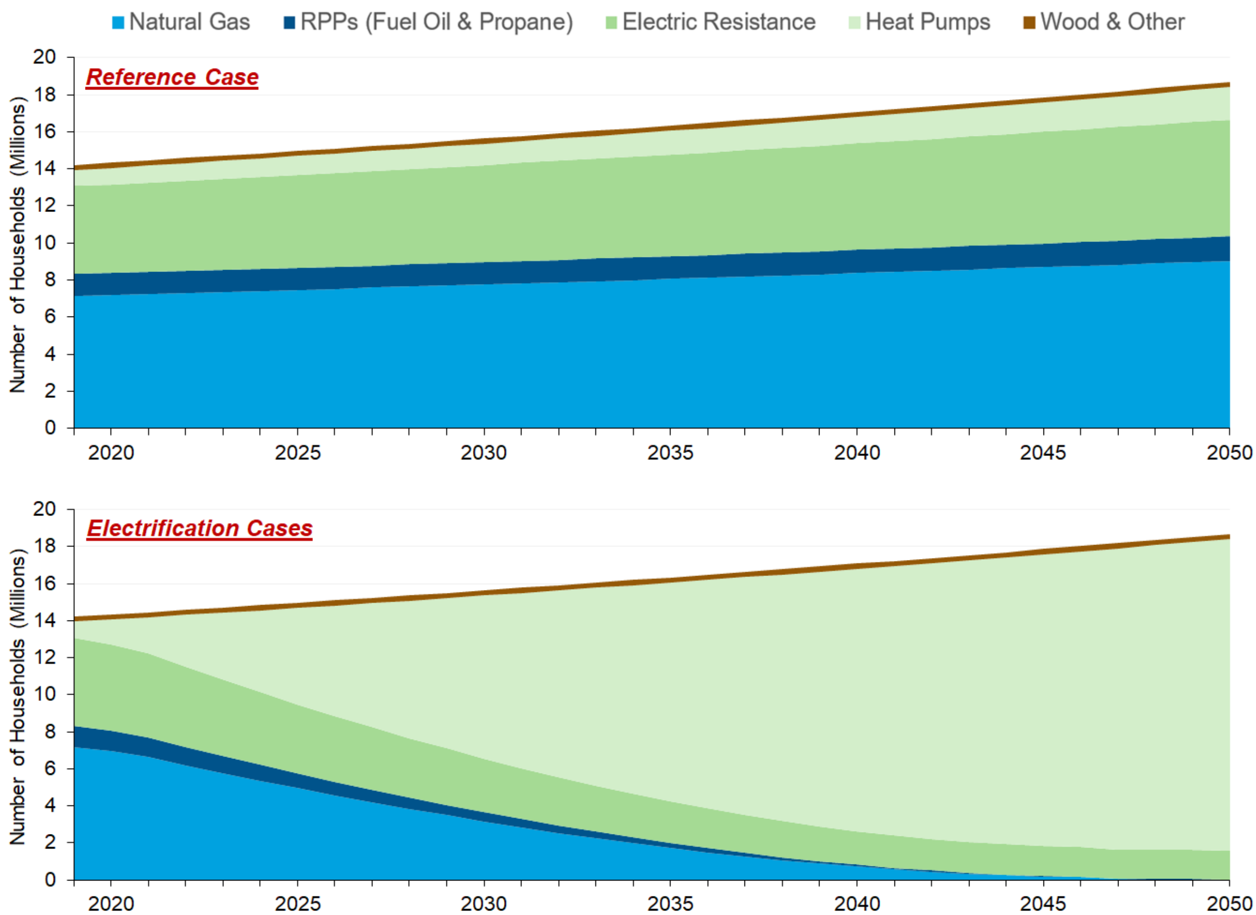


Figure 15 illustrates the result of a similar transition in the commercial sector, contrasting the breakdown in energy consumption in the 'business as usual' reference case to scenarios 1-3 (fully electric heating) and scenario 4 (hybrid gas-electric heating). These charts highlight the significant energy efficiency and technology improvements assumed in these scenarios, as growth in electric energy demand is significantly lower than the reduction in fuel consumption. For scenario 4, the natural gas segment also includes RNG volumes.

Figure 15: Commercial Sector Breakdown of Energy Consumption

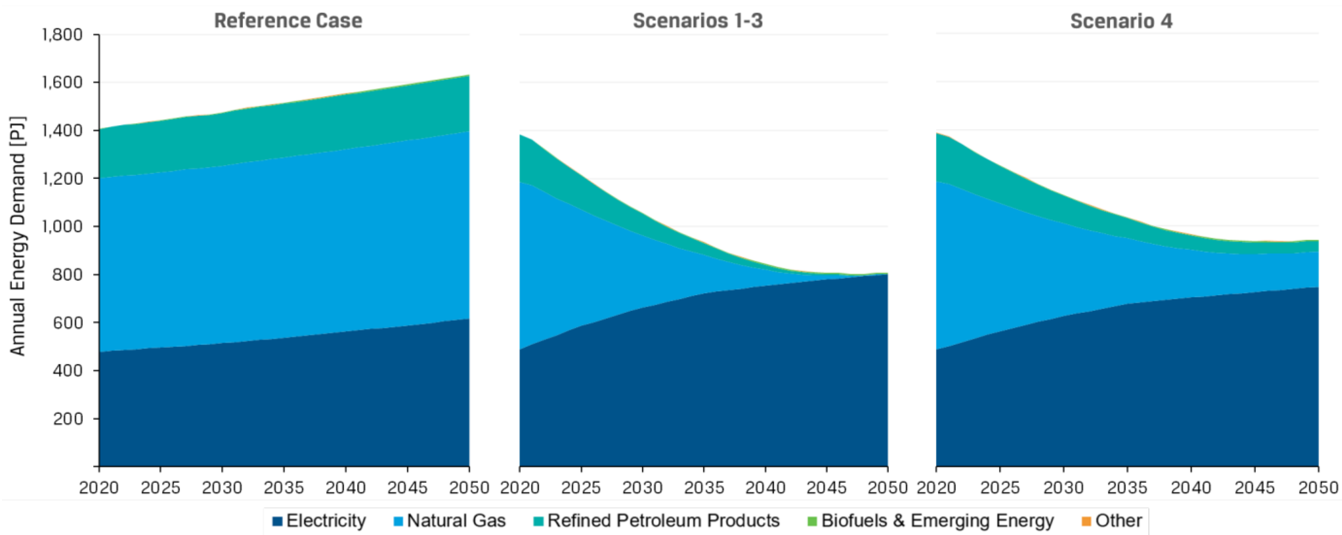

Figure 16 shows the resulting breakdown of energy consumption in the industrial sector, contrasting the 'business as usual' reference case to scenarios 1-3 (~50% electrification) and scenario 4 (~25% electrification) in the simplified analysis for this sector. These charts highlight the impact of conversion from fuels to electricity with more modest efficiency gains than the residential and commercial sectors, and hence less overall demand decline. While significant energy efficiency improvements are included along with electrification of space and process heating, there is little improvement along with the electrification of steam boilers, a major area of industrial fuel consumption. For scenario 4, the natural gas segment also includes RNG volumes.

Figure 16: Industrial Sector Breakdown of Energy Consumption

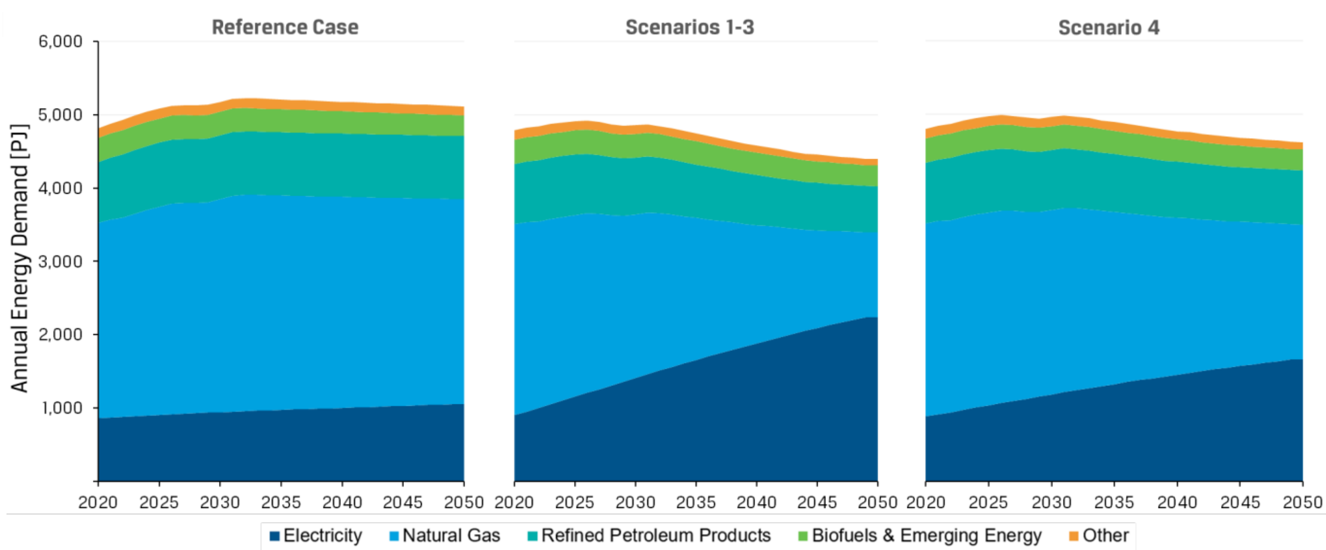

Figure 17 shows the change over in the light-duty vehicle stock from internal combustion engine vehicles to electric vehicles, with more than 20 million EVs on the road by 2050. While electrification of other transportation segments is also included (25% of medium- and heavy-duty trucks, off-road vehicles, and commuter trains), the light-duty segment represents the bulk of the electric load added from the transportation sector in this study. 80% of light-duty vehicles are assumed to be part of a 'managed charging' program – allowing utilities to shift re-charging hours overnight and minimize LDV EV contribution to peak

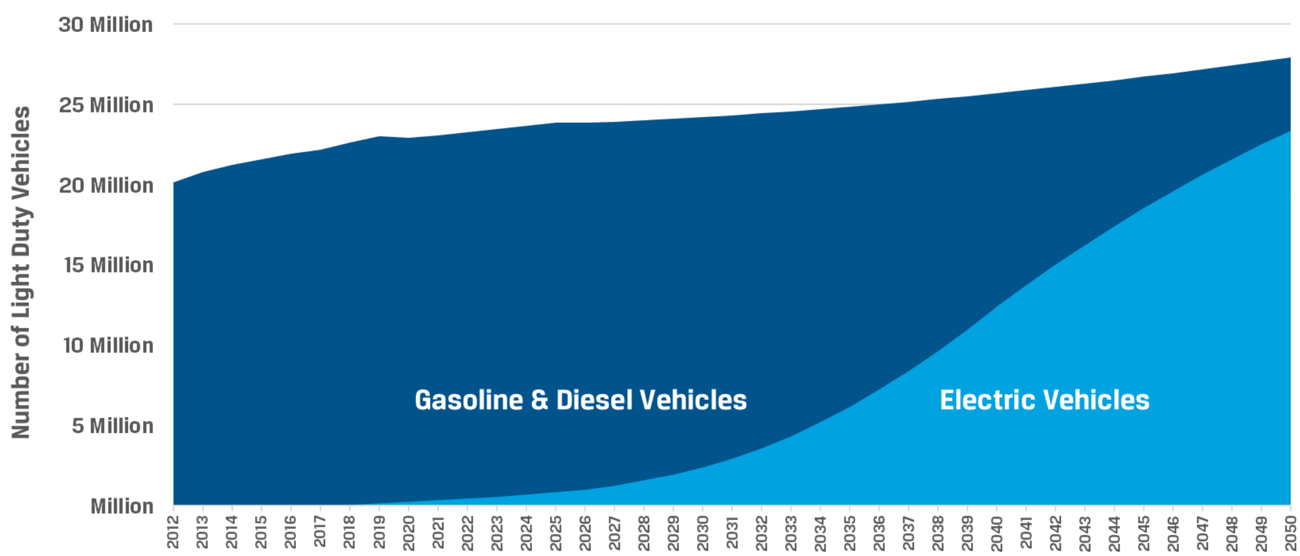
electricity load growth. A range of load shapes are used for other vehicle categories, with a more limited amount of shifting enabled, increasing the peak contributions from other transport segments.

Figure 17: Transition from Gasoline and Diesel to Electric Light Duty Vehicles



Electrification Enabling Assumptions

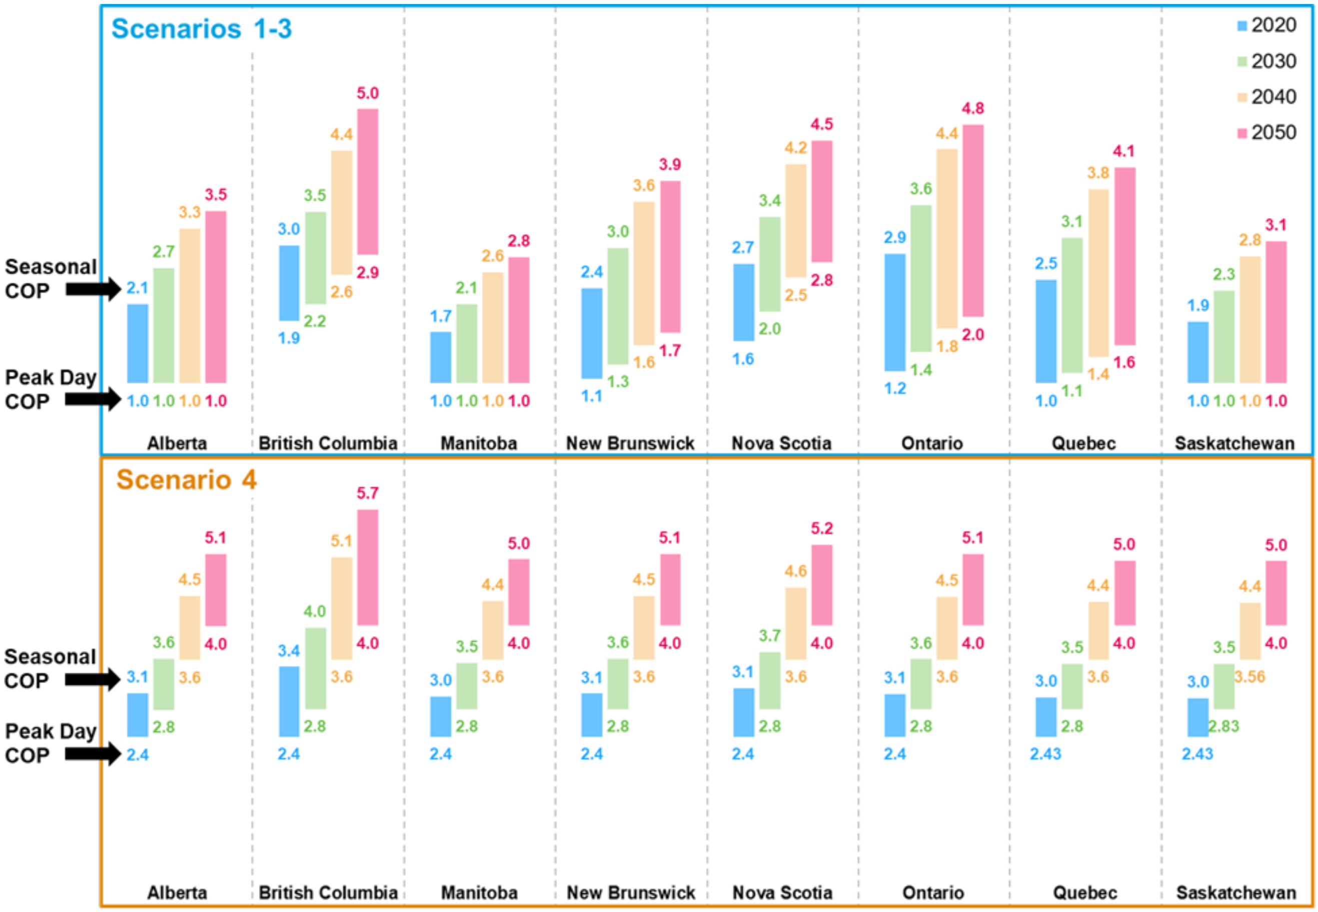
The impacts of electrification will depend on a range of factors, and the level of electric fuel switching illustrated comes with significant uncertainty as to how some of these factors will change by 2050. To enable the levels of electrification illustrated in this study, optimistic assumptions were used in a number of areas to reduce the impacts and costs of these scenarios. Three key enabling assumptions are described below:

- **Electric Technology Performance Improvement**

  For residential and commercial space heating, cold-climate air-source heat pumps were modeled to replace fossil fuel furnaces and boilers. Canadians are assumed to install these more expensive cold-climate heat pumps, despite electric heating options with lower upfront costs being available to them.

  The efficiency of these heat pumps was based on an average of several of the best performing heat pumps available today, and the efficiency was assumed to improve significantly over the 2020-2050 timeframe, as shown in **Figure 18**. The efficiency is presented in terms of the coefficient of performance (COP), which measures the ratio of heat energy delivered to the home to the electrical energy consumed by a heat pump. As an example of this improvement, in **scenarios 1-3** (in which the heat pump operates year-round) the average seasonal COP improves from 1.7 in 2020 to 2.8 in 2050 for the coldest province (MB), and from 3.0 in 2020 to 5.0 in 2050 for the mildest province (BC). Similarly, in scenario 4 (in which the heat pump does not operate below -10°C) the seasonal COP improves from 2.4 in 2020 to 5.0 in 2050 for the coldest province (MB), and from 2.4 in 2020 to 5.7 in 2050 for the mildest province (BC). These advances in performance are consistent with the 'rapid advancement' trajectory for COP improvement from NREL's 2017 Electrification Futures Study.

Figure 18: Assumed Heat Pump Improvement over Study Period



Similarly, residential and commercial water heating efficiencies are assumed to rise to COP 3 by 2050 through the adoption of heat pump water heaters, despite lower-cost electric resistance water heaters (COP 1) being significantly more common in the market today. In particular for water heating, a policy requiring electrification could instead drive adoption of the less expensive electric resistance water heaters, which would triple the load growth from water heater electrification relative to what is modelled here.

Industrial process heating electrification is also assumed to involve significant improvement in energy efficiency – improving from an average efficiency of 50% to an effective average efficiency of 200%, once accounting for improvements in productivity.

- **Reduced Energy Loads**

  Improvements in building envelopes and the adoption of hot water conservation measures were assumed to reduce space and water heating loads, respectively. As such, the model incorporated a gradual reduction of these loads, reaching a 10% reduction by 2050. These reductions in space and water heating loads were included on top of the 1.4% per year reduction in building energy use intensity assumed by the CER Energy Futures reference case. These assumed load reductions combine to significantly reduce the amount of electricity needed to electrify the residential and commercial sector, minimizing the impacts of electrification.

- **Electric Resistance Heating Conversions**

  Roughly 4.75 million homes in Canada currently rely on some form of electric resistance heating as their primary source of heating, with Quebec accounting for more than half of these homes. For a home in Quebec today, the energy requirements for electric resistance heating are two and a half times greater than that of a cold climate heat pump. By 2050, the energy requirements for electric resistance heating are expected to be more than four times greater than that of the cold climate heat pump. This study assumes that 75% of homes currently heated with electric resistance are upgraded to heat pumps by 2050. These heat pump upgrades result in a significant reduction in electricity demand, which dampens the impact of space heating electrification on electricity demand.

It is important to understand these assumptions when envisioning potential low-carbon pathways, as infrastructure and cost requirements in these scenarios would be increased if they did not materialize.

Appendix B Key Electrification Technologies

This section introduces the key electrification technologies considered in this study.

Residential & Commercial Sector

Nearly all fuel consumption in the residential and commercial sectors can be attributed to two end uses: space heating and water heating. As such, the key electrification technologies considered in this study fall into one of these two end use categories. Each space heating technology has its own costs and benefits and can offer potential synergies to minimize the disruptive impacts to consumers and other sectors. The key technologies are introduced below, followed by **Table 5**, which compares each option based on a few important factors.

The main heating systems currently being used:

Natural Gas Heating Systems: There are several types of space heating systems that combust natural gas to produce heat, with the two main types being forced air furnaces and hydronic heating systems. In a forced air furnace, the combustion of natural gas heats the air, which is then distributed throughout the house by the ventilation system. In a hydronic system, the combustion of natural gas heats water, which is then pumped throughout the building in a series of pipes, culminating in a heat delivering device such as a radiator. Natural gas-fired space heating systems have around 50% of the residential market share in Canada, and new systems are typically in the range of 92-98% efficient. Natural gas-fired water heaters are also standard, with 68% of the residential market share in Canada, and have efficiencies around 60-80%. In this study, no new natural gas systems are installed after 2020, and all existing natural gas heating systems are replaced by 2050.

Electric Resistance Systems: This type of system is currently used in the 80% of electrically heated households across Canada (4.75 million homes) and is also typically included as a back-up fuel option for heat pumps. These systems are convenient and inexpensive, can be installed in nearly all household types, and do not typically require an internal air-duct system. However these systems are the least efficient type of electric space heating system – and contribute significantly to peak electric loads. In this study, standalone electric resistance systems are replaced with heat pumps to improve efficiency. Historically, the most common electric water heating option are also electric resistance units.

The new electric heating options focused on in this study:

Conventional Air Source Heat Pumps (ASHP): This technology was chosen because it is well-developed, currently available and deployed across the country, and operates very efficiently most of the year. Some of the downsides of ASHPs are their higher installation costs for retrofits and their steep reduction in performance at low temperatures. The coefficient of performance (COP), which measures the ratio of heat energy delivered to the home to the electrical energy consumed by the ASHP, is typically between 3 and 5 when operating in mild temperatures (≥ 0°C) but quickly approaches a COP of 1 (equivalent to electric resistance heating) when outdoor temperatures fall below -10°C, as the ASHP is unable to extract sufficient heat from the cold ambient air.

Cold Climate Air Source Heat Pumps (ccASHP): ccASHPs have more recently gone from the development and testing phase to being commercially deployed in limited numbers. This technology is optimized to perform at a higher efficiency at colder temperatures, which limits the impact on electric grid requirements over the winter months. The downside of this technology is that the upfront costs are higher compared to a gas furnace and conventional ASHPs. Although ccASHPs are designed to operate more efficiently at lower temperatures, they still rely on back-up heating below certain temperatures.

Natural Gas-Electric Hybrid Heating System: This space heating system utilizes an electric ASHP paired with a natural gas furnace. The natural gas furnace provides back-up heating that supplements the electric system during colder periods, similar to how electric resistance heating currently supplements many electric heat pump systems at lower temperatures. This approach has the benefit of capturing the higher efficiency associated with ASHPs during milder temperatures, while minimizing electric grid impacts during the colder months of the year when natural gas can service as a back-up fuel.

Electric Heat Pump Water Heater (HPWH): Electric HPWH systems use similar methods as ASHPs to move heat from one medium to another, rather than generating direct heat that would be applied to water in a traditional water heater system. HPWHs are typically placed within the heated space of a home (and draw air from the heated space). There are locational concerns with HPWHs given that these units are required to be sited in areas with temperature ranges roughly between 4 to 26°C to allow for the proper functioning of these units. Because HPWHs are typically located within the heated space they have a negative impact on space heating, as the cool exhaust air is expelled into the home. As a result, HPWHs located in a heated space increase the load on any space heating device, an impact not quantified in this assessment. HPWHs are typically more expensive than a comparably sized high efficiency electric water heater.

Other high efficiency heating options not included in this study:

Ground Source Heat Pumps: Ground source heat pumps use the earth or large water bodies as a heat source and can therefore maintain better cold weather performance. However, they require drilling and placement of underground heat exchangers, which results in much higher costs and limits their applicability.

Absorption Heat Pumps: Absorption heat pumps are essentially air-source heat pumps driven not by electricity, but by a heat source such as natural gas, propane, solar-heated water, or geothermal-heated water. Because natural gas is the most common heat source for absorption heat pumps, they are also referred to as gas-fired heat pumps. These emerging systems are typically less efficient that comparable electric ASHP systems, however they are over 100% efficiency, and can both heat and cool a building.

Table 5 summarizes some of the key consideration for each technology option.

Table 5: Summary of Space Heating Technology Options

Used in this study?	Electric Heating System	Upfront Cost	Operating Cost	Impact on Electric Grid
Replaced	*Natural Gas Heating Systems*	Low	Low	None
Replaced	*Electric Resistance*	Low	High	Very High
Installed	*ASHP*	Medium	Medium	High
Installed	*CC ASHP*	Medium	Medium	Medium
Installed	*Hybrid Gas-Electric Heat Pump*	Medium	Low	Very Low
Not Included	*Ground Source Heat Pump*	Very High	Low	Low
Not Included	*Absorption Heat Pumps*	High	Low	None

Electric Heating System Performance

Electric heat pumps transfer heat from outdoors to indoors rather than transforming chemical energy to heat through combustion. While combustion-based systems can never provide more energy than they consume, i.e., be more than 100% efficient, heat pumps can transfer more energy than they consume, i.e., be more than 100% efficient. Heat pump efficiency is measured as coefficient of performance (COP) where a COP of 1 is equal to 100% efficiency. Nominal heat pump efficiency of 300% or a COP of 3 is not unusual. Having a high efficiency electric heating option can minimize the cost impacts for consumers who are typically switching from using low-cost natural gas to significantly higher cost electricity to meet their heating requirements. This high efficiency is also critical to reducing the impacts of electrification on the electricity system. However, heat pump performance degrades as the outdoor temperature drops.

Falling temperatures increase the temperature differential that must be achieved by the heat pump, and affect heat pump performance in three ways:

- The heat pump becomes less efficient.
- The heat pump provides less heat.
- The discharge air temperature of the heat pump gets lower.

At very low temperatures, heat pumps typically cannot provide adequate heat and require some form of back-up energy, typically electric resistance heating, resulting in much lower efficiency on the coldest days relative to the annual average efficiency.

The actual climate-adjusted heat pump performance must be calculated for each region to estimate the implications in that area, as there can be significantly different results for annual energy consumption and peak demand impacts based on different outdoor temperatures.

Transportation Sector

The transportation sector provides significant opportunities for electrification, including the following segments.

Passenger Vehicles: Battery powered electric vehicles (EVs) are increasingly common, and the Federal Government has a target of 100% of new passenger vehicle sales being EVs by 2040. Passenger vehicles can be an attractive electric technology because despite higher upfront costs the EV will save customers money over time (EVs are more efficient, and electricity prices are lower than gasoline prices). From a system perspective, the ability for a utility to control the timing of load, for example ensuring EVs charge at night when other electricity demands are low, could minimize or eliminate any increase to peak load from their adoption. Upgrades to local electricity distribution infrastructure would likely still be required under such a 'managed charging' scenario, and it is unlikely that utilities would be able to influence/control when all EVs charge.

Medium & Heavy Duty Vehicles: For longer range hauling trucks and buses electric options are under development, but not widely available at this time. The timing of battery re-charging for these larger vehicles will generally be less flexible and harder for utilities to manage (e.g. for many applications there will be less flexibility to wait and charge the vehicles over night), so the peak load impacts from this segment may be more significant.

Off-road Vehicles: This diverse category of vehicles can include everything from forklifts to mining haul trucks, and an increasing number of electric options are becoming available to replace fuel vehicles in different off-road segments.

Industrial Sector

In additional the same electric space-heating options outlined above, the industrial sector has electrification opportunities for electric boilers and process heating technologies.

Electric Boilers: Electric boilers can produce the steam required for various industrial applications. Heat is produced directly from electricity, typically using resistive heating elements for smaller applications up to 1-2 MW, while passing electric current directly through the water for larger applications up to 50 MW. The challenge for electric boilers typically lies in their operating costs. Since electric boilers have an efficiency of 100% efficiency (vs. 80-90% for fossil fuel boilers) there is little efficiency improvement to offset the substantial cost increase from purchasing higher-cost electricity instead of low-cost natural gas.

Process Heating Electrotechnologies: Industrial processes are very diverse, and there are a number of electric options to replace traditional fossil fuel use for process heating. These include induction heating and melting, electric infrared processing, microwave drying, ultraviolet curing, and many more examples. These processes often use a more targeted form of heating, for example transferring heat directly to a part, instead of heating the air inside an oven and then putting the part in that hot air to absorb some of the heat. In some applications this can lead to significant efficiency, product quality, and/or productivity improvements. But such overhauls can require the complete replacement of a process line, and electrotechnologies are much better for some applications than others – limiting their potential.

Appendix C Scenario Details for Power Sector Analysis

Table 6 provides an overview of the types of power generation capacity allowed in each of the scenarios to serve the growing electricity demand, and is followed by some additional context on the power generation capacity expansion modelling.

Table 6: Power Generation Scenario Descriptions

Reference Case	**Lowest cost options** *Use the most economic options to meet power generation requirements.*
Scenario 1	**All generation capacity is non-emitting** *All incremental generation requirements met using only renewables (wind & solar) generation and batteries, and all existing fossil-fuel fired generation (including natural gas) retires by 2050.*
Scenario 2	**All new generation capacity is renewables** *Maintain existing (& currently planned) fossil-fuel fired generation capacity (natural gas & oil, but coal retires), but all incremental generation capacity is required to be met with renewable (wind & solar) generation and batteries.*
Scenario 3	**Lowest cost options** *Use the most economic options to meet power generation requirements.*
Scenario 4	**Lowest cost options under a GHG emissions cap** *Capacity expansion that uses the most economic options to meet power generation requirements, while keeping overall GHG emission levels (net power & demand side emissions) for scenario 4 capped at the same level as scenario 2.*

The impact of widespread electrification on peak electric grid capacity requirements and electric infrastructure is often overlooked in studies of policy-driven electrification. This study explicitly projects the potential impact of policy-driven electrification on the power grid infrastructure requirements for generation capacity, and estimated the costs of associated transmission capacity needed to bring the power to market.

For the electric system analysis the study used IPM® to model the power grid requirements and incremental investments needed to meet electric load growth for each of the cases described in the table above. The difference between the reference case and each of the four scenarios is used to project the impact of the electrification policy on:

- New plant construction by province
- Plant retirements
- Capital expenditure on new plants
- Power plant fuel use and emissions

IPM® is a detailed economic capacity expansion and production-cost model of the power sector supported by an extensive database of every generator in the North America. It is a multi-region model that projects capacity expansion plans, unit dispatch and compliance decisions, and power and allowance prices based on power market fundamentals. IPM® explicitly considers fuel prices, power plant costs and performance characteristics, environmental constraints, and other power market fundamentals.

The Reference Case power generation capacity expansion is based on publicly announced plans for generating capacity builds and retirements, as well as legislative requirements such as Canada's phase out of coal. The remaining capacity required to meet reference case demand for electricity were selected by the model to provide the lowest-cost possible solution. The assumptions were then modified for the different scenarios to incorporate the increased electricity consumption and demand from the policy-driven electrification on a provincial and seasonal basis.

Power Model Build Assumptions

Table 7 lists the key costs used in the power modelling, based on the following sources.

- Wind, solar and energy storage cost assumptions were developed from the National Renewable Energy Laboratories Annual Technology Baseline report for 2018.
- Cost and performance assumptions for thermal technologies were based on EIA's 2019 Annual Energy Outlook

Table 7: Average Cost of New Generation Builds by Case and Capacity Type

Technologies	Vintage	Nominal $USD		
		Overnight Capital Costs ($/kW)	Fixed Operations and Maintenance Costs (FOM) ($/KW)	Variable Operations and Maintenance Costs (VOM) ($/MWh)
Combined Cycle	2020	828	10.7	2.1
	2025	918	11.9	2.4
	2030	1,019	13.2	2.6
	2035	1,130	14.7	2.9

		Overnight Capital Costs ($/kW)	Fixed Operations and Maintenance Costs (FOM) ($/KW)	Variable Operations and Maintenance Costs (VOM) ($/MWh)
	2030	1,400	7.0	1.9
	2035	1,376	5.9	1.5
	2040	1,353	4.4	0.9
	2045	1,458	4.9	1.0
	2050	1,573	5.4	1.1

Additional key points of context on the power generation analysis

- Beyond currently planned projects included in the reference case, incremental nuclear & hydro-electric power projects were not considered in this study. Wind, solar, and batteries are the focus of the 'renewables-only' case. There is significant uncertainty surrounding whether new nuclear or hydro-electric mega-projects would be feasible or politically viable going-forward, and the timelines required for their development. Such mega-projects often end up significantly over budget, making costs more difficult to predict - but decreasing wind generation prices compare favourably to meet annual energy requirements, as do battery storage costs for reserve margin contributions (to meet peak demand).

- This project is not intended to be a 'renewable integration study'. The analysis does not aim to predict the maximum amount of wind or solar generation that could realistically be built in each province, the maximum penetration of intermittent renewable generation possible while avoiding unstable grid operations, or the declining contribution to peak demand requirements from incremental intermittent renewable capacity at high levels of penetration. There is uncertainty surrounding each of those challenges, which may or may not be mitigated through technology improvements out to 2050. As such, the study's cost estimates for capacity expansion under the renewables-only conditions likely underestimate the costs of such a scenario, if even feasible.

- The power sector modeling includes a characterization of the existing transmission system and optimizes flows of energy and capacity across the existing transmission system to minimize overall system cost. Inter-provincial transmission expansion is not modeled and transmission cost estimates that are included in this study are estimated based on a simplified ratio to the capital cost of new generation capacity they are connecting. For scenarios including high levels of renewable penetration this is likely to underestimate transmission costs, as there would be a need to build wind and solar resources over a wider footprint (to reduce correlation of generation from resources clustered in the same region).

- The power modelling optimizes, under the constraints of each scenario, to minimize overall power system costs for North American – the results of which provide a more representative depiction of impacts and costs at the national level for Canada and for larger Canadian provinces. The resulting capacity expansion and cost projections do not necessarily represent the lowest cost pathway for an individual province, and the impact of this is more strongly felt in smaller provinces with the ability to import power. The model also has 'perfect foresight' in making its decisions, allowing it to achieve the lowest cost solution over the time horizon of the study, informing decisions on capacity expansion and generation based on the assumptions of what the future demand requirements and construction costs will be (e.g., the model can wait to build solar if it knows cost will drop significantly in 5 years).

Appendix D Costs Assumptions

In order to understand the economic impacts of electrification, assumptions needed to be made related to the costs of energy, equipment, new power generation, transmission expansion, and renewable natural gas. Some of the key assumptions related to these costs are outlined below.

Fuel Costs and Electrical Energy Costs

The energy rates for electricity, natural gas, refined petroleum products, diesel, and gasoline were based on forecasted prices provided in the 2018 CER Energy Futures report. These forecasts were available from 2020 to 2040 at both the provincial and sectoral levels. The forecasts were extended to 2050 by applying a linear trend.

Equipment Upgrade & Conversion Costs

In this study, equipment costs represent the total incremental costs incurred by the end user for the installation of electric options instead of a replacement fossil fuel option, at the end of the life of the existing fossil fuel equipment, when a replacement is required anyways (cost is relative to purchasing equivalent fuel-fired baseline option). In some instances, equipment upgrade costs will also include costs associated with energy efficiency improvements, costs associated with upgrading electrical hardware to accommodate the power requirements of the electric equipment, and costs for the installation of vehicle charging infrastructure. The primary incremental equipment costs are summarized in **Table 8**.

Table 8: Primary Equipment Costs[13]

	Subsector	End Use	Upgrade Description	Average Incremental Cost
Residential	Single family homes	Space Heating	Replacement of furnace/central air conditioner with an air source heat pump (at equipment end of life)	$100 per home
			Replacement of furnace/central air conditioner with a cold climate air source heat pump (at equipment end of life)	$1,050 per home
			Replacement of furnace/central air conditioner with a hybrid heating system (furnace/ASHP) (at equipment end of life)	$1,425 per home
			Installation of cold climate heat pump(s) in a home previously heated with electric resistance (early replacement / full cost)	$8,400 per home
		Water Heating	Replacement of gas water heater with heat pump water heater	$1,500 per home

[13] Average incremental costs were derived from a variety of sources. Some of the key primary sources are listed below.
Residential and Commercial: RSMeans, distributor reported retail sales prices, Heat Pump Retrofit Strategies for Multifamily Buildings (Steven Winter Associates, Inc.)
Industrial: Illustrative cost estimates based on prior consultations with industrial OEMs and the review of various electrification case studies
Transportation: Canada Energy Regulator, U.S. Energy Information Administration Annual Energy Outlook, and ICF market research database

	Subsector	End Use	Upgrade Description	Average Incremental Cost
		Electrical Upgrade	Electrical upgrade to accommodate power requirements for the conversion to a heat pump and/or HPWH[14]	$2,000 per home
	MURBs (45 units per building)	Space Heating	Replacement of a central boiler and chiller with cold climate air source heat pumps	$425,000 per building
		Water Heating	Replacement of a central boiler with central heat pump water heater plant	$175,000 per building
Commercial	Small Commercial (7,500 ft^2)	Space Heating	Replacement of gas RTU with cold climate heat pumps	$9,500 per building
		Water Heating	Replacement of gas boiler with central heat pump water heater plant	$30,000 per building
	Large Commercial (150,000 ft^2)	Space Heating	Replacement of a central boiler and chiller with cold climate air source heat pumps	$590,000 per building
		Water Heating	Replacement of a central boiler with central heat pump water heater plant	$600,000 per building
Industrial	All Industry	Space Heating	Conversion of fuel fired space heating equipment to heat pumps	$30 per GJ/year of equipment fuel consumption
		Process Heating	Conversion of fuel fired process heating applications (e.g., heat treating, brazing, drying) to electrically powered processes (average cost if converting 50% / 25%)	$60 per GJ/year / $30 per GJ/year
		Steam Boilers	Replacement of fuel fired steam boilers to electric/electrode boilers (average cost if converting 100% / 50% of boilers)	$20 per GJ/year / $10 per GJ/year
Transportation	Light Duty Vehicles - Cars		2020 / 2050 incremental cost of EV relative to internal combustion engine (ICE) vehicle	$7,000 / $1,000
	Light Duty Vehicles - Trucks		2020 / 2050 incremental EV cost	$13,000 / $4,000
	Medium Duty Vehicles		2020 / 2050 incremental EV cost	$125,000 / $30,000
	Heavy Duty Vehicles		2020 / 2050 incremental EV cost	$215,000 / $80,000

Power Generation Costs

The power generation costs are calculated in IPM®, as part of the model's optimization for a low-cost solution. These power generation costs include separate capital, fuel, and operations & maintenance (fixed and variable) components. The difference between the costs modelled for each scenario and the reference case costs is calculated to get the incremental cost impact for that scenario.

[14] Assumed that only homes without existing central air-conditioning or electric resistance heating would require electrical upgrades, although it is likely that the combination of EV adoption and the addition of significant space heating electric loads would require upgrades to a portion of homes with air-conditioning as well.

Transmission Costs

The illustrative transmission costs are estimated from the capital cost component of power generation costs, based on a ratio of planned investments in transmission infrastructure and planned new construction investments in generation capacity, using a value of 0.308 that was calculated from data in a Conference Board of Canada study.[15]

Renewable Natural Gas

An average RNG cost of $20/GJ was assumed across all years of the study. RNG costs are expected to vary significantly by feedstock source, but this cost is indicative of the ranges cited in the limited studies of RNG in Canada available at this time. The natural gas commodity price for a given year, from the reference case, was subtracted from this RNG cost to calculate the incremental cost impact from RNG.

A Canadian Gas Association Study
Prepared by ICF | October 2019

Ontario Energy Association

Energy Platform

About

The Ontario Energy Association (OEA) is the credible and trusted voice of the energy sector. We earn our reputation by being an integral and influential part of energy policy development and decision making in Ontario. We represent Ontario's energy leaders that span the full diversity of the energy industry.

OEA takes a grassroots approach to policy development by combining thorough evidence based research with executive interviews and member polling. This unique approach ensures our policies are not only grounded in rigorous research, but represent the views of the majority of our members. This sound policy foundation allows us to advocate directly with government decision makers to tackle issues of strategic importance to our members.

Together, we are working to build a stronger energy future for Ontario.

KEY OBJECTIVES

The purpose of this document is to provide elected officials and key decision makers from Ontario's main political parties with clear and precise recommendations on energy policies to address the needs of Ontario energy consumers. Our recommendations have been guided by the key objectives of ensuring energy in Ontario is:

Affordable

Policies should deliver the lowest cost possible to promote affordability for Ontario consumers and economic growth objectives, while still delivering on the objectives below

Sustainable

Energy policies should be developed in an integrated manner to achieve Ontario's climate change and environmental objectives by reducing energy related emissions and facilitating emissions reductions in other sectors of the economy, such as transportation and industry. It is only through taking a comprehensive approach to energy system planning by linking different types of energy (e.g., electricity, natural gas, and liquid fuels) together with the end-uses (e.g., heating, cooling, transport) that decarbonization targets will be reached

Reliable

Energy policies should ensure that Ontarians continue to have uninterrupted access to reliable energy. Our modern society and economy are dependent on reliable energy, and interruptions can have very serious consequences. Policies should allow for continuous investment in Ontario's energy infrastructure so that it can withstand and recover from extreme weather events and continue to supply Ontario's energy consumers with reliable access to affordable clean energy

RECOMMENDATION

1 | Comprehensive & Co-ordinated Plan

1A A comprehensive energy-use plan is required to ensure that Ontario finds the most affordable, reliable, and sustainable pathway to achieving both energy needs and emissions reductions objectives

1B The plan should eliminate infrastructure planning siloes within the energy sector, but also across sectors (e.g., transportation, buildings, industrial processes)

1C The Ontario Energy Board (OEB) and Independent Electricity System Operator (IESO) need to move swiftly on implementing recent government guidance and direction regarding emissions reductions objectives into their decision-making and policy making. This will ensure that regulated utilities and market participants have certainty and guidance regarding what investments are allowed in the energy system

1D Federal, provincial, and municipal governments need to coordinate and align their policies and programs and collaborate on future programs to ensure that there is a clear, comprehensive, costed, and complementary emissions reduction strategy for Ontario

RECOMMENDATION

2 | Optimize Use of Existing Infrastructure

2A Optimize and co-ordinate the use of Ontario's substantial existing electricity and natural gas assets (transmission, generation, distribution, and storage facilities), where prudent and assessed against alternatives, to decarbonize our economy cost-effectively and provide reliable, sustainable energy choices for Ontario's homes and businesses.

2B To best leverage the natural gas system:

- Provide the OEB with a mandate to enable emissions reductions investments or energy sources even when more costly, when they meet cost of abatement thresholds
- Set targets for the blending of renewable natural gas (RNG) into the gas system, and move away from voluntary RNG option (as is already being done with ethanol for transportation fuel)
- Create a provincial strategy for hybrid heating systems with smart controls, replacing a conventional air-conditioner with a higher efficiency air-source heat pump, and pairing it with a gas furnace and smart controls through collaboration and partnership between electric and natural gas utilities
- Give the OEB a mandate for more aggressive demand-side management DSM targets and expanded programs, to reduce the volume of natural gas used for building heat and therefore reduce emissions
- Implement Automated Metering for natural gas customers to support and monitor DSM initiatives, promote usage awareness, and encourage behaviour change
- Immediately initiate a carbon, capture utilization and sequestration or storage pilot project for natural gas generation in Ontario
- Strengthen investments in RNG, and compressed natural gas to reduce emissions in medium- and heavy-duty transportation

RECOMMENDATION

2 | Optimize Use of Existing Infrastructure

2C To best leverage the electricity system:

- Leverage our existing almost emission-free electricity sector to electrify key segments (e.g., transport, industry, mining) of the economy where it is the most economic option and/or supports sustainability objectives
- Given the long lead times required for new infrastructure (e.g., generation, transmission or distribution upgrades) begin planning now to expand the electricity system so that it will be able to meet the significant increase in demand for electricity as a result of Net Zero and electrification objectives, including enabling investments in the capacity of the distribution system to handle the anticipated fast growth in electric vehicle charging
- Support the integration of distributed energy resources (DERs) into the electricity grid, including power storage and hydrogen, where they provide system benefit, and offer customers choices
- Invest and expand the transmission and distribution grids to address and enable economic development, accommodate changes in generation and prepare for decarbonization
- Invest in and expand conservation and demand management programs to reduce demand, emissions, and pressure on the electricity system. Expand these programs to include fuel switching to electricity to support decarbonization in key sectors such as building heating and industrial processes
- Continue to drive efficiencies in Ontario's distribution sector through collaboration, partnerships, and consolidation

RECOMMENDATION

3 | Invest in Infrastructure, Technology & Adaptation

3A Competitive and regulatory processes should be used, wherever prudent, to procure new infrastructure as they are needed to ensure consumers get the lowest cost reliable clean energy

3B Foster a flexible regulatory regime that enables market participation of new and evolving technology and resource types, including energy storage and demand response

3C Invest in an expansion of province wide hydrogen infrastructure to facilitate a fueling network for heavy transportation; this will also require legislative and regulatory updates to enable production, transportation, and consumption of blue and green hydrogen

3D The provincial government should update the Oil, Gas & Salt Resources Act to remove the current ban on carbon sequestration to unlock opportunities for industry to invest and create jobs in Ontario

3E The OEB should move quickly to consult, develop, and implement recent government direction to provide guidance to utilities on system investments to prepare for electric vehicle adoption, so that utilities can incorporate these investments in distribution rate applications submitted to the OEB for review

3F The provincial government needs a policy on energy efficiency and decarbonization goals for buildings to achieve emissions reductions related to heating and ventilation

3G Continue to make investments in Ontario's cybersecurity framework to protect customers and energy sources

RECOMMENDATION

4 | Invest in Energy Efficiency

4A Ontario should expand investment in energy efficiency and demand response programs that reduce energy needs across all sectors and fuels

4B Ontario should pursue a decentralized delivery model for energy efficiency and energy conservation programs, taking advantage of the strong relationships that utilities and energy services companies have with consumers

4C Regular meetings should be established between the federal government and provincial government with the objective of coordinating and aligning energy efficiency programs (and funding) to eliminate overlap, duplication, and customer confusion

4D The federal government's funding of energy efficiency in Ontario should align with and support the provincial comprehensive plan outlined above, and also be consistent with the principles in the letter from the Ministry of Energy to the federal government encouraging collaboration between DSM and the new Canada Greener Homes Program to benefit Ontario ratepayers

RECOMMENDATION

5 | Achieve Behavioural Change

5A Governments must work together to invest in public education to increase consumer awareness of the impact of daily decisions on emissions and the choices available to them, including

- The emissions impact of our various purchases
- The emissions profile of various products and services
- The impact of our transportation decisions
- How to make cost-effective purchases of goods and services to lower emissions
- Leverage the existing customers relationships of utilities and energy companies to develop and deliver education initiatives

Detailed Discussion of Recommendations

CHARTING THE COURSE

Achieving net zero emissions by 2050 requires a well thought out planning process and plan. The process will require numerous iterations and course corrections as we learn what works and what does not work to achieve the significant emissions reductions needed. Ontario needs to initiate a comprehensive integrated energy planning process. Businesses and investors need a roadmap to provide certainty to ensure consumers are well served during the energy transition and that Ontario attracts the investments necessary to make the transition. Ontario will need a plan to capitalize on the economic opportunities arising out of the energy transition.

The European Union has already taken steps towards integrated energy system planning, and takes the view that "Energy system integration refers to the planning and operating of the energy system "as a whole", across multiple energy carriers, infrastructures, and consumption sectors, by creating stronger links between them with the objective of delivering low-carbon, reliable and resource-efficient energy services, at the least possible cost for society."

The EU strategy states further that "Energy system integration will translate into more physical links between energy carriers. This calls for a new, holistic approach for both large-scale and local infrastructure planning, including the protection and resilience of critical infrastructures. The objective should be to make the most of the existing infrastructure while avoiding both lock-in effects and stranded assets. Infrastructure planning should facilitate the integration of various energy carriers and arbitrate between the development of new infrastructure or re-purposing of existing ones. It should consider alternatives to network-based options, especially demand-side solutions and storage."

Without a similar approach in Ontario (and Canada), businesses and households will experience fluctuating policies, unreliable service, uncertainty, and higher costs as uncoordinated and random policies and programs fail to both serve consumers and achieve net zero goals. Importantly, a credible plan is necessary to create coverall citizen and voter support in the implementation of the significant changes in energy use and individual behaviour required to meet climate targets.

1 COMPREHENSIVE & CO-ORDINATED PLAN

The past two decades have shown that without a transparent, coordinated plan to tackle emissions, we will see further inaction or slow response. This outcome is no longer acceptable as evidence continues to accumulate that the cost of inaction on climate change will far outweigh the costs of making the investments needed to reach net zero targets. The planning process will need to pull together all levels of government, industry, and the public to achieve success.

1A A comprehensive energy-use plan is required to ensure that Ontario finds the most affordable, reliable, and sustainable pathway to achieving both energy needs and emissions reductions objectives

1B The plan should eliminate infrastructure planning siloes within the energy sector, but also across sectors (e.g., transportation, buildings, industrial processes)

1C The Ontario Energy Board (OEB) and Independent Electricity System Operator (IESO) need to move swiftly on implementing recent government guidance and direction regarding emissions reductions objectives into their decision-making and policy making. This will ensure that regulated utilities and market participants have certainty and guidance regarding what investments are allowed in the energy system

1D Federal, provincial, and municipal governments need to coordinate and align their policies and programs and collaborate on future programs to ensure that there is a clear, comprehensive, costed, and complementary emissions reduction strategy for Ontario

In Canada, the provinces and territories are responsible for energy security, development and management of resources, regulation and legislative framework for energy supply, and energy pricing at the distribution level. However, increasingly, the federal, provincial, and municipal governments are all active in advancing energy policies related to emissions reductions strategies. Therefore, given the responsibilities of the provinces, and that the powers of municipalities are granted and defined by the provincial government, it is the view of the OEA that any comprehensive energy plan would best be led and developed by the provincial government (and its agencies), but in coordination with municipalities and the federal government.

This planning process will require clear and transparent mandates across government ministries and agencies (such as the OEB and IESO) to incorporate emission reductions into their policy, regulatory, system planning and other relevant decision-making.

The government has recently taken action to provide direction to the OEB (e.g., the Minister of Energy's renewed Mandate Letter) that provide guidance to the OEB with respect to developing policies related to electrification, integration and alignment between natural gas and electricity conservation programs, and support the decarbonization of the economy. Similarly, the Ministry of Energy has asked the IESO to evaluate a moratorium on procurements of new natural gas generating stations in Ontario and develop a pathway to zero emissions in the electricity sector.

Critical to this planning is that the energy industry be a partner in the development of plans as our industry is in the best position with respect to building the infrastructure necessary for the energy transition, the ability to quickly make course corrections when necessary, and understanding the differing needs and concerns of customers and communities.

The energy industry is keenly aware of the planning siloes (e.g., transportation infrastructure; building codes and standards; the needs of industrial customers) that need to be address across sectors of the economy to tackle the energy transition.

Energy industry partnership with government (and its agencies) has been extremely successful in Ontario with many recent examples in collaborating in developing Ontario energy plans and policy:

- During the COVID-19 pandemic, the Ministry of Energy and the sector and successfully worked together to develop and implement customer protections such as the COVID-19 Energy Assistance Program as well as extending the ban on disconnections related to non-payment

- The existing regional planning process, overseen by the OEB, recognizes that each region in Ontario has unique needs and that there are many ways for these needs to be met (e.g., conservation, generation, transmission, distribution, and innovative solutions, such as Distributed Energy Resources). It is an inclusive process with the IESO, local utilities, generators, local transmitter, gas utilities, Indigenous communities, and the public (i.e., municipalities, individuals, and business groups) working together to determine the best way for electricity needs to be met.

- Recent collaborations between the OEB and the sector and on planning and policy development, include the Energy[X]Change, Adjudication Modernization Committee, and the Framework for Energy Innovation Working Group.

- The IESO has a well-established Stakeholder Advisory Committee, in addition to Standing Committees and Working Groups.

This successful track record of industry-government cooperation outlined above provides a strong foundation for the sector, the provincial government, and other partners to work together to create and implement solutions to accomplish net zero goals on time, reliably, and cost-effectively

When considering issues related to costs the OEA believes energy costs should be borne typically by those that benefit from the access to energy. The widespread socialization of cost across all ratepayers and/or taxpayers should be avoided to achieve cost effective solutions. However, it is likely that affordability and access to energy will be an issue for some groups and targeted relief will be warranted to help those that need it. This will require careful analysis to ensure that the costs of pursuing the public policy objective of net zero will be allocated equitably among different customer classes of ratepayers, between ratepayers and taxpayers, and among different income levels.

STARTING THE JOURNEY

Once the course to reaching net zero is established, the journey to reach the destination can begin. A key component of this will be making the best use of Ontario's existing energy assets.

To its credit, the province has already started this work through the IESO's Natural Gas Phase-out study which found that completely phasing out natural gas generation by 2030 would lead to blackouts, require system changes that would increase residential electricity bills by 60 per cent, and also hinder the advancement of electrification of the broader economy (e.g., transportation). However, there is more work to be done.

2 OPTIMIZE USE OF EXISTING INFRASTRUCTURE

The first step in the energy transition is making the best use of our vast existing energy infrastructure investments. Prudent public policy should adopt a cost-effective approach that seeks to optimize the use of existing assets (and minimizing stranded assets). Pipelines, transmission lines, distribution infrastructure, power plants, refineries, storage facilities, distributed energy resources, demand response and energy efficiency resources are all major investments that have been made by utilities, customers, and other parties. These assets shape the energy landscape of the province.

Experience has shown that the public (i.e., voters) are very price sensitive to increases in the cost of energy. Taking advantage of existing infrastructure is the best way to ensure cost effective energy services and reliable supply for Ontario's residential and business consumers and meet public policy objectives.

As new system needs emerge in the future, Ontario should ensure that existing assets and their locations are assessed fairly for reinvestment potential. The recent past, in Ontario and other provinces, reveals that siting new energy infrastructure such as generation facilities and transmission lines can be very controversial and costly; this makes communities with existing facilities attractive locations for additional investment.

2A Optimize and co-ordinate the use of Ontario's substantial existing electricity and natural gas assets (transmission, generation, distribution, and storage facilities), where prudent and assessed against alternatives, to decarbonize our economy cost-effectively and provide reliable, sustainable energy choices for Ontario's homes and businesses.

2B To best leverage the natural gas system:

- Provide the OEB with a mandate to enable emissions reductions investments or energy sources even when more costly, when they meet cost of abatement thresholds
- Set targets for the blending of renewable natural gas (RNG) into the gas system, and move away from voluntary RNG option (as is already being done with ethanol for transportation fuel)

- Create a provincial strategy for hybrid heating systems with smart controls, replacing a conventional air-conditioner with a higher efficiency air-source heat pump, and pairing it with a gas furnace and smart controls through collaboration and partnership between electric and natural gas utilities
- Give the OEB a mandate for more aggressive demand-side management DSM targets and expanded programs, to reduce the volume of natural gas used for building heat and therefore reduce emissions
- Implement Automated Metering for natural gas customers to support and monitor DSM initiatives, promote usage awareness, and encourage behaviour change
- Immediately initiate a carbon, capture utilization and sequestration or storage pilot project for natural gas generation in Ontario
- Strengthen investments in RNG, and compressed natural gas to reduce emissions in medium- and heavy-duty transportation

2C To best leverage the electricity system:

- Leverage our existing almost emission-free electricity sector to electrify key segments (e.g., transport, industry, mining) of the economy where it is the most economic option and/or supports sustainability objectives
- Given the long lead times required for new infrastructure (e.g., generation, transmission or distribution upgrades) begin planning now to expand the electricity system so that it will be able to meet the significant increase in demand for electricity as a result of Net Zero and electrification objectives, including enabling investments in the capacity of the distribution system to handle the anticipated fast growth in electric vehicle charging
- Support the integration of distributed energy resources (DERs) into the electricity grid, including power storage and hydrogen, where they provide system benefit, and offer customers choices
- Invest and expand the transmission and distribution grids to address and enable economic development, accommodate changes in generation and prepare for decarbonization
- Invest in and expand conservation and demand management programs to reduce demand, emissions, and pressure on the electricity system. Expand these programs to include fuel switching to electricity to support decarbonization in key sectors such as building heating and industrial processes
- Continue to drive efficiencies in Ontario's distribution sector through collaboration, partnerships, and consolidation

Ontario has existing electricity distribution system assets of over $29 billion, electricity transmission assets of over $13 billion, and natural gas distribution system assets of over $25 billion. In addition, Ontario has billions of dollars of existing electricity generation, distributed energy resources, and other energy infrastructure assets located on the transmission and distributions systems as well as behind-the-meter on a customer's premise.

Maximizing the value of existing assets is the only way to meet NZ2050 targets in an affordable and reliable manner.

These investments are an important part of Ontario's energy future and must be leveraged by the government as it pursues the dual objectives of meeting climate change objectives. This should include giving the IESO clear direction on extending the life of existing power generation assets (particularly those with lower emissions and/or emissions-mitigation measures in place).

Additionally, the transportation sector is currently Ontario largest source of greenhouse gas emissions, representing Ontario's best opportunity to lower its carbon footprint in a cost-effective way by taking advantage of existing infrastructure (e.g., incorporating EV's into the electrical grid and RNG and CNG for heavy- and medium-duty transportation).

It is important to recognize that these existing assets include energy efficiency and demand response capacity. Ontario's utilities have invested significantly in conservation programs that deliver cost effective capacity to Ontario's energy system. The programs delivered by Ontario's electricity and gas utilities have an excellent track record of delivering value to their customers. Further, customers and other energy services providers have made investments in energy efficiency and demand response to lower their energy costs and reduce their environmental footprint.

For example, the government should leverage existing energy utility energy efficiency and conservation leadership and expertise for an expanded role in meeting GHG reduction goals. Utilities are in the best position to further expand conservation program offerings to the residential, multi-residential and commercial building sector as well as large industrial energy users.

Further, the investment by customers in new technologies and innovations that offer them greater autonomy over their energy use is steadily increasing. These distributed energy resources represent more existing infrastructure investments, and can include renewable generation, energy storage, combined heat and power, and micro-grids.

It behooves the province to take the fullest advantage possible of all the significant existing infrastructure described above that has already been paid for by ratepayers, taxpayers, utilities, energy service providers, and customers.

REACHING THE DESTINATION

Maximizing the value and utility of existing infrastructure as described in the previous section will enable the province to move forward with the new investments to reach NZ2050 in an expeditious, reliable, and cost-effective way. In many areas, industry and customers are already taking action to make the energy transition within the existing policy and regulatory framework. However, there are limitations in the current environment, requiring leadership and direction from the government to enable the sector to make additional infrastructure investments efficiently.

Moreover, Ontario will clearly have to develop new electricity generation capacity as the demands for electricity fuel switching increase. Any plans for a significant increase in generation capacity or imports will require a proportionate need for increased transmission and distribution capacity. New infrastructure will be required to reliably deliver this additional electricity from generators to loads, to allow for system optimization, and accommodate increases in two-way power flows. These long-lived key assets require long-lead times to both plan and build-out, involving intensive major planning processes, regulatory approvals, and extensive consultation processes. Therefore, it is imperative that work begin well before needs materialize to ensure this essential transmission and distribution infrastructure expansion will be ready on time to meet our 2050 targets.

Again, to its credit, the province has started work in this area through the request by the Minister of Energy that the develop an achievable pathway to phase-out natural gas generation and achieve zero emissions in the electricity system, taking into consideration reliability, cost, electrification of the broader economy, and the use of green fuels (e.g., hydrogen and RNG) and other technologies (e.g., pumped storage, battery storage, and demand response).

3 INVEST IN INFRASTRUCTURE, TECHNOLOGY & ADAPTATION

The path to net zero is uncertain. Experimentation and pilot projects will be necessary to reach the ultimate destination. There will be successes and failures along the way, but whether technologies live up to (or fail to live up) their promise will not be predictable. Therefore, the approach to planning should be technology agnostic going forward and evaluate promising evolving fuels and technologies based on their cost, feasibility, and scalability.

Timely technology investments, incentives, funding, and red tape reduction will be needed to achieve efficiency and commercial-scale in energy sources and production (e.g., alternative fuels, storage, and carbon capture and sequestration), but also in how energy is used across sectors (e.g., transportation, buildings, industrial processes).

Critically, these strategies and policies need to recognize that investments are required to not only lower emissions, but also to assist in adapting to climate change by making energy infrastructure more able to withstand and recover from extreme weather events (e.g., wind and flooding) caused by climate change

3A Competitive and regulatory processes should be used, wherever prudent, to procure new infrastructure as they are needed to ensure consumers get the lowest cost reliable clean energy

3B Foster a flexible regulatory regime that enables market participation of new and evolving technology and resource types, including energy storage and demand response

3C Invest in an expansion of province wide hydrogen infrastructure to facilitate a fueling network for heavy transportation; this will also require legislative and regulatory updates to enable production, transportation, and consumption of blue and green hydrogen

3D The provincial government should update the Oil, Gas & Salt Resources Act to remove the current ban on carbon sequestration to unlock opportunities for industry to invest and create jobs in Ontario

3E The OEB should move quickly to consult, develop, and implement recent government direction to provide guidance to utilities on system investments to prepare for electric vehicle adoption, so that utilities can incorporate these investments in distribution rate applications submitted to the OEB for review

3F The provincial government needs a policy on energy efficiency and decarbonization goals for buildings to achieve emissions reductions related to heating and ventilation

3G Continue to make investments in Ontario's cybersecurity framework to protect customers and energy sources

As Ontario builds its energy system for the future, when Ontario's requires resources, the use of a competitive (IESO procurement) and regulatory (OEB review) processes should be the main avenues of infrastructure acquisition to ensure that the system can meet environmental and reliability objectives at the lowest possible cost for consumers. In the case of the IESO, the government should also include access to procurement mechanisms with longer periods of return to support upgrades, repowering, and the addition of emerging technologies.

Also, given the likely long lead times required for new infrastructure (e.g., pipelines, underground carbon capture, large scale energy storage, generation, transmission or distribution) policy clarity as well as investments, incentives and regulatory mandates are in place in the near future to (1) expand the electricity system so that it will be able to meet the significantly increase in demand for electricity from transport and buildings (which are two of the largest sources of GHG in the province); and, (2) expanding the ability of the gas distribution system for the use of hydrogen in transportation and other future applications, that meeting emissions reduction targets requires.

As the province looks toward making these investments infrastructure and new technology, it should make sure that it leverages the significant amount of funds available from federal sources (e.g., Net Zero Accelerator Zero-Emission Vehicle (ZEV) programs) and encourage the growth of made-in-Ontario solutions.

4 INVEST IN ENERGY EFFICIENCY & DEMAND RESPONSE

Until recently, Ontario had projected a surplus electricity generation capacity and energy into 2030s, which led logically to system efficiency and affordability being policy priorities. However, pursuing NZ2050 changes the outlook significantly because it will result in a large increase in the use of cleaner forms of energy. The electrification of transportation and building will result in a significant increase in the demand and consumption of electricity. RNG and hydrogen will also increase in usage. Therefore, maintaining the critical need for both a reliable supply of energy and keeping energy costs affordable require that we not just increase the supply of clean energy and the infrastructure to deliver that energy to consumers, but produce and use all energy more efficiently.

Ontario has had great success in developing a culture of conservation behaviour that has demonstrably reduced the amount of electricity and natural gas we use at home and at work. The value of this conservation will need to be harnessed and expanded greatly as Ontario approaches 2050.

4A Ontario should expand investment in energy efficiency and demand response programs that reduce energy needs across all sectors and fuels

4B Ontario should pursue a decentralized delivery model for energy efficiency and energy conservation programs, taking advantage of the strong relationships that utilities and energy services companies have with consumers

4C Regular meetings should be established between the federal government and provincial government with the objective of coordinating and aligning energy efficiency programs (and funding) to eliminate overlap, duplication, and customer confusion

4D The federal government's funding of energy efficiency in Ontario should align with and support the provincial comprehensive plan outlined above, and also be consistent with the principles in the letter from the Ministry of Energy to the federal government encouraging collaboration between DSM and the new Canada Greener Homes Program to benefit Ontario ratepayers

Ontario's energy capacity can be enhanced through increased energy efficiency. Energy efficiency is a proven low-cost system resource in Ontario. As we look to expand the capability of our electricity system and other clean energy sources to replace carbon fuels, energy efficiency will have significant cost-effective potential.

Further, expanding DSM programs in the natural gas sector are also a critical component to reducing emissions.

Energy companies have the insights required to best deliver energy efficiency programs to customers; both residential (houses, apartments, and condominiums) and businesses (commercial and industrial), which require specifically tailored programs depending size, location on the energy system, region of the province (North v. South) and/or their particular line of business/industry. A decentralized delivery model would take the greatest advantage of the creativity and nimbleness of utilities and energy companies compared to the current centralized structure.

Ontario has been very successful in developing a new capacity auction in which demand response resources compete to provide low-cost energy capacity to our system. Demand response aggregators bring together electricity users who are willing to reduce their consumption in times of peak need. By reducing peak demand, the reliance on expensive, under-utilized peaking resources is reduced and in most cases carbon emissions are lowered. This resource has the potential to grow and to cost-effectively enhance Ontario's grid capacity with existing aggregation strategies.

As with other funding measures discussed earlier, investments in Ontario on energy efficiency and demand management should align with and leverage funding be offered by federal sources.

5 ACHIEVE BEHAVIOURAL CHANGE

Meeting NZ2050 requires a fundamental change in the behaviour and attitudes of society towards energy use. Lowering emissions and adaptation to climate change requires investments in ongoing communication with citizens and customers to make them aware of the role they can play in reducing their individual emissions, the options available to them to help them do so, and how to choose the options that best align with their needs and household budgets.

Greater awareness will allow consumers, families, and businesses to make informed choices about the impact they are having on emissions. Industry is in the best position to take a leadership role in delivering education and opportunities to customers, enabling their ability to change behaviour, lifestyle choices, and/or adopt low/zero emission technology.

5A Governments must work together to invest in public education to increase consumer awareness of the impact of daily decisions on emissions and the choices available to them, including

- The emissions impact of our various purchases
- The emissions profile of various products and services
- The impact of our transportation decisions
- How to make cost-effective purchases of goods and services to lower emissions
- Leverage the existing customers relationships of utilities and energy companies to develop and deliver education initiatives

Our behaviour can have a significant impact on our emissions footprint generally, including choices we make that impact how we use energy. As discussed earlier, Ontario has had great success in developing a culture of conservation behaviour with respect to electricity and natural gas. We also saw how behavioural practices have resulted in increasing transportation emissions even when technological advancement has resulted in much more fuel-efficient vehicles.

Reaching NZ2050 will require Ontarians to build on this progress by adapting our behaviour to continually reduce our emissions profile through all our activities and purchases. The education required to achieve emissions targets must go beyond the success Ontario has had in building a culture of conservation of electricity that was led by the utilities. It will require significant customized and individualized messaging to a diverse set of residential and business customers.

> Governments and the energy sector need to work together to provide ongoing education of citizens and all customers (residential and business) to make them aware of the role they can play in reducing their individual emissions and the options available to them to help them do so.

And we must all work together to build a culture of emissions consciousness just as we have successfully built a culture of conservation with respect to household energy consumption within our homes.

KEY OBJECTIVES

The purpose of this document is to provide elected officials and key decision makers from Ontario's main political parties with clear and precise recommendations on energy policies to address the needs of Ontario energy consumers. Our recommendations have been guided by the key objectives of ensuring energy in Ontario is:

Affordable

Policies should deliver the lowest cost possible to promote affordability for Ontario consumers and economic growth objectives, while still delivering on the objectives below

Sustainable

Energy policies should be developed in an integrated manner to achieve Ontario's climate change and environmental objectives by reducing energy related emissions and facilitating emissions reductions in other sectors of the economy, such as transportation and industry. It is only through taking a comprehensive approach to energy system planning by linking different types of energy (e.g., electricity, natural gas, and liquid fuels) together with the end-uses (e.g., heating, cooling, transport) that decarbonization targets will be reached

Reliable

Energy policies should ensure that Ontarians continue to have uninterrupted access to reliable energy. Our modern society and economy are dependent on reliable energy, and interruptions can have very serious consequences. Policies should allow for continuous investment in Ontario's energy infrastructure so that it can withstand and recover from extreme weather events and continue to supply Ontario's energy consumers with reliable access to affordable clean energy

To shape our energy future for a stronger Ontario

EUROPEAN
COMMISSION

Brussels, 8.7.2020
COM(2020) 299 final

COMMUNICATION FROM THE COMMISSION TO THE EUROPEAN PARLIAMENT, THE COUNCIL, THE EUROPEAN ECONOMIC AND SOCIAL COMMITTEE AND THE COMMITTEE OF THE REGIONS

Powering a climate-neutral economy: An EU Strategy for Energy System Integration

EN EN

1. AN INTEGRATED ENERGY SYSTEM FOR A CLIMATE-NEUTRAL EUROPE

The European Green Deal[1] puts the EU on a path to climate neutrality by 2050, through the deep decarbonisation of all sectors of the economy, and higher greenhouse gas emission reductions for 2030.

The energy system is crucial to deliver on these goals. The recent decline in the cost of renewable energy technologies, the digitalisation of our economy and emerging technologies in batteries, heat pumps, electric vehicles or hydrogen offer an opportunity to accelerate, over the next two decades, a profound transformation of our energy system and its structure. Europe's energy future must rely on an ever growing share of geographically distributed renewable energies, integrate different energy carriers flexibly, while remaining resource-efficient and avoiding pollution and biodiversity loss.

Today's energy system is still built on several parallel, vertical energy value chains, which rigidly link specific energy resources with specific end-use sectors. For instance, petroleum products are predominant in the transport sector and as feedstock for industry. Coal and natural gas are mainly used to produce electricity and heating. Electricity and gas networks are planned and managed independently from each other. Market rules are also largely specific to different sectors. This model of separate silos cannot deliver a climate neutral economy. It is technically and economically inefficient, and leads to substantial losses in the form of waste heat and low energy efficiency.

Energy system integration – the coordinated planning and operation of the energy system 'as a whole', across multiple energy carriers, infrastructures, and consumption sectors – is the pathway towards an effective, affordable and deep decarbonisation of the European economy in line with the Paris Agreement and the UN's 2030 Agenda for Sustainable Development**.**

Declining costs for renewable energy technologies, market developments, rapid innovation regarding storage systems, electric vehicles, as well as digitalisation are all factors leading naturally towards greater energy system integration in Europe. However, we have to go one step further and connect the missing links in the energy system in order to achieve higher decarbonisation objectives for 2030 and climate neutrality by 2050 – and do it in manner that is both cost effective and consistent with the European Green Deal's green oath to "do no harm". Relying on greater use of clean and innovative processes and tools, the path towards system integration will also trigger new investments, jobs and growth, and strengthen EU industrial leadership at a global level. It can also be a building block of the economic recovery in the aftermath of COVID-19 crisis. The Commission's recovery plan[2] presented on 27 May 2020 highlights the need to better integrate the energy system, as part of its efforts to unlock investment in key clean technologies and value chains and increase economy-wide resilience. In addition, the EU sustainable finance taxonomy will guide investment in these activities to ensure they are in line with our long-term ambitions[3]. An integrated energy system will minimise the costs of transition towards climate neutrality for consumers and open new opportunities for reducing their energy bills and active participation in the market.

[1] COM(2019) 640 final.

[2] 'Europe's moment: Repair and Prepare for the Next Generation', COM(2020) 456 final.

[3] Regulation (EU) 2020/852 of the European Parliament and of the Council of 18 June 2020 on the establishment of a framework to facilitate sustainable investment, and amending Regulation (EU) 2019/2088

The Clean Energy Package[4], adopted in 2018, provides a basis for better integration across infrastructure, energy carriers and sectors; however, regulatory and practical barriers remain. Without robust policy action, the energy system of 2030 will be more akin to that of 2020 than a reflection of what is needed to achieve climate neutrality by 2050.

This Strategy sets out a **vision on how to accelerate the transition towards a more integrated energy system**, one that supports a climate neutral economy at the least cost across sectors – while strengthening energy security, protecting health and the environment, and promoting growth, innovation and global industrial leadership.

Turning this vision into a reality requires resolute action, now. Investments in energy infrastructure typically have an economic life of 20 to 60 years. The steps taken in the next five-to-ten years will be crucial for building an energy system that drives Europe towards climate neutrality in 2050.

Thus, this **Strategy proposes concrete policy and legislative measures at EU level to gradually shape a new integrated energy system**, while respecting the differing starting points of Member States. It contributes to the work of the Commission on a comprehensive plan to increase the EU 2030 climate target to at least 50% and towards 55% in a responsible way and identifies follow-up proposals that will be prepared as part of the legislative reviews of June 2021, announced in the European Green Deal.

The parallel Communication '***A hydrogen strategy for a climate-neutral Europe***'[5] complements this Strategy to elaborate in more detail on the opportunities and necessary measures to scale up the uptake of hydrogen in the context of an integrated energy system.

2. ENERGY SYSTEM INTEGRATION AND ITS BENEFITS TO COST-EFFECTIVE DECARBONISATION

2.1. What is energy system integration?

Energy system integration refers to the planning and operating of the energy system "as a whole", across multiple energy carriers, infrastructures, and consumption sectors, by creating stronger links between them with the objective of delivering low-carbon, reliable and resource-efficient energy services, at the least possible cost for society. It encompasses three complementary and mutually reinforcing concepts.

First, a more 'circular' energy system, with energy efficiency at its core, in which the least energy intensive choices are prioritised, unavoidable waste streams are reused for energy purposes, and synergies are exploited across sectors. This is happening already in combined heat and power plants or through the use of certain waste and residues. There is however further potential, for example, in reusing waste heat from industrial processes, data centres, or energy produced from bio-waste or in wastewater treatment plants.

Second, a greater direct electrification of end-use sectors. The rapid growth and cost competitiveness of renewable electricity production can service a growing share of energy

[4] https://ec.europa.eu/energy/topics/energy-strategy/clean-energy-all-europeans_en.
[5] COM(2020) 301 final.

demand – for instance using heat pumps for space heating or low-temperature industrial processes, electric vehicles for transport, or electric furnaces in certain industries.

Third, the use of renewable and low-carbon fuels, including hydrogen, for end-use applications where direct heating or electrification are not feasible, not efficient or have higher costs. Renewable gases and liquids produced from biomass, or renewable and low-carbon hydrogen can offer solutions allowing to store the energy produced from variable renewable sources, exploiting synergies between the electricity sector, gas sector and end-use sectors. Examples include using renewable hydrogen in industrial processes and heavy-duty road and rail transport, synthetic fuels produced from renewable electricity in aviation and maritime transport, or biomass in the sectors where it has the biggest added value.

A more integrated system will also be a 'multi-directional' system in which consumers play an active role in energy supply. 'Vertically', decentralised production units and customers contribute actively to the overall balance and flexibility of the system – for instance, biomethane produced from organic waste injected in gas networks at a local level, or "vehicle-to-grid" services. 'Horizontally', exchanges of energy increasingly take place between consuming sectors – for instance, energy customers exchanging heat in smart district heating and cooling systems, or feeding in the electricity that they produce individually or as part of energy communities.

2.2. What are the benefits of energy system integration?

Energy system integration helps to **reduce greenhouse gas emissions in sectors that are more difficult to decarbonise**, for instance by using renewable electricity in buildings and road transport, or renewable and low carbon fuels in maritime, aviation, or certain industrial processes.

It could also ensure a more efficient use of energy sources, **reducing the amount of energy needed and related climate and environmental impacts**. In certain end-uses, new fuels will likely be required that use significant amounts of energy to be produced, such as hydrogen or synthetic fuels. At the same time, the electrification of a large share of our consumption can cut primary energy demand by a third[6] thanks to the efficiency of electrical end-use technologies. Also, 29% of industrial energy demand dissipates as waste heat, which can be reduced or reused. Small- and medium size enterprises can create synergies by both improving energy efficiency and increasing the use of renewable resources and waste heat. Overall, the transition to a more integrated energy system is projected to reduce gross inland consumption by a third by 2050[7], whilst supporting an increase in GDP of two thirds[8].

[6] For example, electric vehicles have an efficiency of around 60% compared to 20% for combustion engines on a tank-to-wheel basis, and heat pumps can deliver heat with three times less energy input than boilers.

[7] See COM(2018) 773 final, A Clean Planet for all. A European long-term strategic vision for a prosperous, modern, competitive and climate neutral economy. In-depth analysis in support of the Commission communication (LTS), figure 18: -21% in the 1.5TECH and -32% in the 1.5LIFE.

[8] See LTS, figure 92: 2050 GDP between 166% and 174% of 2015 or between GDP 154% and 161% of 2020 GDP.

Beyond energy and greenhouse gases emissions savings, it would also reduce air pollution and the energy water footprint[9], which is essential for climate adaptation, for health and to preserve natural resources.

Energy system integration will also **strengthen the competitiveness of the European economy** by promoting more sustainable and efficient technologies and solutions across industrial ecosystems related to the energy transition, their standardisation and market uptake. Specialised companies will provide services locally and create more regional economic benefits. This creates an opportunity for the Union to maintain and leverage its leadership in clean technologies such as smart grid technologies and district heating system, and lead on new, more efficient and complex technologies and processes that are expected to play a growing role in the energy systems worldwide, such as batteries or hydrogen technologies. Territories, regions and Member States facing the biggest transition challenges will be supported by the Just Transition Mechanism and, as part of it, the Just Transition Fund.

Moreover, better integration will **provide additional flexibility** for the overall management of the energy system and thus help to integrate increased shares of variable renewable energy production. It will also boost **storage technologies**: pumped hydropower, grid-scale batteries and electrolysers provide flexibility in the electricity sector. Home batteries and electric vehicles ('behind-the-meter') in buildings can help manage better the distribution grids. By 2050, electric vehicles could provide up to 20% of the flexibility required on a daily basis[10]. Thermal storage at factory-level can provide flexibility in the industrial sector. Through the closer integration of the power and heat sector, electric heat appliances could already make use of real time electricity prices to smarten demand response. Hybrid heat pumps[11] and smart district heating also provide opportunities for arbitrage between electricity and gas markets. Moreover, electrolysers can transform renewable electricity into renewable hydrogen, providing long-term storage and buffering capability, and further integrating the electricity and gases markets.

Finally, by linking up the different energy carriers and through localised production, self-production and smart use of distributed energy supply, system integration can also contribute to **greater consumer empowerment, improved resilience and security of supply.** Some of the technologies needed in an integrated energy system will require large amounts of raw materials, including some listed on the EU list of critical raw materials. But replacing imported natural gas and petroleum products with locally produced renewable electricity, gases and liquids, combined with the greater implementation of circular models, will first and foremost reduce the import bill and lessen dependency on external fossil fuel supplies, creating a more resilient European economy.

3. MAKING IT HAPPEN - AN ACTION PLAN TO ACCELERATE THE CLEAN ENERGY TRANSITION THROUGH ENERGY SYSTEM INTEGRATION

This strategy identifies six pillars where coordinated measures are outlined to address existing barriers for energy system integration.

---

9 The water footprint of EU energy production was in 2015 198 km3 or 1068 litres per person and per day, or 242 km3 or 1301 litres per person and per day including energy imports. Source: JRC, Water – Energy Nexus in Europe, 2019.

10 According to METIS-2 S6 Study, baseline scenario (186TWh of 951TWh of total daily flexibility needs) would be provided by e-vehicles. Study to be published.

11 Heat pumps coupled with a boiler.

3.1. A more circular energy system, with ‘energy-efficiency-first’ at its core

Applying the energy-efficiency-first principle across sectoral policies is at the core of system integration. Energy efficiency reduces the overall investments needs and costs associated with energy production, infrastructure and use. It also reduces the related land and material resources use, and associated pollution and biodiversity losses. At the same time, system integration can help the EU achieve greater energy efficiency, through a more circular use of available resources and by switching to more efficient energy technologies. For instance, electric vehicles show much higher energy efficiency than combustion engines; and replacing a fossil-fuel based boiler with a heat pump using renewable electricity saves two thirds of primary energy[12].

The first challenge is to **apply the energy-efficiency-first principle consistently across the whole energy system**. This includes giving priority to demand-side solutions whenever they are more cost effective than investments in energy supply infrastructure in meeting policy objectives, but also properly factoring in energy efficiency in generation adequacy assessments. The Energy Efficiency Directive[13] and Energy Performance of Buildings Directive[14] already provide incentives for customers, but not enough for the full supply chain. Further measures are needed to ensure that customers’ decisions to save, switch or share energy **properly reflect the life cycle energy use and footprint** of the different energy carriers, including extraction, production and reuse or recycling of raw materials, conversion, transformation, transportation and storage of energy, and the growing share of renewables in electricity supply. In certain industries for which the shift from fossil fuels towards electricity will result in more consumption, trade-offs will have to be carefully considered.

In this context, the **Primary Energy Factor** (PEF)[15] is an important tool to facilitate comparisons of savings across energy carriers. Most renewables are 100% efficient and have a low PEF. The PEF should reflect the real savings brought about by renewable electricity and heat. The Commission will review the level of the PEF and assess whether current provisions in EU legislation ensure an adequate application of the PEF by Member States.

The upcoming ‘**Renovation Wave**’ initiative, announced in the European Green Deal, will also propose concrete actions to accelerate the uptake of energy and resource efficiency measures and of renewables in buildings across the EU in the next few years.

The second challenge is that **local energy sources are insufficiently or not effectively used in our buildings and communities**. Applying the principle of circularity in line with the new Circular Economy Action Plan[16], a big, yet largely unused potential is the reuse of **waste heat** from industrial sites, data centres, or other sources. Energy reuse can take place on-site (for example through the re-integration of process heat within manufacturing plants) or via a district heating and cooling network. The Energy Efficiency and Renewable Energy

---

12 Kavvadias, K., Jimenez Navarro, J. and Thomassen, G., Decarbonising the EU heating sector: Integration of the power and heating sector, 2019.

13 Directive (EU) 2018/ 2002.

14 Directive (EU) 2018/844.

15 The primary energy factor indicates the amount of primary energy used to generate a unit of final energy (electrical or thermal), allowing a comparison of the primary energy consumption of products with the same functionality using different energy carriers. It shall be revised periodically according to Annex IV of the Energy Efficiency Directive.

16 COM(2020) 98 final.

Directives already contain provisions targeting this potential, but there is a need to further strengthen the regulatory framework to lift barriers hampering the wider application of these solutions. These barriers include insufficient awareness and knowledge about these solutions, the reluctance of companies to enter into a new business that is not their core activity, a lack of regulatory and contractual frameworks to share the costs and benefits of new investments, and barriers related to planning, transaction costs, and pricing signals. As regards data centres specifically, the Digital Strategy[17] has announced the ambition to make them climate-neutral and highly energy-efficient by no later than 2030; a greater re-use of their waste heat will significantly contribute to that objective.

A third challenge is linked to the untapped use of **wastewater**[18] **and biological waste and residues for bioenergy production**, including biogas. Biogas can be exploited on-site to reduce fossil fuel consumption, or upgraded to biomethane to allow injection into the natural gas grid or use in transport. Also, some farm infrastructures are suitable for an integrated production of solar-origin electricity and heat, creating the potential for renewable energy self-consumption and injection into the grid. The implementation of the new Circular Economy Action Plan and waste legislation and sustainable agriculture and forestry management systems could result in increased sustainable production of bioenergy from wastewater, waste and residues[19]. More efforts are needed to take advantage of the full potential for energy system integration, exploiting synergies and avoiding trade-offs. In agriculture, through the Common Agriculture Policy, farmers could be incentivised to contribute to a greater mobilisation of sustainable biomass for energy. Renewable energy communities can provide a sound framework for the use of such energy in a local context.

Key actions

To better apply the energy-efficiency-first principle:

- Issue **guidance** to Member States on how to **make the energy-efficiency-first principle operational** across the energy system when implementing EU and national legislation (by 2021).
- **Further promote** the energy-efficiency-first principle in all upcoming relevant methodologies (e.g. in the context of the European resource adequacy assessment) and legislative revisions (e.g. of the TEN-E Regulation[20]).
- Review the **Primary Energy Factor**, in order to fully recognise energy efficiency savings via renewable electricity and heat, as part of the review of the Energy Efficiency Directive (June 2021).

To build a more circular energy system:

- Facilitate the **reuse of waste heat from industrial sites and data centres,** through strengthened requirements for connection to district heating networks, energy

[17] C(2018) 7118 final.

[18] Wastewater treatment plants represent almost 1% of electricity consumption in Europe. This consumption can be reduced with more efficient technologies, and energy can be better recovered from those plants.

[19] The overall potential for increased biogas production from waste and residues remains high and, if fully exploited, could lead to biogas and biomethane production levels in 2030 of 2.7–3.7% of the EU’s energy consumption in 2030. See CE Delft, Eclareon, Wageningen Research, Optimal use of biogas from waste streams. An assessment of the potential of biogas from digestion in the EU beyond 2020, 2017.

[20] Regulation on Trans-European Networks in Energy, Regulation (EU) 347/2013.

performance accounting and contractual frameworks, as part of the revision of the Renewable Energy Directive and of the Energy Efficiency Directive (June 2021).

- Incentivise the **mobilisation of biological waste and residues from agriculture**, **food and forestry** sectors and support capacity-building for **rural circular energy communities** through the new Common Agriculture Policy, Structural Funds and the new LIFE programme (from 2021 onwards).

3.2. Accelerating the electrification of energy demand, building on a largely renewables-based power system

Electricity demand is projected to increase significantly on a pathway towards climate neutrality, with the share of electricity in final energy consumption growing from 23% today to around 30% in 2030, and towards 50% by 2050[21]. In comparison, that share has only increased by 5 percentage points over the last thirty years.

This growing electricity demand will have to be largely based on renewable energy. By 2030, the share of renewable energy in the electricity mix should double to 55-60%, and projections show a share of around 84% by 2050. The remaining gap should be covered by other low-carbon options[22].

Significant cost reductions in renewable power generation technologies have occurred in the last decades and are expected to continue – providing prospects that market forces will increasingly deliver investments. However, given the scale of the investments needed, it is urgent to tackle the barriers that still prevent a massive roll-out of renewable electricity, across all technologies. These include underdeveloped supply chains, the need for more and smarter grid infrastructure at national and cross-border level, the lack of public acceptance, administrative barriers and lengthy permitting (including for repowering), financing, the need for public or private long-term hedging options, or high costs for some less mature technologies.

The need for increased electricity supply can, alongside other relevant onshore renewable power technologies such as solar or wind energy, partly be met by offshore renewable energy production. The potential of offshore wind energy in the EU is between 300-450 GW by 2050[23], against today's capacity of some 12 GW[24]. This represents a huge opportunity for the EU industry to become the global leader in offshore technology, but will require considerable efforts to increase the European industrial capacity and build new value chains. Offshore electricity production also creates an opportunity for the nearby localisation of electrolysers for hydrogen production, including the possible reuse of the existing infrastructure of depleted natural gas fields. In addition, the development of solar energy will be further facilitated.

In the short term, the Commission will use the new recovery instrument Next Generation EU to support the continued deployment of renewable energy. It will assess opportunities to

[21] LTS, figure 20, looking at the 1.5LIFE and 1.5TECH scenarios for 2050.
[22] LTS, figure 23, looking at the 1.5LIFE and 1.5TECH scenarios for 2050.
[23] LTS, figure 24, including the UK.
[24] 20 GW including the UK.

channel EU funds through, or in combination with, the new **EU renewable energy financing mechanism**[25].

On the demand side, certain incentives to electrification are provided for instance through the sectoral targets set out in the Renewable Energy Directive, and in transport through CO_2 standards for vehicles, in the Alternative Fuel Infrastructure Directive and the Clean Vehicles Directive[26]. But challenges for **increased electrification remain** and differ per sector and across Member States **and more needs to be done**.

In **buildings,** electrification is expected to play a central role, in particular through the roll-out of heat pumps for space heating and cooling. In the residential sector, the share of electricity in heating demand should grow to 40% by 2030 and to 50-70% by 2050; in the services sector, these shares are expected to be around 65% by 2030 and 80% by 2050[27]. Large-scale heat pumps will play a relevant role in district heating and cooling. The most important barrier is the relatively higher level of taxes and levies applied to the electricity, and the lower levels of taxation for fossil fuels (oil, gas and coal) used in the heating sector, leading to lack of level playing field. Progress is also hampered by a number of other barriers, including unfit infrastructure planning, building codes and products standards, lack of skilled workforce for installation and maintenance, lack of public and private financing instruments, and lack of internalisation of CO_2 costs in heating fuels. This translates into low replacement rates of the EU fossil heating stocks, low development and modernisation of district heating/cooling networks, and low building refurbishment rates. With the Renovation Wave initiative, the Commission will ensure a higher penetration of renewables in buildings. It will also support training programmes under the Updated Skills Agenda.

In **industry**, heat represents more than 60% of energy use. Industrial heat pumps can help decarbonise the low temperature heat supply within industries, and can be coupled with waste heat recovery. Other technologies are being developed for higher temperature heating (such as microwave or ultrasound) and for electrifying processes by electrochemistry. Barriers to deployment include lack of information and long pay-back, due to the high price of electricity relative to gas and the high abatement cost associated with these technologies, relative to current CO_2 prices. Changes in the production process leading to higher costs could also affect the competitiveness of sectors exposed to international competition. EU support could help develop a number of flagship projects and demonstrate innovative electricity-based processes. Furthermore, the industrial supply chain for these technologies is not sufficiently mature and the integration of these electrification technologies into industrial processes requires training and new skills. The Commission will explore, together with industry, ways to address these issues.

In **transport**[28], the Sustainable and Smart Mobility Strategy is foreseen for later this year, and will set out how our transport system needs to decarbonise and modernise to reduce its emissions by 90% in 2050[29]. Electric mobility is key, and will accelerate decarbonisation and reduce pollution, especially in our cities, and new mobility services will increase the efficiency of the transport system and reduce congestion. The rapidly falling cost of electric

[25] https://ec.europa.eu/info/law/better-regulation/have-your-say/initiatives/12369-Union-renewable-Financing-mechanism
[26] Directive (EU) 2019/1161 on the promotion of clean and energy-efficient road transport vehicles.
[27] LTS, figure 42.
[28] Including mobile machinery.
[29] LTS

vehicles means that they could be competitive with combustion engine vehicles around 2025, on a total cost of ownership basis[30]. The European Green Deal points to the need of stepping up the roll out of recharging infrastructure, starting with the ambitious objective of having at least one million publicly accessible recharging and refuelling points by 2025, as well as the use of on-shore power supply in ports. To that end the Commission will mobilise InvestEU – which will be reinforced and include a new Strategic Investment Facility – and the Connecting Europe Facility funding to broaden the coverage of the charging infrastructure network. Support through the Recovery and Resilience Facility and through Cohesion Policy to clean vehicles and alternative fuels infrastructure will be a priority as part of the strengthened focus on delivering the European Green Deal in our regions and cities, including in public buildings, offices, depots and private dwellings. The Renovation Wave initiative also offers opportunities to promote electric chargers and electric vehicle charging stations. The Commission will also propose to revise the Alternative Fuels Infrastructure Directive and the TEN-T Regulation – also assessing how to further strengthen synergies between the TEN-T and TEN-E policies. The Commission will accompany the continued support under the Connecting Europe Facility with a further mapping of funding opportunities and regulatory initiatives for the roll-out of recharging infrastructure. The Commission will also tackle challenges to make electro-mobility more attractive to the user such as the non-transparent pricing at public charging stations and the persistent lack of cross-border interoperability of charging services. Measures are also needed to boost the use of renewable electricity at ports, to facilitate the electrification of road freight transport. Further electrification of railways could be explored taking into account its economic viability[31].

Overall, **a growing use of electricity in end-use sectors will mean a need to keep under review the adequacy of renewable electricity supply**, to ensure that it can match the scale required to support the decarbonisation of the abovementioned sectors.

Electrification can present challenges for the management of the electricity system. Regional and cross-border coordination between Member States will become increasingly important. This will be addressed by the development of Regional Coordination Centres[32] in 2022, allowing for more robust security analysis, emergency and outage coordination and common infrastructure planning, and the deployment of storage and other flexibility options. The Commission will support the **uptake of energy storage** through full implementation of the Clean Energy Package and in the upcoming legislative reviews, including the review of the TEN-E Regulation.

Challenges are also expected at a more local level. For instance, the full electrification of passenger road transport will require in parts of the Union upgrades to the local grid infrastructure. At the same time, it can create **opportunities for providing storage and flexibility** to the system[33]. In particular, **smart charging** and so-called **Vehicle-to-Grid** (V2G) services will be essential to manage grid congestion and limit costly investments in grid capacity. The Electricity Directive contains a number of provisions that lay the basis for enabling smart charging and the development of V2G services, but challenges still remain, for instance regarding the deployment of smart recharging points, common standards and communication protocols, grid charges, taxation and access to the in-vehicle data. The

[30] See for instance BNEF, Electric Vehicle Outlook, 2020.
[31] Over 50% of the rail network and around 80% of the rail traffic is already electrified.
[32] Regulation (EU) 2019/943.
[33] See Trinomics, Energy storage – Contribution to the security of the electricity supply in Europe, 2020.

development of a new Network Code on Demand Side Flexibility as well as the review of the Alternative Fuels Infrastructure Directive both present opportunities to create a robust framework for the successful integration of demand-side flexibility in general, and electric vehicles in particular.

Electrification efforts of areas not connected to the continental grid, such as the Outermost Regions, some islands, or remote or sparsely populated areas present specific challenges. Technical and financial support for energy system integration is particularly relevant for a cost-effective transition in these regions.

Key actions

To ensure continued growth in the supply of renewable electricity:

- Through the Offshore Renewable Strategy and follow-up regulatory and financing actions, ensure the cost-effective planning and deployment of **offshore renewable electricity**, taking into account the potential for on-site or nearby hydrogen production, **and strengthen EU's industrial leadership in offshore technologies** (2020).
- Explore establishing minimum **mandatory green public procurement** (GPP) criteria and targets in relation to **renewable electricity**, possibly as part of the revision of the Renewable Energy Directive (June 2021), supported by **capacity building** financing under the LIFE programme.
- Tackle remaining barriers to a **high level of renewable electricity supply** that matches the expected growth in demand in end-use sectors, including through the review of the Renewable Energy Directive (June 2021).

To further accelerate the electrification of energy consumption:

- As part of the **Renovation Wave** initiative, promote the further electrification of buildings' heating (in particular through heat pumps), the deployment of on-buildings renewable energy, and the roll-out of electric vehicle charging points (from 2020 onwards) , using all available EU funding, including the Cohesion Fund and InvestEU.
- Develop more specific measures for the use of **renewable electricity in transport**, as well as for **heating and cooling** in buildings and industry, in particular through the revision of the Renewable Energy Directive, and building on its sectoral targets (June 2021).
- Finance pilot projects for the **electrification of low-temperature process heat in industrial sectors** through Horizon Europe and the Innovation Fund (by 2021).
- Assess options to support the further decarbonisation of industrial processes, including through electrification and energy efficiency, in the revision of the **Industrial Emissions Directive** (2021)[34].
- Propose to revise **CO_2 emission standards for cars and vans** to ensure a clear pathway from 2025 onwards towards zero-emission mobility (June 2021).

To accelerate the roll-out of electric vehicle infrastructure and ensure the integration of new loads:

- Support the roll-out of **1 million charging points by 2025**, using available EU funding, including the Cohesion Fund, InvestEU and Connecting Europe Facility funding, and communicate regularly on the funding opportunities and regulatory environment to roll out a charging infrastructure network (from 2020 onwards).

- Use the upcoming **revision of the Alternative Fuels Infrastructure Directive** to accelerate the roll-out of the alternative fuels infrastructure, including for electric vehicles, strengthen interoperability requirements, ensure adequate customer information, cross-border usability of charging infrastructure, and the efficient integration of electric vehicles in the electricity system (by 2021).
- Take up corresponding requirements for charging and refuelling infrastructure in the **revision of the** Regulation for the Trans-European Transport network **(TEN-T)** (by 2021) and explore greater synergies through the revision of the **TEN-E** Regulation in view of possible energy network related support for cross border high capacity recharging as well as possibly hydrogen refuelling infrastructure (by 2020).
- Develop a **Network Code on Demand Side Flexibility**[35] to unlock the potential of electric vehicles, heat pumps and other electricity consumption to contribute to the flexibility of the energy system (starting end-2021).

3.3. Promote renewable and low-carbon fuels, including hydrogen, for hard-to-decarbonise sectors

While direct electrification and renewable heat present the most cost-effective and energy-efficient decarbonisation options in many cases, there are a number of end-use applications where they might not be feasible or have higher costs. In such cases, a number of renewable or low-carbon fuels could be used, such as sustainable biogas, biomethane and biofuels, renewable and low-carbon hydrogen or synthetic fuels. These cases include a number of industrial processes, but also transport modes such as aviation and maritime, where sustainable alternative fuels such as advanced liquid biofuels and synthetic fuels will have an essential role to play. Rapid action is necessary: for example, in aviation, only around 0.05% of total jet fuel consumption comes from liquid biofuels.

Unlocking the potential of renewable fuels produced from sustainable biomass

Today, **biofuels**[36]**, biogas and biomethane**[37] account for only 3.5% of all gases and fuels consumption[38] and are largely based on food and feed crops. Their full potential should be achieved in a sustainable manner, which mitigates climate, pollution and biodiversity risks [39].

Biofuels will have an important role to play, notably in hard-to-decarbonise transport modes, such as aviation or maritime – including through hybridisation projects linking biofuels and renewable hydrogen production. The Commission will in particular explore how to support to

[35] Under Regulation (EU) 2019/943.

[36] Biofuels are liquid fuels produced from biomass, through a variety of processes and using a variety of feedstock, such as biodiesel, bioethanol and Hydrotreated Vegetable Oils (HVO).

[37] Biogas is a gaseous mixture (primarily methane and carbon dioxide) produced from biomass, through the decomposition of organic matter in the absence of oxygen (anaerobically). Biogas can be used directly as a fuel, or be purified or "upgraded" into biomethane, which can thus be used for the same applications as natural gas and injected into the gas grid.

[38] Source: Eurostat.

[39] Directive 2018/2001 establishes a cap to first generation biofuels and limitations to high Indirect Land Use Change (ILUC) risk food and feedstocks, while reinforcing and extending sustainability criteria.

the quick development of innovative low-carbon fuels such as advanced biofuels, alongside synthetic fuels, across the whole value chain of the industry in Europe, leading to better coordination of the market actors and rapid increase of production capacity. Biomethane can contribute to the decarbonisation of the gas supply. However, the deployment of biofuels and biogases has so far been hampered by regulatory uncertainty. The revised Renewable Energy Directive has taken a first step to address these issues by introducing a target of 3.5% for the consumption of advanced biofuels and biogas in transport[40]. The 6% greenhouse gas emission target of the Fuel Quality Directive also supports the deployment of biofuels. In addition, the Communication '*The role of Waste to Energy in the circular economy*'[41] clarifies which waste-to-energy approaches are more sustainable, including for the production of biomethane, while the Biodiversity Strategy underlines that the use of whole trees and food and feed crops for energy production should be minimised.

The revision of the Renewable Energy Directive, as well as the Commission initiatives to boost the supply and uptake of sustainable aviation and maritime fuels announced in the European Green Deal, will present opportunities for further targeted support to accelerate the development of the market for biofuels and biogases.

Promoting the use of renewable hydrogen in hard-to-decarbonise sectors

Today, hydrogen contributes less than 2% of Europe's energy consumption[42], and is almost exclusively produced from unabated fossil fuels. Hydrogen has an important role to play in reducing emissions in hard-to-decarbonise sectors, in particular as a fuel in certain transport applications (heavy-duty road transport, captive fleets of buses, or non-electrified rail transport, maritime transport and inland waterways) and as a fuel or feedstock in certain industrial processes (steel, refining or chemical industries – including to produce 'green fertilisers' for agriculture). Carbon dioxide in reaction with hydrogen can also be further processed into synthetic fuels, such as synthetic kerosene in aviation. In addition, hydrogen brings other environmental co-benefits, such as the lack of air pollutant emissions.

Hydrogen produced through electrolysis using renewable electricity can play a particularly important "nodal" role in an integrated energy system, where it can help integrate large shares of variable renewable generation, by offloading grids in times of abundant supply, and providing long term storage to the energy system. It can also allow local renewable electricity production to be used in a range of additional end-use applications.

The Hydrogen Strategy, adopted today, presents measures to create the conditions for hydrogen to contribute to decarbonising the economy in a cost-effective way, addressing the whole hydrogen value chain to support economic growth and recovery. The priority for the EU is to develop hydrogen production from renewable electricity which is the cleanest solution. In a transitional phase however, other forms of low-carbon hydrogen are needed to replace existing hydrogen and kick-start an economy of scale. In addition to providing financial support in certain end-use applications, the Commission will consider establishing

[40] The use of "advanced" biofuels and biogas (gained from certain residues and by-products from agriculture and forestry activities, industrial and municipal waste in full respect of the waste hierarchy, and other ligno-cellulosic material) is encouraged under the Directive 2018/2001. Biofuels and biogas need to meet sustainability requirements to be statistically accounted as renewable under that Directive.

[41] COM(2017) 034 final.

[42] Calculated on the basis of production data provided by Fuel Cells and Hydrogen Joint Undertaking, includes the use of hydrogen as a feedstock; FCHJI, Hydrogen roadmap, 2019.

minimum shares or quotas of renewable hydrogen in specific end-use sectors. Renewable and low-carbon fuels (including hydrogen) can be promoted most effectively if they can be easily distinguished from more polluting energy sources. Therefore, the Commission will work to introduce a comprehensive terminology and a European certification system covering all renewable and low carbon fuels[43]. Such a system, based notably on full life cycle greenhouse gas emissions savings, will allow for more informed choices when deciding on policy options at the EU or national level.

Enabling carbon capture, storage and use to support deep decarbonisation, including synthetic fuels

Even a fully integrated energy system cannot completely eliminate CO_2 emissions from all parts of the economy. Together with alternative process technologies**, carbon capture and storage** (CCS) is likely to play a role in a climate-neutral energy system. In particular CCS can address hard-to-abate emissions **in certain industrial processes**, thus enabling these industries to have a place in a climate neutral economy and maintaining industrial jobs in Europe. In addition, if the stored CO_2 was captured from biogenic sources or directly from the atmosphere, CCS could even compensate residual emissions in other sectors.

An alternative to the permanent storage of CO_2 is to combine it with renewable hydrogen to produce synthetic gases, fuels and feedstock (Carbon Capture and Use, or CCU). Synthetic fuels can be associated with very different levels of greenhouse gas emissions depending on the origin of CO_2 (fossil, biogenic, or captured from the air), and the process used. Fully carbon-neutral synthetic fuels require sourcing the CO_2 from biomass or the atmosphere. Synthetic fuels are currently inefficient in terms of energy required for production and are confronted with high production costs. Support to progress the development of this conversion technology, including demonstration and upscaling of the full production process, is relevant with a view to having substitutes for fossil fuels in particular in the most difficult to decarbonise sectors, which may continue to rely on high energy density liquid fuels, such as aviation. As their production requires large amounts of renewable energy, their uptake would have to be matched by a corresponding increase in renewable energy supply.

It is of key importance to properly monitor, report and account the emissions and removals of CO_2 associated with the production of synthetic fuels to reflect correctly their actual carbon footprint. Complementing the current greenhouse gas emission monitoring and reporting system, a robust carbon removal certification mechanism will ensure the traceability of the CO2 along its emission, capture, use and potential reemission throughout our economic system. The Development of a carbon removal certification system, as announced in the Circular Economy Action Plan[44], can provide regulatory incentives for market take-up of synthetic fuels.

The uptake of CO_2 capture and usage in Europe is slow, with investment and operational costs still high. There are also barriers that prevent the transport of CO_2 to those places where it will be stored or used. In some parts of the EU, there are also concerns among citizens and political decision-makers regarding the storage of CO_2. An annual European CCUS Forum could be convened as part of the Clean Energy Industrial Forum to further study options to foster CCUS projects.

[43] See also Hydrogen Strategy, COM(2020) 301 final.
[44] COM(2020) 98 final.

Key actions

- Propose a **comprehensive terminology for all renewable and low-carbon fuels** and a **European system of certification** of such fuels, based notably on full life cycle greenhouse gas emission savings and sustainability criteria, building on existing provisions including in the Renewable Energy Directive (June 2021).
- Consider **additional measures to support renewable and low-carbon fuels,** possibly through minimum shares or quotas in specific end-use sectors (including aviation and maritime), through the revision of the Renewable Energy Directive and building on its sectoral targets (June 2021), complemented, where appropriate, by additional measures assessed under the REFUEL Aviation and FUEL Maritime initiatives (2020). The support regime for hydrogen will be more targeted, allowing shares or quota only for renewable hydrogen.
- Promote the financing of **flagship projects** of **integrated, carbon-neutral industrial clusters** producing and consuming renewable and low-carbon fuels, through Horizon Europe, InvestEU and LIFE programmes and the European Regional Development Fund (from 2021).
- Stimulate first-of-a-kind production of **fertilisers from renewable hydrogen** through Horizon Europe (from 2021).
- Demonstrate and scale-up the **capture of carbon** for its use in the production of **synthetic fuels**, possibly through the Innovation Fund (from 2021).
- Develop a regulatory framework for the **certification of carbon removals** based on robust and transparent carbon accounting to monitor and verify the authenticity of carbon removals (by 2023).

3.4. Making energy markets fit for decarbonisation and distributed resources

In an integrated energy system, trustworthy and efficient markets should guide customers towards the most energy-efficient and cheapest decarbonisation option, on the basis of prices that properly reflect all the costs of the energy carrier used.

Ensuring non-energy price components contribute to decarbonisation across energy carriers

In many EU Member States, **taxes and levies on electricity are higher than for coal, gas or heating oil**, both in absolute value and as a share of total price[45]. Over the past years, charges and levies on electricity, such as those financing renewable support schemes, have continued to increase. At the same time, the *energy component* of the final (retail) electricity price has reduced both in absolute and relative terms. This has widened the asymmetry in non-energy costs between electricity and gas: for retail household electricity prices, for instance, taxes and levies now add up to 40% of the final price, compared to 26% of gas or 32% for heating oil[46]. Some other energy- or carbon-intensive sectors such as international aviation and maritime transport, as well as agriculture, can be subject to low or no VAT, and, under the current Energy Taxation Directive, to low energy excise duties.

Also, carbon costs are only partially internalised, or not internalised at all, in some sectors (e.g. road and maritime transport or space heating) or in some Member States, or may not be

[45] DG Energy, Energy Prices and Costs Report, 2019.
[46] DG Energy, Energy Prices and Costs Report, 2019.

sufficient to incentivise decarbonisation in some sectors covered by the ETS (e.g. aviation). Finally, fossil fuel subsidies also persist in the EU.

Overall, applicable taxes and levies, including carbon pricing, are not applied homogeneously across energy carriers and sectors, and create distortions towards the use of specific carriers.

Finally, the specificities of electricity used for energy storage or for hydrogen production should also be considered, avoiding double taxation (so that energy is only taxed once when delivered for final consumption), and avoiding unjustified double grid charges.

Placing consumers at the centre

Clear and easily accessible information is essential to enable citizens to change energy consumption patterns and switch to solutions that support an integrated energy system. Customers – citizens and businesses alike – should be informed on their rights, on the technology options available to them and their associated carbon and environmental footprint, so they can make informed choices and truly drive decarbonisation. It is important that vulnerable households are not left behind and energy poverty is addressed[47]. In the context of the Climate Pact, the Commission will launch a **consumer information campaign** on their rights related to the energy market.

Customer information rights for electricity customers have been enhanced with the Clean Energy Package – further work remains to be done for **gas and district heating customers** to align those with the electricity sector.

Furthermore, **markets for sustainable products and services** are still missing, for instance for products such as steel, cement and chemicals produced from renewable or low-carbon fuels. As part of the broader efforts announced in the Circular Economy Action Plan to improve sustainability of such intermediary products, consumers should receive relevant information that may encourage them to pay a price premium.

Making electricity and gas markets fit for decarbonisation[48]

The Clean Energy Package already laid the foundation to make **electricity markets** fit to integrate large amounts of variable electricity and the integration of flexibility from demand response and storage, while improving the market signals to stimulate investments and empowering electricity customers. The challenge now lies in implementing the measures properly, in particular the completion of market coupling through day-ahead and intraday trading.

As we progress towards climate-neutrality, the volume of natural gas consumed in Europe will progressively reduce. While **gaseous fuels** are expected to continue to play an important role in our energy mix[49], the mix of gaseous fuels will highly depend on the chosen decarbonisation pathway. By 2050, the share of natural gas in gaseous fuels is projected to

---

[47] In line with the European Pillar of Social Rights (principle 20) that guarantees the access to essential services, including energy.

[48] Issues connected to the creation of open and competitive markets for hydrogen are covered in the dedicated Hydrogen Strategy.

[49] LTS, figure 33: the 1.5TECH and LTS 1.5LIFE scenarios project a share of 18-22% for gaseous fuels in the EU energy mix by 2050, compared to 25% today.

reduce to 20%, and most of the remaining 80% gaseous fuels should be of renewable origin[50]. But the future mix of these gaseous energy carriers – biogas, biomethane, hydrogen or synthetic gases – is hard to project.

The gas market regulatory framework should be re-examined so as to facilitate the uptake of renewable gases and customer empowerment, whilst ensuring an integrated, liquid and interoperable EU internal gas market.

In this context, issues to consider include the connection to infrastructure and the market access for distributed production of renewable gases, including at the distribution level, which would complement the use of renewable gases in a more local, circular context (such as biogas used on farm). In addition, with renewable gases injected into the gas network, and supply sources further diversified, the quality parameters of gas consumed and transported in the EU would change. To avoid this leading to market segmentation and trade restrictions, there is a need to look at how to ensure the interoperability across gas systems and the unhindered flow of gases across Member States' borders.

Updating the State aid framework

The current review of the State aid framework, and notably its guidelines on energy and environmental protection, will contribute to energy system integration by providing a fully updated and fit-for-purpose enabling framework for a cost-effective deployment of clean energy and the well-functioning of energy markets[51].

Key actions

To promote a level-playing field across all energy carriers:

- **Issue guidance to Member States** to address the high charges and levies borne by electricity and to ensure the **consistency of non-energy price components across energy carriers** (by 2021).
- Align the taxation of energy products and electricity with EU environment and climate policies, and ensure a harmonised taxation of both storage and hydrogen production, avoiding double taxation, through the **revision of the Energy Taxation Directive**[52].
- Provide more consistent carbon price signals across energy sectors and Member States, including through a **possible proposal for the extension of the ETS to new sectors** (by June 2021).
- Further work towards the **phasing out of direct fossil fuel subsidies,** including in the context of review of the State aid framework and the revision of the Energy Taxation Directive (from 2021 onwards).
- Ensure that the revision of the **State aid framework** supports cost-effective decarbonisation of the economy where public support remains necessary (by 2021).

---

50 LTS, figures 28 to 32.

51 Beyond those provisions, the Research, Development and Innovation Framework and the Communication setting out criteria for the analysis of the compatibility with the internal market of State aid to promote the execution of important projects of common European interest are also relevant.

52 Initial Impact Assessment for the revision of the Energy Taxation Directive: https://ec.europa.eu/info/law/better-regulation/have-your-say/initiatives/12227

To adapt the gas regulatory framework:

- **Review the legislative framework to design a competitive decarbonised gas market,** fit for renewable gases, **including to empower gas customers** with enhanced information and rights (by 2021).

To improve customer information:

- In the context of the Climate Pact, launch a **consumer information campaign** on energy customer rights (by 2021).
- **Improve information to customers on the sustainability of industrial products** (in particular steel, cement and chemicals) as part of the sustainable product policy initiative, and, as appropriate, through complementary legislative proposals (by 2022).

3.5. A more integrated energy infrastructure

Energy system integration will translate into more physical links *between* energy carriers. This calls for a **new, holistic approach for both large-scale and local infrastructure planning**, including the protection and resilience of critical infrastructures. The objective should be to make the most of the existing infrastructure while avoiding both lock-in effects and stranded assets. Infrastructure planning should facilitate the integration of various energy carriers and arbitrate between the development of new infrastructure or re-purposing of existing ones. It should consider alternatives to network-based options, especially demand-side solutions and storage.

The various components of the energy network will all need to evolve. Modern low-temperature **district heating systems** should be promoted, as they can connect local demand with renewable and waste energy sources, as well as the wider electric and gas grid – contributing to the optimisation of supply and demand across energy carriers. However, district heating networks account for 12% of the total final heating and cooling energy consumption, are highly concentrated in a few Member States, and only a limited share of them are highly efficient and based on renewables.

Implementing the Clean Energy Package will contribute to a more efficient use of **electricity grids**. Nevertheless, accelerated electrification of new end-uses will require to reinforce the grid, mainly at distribution but also at transmission level[53], and to make it smarter. Electrolysers will link up to the electricity grids, and possibly to existing gas grids. In the context of the assessment of Member States' National Energy and Climate Plans, the Commission will also analyse the progress towards the 15% electricity interconnection target and consider appropriate action, including in the context of the revision of the TEN-E Regulation.

The existing **gas network** provides ample capacities across the EU to integrate renewable and low-carbon gases and repurposing gas network for hydrogen applications may provide in some cases a cost-efficient solution, including to transport renewable hydrogen from offshore renewable electricity parks. Ports could transform into centres receiving electricity produced offshore, as well as liquid hydrogen, and thereby contribute to enable the global trade of renewable hydrogen or synthetic fuels.

---

[53] In line also with the EU electricity interconnection target included under Regulation (EU) 2018/1999 on the Governance of the Energy Union and Climate Action

While gas networks may be used[54] to enable blending of hydrogen to a limited extent during a transitional phase, **dedicated infrastructures for large-scale storage and transportation of pure hydrogen**, going beyond point-to-point pipelines within industrial clusters, may be needed. The expansion of hydrogen refuelling stations will also be assessed as part of the revision of the Alternative Fuels Infrastructure Directive and the Regulation on the TEN-T guidelines.

Similarly, further reflection is needed on the role of **CO_2-dedicated infrastructure,** transporting CO_2 across industrial sites for further use, or to large scale storage facilities.

The Regulation on Trans-European Networks in Energy (TEN-E) provides a framework for the selection of infrastructure projects of common interest in electricity, gas and CO_2 networks. In this context, currently, **10-Year Network Development Plans** (TYNDPs) at national and EU level are developed in parallel for gas and electricity by Transmission System Operators. Future network planning will require a more integrated and cross-sectoral approach, notably of the electricity and gas sectors. It will also require full consistency with climate and energy targets, including alignment with National Energy and Climate Plans, an adequate consideration of all relevant actors, and should be informed by local conditions.

The Commission will ensure that the ongoing revision of the **TEN-E Regulation** makes it fully consistent with climate neutrality and enables the cost-effective integration of the energy system, as well as its integration with the digital and transport systems. The ongoing revision of the Regulation on the Trans-European Transport network (TEN-T) will also seek synergies with the TEN-E Regulation, aiming to generate additional opportunities for the decarbonisation of transport from the new vision of energy infrastructure planning.

Finally, increasing interdependencies mean that disruptions in one sector can have an immediate impact on operations in others and a new coherent security approach for both physical and digital infrastructures is necessary. The new Security Union Strategy will address both critical infrastructure and cybersecurity and needs to be accompanied by sector-specific initiatives to tackle the specific risks faced by critical infrastructures such as in an integrated energy system and infrastructure.

Key actions

- Ensure that the **revisions of the TEN-E and TEN-T regulations** (in 2020 and 2021, respectively) fully support a more integrated energy system, including through greater synergies between the energy and transport infrastructure, as well as the need to achieve the 15% electricity interconnection target for 2030.
- **Review the scope and governance of the TYNDP** to ensure full consistency with the EU's decarbonisation objectives and cross-sectoral infrastructure planning as part of the revision of the TEN-E Regulation (2020) and other relevant legislation (2021).
- Accelerate investment in **smart, highly-efficient, renewables-based district heating and cooling networks**, if appropriate by proposing stronger obligations through the revision of the Renewable Energy Directive and the Energy Efficiency Directive (June 2021), and the

[54] A blend of 5-20% by volume can be tolerated by most systems without the need for major infrastructure upgrades or end-use appliance retrofits or replacements. See for instance BNEF, Hydrogen Economy Outlook, 2020.

financing of flagship projects.

3.6. A digitalised energy system and a supportive innovation framework

Digitalisation supports energy system integration – it can enable dynamic and interlinked flows of energy carriers, allow for more diverse markets to be connected with another, and provide the necessary data to match supply and demand at a more disaggregated level and close to real time. A combination of novel sensors, advanced data exchange infrastructures, and data handling capabilities that make use of Big Data, Artificial Intelligence, 5G and distributed ledger technologies can enhance forecasting, allow the remote monitoring and management of distributed generation and improve asset optimisation, including the on-site use of self-generation. Digitalisation is also key to unleash the full potential of customers having a flexible energy consumption across different sectors to contribute to the efficient integration of more renewables. More generally, digitalisation provides an opportunity for economic growth and worldwide **technological leadership**.

Digitalisation represents a challenge in terms of **increased energy demand** for ICT equipment, networks and services which needs to be adequately managed in the context of an integrated energy system. Digitalisation also brings other challenges for the energy sector, in particular on **ethics, privacy and cybersecurity,** with consideration to the specificity of the energy sector.

A system-wide **Digitalisation of Energy action plan** could accelerate the implementation of digital solutions, building on the Common European energy data space[55], announced in the European Data strategy. As part of the implementation of the Clean Energy Package, it will roll-out smart metering, foster demand response, and ensure the interoperability of energy-related data. It will also use EU funding opportunities such as the Connecting Europe Facility, InvestEU, the Digital Europe Programme, and structural funds to scale-up solutions developed through Horizon Europe.

Finally, **research and innovation** will be a key enabler to create and exploit new synergies in the energy system, for instance in relation to e-mobility, to heating or to the decarbonisation of energy intensive industries. Research should focus on enabling lower maturity technologies to come into the market, while more mature and innovative technologies should be scaled up through large scale demonstrations through the proposed Horizon Europe and its partnerships and making use of complementarities among the various EU funding programmes. Technology development must go hand in hand with societal innovation.

Key actions

- Adopt a **Digitalisation of Energy Action plan** to develop a competitive market for digital energy services that ensures data privacy and sovereignty and supports investment in digital energy infrastructure (2021).
- Develop a Network Code on **cybersecurity in electricity**[56] with sector-specific rules to increase the resilience and cybersecurity aspects of cross-border electricity flows,

[55] https://ec.europa.eu/info/sites/info/files/communication-european-strategy-data-19feb2020_en.pdf
[56] Under Regulation (EU) 2019/943.

common minimum requirements, planning, monitoring, reporting and crisis management (by end 2021).

- Adopt the implementing acts on **interoperability** requirements and transparent procedures for access to data within the EU (first one in 2021)[57].
- Publish a new **impact-oriented clean energy research and innovation outlook** for the EU to ensure research and innovation supports energy system integration (by end 2020).

4. CONCLUSIONS

This communication sets out a strategy and a set of actions to ensure that energy system integration can contribute to the energy system of the future – one that is efficient, resilient, secure and driven by the twin goals of a cleaner planet and a stronger economy for all.

The transition to a more integrated energy system is of crucial importance for Europe, now more than ever. First, for recovery. The COVID-19 outbreak has weakened the European economy and undermines the future prosperity of European citizens and business. This strategy is part of the recovery plan. It proposes a path forward that is cost-effective, promotes well-targeted investments in infrastructure, avoids stranded assets and leads to lower bills for businesses and customers. In short, it is key to accelerating the EU's emergence from this crisis and for mobilising necessary EU funding, including the Cohesion Fund, as well as private investments. Second, for climate neutrality. Energy system integration is essential to reach increased 2030 climate targets and climate neutrality by 2050. It exploits energy efficiency potential, enables a larger integration of renewables, the deployment of new, decarbonised fuels, and a more circular approach to energy production and transmission.

Finally, a truly integrated energy system is vital for shaping Europe's global leadership in clean energy technologies, by leveraging Europe's existing strengths – an established leadership in renewable energy; a regional approach to system operation and infrastructure planning; liberalised energy markets; and excellence in energy innovation and digitalisation.

We are still far from where we need to be by 2050. To get there, both fundamental and far-reaching action is urgently needed. The Clean Energy Package adopted in 2018-2019 lays the foundation for system integration and should be fully implemented. In the context of the Green Deal, the new actions outlined in this communication will add the necessary scope and speed to move towards the energy system of the future, contributing to the EU's increased climate ambition and to shaping the legislative revisions to be proposed in June 2021. The time to act is now.

Obviously, system integration will not be a one-size-fits-all process: despite a common objective of EU climate neutrality by 2050, EU Member States have different starting points. As such, Member States will follow different pathways, depending on their respective circumstances, endowments and policy choices, which are already reflected in the respective National Energy and Climate Plans (NECPs). This strategy offers a compass to direct these efforts in the same direction.

Citizens have a central role in system integration. This means that they should contribute to shape the implementation of this Strategy, using the Climate Pact as well as other existing citizen fora to advance the system integration agenda.

---

[57] Under Article 24 of Directive (EU) 2019/944.

With this document, the Commission invites the Council, the Parliament, other EU institutions and all stakeholders to focus on how to take forward energy system integration in Europe. It intends to invite interested parties to debate in a **large dedicated public event** at the end of this year and to contribute to the **public consultations and impact assessments that will inform the preparation of the follow-up proposals envisaged for 2021 and beyond**.

DECARBONISING HEAT IN BUILDINGS

PUTTING CONSUMERS FIRST

APRIL 2021

FOREWORD

As a nation, we are fast approaching a crunch point, with Net Zero and associated policies leading the pull away from fossil fuels. When discussing decarbonisation with friends and at work, I am struck by how often heat in homes is omitted from the conversation, and when it is remembered, by how much the peak heat demand in winter is underestimated. I therefore very much welcome the thoughtful contributions this report provides.

Clearly heat pumps have a huge role to play in the transition to low carbon heat in homes. Indeed, there is a temptation to assume we can rely on them exclusively. After all, they are available now and can be delivered house by house, while other solutions such as hydrogen must take place at the community or street scale, which introduces a whole new set of barriers to overcome, including finding new low carbon ways to scale up hydrogen production.

It is however, as this report highlights, much more complicated than simply switching from boilers to heat pumps, not least due to the unsuitability of some homes for heat pumps, but also because it appears that delivering peak heat to homes in winter may be an insurmountable challenge for all electrically delivered heat. Thus, alternative, and complimentary approaches are needed, to align with practical constraints of people's homes and deliver huge swings in demand and service peak heat, which is perhaps the brightest feather in the hydrogen's proponents cap.

Where the balance lies between combinations of these, and other technologies identified in this report, is not yet known. It will depend on many factors, not least the success of any future national domestic retrofit campaigns, consumer acceptance of different technologies, the speed of the decarbonisation of electricity and the emergence of new solutions like house batteries and energy storage.

It is a cliché to say there is no silver bullet to low carbon heating, but this document provides tangible evidence to inform policy decisions around the scale, speed and direction of future low carbon heating in UK homes. It presents a refreshingly accessible and pragmatic evaluation of low carbon heating options from the point of view of one of the most important stakeholders, who are -sadly - often excluded from discussions and decision making associated with decarbonising heat in homes: householders like you and me.

Dr David Glew,
Head of Energy Efficiency and Policy at the Leeds Sustainability Institute

EXECUTIVE SUMMARY

From an evaluation of the GB housing stock, it is clear that a mosaic of low carbon heating technologies will be needed to reach net zero. While heat pumps are an important component of this mix, our analysis shows that it is likely to be impractical to heat many GB homes with heat pumps only.

A combination of lack of exterior space and/or the thermal properties of the building fabric mean that a heat pump is not capable of meeting the space heating requirement of 8 to 12m homes (or 37% to 54% of the 22.7m homes assessed in this report) or can do so only through the installation of highly disruptive and intrusive measures such as solid wall insulation. Hybrid heat pumps that are designed to optimise efficiency of the system do not have the same requirements of a heat pump and may be a suitable solution for some of these homes. This is likely to mean that decarbonised gas networks are therefore critical to delivery of net zero.

3 to 4m homes[1] (or 14% to 18% of homes assessed in our analysis) could be made suitable for heat pump retrofit through energy efficiency measures such as cavity wall insulation. For 7 to 10m homes there are no limiting factors and they require minimal/no upgrade requirements to be made heat pump-ready.

Nevertheless, given firstly the levels of disruption to the floors and interiors of homes caused by the installation of heat pumps, and secondly the cost and disruption associated with the requirement to significantly upgrade the electricity distribution networks to cope with large numbers of heat pumps operating at peak demand times - combined with the availability of a decarbonised gas network which requires a simple like-for-like boiler replacement - is likely to mean that many of these 'swing' properties will be better served through a gas based technology such as hydrogen (particularly when consumer choice is factored in) or a hybrid system. A recent trial run in winter 2018-19 by the Energy System Catapult revealed that all participants were reluctant to make expensive investments to improve the energy efficiency of their homes just to enhance the performance of their heat pump. They were more interested in less costly upgrades and tangible benefits, such as lower bills or greater comfort.

This means that renewable gases including hydrogen as heating fuels are a crucial component of the journey to net zero and the UK's hydrogen ambitions should be reflective of this.

The analysis presented in this paper focuses on the external fabric of the buildings, further analysis should be undertaken to consider the internal system changes that would be required for heat pumps and hydrogen boilers, for example BEIS Domestic Heat Distribution Systems: Gathering Report from February 2021 which considers the suitability of radiators for the low carbon transition.

1 The analysis takes into account the number of energy efficiency measures that have already been installed in GB homes.

THE CHALLENGE OF DECARBONISING HEAT

Near-full decarbonisation of heat for buildings is one of the biggest challenges in reducing emissions from the energy system to net zero by 2050.

To date much of the success in reducing emissions has come from the power sector, with more recent successes in the transport sector. Having plucked the low hanging fruit, we now need to work on reaching the harder to decarbonise areas, and in particular heat in buildings.

In 2019, the residential sector emitted 65.2 Mt of carbon dioxide emissions (CO_2), accounting for 19 per cent of all CO_2[2]. The main source of emissions in the residential sector is the use of fossil fuels (mainly natural gas) for heating and cooking.

Currently 85% or 23 million homes are connected to the gas grid with the remaining 15% or 4 million using oil or LPG as their main heating fuel or electric heating. In the next 10 to 15 years, the majority of these systems will need to be replaced with low-carbon alternatives if the UK is to meet its net zero target.

Compared to decarbonisation of the power sector, where emission reductions were delivered without shifts required in consumer behaviour, reducing emissions from buildings need support from consumers and access to their homes.

This means it is also critical to consider what the consumer experience of the transition to low carbon heat feels like and how this might affect preferences.

A COMBINATION OF LOCALITY-SPECIFIC SOLUTIONS WILL DELIVER HEAT DECARBONISATION IN HOMES

Residential building emissions can be reduced through a combination of switching to low-carbon sources and energy efficiency improvements. However, the heterogeneity of the UK building stock means that heating decarbonisation will not be through a single nationwide solution and will likely require a mix of locality-specific solutions tailored to the opportunities, requirements and constraints of each location.

The two primary routes to reducing emissions in buildings are electrification of heat using heat pumps and/or to repurpose gas distribution grids to carry hydrogens rather than natural gas. A mix of electric and low-carbon gas technologies are expected to be predominantly used.

Other solutions such as biomethane, heat networks, hybrid heat pumps and direct electric heating are also expected to be part of the mosaic of technologies needed to deliver heat decarbonisation in different locations.

ENERGY EFFICIENCY WILL BE CRUCIAL TO ACHIEVE NET ZERO

Reducing underlying energy demand through increasing energy efficiency will be critical. Installing energy efficiency measures in homes and buildings has an upfront cost but reduces energy demand and carbon emissions. Some energy efficiency measures are simple to install and pay for themselves quickly, these should be installed in combination with any heating system replacement. For example, thermostatic radiator valves, smart thermostats and draughtproofing interventions fall into this category.

Insulation is a more tricky case, some types of insulation are relatively cheap and easy to install, whereas others can be highly disruptive. Insulation of cavity walls falls into the first category, as it is a non-intrusive measure which has a major impact on heat lost through the walls[3]. Over two-third of homes in the GB were built with cavity walls, and in nearly 65% of these, or 11.2[4] million homes, there is evidence of insulation being installed. Insulation of the remaining ~4,8 million homes that have unfilled walls should be a priority.

Meanwhile, nearly one third of homes in the GB were built with brick and stone solid walls, most of which remain uninsulated due to the costs and disruption caused by the installation of solid wall insulation. This typically involves either installing cladding on the exterior of the building, which fundamentally changes the aesthetic of the property and may require planning permission, or installing insulation on the interior face of the walls which is highly disruptive and reduces interior floor area as well as requiring redecoration works, floor insulation installation also follows a similarly disruptive process[5]. For this reason, it is likely to be highly challenging to make the case for these types of measures to be installed in significant numbers.

2 BEIS (2020). UK Greenhouse gas emissions, provisional figures 2019.
3 Loft insulation also falls into this category
4 Estimates based on sample of 22.7m properties used in this analysis. For further details on the methodology, please see section 'Housing stock analysis'
5 New technology solutions such as Q-Bot can be less disruptive

CUSTOMER EXPERIENCE IS KEY

Heat and comfort are necessities for life. And as the decarbonisation of heat will require changes to people's homes, the consumer needs to be bought into the process and actively participate. Therefore, in transitioning to a zero-carbon future it is imperative that firstly the quality of these services is maintained or improved and secondly that they are inclusive and accessible to all customer types, not just a subset.

Different heating technologies have different impacts on customer experience, both in terms of the enduring interaction with the product and also of the installation itself.

THE ENDURING EXPERIENCE OF DIFFERENT TECHNOLOGIES WILL SUIT DIFFERENT TYPES OF CONSUMERS

On the enduring experience, it is important to recognise that heat pumps tend to produce heat at lower temperatures to hydrogen boilers, meaning they are more suited to maintaining relatively static room temperatures and require larger surface areas for heat dissipation, making them highly suitable for underfloor heating, or otherwise requiring relatively larger radiators than boilers.

Heat pumps are also not suitable for replacing combi boilers for instantaneous production of hot water, instead requiring a hot water storage tank. Again the temperature output of heat pumps means this tank needs to run more continuously given the longer time required to heat the water.

THE INSTALLATION OF DIFFERENT HEAT TECHNOLOGIES WILL SUIT DIFFERENT TYPES OF PROPERTIES

The majority of homes in Great Britain are heated by either a natural gas or other fossil fuel boiler system. Replacing a boiler with a heat pump has a number of key challenges.

INSTALLING A HEAT PUMP IN EXISTING HOMES

For heat pumps to work effectively as the sole heating source, the buildings need to be thermally efficient. Heat pumps typically require both internal and external space as well as changes to internal systems such as radiators which can cause disruption to consumers.

INSTALLING A HYDROGEN-READY BOILER IN EXISTING HOMES

The installation of a hydrogen boiler is a like-for-like replacement for a conventional heating system which does not need to be supported by the interventions needed to fit a heat pump in a home. There is also no requirement in this case for exterior or additional interior space in the home. This can also be the case for some compact hybrid systems.

KEY ☆ New

THERMAL PROPERTIES

Buildings need to be thermally efficient in order for heat pumps to be a viable heating technology. As building regulations have evolved over the last century, the thermal properties of new builds have improved - however this means that there is a wide range of thermal characteristics depending on a properties age. In general, the older the property, the worse the thermal efficiency and hence the greater level of intervention required to make the property suitable for retrofit. As discussed above, while some insulation measures are entirely rational, others may well be impractical. This means there is likely to be a correlation between the construction date of a property and its applicability for heat pumps.

HEATING SYSTEMS

Heat pumps produce lower output temperatures than boilers meaning that the internal heating systems of properties need to be altered. Depending on the floor construction and covering, an underfloor heat distribution system may be most suitable alternatively, new, larger radiators may need to be added or replaced. The cost and disruption of changing internal systems mean that customer preference will play a role in uptake of different technologies.

SPACE REQUIREMENTS

There are interior and exterior space requirements for the installation of a heat pump. Storage cylinders for hot water are required [and are typically larger than those required for boilers]. Aside from the necessity of hot water storage, the heat pump itself requires equipment to be installed both on the exterior of the property and the interior. Whilst the internal equipment is similar in footprint to a boiler, the necessity of availability of exterior space can be a constraint especially in more densely populated areas and may also feature in consumer preference decisions.

On the other hand, the installation of a hydrogen boiler is a like-for-like replacement for a conventional heating system which does not need to be supported by the interventions needed to fit a heat pump in a home. There is also no requirement in this case for exterior or additional interior space in the home. This can also be the case for some compact hybrid systems.

Experience from schemes that require work to be carried out in the home such as the smart meter roll out or the energy company obligation (ECO) show that consumers are generally reticent to what are perceived to be enforced changes within their homes. Both of these schemes have ultimately underdelivered against expectations and they only required relatively small interventions. It is likely to be politically and practically challenging to impose obligations on householders to install highly intrusive and disruptive measures.

This has been evidenced in early heat pump retrofit trials, where even proactive consumers that were interested in heat pump installation have dropped out of the schemes once the scale of associated works to the home became apparent.

IT IS IMPORTANT TO CONSIDER THE REALITY NOT THE ABSTRACT

When considering the likely technology mix it is crucial to examine the actual make up of the housing stock, both in terms of the age and therefore thermal properties and the archetype and therefore likely availability of space. It is also imperative to consider consumer preference given the scale of challenge and need to engage with them.

Heat pumps are expected to be the most suitable technology to decarbonise heat in a number of situations. However, in other cases with less potential for electrification, low-carbon gas-based solutions will be the optimal solution. Examples of where heat pumps may be an optimal solution and where they may not be suitable are discussed next based on property archetypes.

LOW CARBON HEATING OPTIONS

HEAT PUMPS

Heat pumps are an established technology that can immediately and substantially reduce emissions from heating and hot water consumption. A heat pump uses the heat in the air or the ground as the main source of energy and requires electricity to operate. For every unit of electricity that is put in, the technology has the potential to produce 3 to 4 units of heat, depending on the type of heat pump.

Running costs will depend on heat demand, system efficiency and electricity prices. Depending on the heating fuel that it replaces, it can lead to energy bill savings. A heat pump operates at higher efficiencies at low flow temperatures which means that in buildings that are poorly insulated, the technologies is less efficient. Therefore, in order to make heat pumps viable, buildings need to be highly thermally efficient.

A report[6] prepared for BEIS in 2018 found the costs of the work involved to install an air-source heat pump to be between £8,750 and £21,550 depending on the heat pump size and interventions required. Meanwhile, the same report found the costs of the work involved to install a ground-source heat pump to be between £13,200 and £27,350, depending on the heat pump size and interventions required. Ground-source heat pumps may be more suitable for communal heating.

In 2019, heat pumps represented two per cent of the heat market.

HYDROGEN BOILERS

Hydrogen boilers can replace conventional gas boilers on a like-for-like basis and has the potential to eliminate carbon emissions from heating completely, with water as the only by-product. Hydrogen-ready boilers are being developed by UK leading boiler manufacturers in the UK. Two UK boiler manufacturers are currently involved in the Government's Hy4Heat programme that looks at the technical and safety challenges of replacing conventional appliances with hydrogen-ready ones. One of the workstreams of the programme focuses on development of consumer ready and fully certified prototype hydrogen boilers to be installed in consumer homes. The programme has already reported on the technical details of the technologies and more information will be made available in the annual report to be published in December. It is expected that hydrogen-ready boilers will be available to consumer at no or small additional cost to methane boilers.

'Green hydrogen' can be produced through a process that makes use of electricity - if the electricity comes from renewable sources such as wind, solar or hydro, then the hydrogen is effectively green. In the production of 'blue hydrogen', the gas is produced by steam methane reformation and the emissions are curtailed using carbon capture and storage.

HYBRID HEAT PUMPS

Hybrid heat pump systems combine a boiler and a heat pump to meet a building's space heating and hot water requirements. Hybrid heat pumps are a low-carbon heating solution that can deliver emission savings that vary depending on the overall efficiency of the system that in turn is determined by the mode of operation. Hybrids can be run such that the boiler meets the entire heat demand at times when the heat pump is unable to operate ('switch' mode) or such that the heat pump contributes to meeting the space heating demand and the boiler provides the remaining heat required for the water to reach the right temperature at all times ('parallel' mode).

Hybrid heat pumps can either be installed alongside existing high temperature emitters or with low temperature emitters. In contrast to electric heat pumps, relying on high temperature emitters is possible because the boiler component is capable of meeting the peak heat demand with higher flow temperatures, ensuring comfort can be achieved. Costs for installation are similar to heat pump only systems, on a £/kW basis though the heat pump size will be lower due to the hybrid nature of the system.

BIOMETHANE

Biomethane is a green gas chemically identical to methane that can be injected in the gas grid and deliver immediate carbon emission savings, without the requirement from consumers to change existing appliances.

Production of biomethane is based on anaerobic digestion of waste organic material through the breakdown of organic material by micro-organisms in the absence of oxygen to produce biogas. The biogas is then refined to produced biomethane.

The technology to produce biomethane is a commercially available solution. Until recently, installations have been supporting the injection of biomethane in the gas distribution network. In July 2020, National Grid connected a biomethane production facility (a farm) to the National Transmission System (NTS), injecting biomethane in the grid for the first time. The plant will support up to 15,000 cubic metres per hour of biogas flows which is enough renewable gas to supply ten households every hour.

The total potential supply of biomethane from waste in the UK will be limited by the amount of waste that can be cost-effectively accessed.

6 Delta-ee (2018). The Cost of Installing Heating. Measures in Domestic Properties. The findings are also reported in the fourth Environmental Audit Committee report on energy efficiency of existing homes.

HOUSING STOCK ANALYSIS

We have carried out an analysis of the GB housing stock based on the challenges discussed above.

Property archetypes are defined by their type and age. Data published in the National Energy Efficiency Data-Framework (NEED) Multiple Attributes Tables[7] is used to define the size of each archetype segment. This dataset, compiled in 2020, uses all properties contained on the 2019 VOA council tax database in Great Britain[8], where the property is assessed to have valid gas or electricity consumption. The dataset covers 82%[9] of properties registered to pay council tax in England and Wales[10] and 65%[11] in Scotland[12]. Building insulation and thermal elements are sourced from the English Housing Survey[13] from England and Wales[14] and from the House Condition Survey for Scotland[15,16].

While decarbonising heat will require a mosaic of solutions, our analysis focuses on the suitability of different building archetypes to the installation of an electric heat pump as the sole decarbonisation solution. We have considered heat pump suitability for each property archetype, focusing on the properties thermal efficiency, space availability and period features. When heat pump is not found to be a likely solution for the property archetype, a gas-based heating solution needs to be considered. Gas-based solutions include a range of options such as hydrogen boilers, hybrid heat pumps and biomethane injection into the grid. This approach allows us to establish whether network infrastructure to deliver gas-based solutions to consumer homes is requirement to deliver the country decarbonisation goals or whether the same objective can be achieved without it.

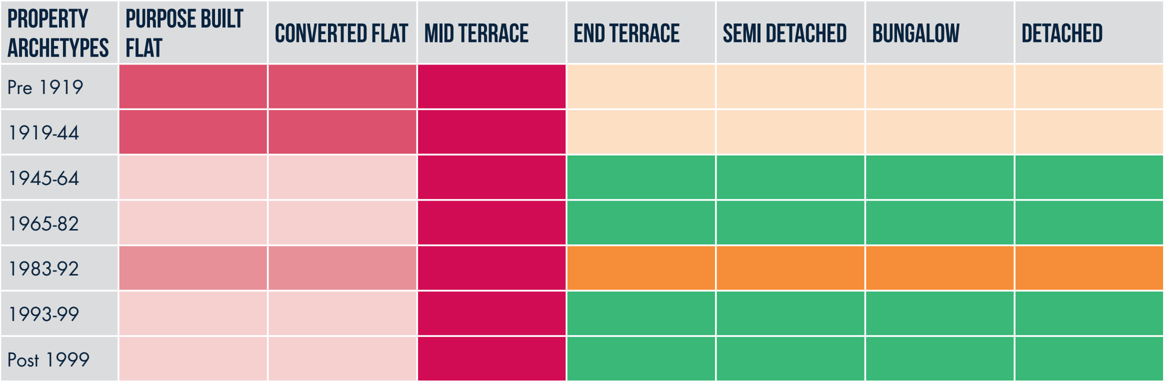
The results of this analysis are presented using a RAG assessment[17]. Based on their score against thermal efficiency and space availability metrics, each property archetype is considered as either:

- Likely suitable for a heat pump: these property archetypes require minimal or no energy efficiency upgrades and are not space-constrained;
- Possibly suitable for a heat pump: these property archetypes are either space-constrained or require energy efficiency and heating system upgrades;
- Not suitable for a heat pump: these property archetypes require significant energy efficiency and heating system upgrades, such as solid wall or underfloor insulation and/or are space-constrained.

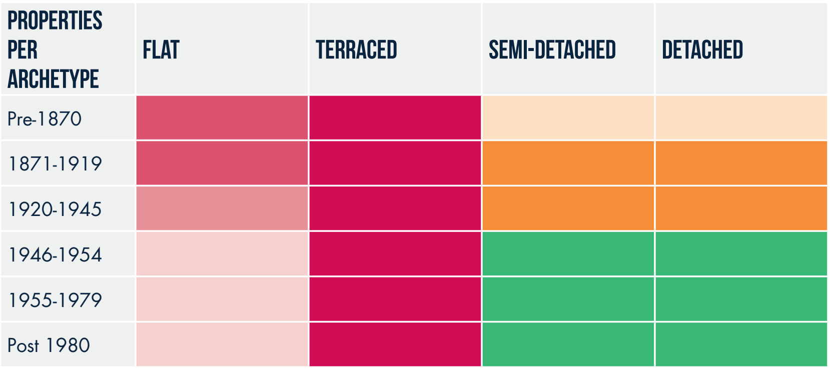
The score and suitability to a heat pump for each archetype is assigned based on the features of the typical property in each segment and on the overall number of properties that would require interventions in each group. The analysis of the estimated number of properties that may be suitable/possibly suitable/not suitable that is presented in the next section, takes into account the actual number of properties in each segment, the type of wall[18], and the number of energy efficiency upgrades that have been completed to date.

7 Multiple Attributes Table 2018 and Scotland Multiple Attribute Table 2018
8 The VOA database only covers properties that are registered to pay council tax. There are properties not included due to an inability to accurately match the property to an ordnance survey UPRN. The VOA dataset used for Scotland is based on 2014 data.
9 21.1 million
10 Coverage is limited by availability of information on electricity or gas consumption
11 1.57 million
12 Coverage is limited by availability of information on electricity or gas consumption.
13 DA6201: insulation - dwellings
14 Insulation and thermal properties of properties in Wales assumed to be the same as in England.
15 For Scotland, we used the wall type and insulation estimates published in the House Condition Survey as starting point. The percentage of homes with cavity walls and with insulation reported in the survey is broadly in line with the estimates reported for England. Given the lack of data on wall type and insulation by type and age for Scotland, we have assumed the same distribution observed for homes in England.
16 The percentage of homes build with solid walls assumed to be insulated is 8%, in line with the estimated published by the Climate Change Committee in 'Annex 2. Heat in UK buildings today'.
17 Please see appendix - RAG Assessment for the complete RAG assessment
18 For example, while the majority of properties built before 1940 were built with solid walls, some properties in this archetype were built with cavity walls. This is reflected in the analysis, as well as the number of energy efficiency interventions that has already been installed.

OVERALL SUITABILITY OF PROPERTIES IN ENGLAND AND WALES TO A HEAT PUMP[19]



OVERALL SUITABILITY OF PROPERTIES IN SCOTLAND TO A HEAT PUMP[20]



KEY

- Possibly suitable for communal heat pump with solid wall insulation/ not suitable
- Possibly suitable for communal heat pump with cavity wall insulation/ not suitable
- Possibly suitable for communal heat pump/ not suitable
- Possibly suitable for heat pump with cavity wall insulation
- Likely suitable for a heat pump
- Possibly suitable for heat pump with solid wall insulation
- Not suitable

Based on this analysis it is likely that heat pump only systems will be unsuitable for 37% to 54% of the existing housing stock.

While 14 to 18% could be practically adapted to be made suitable, consumer and societal choice will need to be factored in to determine whether this is the optimal technology solution.

There are limiting factors to installing a heat pump which means that the technology is highly unlikely to be suitable solution for 8 to 12m of homes or 37% to 54% of the properties considered in this analysis. These buildings include properties that were built with solid brick walls, uninsulated and/or space constrained e.g., flats and mid-terrace buildings as well as high rise buildings that would require non-standard insulation measures. There is likely to be variation among properties in the purpose-built flat and converted flat segments (some of these flats will be space constrained, others will not). This uncertainty is captured by the range estimate of properties considered to be unsuitable to a heat pump.

Hybrid heat pumps that are designed to optimise efficiency of the system do not have the same requirements of a heat pump and may be a suitable solution for some of the homes where a heat pump cannot work effectively as the sole heating source. Compact hybrids may be suitable for properties with space constraints.

Our analysis suggests that 3 to 4m homes or, 14% to 18% of homes considered in this paper could be made suitable for a heat pump following some energy efficiency improvements such as insulation of cavity walls. This includes detached, semi-detached, bungalow and end-terrace properties built with cavity walls. There is likely to be variation among properties in the purpose-built flat and converted flat segments (some of these flats will be space constrained, others will not). This uncertainty is captured by the range estimate of properties considered to be potentially suitable to a heat pump.

Our analysis suggests that 7 to 10m homes including detached, semi-detached, bungalow, end-terrace properties could be suitable for a heat pump given the limited space constraint and thermal efficiency of the buildings.

19 While the RAG assessment for mid terrace houses is the same as the assessment for flats, the installation of communal heat pump is not considered a potential solution for mid-terrace buildings given the buildings layout.

20 The assessment of terrace properties will vary depending on whether the properties are assumed to be mid-terrace or end-terrace houses. 70% of terrace properties in England are mid-terraces, the same assumption is made for Scotland, hence the table shows the assessment using this assumption. Our range captures the uncertainty in this variable.

CASE STUDIES

PRE-WAR MID-TERRACE

For nearly 1.6 million homes a combination of lack of exterior space and the thermal properties of the building fabric mean that a heat pump is not capable of meeting the space heating requirement of the property or can do so only through the installation of highly disruptive and intrusive measures.

Mid terraced houses are one of the most popular forms of housing in GB. There are 3.9 mid-terraced properties in GB[21] and 1.7 million were built pre 1930s, using solid bricks, the majority of which remains uninsulated

Several improvements to these properties would be required to make them suitable for a heat pump and lack of exterior space could make the installation challenging.

Insulating the envelope of the building is key to reduce the heat loss of the property. In addition to insulating the walls, a combination of roof, ceiling and/or floor insulation is likely to be necessary to reduce the heat loss to a level that can guarantee the efficient operation of the heat pump.

Replacement of existing radiators is likely to be needed to ensure the heat pump can operate at a low flow temperature. Alternatively, underfloor heating pipes may need to be installed.

Some of these interventions can be intrusive and disruptive to the householder. In addition, mid-terraced houses often lack the exterior space that is necessary to install the heat pump.

Another consideration is the period features of these properties which may be impacted by the interventions required to make them heat-pump ready and may reduce their value.

Overall, the building fabric requirements necessary for the efficient operation of a heat pump and the lack of exterior space means that the technology will not be the optimal solution to reduce emissions from heating from these properties.

DECARBONISING HEAT EMISSIONS FROM PRE-WAR MID-TERRACES

There are 1.8m mid-terrace houses in the UK that were built pre-war, using solid bricks. To be made heat-pump ready, a combination of the following interventions is likely to be required:

- Insulation of solid wall
- Insulation of ceiling and floor
- Replacement of radiators or installation of underfloor heating

These measures can cause significant disruption to the consumer. Even with these interventions, the installation of a heat pump may not only be challenging due to the disruptive improvements required but also impractical given the space constraint.

Given these barriers, decarbonisation of pre-war mid-terraced houses through a heat pump may be impractical. **A hydrogen boiler or compact hybrid is likely to be the most suitable and practical solution in this case.**

21 These estimates are based on a sample of 22.7m properties used in this analysis.

CONVERTED FLATS

For nearly 520,000 converted flats, a heat pump is not likely to be the optimal decarbonisation solution, due to the thermal properties of the buildings and space constraints.

Nearly 850,000 homes in the GB are converted flats, 60% of them built with uninsulated solid walls[22].

Several improvements are likely to be required to make the properties suitable for a heat pump.

The building envelope will require insulation. In addition to walls, ceiling and or floor will need to be insulated. Radiators or underfloor heating may need to be added or replaced to allow the heating system to operate optimally. These interventions can be intrusive and cause significant disruption to the householder.

In addition, converted flats could have limited exterior space and can be space constrained, particularly in dense urban areas. The space constraint combined with the thermal characteristics of converted flats means that a heat pump is not likely to be the optimal solution for the majority of converted flats.

DECARBONISING HEAT EMISSIONS FROM CONVERTED FLATS

There are 520,000 converted flats in GB that were built using solid bricks and that have not been insulated.

To be made heat-pump ready, a combination of the following interventions is likely to be required:

- Insulation of solid wall
- Insulation of ceiling/floor
- Replacement of radiators or underfloor heating

These measures can cause significant disruption to the end-user. Even with these interventions, the installation of a heat pump may still be impractical due lack of exterior and interior space for the installation of the technology.

Given these constraints, decarbonisation of converted flats through heat pump may not only be challenging due to the disruptive improvements required but also impractical. **A hydrogen boiler or compact hybrid is likely to be the most suitable and practical solution in this case.**

22 These estimates are based on a sample of 22.7m properties used in this analysis.

POST-WAR SEMI-DETACHED

For nearly 2.3m semi-detached properties built between 1945 and 1980s with cavity walls, heat pumps could be a suitable solution due to the thermal characteristics of the buildings and availability of both exterior and interior space. However, in some cases refurbishment work may still be required.

There are nearly 3.2 million semi-detached homes in GB[23], built between 1945 and 1980s with cavity walls. There is evidence of insulation in 2.3 million of these homes.

There properties are likely to be suitable for a heat pump, however some of them will require refurbishment work to ensure the heat loss is minimised. In addition, these buildings have no exterior or interior space constraints.

There is evidence that nearly 70% of semi-detached properties have filled cavity walls, however heating system upgrades such replacement or installation of radiators and underfloor heating may still be required.

Semi-detached properties are not space constrained, hence heat pumps could be fitted easily outside the property and a hot water cylinder and radiators be installed within the home.

Overall, heat pumps are likely to be a plausible solution for semi-detached homes with filled cavity walls, after small improvements to the properties.

DECARBONISING HEAT EMISSIONS FROM POST-WAR SEMI DETACHED HOMES

There are nearly 2.3 million semi-detached properties built between 1945 and 1964 with filled cavity walls.

These properties are likely to be suitable for a heat pump, however some of them will require refurbishment work, such as replacement of radiators or underfloor heating.

There less likely to be exterior or interior space constraints, hence a heat pump is likely to be a suitable solution, equally consumers may prefer a hydrogen boiler or hybrid system.

23 These estimates are based on a sample of 22.7m properties used in this analysis.

MODERN DETACHED

For nearly 720,000 detached properties in GB heat pumps are likely to be the optimal heating solution due to thermal characteristics of these buildings and availability of both exterior and interior space.

There are nearly 720,000 detached properties in the GB that were developed after 1999[24].

A heat pump is likely to be the optimal solution for detached properties built in the last two decades. There are no thermal insulation barriers and detached homes usually have both exterior and interior space.

With the tightening of building regulations, the majority of homes built after 1996 are assumed to have filled cavity walls.

Detached properties have adequate exterior space for the installation of a heat pump and sufficient interior space for heating system upgrades such as the installation or replacement of radiators, where that is a requirement. Overall, a heat pump is likely to be the optimal solution for these homes.

DECARBONISING HEAT EMISSIONS FROM MODERN DETACHED HOUSES

There are nearly 720,000 detached properties built in recent years.

The majority of properties built after 1996 are assumed to have filled cavity walls.

No major intervention is expected to be required in these homes to make them suitable for the installation of a heat pump, the optimal solution may however be driven by consumer preference.

24 These estimates are based on a sample of 22.7m properties used in this analysis.

FINDINGS

- Heat decarbonisation will require a mix of locality-specific solutions tailored to the needs of the housing stock and other geographical features. The best solution for each home will depend on a number of factors including the thermal insulation, space constraints, housing density, availability and capacity of energy infrastructure and whether the home is existing or new build. It is expected that both heat pumps and decarbonised gases amongst others will play a crucial role in the transition to Net Zero.
- However, there is no practical way of heating the majority of UK homes with heat pumps only. For 8 to 12m homes a combination of lack of exterior space and/or the thermal properties of the building fabric mean that a heat pump is not capable of meeting the space heating requirement of the property or can do so only through the installation of highly disruptive and intrusive measures such as solid wall insulation. Hybrid heat pumps that are designed to optimise efficiency of the system do not have the same requirements of a heat pump and may be a suitable solution for some of these homes. This is likely to mean that decarbonised gas networks are therefore critical to delivery of net zero.
- 3 to 4m homes could be made suitable for heat pump retrofit through energy efficiency measures such as cavity wall insulation.
- Nevertheless, given firstly the levels of disruption to the floors and interiors of homes caused by the installation of heat pumps and secondly the cost and disruption associated with the requirement to significantly upgrade the electricity distribution networks to cope with large numbers of heat pumps operating at peak demand times combined with the availability of a decarbonised gas network, many of these 'swing' properties will be better served through a gas-based technology (particularly when consumer choice is factored in).
- The analysis presented in this paper focuses on the external fabric of the buildings, further analysis should be undertaken to consider the internal system changes that would be required for heat pumps and hydrogen boilers, for example BEIS Domestic Heat Distribution Systems: Gathering Report from February 2021 which considers the suitability of radiators for the low carbon transition.
- In some cases, the best solution may be a combination of electrification and hydrogen. This would be delivered by hybrid heat pumps that combine a hydrogen boiler with an electrically driven heat pump, where the hydrogen boiler meets the winter peak and the heat pump provides the base heat demand.
- The UK gas transportation infrastructure can be converted incrementally from natural gas to hydrogen to support the switchover with limited disruption to the consumer. A number of trials focused on hydrogen as a potential option for decarbonising heat have already demonstrated the technical and economic feasibility of the conversion.
- This means that hydrogen as a heating fuel alongside renewable gases more broadly are a crucial component of the journey to net zero and the UK's hydrogen ambitions should be reflective of this.

Decarbonization of the building heating system in Metro Vancouver: comparison of two transition pathways.

A report prepared for FortisBC Inc.

by:

Dr. Kevin Palmer-Wilson

Dr. Andrew Rowe

Dr. Peter Wild

07 May 2021

Executive summary

This report documents preliminary modelling methods and results from the investigation of natural gas substitution in the building heating sector of Metro Vancouver, British Columbia. The investigation aims to identify energy system transition pathways that achieve substantial greenhouse gas emission reductions from heating decarbonization. This report aims to inform stakeholders on the work completed to date, and to provide opportunity for comment in an effort to align future work with stakeholder needs.

Energy consumption in buildings causes 25% of greenhouse gas emissions in Metro Vancouver. Natural gas combustion for space and water heating is responsible for the vast majority of those emissions, making buildings the second largest source of greenhouse gases behind the transportation sector. The elimination of those emissions by mid-century is necessary to mitigate the global climate change.

Optimal approaches to address emissions in the building sector have been focused on improving efficiency and substituting natural gas with low-carbon electricity. Building heating electrification has been highlighted in BC's Building Electrification Roadmap as a key strategy to decarbonize this sector. Although British Columbia's hydroelectric power system provides very low-carbon electricity, the available energy and power generation capacity likely cannot replace all fossil fuels consumed in other sectors. Operating constraints limit flexible dispatch to about one third of annual hydroelectric energy supplies. The majority of water inflows occur in early summer when electricity and heat demand is low. This report concludes that significant additional low-carbon electricity production and storage capacity will be needed if electrification were chosen as a primary strategy to meet emission reduction targets.

This study conducts a quantitative assessment of key issues that require consideration when addressing heating decarbonization in Metro Vancouver. An energy system model is used to compare two transition pathways that substitute natural gas with electricity (electrification pathway) or biogas and electrolytic hydrogen (renewable gas pathway). The study evaluates the pathway differences and key uncertainties that impact the outcomes. The analysis starts by developing a representation of the region's building heat demand by fuel and equipment type. Next, the model cost-optimizes energy production and storage capacities able to supply space heat, water heat, and electricity for a one-year period at hourly resolution. To quantify energy system requirements for range of possible futures, seven scenarios are developed to evaluate different assumptions on technology costs, performance characteristics, energy demand, and renewable resource supply.

Preliminary results show that exclusive electrification can increase the peak electricity demand beyond available hydropower capacity. Lack of dispatchable generation alternatives then requires significant electricity storage. In this study, a five-day period without wind and solar availability required over 350 GWh of electric energy storage, equivalent to approximately 35 large pumped storage facilities. The environmental impact and the public opposition to such facilities may bar the installation of this infrastructure and pose a barrier to emission reduction targets. Due to the high cost of meeting peak electricity demand with storage technologies, avoiding an increase in this peak indicates high value.

Replacing natural gas with renewable gas can avoid increasing the peak electricity demand and use surplus electricity during off-peak times to produce hydrogen. Installing 4.5 GW of electrolyzers and 1000 GWh (3.6 PJ) of hydrogen storage capacity can sufficiently supplement limited biogas supplies to meet peak gas and electricity demand if wind and solar are unavailable during low-temperature weather conditions. That storage capacity may be available at low cost if barriers to underground hydrogen storage can be overcome. For comparison, the underground Aitken Creek facility can store up to 80,000 GWh of natural gas. Although the process of converting electricity to hydrogen to heat provides lower overall efficiency than direct electrification, this process can be cost-effective to avoid large electricity storage requirements.

The scenario analysis shows that costs of the electrification and renewable gas transition pathways are sensitive to assumptions around heat demand and variability of energy supply, but either pathway can be lower cost. At low heat demand, the existing hydroelectric capacity is almost sufficient to serve the additional electric power demand, making electrification the lowest cost option. If variable wind and solar power are not available during very cold periods, then the renewable gas pathway is lower cost because this pathway avoids the high cost of electricity storage. Overall, either pathway can be lower cost, but the range of costs is more narrow in the renewable gas pathway.

1. Foreword

This report documents a collaborative research project between FortisBC Inc. and the Institute for Integrated Energy Systems (IESVic) at the University of Victoria. FortisBC is the largest retailer of natural gas in British Columbia. The organisation serves gas to over 1,000,000 customers across the province, and provides electricity to 180,000 customers across a smaller regional network. FortisBC is developing comprehensive plans to reduce greenhouse gas emissions in the province by expanding biogas production, replacing higher-emission fuels, and implementing energy efficiency measures.

IESVic unites interdisciplinary research capacity to identify feasible pathways that result in sustainable energy systems. Research on renewable energy, clean transportation, energy technology, sustainable communities, and human dimensions create comprehensive solutions for complex problems. Throughout its 30-year history, IESVic research has been driven by collaborations with numerous partners in academia, government, and the private sector. As a comprehensive resource and key partner for implementing Canada's climate strategy, IESVic is pleased to submit this report to help inform effective decarbonization policy and adaptation to a low-carbon economy.

Funding for this research was provided by FortisBC Inc., MITACS, and the Energy Modelling Initiative.

2. Introduction

Mitigating climate change and limiting global warming to below 2 °C by 2100 will require reducing global greenhouse gas emissions to net-zero by mid-century. The Canadian province of British Columbia (BC) has committed to reducing its 2007-level emissions by at least 80% by 2050. The Metro Vancouver Regional District plans to become carbon neutral that same year. Achieving these targets necessitates the elimination of fossil fuel combustion as an energy source.

Replacing fossil fuels with low-carbon electricity has been identified as among the lowest-cost strategies to mitigating climate change (Trottier Energy Futures Project, 2016). The BC Building Electrification Roadmap highlights the economic opportunities of this strategy, and details the necessary actions by public and private actors to facilitate the transition (Integral Group, 2021). BC generates 98% of its electricity from renewable sources; hydro power contributes the largest share at 91%, biomass and wind provide another 6% and 1%, respectively (Canada Energy Regulator, 2021). This low-carbon electricity offers immediate emission reduction potential via electrification, but the available energy and power generation capacity cannot replace the vast quantity of fossil fuel consumed in all other sectors.

Comparison of the fossil fuel-based energy consumption with sectoral greenhouse gas emissions highlights the large challenge of decarbonization via electrification. In the residential, commercial and institutional building sectors of British Columbia, natural gas provided 68% (124 PJ) of space and water heating in 2018, or 45% of the total secondary energy consumption in those building sectors (Natural Resources Canada, 2020). These 124 PJ of natural gas caused 12% (6.1 $Mt_{CO2eq.}$) of the province's overall emissions related to fossil fuel combustion, but the energy contained in that natural gas would equate to 46% (34.4 TWh) of the province's total electricity generation in that year (Canada Energy Regulator, 2021; Natural Resources Canada, 2020). An energy-equivalent replacement of that natural gas with electricity would eliminate a relatively small fraction of overall emissions while significantly increasing electricity demand.

To enable electrification, replacement of furnaces with energy efficient heating appliances like heat pumps can reduce energy consumption considerably. Improving the energy efficiency of building envelopes can further reduce thermal demand. Nevertheless, electrifying the heating system increases winter peak electricity demand because air-source heat pump efficiency declines in very low-temperature weather. Ground-source heat pumps are less affected by cold weather, but their underground complexity often prevents retrofitting existing building stock. Increasing the peak electricity demand will require installation of additional dispatchable generation capacity. Only one third of annual hydroelectric energy supplies can be dispatched flexibly in British Columbia, and the majority of water inflows occur in early summer when electricity demand is low (BC Hydro, 2017a). An additional challenge arises from the need to simultaneously reduce greenhouse gas emissions in other sectors because electrification of road transportation and industry would further increase electricity demand.

Figure 1 shows that between 2007 and 2018, the all-time peak hourly load on British Columbia's integrated transmission system approached BC Hydro's 2018 load carrying capability. That figure suggests that British Columbia's installed electricity generation capacity is constrained in peak demand hours with little surplus to accommodate additional winter peak load. Note that load on the integrated transmission system is likely not equivalent to loads "carried" exclusively by BC Hydro, and the electricity system may be able to accommodate a larger additional peak load than this analysis suggests. Nevertheless, meeting electrification demands in the absence of other dispatchable generation capacity will likely require installation of designated electricity storage facilities like batteries or pumped hydro.

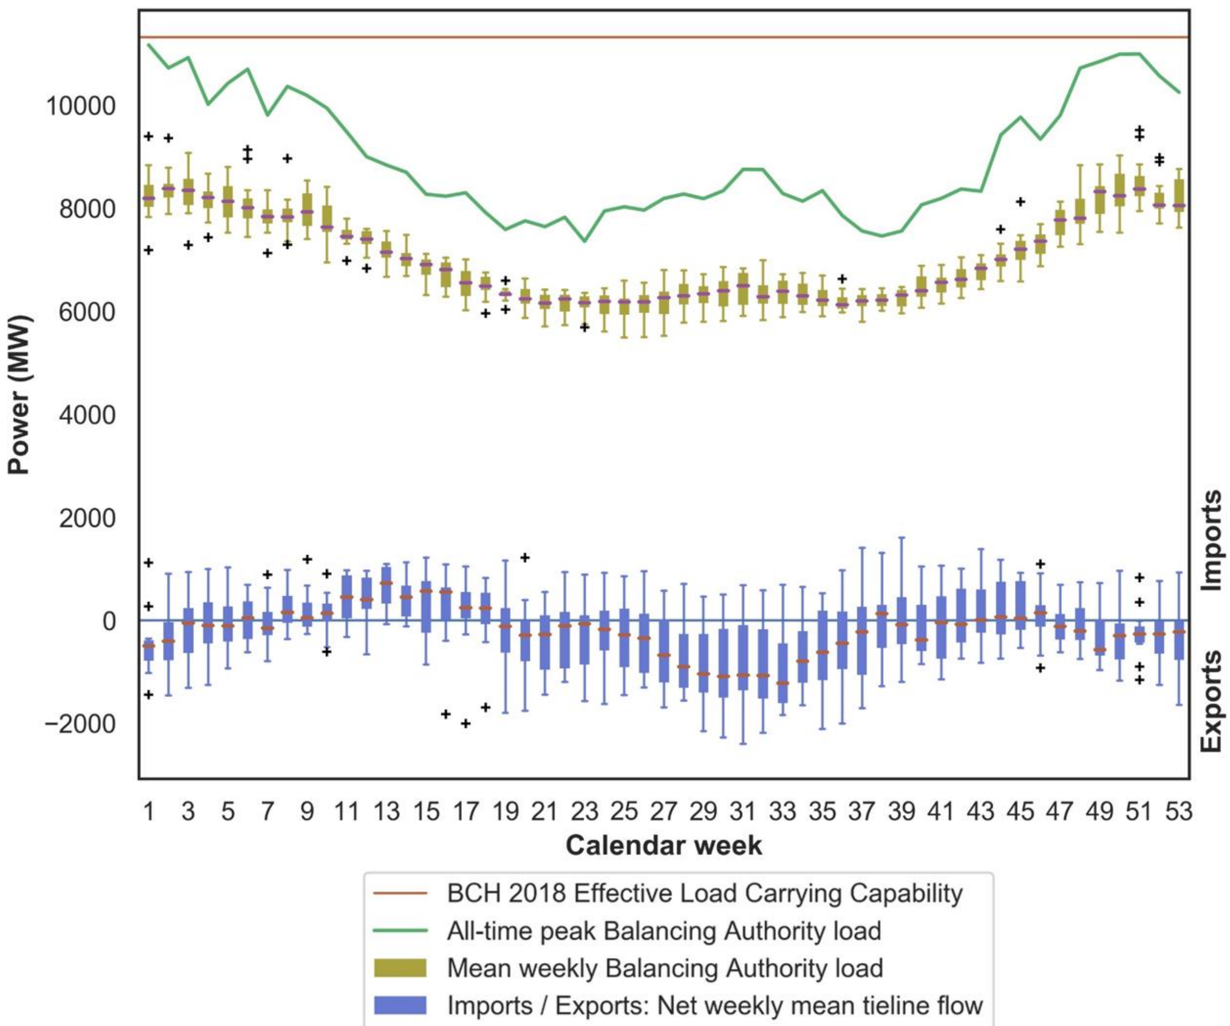

Figure 1. Comparison of electric load, cross-border trade, and load-carrying capability in British Columbia highlights the capacity constraint in winter peak-demand periods. The red straight line shows BC Hydro's 2018 Effective Load Carrying Capability of 11,315 MW (BC Hydro, 2016, Ch. 3, Table 3-9). The green line shows all-time peak load between 2007 and 2018 as recorded by the Balancing Authority's "Telemetred Load" (BC Balancing Authority, 2021). Boxplots of telemetered load in yellow and electricity net import/export in blue (BC Hydro, 2021) show the variability of weekly means between 2007 and 2018. Imports/exports show the sum of flows across BC-US and BC-AB tie lines.

Replacing natural gas with biogas or electrolytic hydrogen offers an alternative to direct electrification and does not increase winter-peak electricity demand. Power-to-gas technologies facilitate use of low-cost gas storage capacity to indirectly store electricity from variable renewable sources, reducing electricity storage requirements, retaining gas infrastructure to avoid stranded assets, and increasing resilience to energy demand and supply variability.

This report describes the investigation of substituting natural gas in the building heating sector of the Metro Vancouver Regional District in British Columbia, Canada. The following sections describe the system model development, energy demand estimation, scenario assumptions, and highlights important modelling results and sensitivities, followed by recommendations for future research.

3. Methods

The study presented in this report cost-optimizes a combined electricity and gas system model of the Metro Vancouver Regional District in British Columbia, Canada. Two distinct transition pathways compare electrification and renewable gas alternatives. The model reveals system costs, emission reductions, and electricity and gas production and storage capacity requirements. Along each transition pathway, seven scenarios vary technology costs, energy demand, and renewable energy resource availability. These scenarios delineate probable upper and lower energy system bounds for a range of potential futures.

Energy demands include space heat, water heat, and electricity that excludes heating. To overcome limited data availability, annual end-use energy demands are calculated from historic secondary energy consumption and technology efficiency records. Next, hourly demands are constructed by estimating normalized profiles and scaling these profiles to match annual demands (Section 3.2). Residential profiles are derived from proprietary electricity consumption data recorded at the household level. Commercial and institutional profiles are derived from building models. Correlating temperature records and space heat demand produces a profile for low-temperature conditions. The resulting hourly data enables the investigation of supplying demand with variable renewables like wind and solar power, and related storage requirements.

Note that the analysis investigates to supply past end-use energy demands. No estimation of future end-use demand occurs. This approach is chosen to avoid the additional uncertainty related to forecasting energy demand at hourly resolution. Building efficiency improvements might reduce energy demands, population growth might increase demand, and climate change might shift the demand profile. These factors and their effect on energy system requirements are not included here but warrant further study.

3.1. Energy system model

This study applies the Open Source Energy System Model OSeMOSYS (Howells et al., 2011) to investigate the energy system transition of Metro Vancouver. This linear programming framework expands and dispatches gas and electric energy production and storage to supply energy demands at minimum total annualized costs (Figure 2). The model determines the necessary capacities for natural gas substitution rates from 0 to 100% for a one-year period at hourly resolution.

In the electrification pathway, air-source heat pumps and electric resistance water heaters exogenously replace natural gas-consuming space and water heaters. Baseboard heaters are not replaced. In the renewable gas pathway, biogas and hydrogen replace natural gas via exogenously mandated renewable gas consumption rates. To limit the computational complexity of hourly time steps, the substitution occurs "overnight" at the beginning of the modelling period. No long-term evolution occurs. Instead, the model separately optimizes the energy system for each substitution rate. Iterating over the same one-year model period with varying electrification and renewable gas rates reveals energy system expansion trends.

The energy demands water heat and space heat constitute end-use demands. Electricity constitutes demand that serves non-heating loads. Air-source heat pumps and baseboard resistance heaters consume electricity, and furnaces consume gas to provide space heat. Electric and gas water heaters provide hot water.

The model uses existing hydro electricity and natural gas production to supply demands at the zero substitution rate. As necessary to meet demand at higher substitution rates, the model can choose to expand wind and solar electricity generation, biogas production, electricity and gas storage, and hydrogen production via electrolysis. This substitution reduces greenhouse gas emissions endogenously.

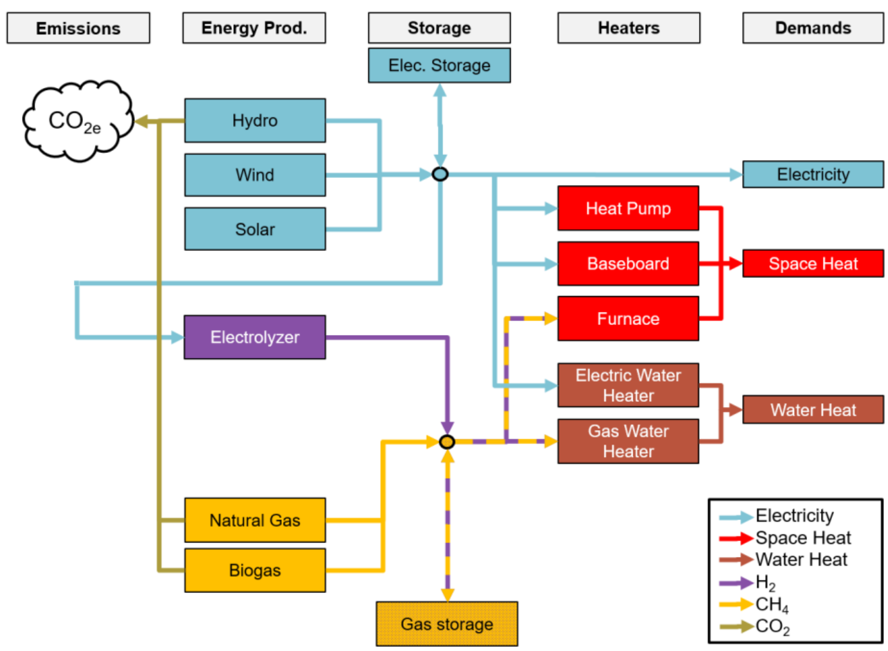

Figure 2. Energy system model used to investigate electrification and renewable gas pathways for Metro Vancouver. In the electrification pathway furnaces and gas water heaters are replaced by electric heat pumps and electric water heaters. In the renewable gas pathway, natural gas is replaced by biogas and electrolyzed hydrogen.

3.2. Energy demands

The end-use space heat, end-use water heat, and non-heating electricity demands shown in Figure 3 are each constructed from an annual demand and a normalized profile. The total annual space and water heat demands are population-scaled from provincial secondary energy consumption records for the year 2016 (Natural Resources Canada, 2020). Space heat and water heat include natural gas and electricity consumed in the residential and commercial sectors. Annual electricity demand is based on the BC Hydro fiscal 2016 total electricity supply (BC Hydro, 2016). Non-heating electricity excludes electric heating. Space heater efficiencies (Natural Resources Canada, 2020) and water heater efficiencies (NRCan, 2012) are used to estimate end-use energy demands from the available secondary energy consumption data.

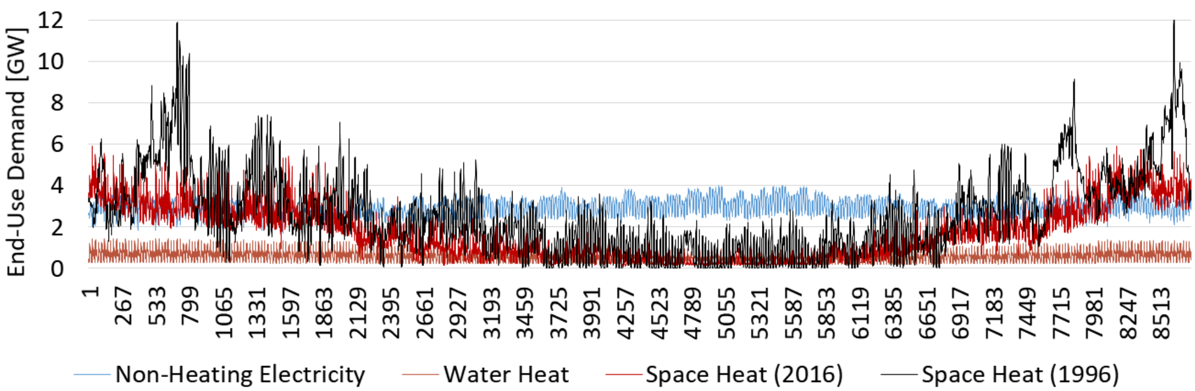

Figure 3. Estimated hourly end-use energy demands for Metro Vancouver are the product of annual secondary energy demand records, heater efficiencies, and normalized hourly demand profiles. The 2016 space heat demand profile is based on residential sector data recorded in 2016, and modelled commercial sector data produced from typical meteorological year (TMY3) temperatures. The 1996 space heat demand profile is hindcast using 1996 temperatures and represents the demand that Metro Vancouver – as it existed in 2016 – would have experienced under a 1996 temperature profile.

The energy demand profiles determine the fraction of annual energy demand that the model must provide in each hour of the year. The commercial space and water heat demand profiles are based on 15 commercial reference building models that represent ~ 70% of the commercial building stock in the United States of America (NREL, 2011). The residential water heat demand profile is based on data in the Cost Effectiveness tool published by Ontario's Independent Electricity System Operator (IESO, 2019). The residential space heat demand profile is derived from proprietary residential electricity demand data provided to the authors of this report by the utility BC Hydro, as described by Palmer-Wilson (2020, chap. 5.6). The non-heating electricity demand profile is the difference between the provincial electricity demand profile (BC Balancing Authority, 2021) and the space and water heat demands served by electricity.

Based on 2016 residential demand and typical mean year commercial demand, the estimated hourly end-use space heat energy demand in Metro Vancouver peaks at 5.9 GW. That demand may underestimate the peak demand under low temperature conditions. Personal correspondence between the authors of this report and FortisBC Inc. revealed that natural gas delivery in British Columbia reached over 18 GW of secondary energy above baseload during a minimum temperature weather event in 2020.

To better represent energy system requirements during low-temperature conditions, a regression analysis between space heat demand and ambient temperature is performed using hourly temperatures recorded at the Pitt Meadows Climate Station between 1995 and 2019. In that dataset, the lowest temperature of -16 °C occurred in 1996. The 3197 heating degree days in that year are the third highest in the dataset. For comparison, the lowest temperature in 2016 was -12.8 °C with 2568 heating degree days.

To hind cast a low-temperature space heat demand profile, the regression analysis is applied to the residential and commercial sectors separately (Figure 4). For the residential sector, a second-degree polynomial equation minimizes square errors between hourly end-use space heat demand and ambient temperature. For the commercial sector, the equation was fitted onto the 90th percentiles of 20 temperature bins of equal width. This fitting onto 90th percentiles introduces uncertainty to the analysis but better captures the expected peak space heat demand during low temperature events. This adaptation is chosen because the bottom-up method that created the commercial heat demand data for separate building types does not produce normally distributed residuals around the equation of best fit.

Next, the residential and commercial equations of best fit each hind cast respective hourly space heat demand profiles using the 1996 temperatures. The resulting demand profile peaks at 12 GW for the temperature profile recorded in 1996.

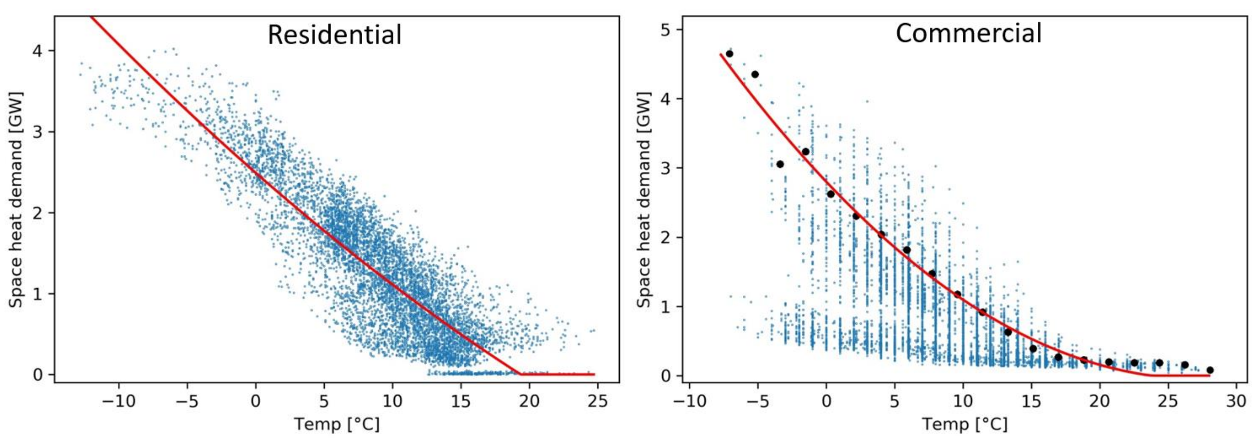

Figure 4. End-use space heat demand versus temperature in the residential and commercial sectors. The red curve shows the second-degree polynomial equation of best fit. The residential equation is fitted directly onto the temperature data and results in a Coefficient of Determination $R^2 = 0.84$. The commercial equation is fitted onto the 90th percentiles (black dots in right graph) of 20 temperature bins of equal width to better capture peak space heat demand during low temperature events.

3.1. Heating technologies

Heating technologies consume electricity or gas to supply the end-use space and end-use water heat demands. Heating efficiencies listed in Table 1 are constant throughout the modelling period for all technologies except heat pumps. Their coefficient of performance (COP) varies by hour and depends on ambient temperature recorded at the Pitt Meadows Climate Station.

Table 1. Space and water heater efficiencies or coefficient of performance (COP). The efficiency determines the quantity of secondary energy that the model must supply to heating technologies in order to meet end-use demands.

Technology	**Efficiency/COP**	**Rationale**
Heat Pump Space Heater	1.5 to 3.0 (-16 to +20 °C)	Temperature-dependant average coefficient of performance observed on 23 residential non-cold-climate heat pumps (The Cadmus Group Inc., 2016, fig. 55)
Baseboard Space Heater	1.0	Assumed
Furnace Space Heater	0.95	Annul Fuel Utilisation Efficiency energy performance standard for gas furnaces without an integrated cooling component (Natural Resources Canada, 2019)
Electric Water Heater	0.95	Assuming 5% standby losses for electric tank water heaters
Gas Water Heater	0.735	Mean Energy Factor of storage and tankless gas water heaters (NRCan, 2012, p. 10)

The COP is derived from data collected for several different non-cold-climate heat pump models in Massachusetts and Rhode Island in the winter of 2016 (The Cadmus Group Inc., 2016, fig. 55). A linear interpolation between the known COP of two temperatures creates an hourly COP profile. The COP ranges from 1.5 at -16 °C to 3.0 at +20 °C where the latter is the highest temperature at which space heat demand occurs. Figure 5 shows COP and end-use space heat demand within the recorded temperature range. For explanation, at -16 °C the heat pumps with a COP of 1.5 consume 8 GW of electric power to supply 12 GW end-use space heat demand.

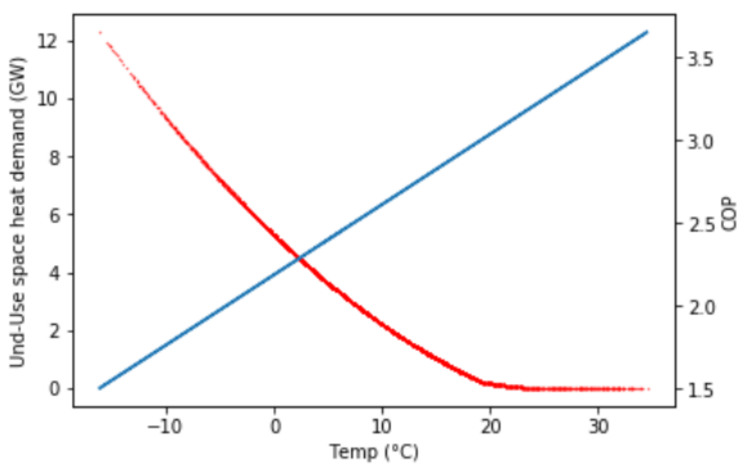

Figure 5. Coefficient of performance (blue line) and hourly end-use space heat demand using the 1996 temperature profile (red dots).

3.2. Energy production

Hydro power generation capacity (12.9 GW) and annually available energy (60 TWh) in British Columbia are based on the BC Hydro load-resource balance for fiscal year 2015 (BC Hydro, 2013, Tables 2 and 3). The energy and power available to the model are population-scaled to Metro Vancouver. The available energy is dispatched on a partially flexible, partially pre-determined profile (Figure 6) to simplify the complex operating constraints observed by British Columbia's large hydro and run-of-river power stations. These constraints include snowmelt-driven water inflows, minimum water discharge rates, or flood control. This study estimates that approximately 41 TWh are dispatched to meet operating constraints; approximately 19 TWh are dispatchable at any time of the year (BC Hydro, 2017b). The assumed cost and emission intensity of hydroelectric energy are 60 $/MWh and 29.9 $g_{CO2\_eq.}$/kWh (Government of British Columbia, 2019).

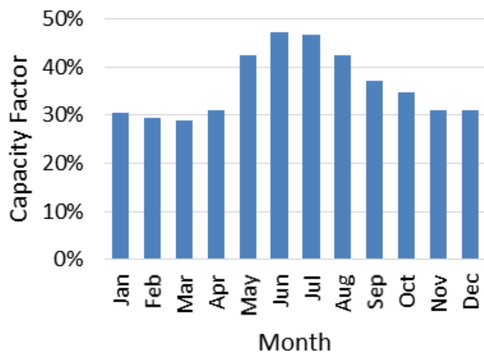

Figure 6. Estimated monthly minimum capacity factors define the profile shape of ~ 41 TWh generated by British Columbia's hydroelectric power stations on a pre-determined schedule (BC Hydro, 2017). Generation peaks in June and July when snowmelt-freshet inflows dominate.

Hydro power capacity is fixed and cannot be expanded by the model. Although the Site-C hydroelectric facility that is under construction on the Peace River will expand capacity and annual energy production by 1.1 GW and 5 TWh beyond 2024, this study models the transition of a past state and does not take into consideration future changes in energy supply or demand. This approach to disregard future capacity becoming available reflects the capacity deficit expected to occur by 2029 in spite of the Site-C expansion (BC Hydro, 2016, Table 3-9).

The model installs wind power capacity at scenario-dependant costs between 1219 and 2395 $/kW. The exogenous wind generation profile is based on the hourly mean capacity factor of 30 potential sites located in southern, central, coastal, and eastern British Columbia (GE Energy Consulting, 2016). The annual mean capacity factor is 33.2%.

The model chooses to install solar power capacity at scenario-dependant costs between 669 and 2021 $/kW. The exogenous solar generation profile is based on single-axis tracking potential in Vancouver as published by NREL's PV Watts (National Renewable Energy Laboratory, 2013). The annual mean capacity factor is 24.3%.

Gas production includes natural gas, biogas, and hydrogen produced from electrolysis. In this study, biogas and hydrogen substitute natural gas on an energy-equivalent basis. Natural gas costs 1.19 \$/GJ (U.S. Energy Information Administration, 2020) and emits 50.3 g_{CO2}/MJ (U.S. Energy Information Administration, 2011). FortisBC plans to procure 30 GJ of biogas that emit 11 g_{CO2}/MJ to meet renewable gas and emission reduction targets by 2030. Costs of biogas were estimated at 23 \$/GJ by the authors. Specific costs are confidential, but FortisBC confirmed that this estimate reasonably aligns with their portfolio average. Beyond the 30 GJ of biogas, the energy system model can choose to produce hydrogen by installing electrolyzer capacity at a scenario-dependant cost of 1400 \$/kW (ZEN, 2019) or 500 \$/kW (Thema et al., 2019) and an assumed efficiency of 78%.

3.3. Energy storage

Electricity and gas storage technologies provide flexibility to balance supply and demand. Storage technologies can store energy up to their installed energy capacity. Storage technologies can provide power to supply demand, or demand power to increase stored energy, up to the installed power and energy capacities, respectively. The model determines energy and power capacities independently of each other.

The model can choose to install electricity and gas storage technologies. Electricity storage has a round-trip efficiency of 86%. Installation costs are scenario dependant to reflect 2030 or 2050 battery storage as forecast by Schmidt et al. (2019). Gas storage capital costs (1 \$/kW and 0.1 \$/kWh) are consistent across all scenarios, with assumed operating costs being nil. Gas storage has an assumed round-trip efficiency of 100%.

3.4. Scenarios

Seven scenarios investigate energy system costs and capacity requirements across a range of possible futures. Technology costs, technology performance, energy demand, or renewable energy supply varies between each scenario. Table 2 summarizes the defining variation of each scenario.

- The *Reference* scenario applies 2030 lithium-ion battery storage costs, and present-day wind and solar costs determined by the latest resource options report performed by BC Hydro. FortisBC's provincial biogas target of 30 PJ is scaled to Metro Vancouver by population. The space heat demand is based on historic temperature correlation and hind cast for the 1996 temperature profile.

- The *LowCost* scenario applies 2050 capital costs for battery, wind, solar, and electrolyzer installation. The assumed 2050 battery cost is approximately equivalent to present-day pumped storage costs.

- The *MuchBiogas* scenario applies a large availability of biogas resources. The 93 PJ include estimated wood gasification supplies in British Columbia.

- The *LowHeatDemand* scenario applies 2016 space heat demand data. That data has a lower peak and lower overall energy demand than the hind cast 1996 demand applied in all other scenarios.

- The *GasHeatPump* scenario replaces all gas furnaces with gas heat pumps. The replacement increases gas-based space heating efficiency from 95% to 140% and consequently reduces natural gas and biogas consumption.

- The *Resilient* scenario forces the model to install sufficient energy storage capacity to supply energy demand during a five-day peak space heat demand event where no wind or solar generation is available. In the absence of other dispatchable technology alternatives, all capacity demand that exceeds the existing capacity of hydro power must be supplied by energy storage during that event.

- The *Transport* scenario assumes full electrification of the road transportation sector. This additional demand is implemented by increasing the electricity demand to include an evening-peaking battery-electric vehicle charging profile. This increase equally applies to the renewable gas and electrification pathways. This scenario serves to investigate the simultaneous electrification of several economic sectors.

Table 2. Seven scenarios determine low-carbon energy system costs and capacity requirements for a broad range of future technology costs, technology, performance, energy demand, and renewable energy resource potential.

Scenario	Description	Rationale
Reference	a) 2030 Li-Ion battery cost b) BC Hydro Wind/Solar cost c) 2030 Biogas target (30 PJ x 53%) d) 1996 temperature profile (high heat demand)	a) (Schmidt et al., 2019) b) (BC Hydro, 2020) c) Personal correspondence with FortisBC Inc. d) Section 3.2
LowCost	a) 2050 Battery ≈ pumped storage cost b) NREL 2050 Wind/Solar cost c) 2050 Electrolyzer cost	a) (Schmidt et al., 2019) b) (National Renewable Energy Laboratory, 2018) c) (Thema et al., 2019)
MuchBiogas	High biogas availability (93.6 PJ x 53%)	(Hallbar Consulting, 2017)
LowHeatDemand	2016 temperature profile	Section 3.2
GasHeatPump	Gas heating efficiency increases from 95% to 140%	Estimated gas heat pump efficiency
Resilient	No wind and solar electricity generation during five-day peak space heat demand event	Determines hydro + storage capacity requirements when electrified demand exceeds hydro's load carrying capability
Transport	Light- and heavy-duty road transport is electrified: -60% annual electricity demand increase -Doubles peak electricity demand	Electrification of additional sectors increases storage demand. Electrified demand estimate taken from (Palmer-Wilson, 2020)

4. Modelling Results

4.1. Greenhouse gas emissions

Substituting natural gas with electricity or renewable gas significantly reduces greenhouse gas emissions. The bars in Figure 7 show *Reference* scenario emissions in the electrification pathway (Elec) on the left and the renewable gas pathway (RNG) on the right. The whiskers delineate the range of emissions observed across all seven scenarios.

The annual emissions decline as natural gas substitution rates increase from 0 to 100%. At a substitution rate of 100%, the remaining emissions result from hydro power and, in the renewable gas pathway, from biogas.

The *MuchBiogas* scenario retains the largest emissions (top whiskers) because the larger biogas resource-availability enables larger emissions. The *LowHeatDemand* scenario retains the lowest emissions (bottom whiskers) because lower overall energy production leads to lower emissions.

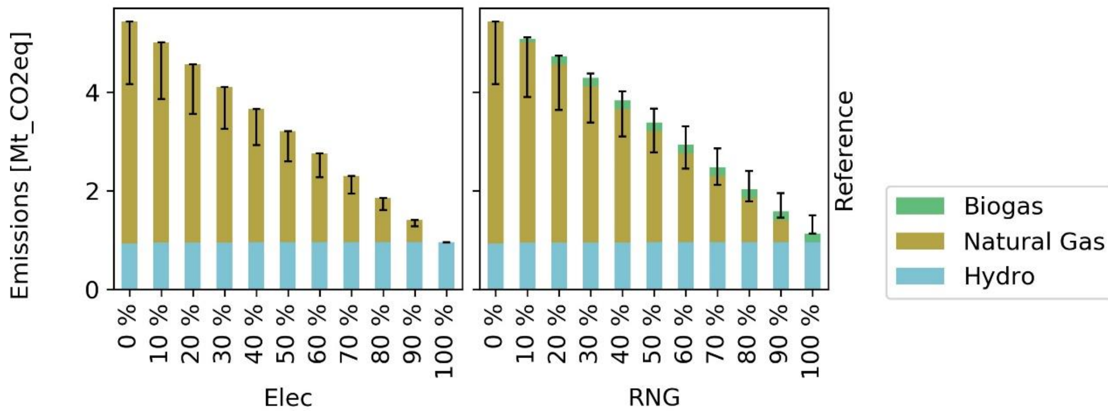

Figure 7. Greenhouse gas emissions related to all-sector electricity generation and gas combustion in the building heating sector of Metro Vancouver. Each stacked bar on the horizontal axes shows total emissions in the Reference scenario for the one-year modelling period as natural gas substitution rates increase from 0% to 100% in 10% increments. Whiskers denote emissions observed across all scenarios. The electrification pathway (Elec) is shown on the left, and in the renewable gas pathway (RNG) on the right.

4.2. Electricity generation and storage capacity

Substituting natural gas with electricity or renewable gas increases annual electricity production and necessitates installation of additional generation capacity. In this study, available generators are limited to the most abundant renewable energy sources wind and solar power. Their variability requires energy storage to balance supply and demand.

Figure 8 shows annual electricity generation (top row), generation capacity (center row), and energy storage capacity (bottom row) in the *Reference* scenario. Electrification (left column) or renewable gas (right column) gradually replace natural gas in 10% increments. Wind and solar electricity generation supplements hydro electricity in both pathways. Installed generation capacities increase more significantly in the electrification pathway. In the *Reference* scenario, electricity storage reaches 80 GWh in the electrification pathway, and gas storage reaches ~1000 GWh in the renewable gas pathway. Only in the *Transport* scenario does the larger electricity demand require installation of electricity and gas storage in the renewable gas pathway.

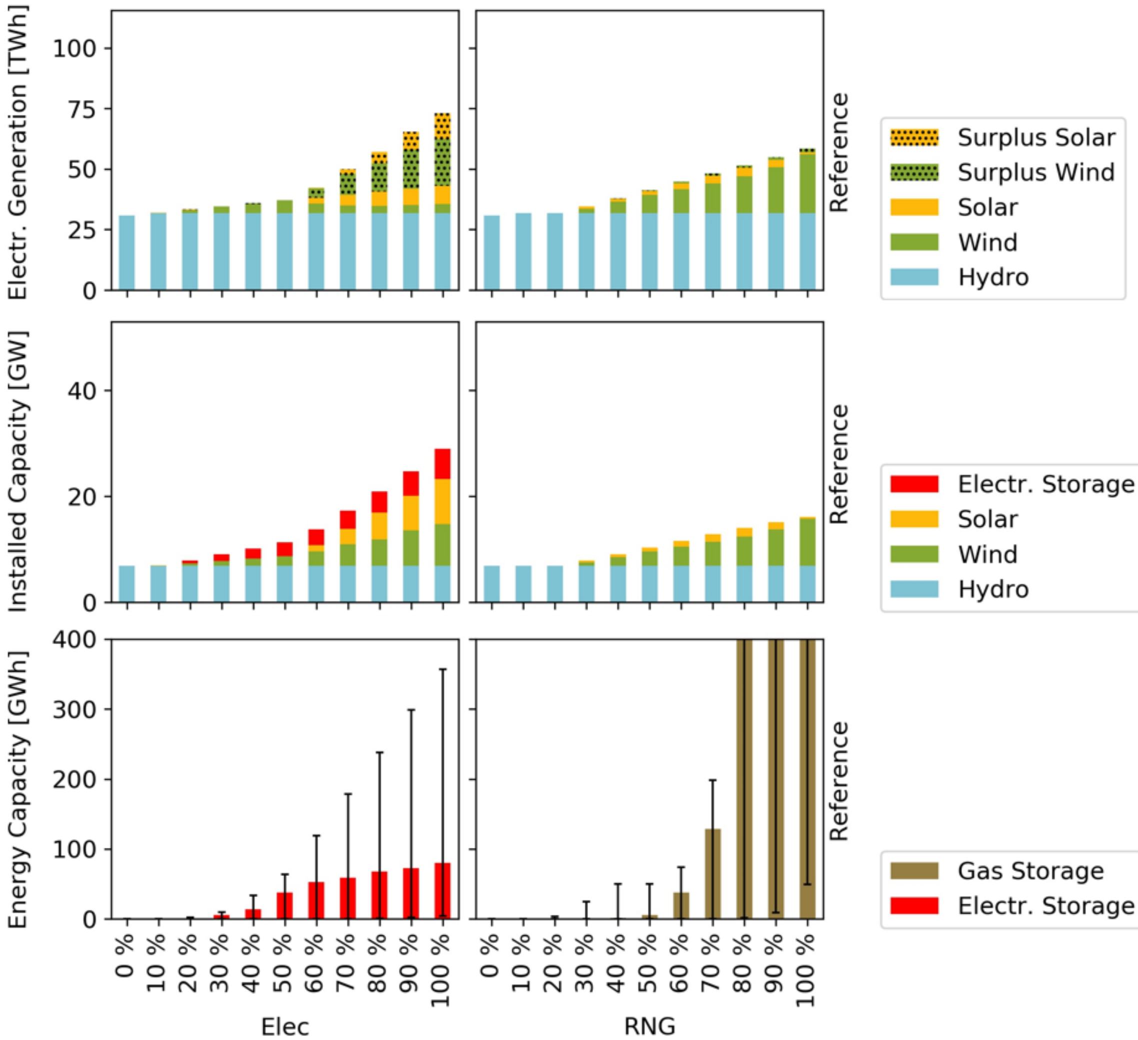

Figure 8. Reference scenario energy system transition in the electrification (Elec) and renewable gas (RNG) pathways. Horizontal axes show natural gas substitution rates ranging from 0% to 100% in 10% increments. The top row shows electricity generation and potential surplus for the one-year modelling period. The center row shows installed electric power generation capacities. The bottom row shows energy storage capacity. Gas storage capacity reaches ~ 1000 GWh; the axis range highlights the electric energy storage capacity because gas storage is low cost in comparison. Whiskers show minimum and maximum energy storage capacities observed across all scenarios.

In the electrification pathway of the *Reference* scenario, large wind and solar capacity installation generates a large electricity surplus. That large capacity installation is chosen by the model to meet peak space heat demand during a five-day cold period in January/February due to lack of dispatchable generation technology alternatives. The excess capacity generates surplus electricity in the remaining year, but is lower cost than installing additional high-cost electricity storage.

The magnitude of this peak-driven capacity installation is sensitive to the exogenous wind and solar profiles that, by coincidence, provide small amounts of power during the peak demand event. Figure 9 highlights this sensitivity by comparing electricity generation and storage levels in the *Resilient* and *Reference* scenarios. During the five-day peak period, demand exceeds the installed hydro power capacity. In the *Reference* scenario, wind, solar, and electricity storage supply demand in excess of hydro capacity. The 80 GWh of electric energy storage drain from maximum to nil within the first three days; the installation of 8 and 9 GW of wind and solar power result from the relatively low exogenous capacity factors during that period.

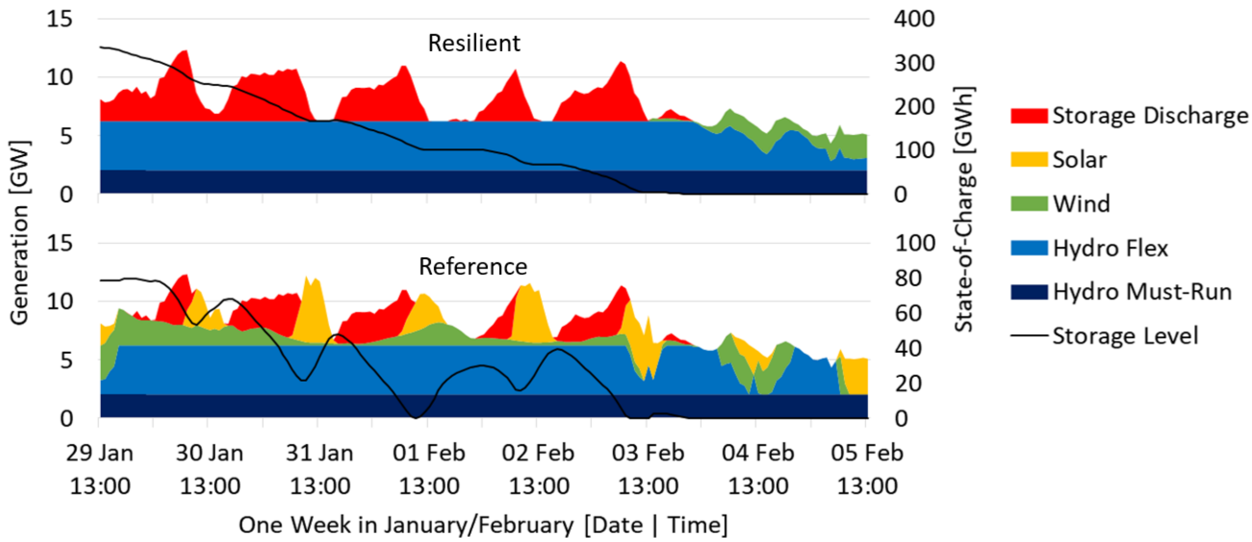

Figure 9. Electricity generation and storage level during the five-day peak demand event in the Resilient (top) and Reference (bottom) scenario of the electrification pathway. The top of the stacked areas delineates the electricity demand.

The *Resilient* scenario exogenously reduces wind and solar availability to zero for the five-day peak demand event. The model installs 357 GWh of electricity storage capacity (top whiskers in Figure 8), sufficient to meet all excess demand during the five-day period. That storage capacity reduces wind and solar installation and almost eliminates surplus electricity generation. In contrast to the *Resilient* scenario, the *LowHeatDemand* scenario requires only 4 GWh of electricity storage capacity (bottom whiskers in Figure 8) because peak electricity demand remains below the capacity of dispatchable hydro power. Table 3 shows the full list of energy and power capacities for electric energy storage installed by the model in each scenario.

Table 3. Installed energy and power capacity for electric energy storage in the electrification pathway of each scenario.

Scenario	Power Capacity [GW]	Energy Capacity [GWh]
Reference	6	80
LowCost	6	123
MuchBiogas	6	80
LowHeatDemand	1	4
GasHeatPump	6	80
Resilient	7	357
Transport	12	87

In the renewable gas pathway, the *Resilient* scenario requires 4.6 GW of electrolyzers and 1000 GWh of gas storage capacity. The electrolyzers operate at an annual average capacity factor of 66%. In this configuration, gas storage drains to nil from a full state-of-charge only once during the 1-year modelling period. In effect, gas storage balances supply and demand between seasons.

4.3. Pathway costs

The large range of storage capacity installation leads to significant total system cost differences between the electrification and the renewable gas pathways. Either pathway can result in lower overall costs, but the range of costs observed across all scenarios is more narrow in the renewable gas pathway. Figure 10 highlights the large range of total annualized system costs across scenarios. Note that costs include the annualized capital costs, and operation and maintenance costs for gas production, electricity generation, and electricity and gas storage. Costs do not include any costs associated with space and water heaters, and do not include costs for gas and electricity transmission and distribution.

The *Transport* scenario has the highest overall costs because the additional electricity demand increases costs across both pathways. Costs in the *Resilient* scenario are slightly lower than the *Transport* scenario in the electrification pathway, but much lower in the renewable gas pathway. This difference is caused by the low-cost gas storage available in the renewable gas pathway. The *LowHeatDemand* scenario has the lowest overall costs because the low demand requires the least amount of energy production. Due to the low peak demand and small electricity storage requirement, low-cost wind and solar render the *LowHeatDemand* scenario the only scenario where electrification pathway costs remain below renewable gas pathway costs.

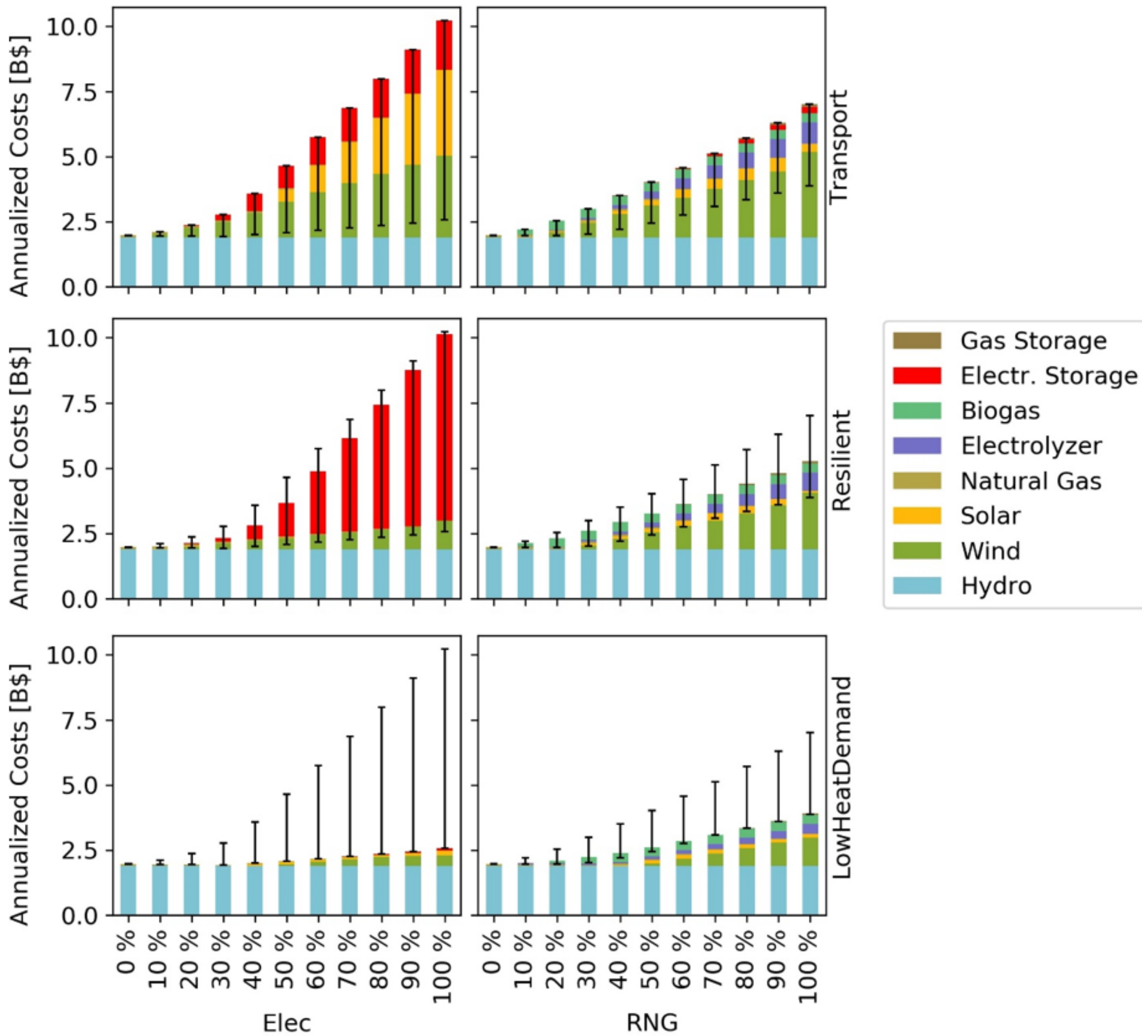

Figure 10. Annualized total system costs in the electrification (Elec) and renewable gas (RNG) pathways in the Transport, Resilient, and LowHeatDemand scenarios. Horizontal axes show natural gas substitution rates ranging from 0% to 100% in 10% increments. Whiskers show the full range of annualized costs observed across all scenarios.

To compare costs across scenarios, Figure 11 shows the percentage difference between electrification and renewable gas pathway costs at 100% natural gas substitution rates. Across all scenarios, the cost differences range from -52% in favour of electrification, to +48% in favour of renewable gas. The electrification pathway is most cost-favourable (-52%) in the *LowHeatDemand* scenario because the lower peak electricity demand requires relatively little electricity storage. The renewable gas pathway is most cost-favourable (+48%) in the *Resilient* scenario because the lower-cost storage of electrolytic hydrogen avoids the 357 GWh of electric energy storage required in the electrification pathway.

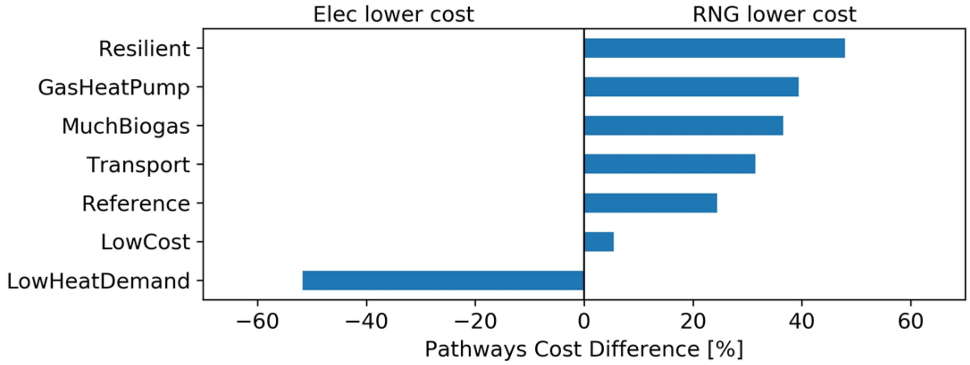

Figure 11. Percentage cost difference between electrification and renewable gas pathways at 100% natural gas substitution across all scenarios.

5. Discussion

This report investigates the elimination of natural gas consumption in the Metro Vancouver residential, commercial and institutional building heating sectors. The cost-optimization model shows that direct electrification or substitution via renewable gas provide feasible solutions to supply space heat, water heat, and electricity that serves non-heat demands. Scenario analysis reveals that energy storage capacity requirements and resulting total system costs are sensitive to technology costs, resource supplies, and energy demand.

Both transition pathways require the installation of additional electricity generation capacity to accommodate direct electrification or production of electrolytic hydrogen. The existing hydroelectric energy and power capacity is insufficient to substitute all natural gas in the building heating sector. In the absence of other dispatchable generation technologies, the installation of wind and solar power requires installation of energy storage. Consequently, the peak electricity demand that exceeds present-day dispatchable capacity is the largest cost driver in the electrification pathway. Avoiding the increase of peak demand can save costs. Since the present-day electricity demand peaks in winter months, electrifying economic sectors that do not peak in winter may render a better cost-benefit for use of surplus energy and the limited load-carrying capability of British Columbia's hydropower system.

Low-cost biogas supply (or lack thereof) is the largest cost driver in the renewable gas pathway. Higher-cost hydrogen production requires expansion of electrolyzers, additional electricity generation capacity, and gas storage. However, the significantly lower cost of storing gas instead of electricity may render the renewable gas transition cost effective. Designing an electrified energy system to accommodate low availability of wind and solar power during a peak demand event requires vast amounts of storage. The installation of 357 GWh of electricity storage in this study's *Resilience* scenario would equate to ~35 pumped storage facilities. Considering the associated environmental impact, public opposition to building pumped storage infrastructure may render an exclusive electrification pathway challenging to implement. For comparison, the existing underground Aitken Creek gas storage facility in northeastern BC can store 80,000 GWh of natural gas. Underground hydrogen storage may become possible at similar scale if geological, technological, economic, legal and social barriers can be overcome (Tarkowski, 2019).

Both pathways reduce the combined electricity and heating emissions by around 80%, but these sectors represent a fraction of overall sources. Grid-tied hydroelectric power with an emissions factor of ~30 $t_{CO2eq.}$/GWh (Government of British Columbia, 2019) causes the majority of remaining emissions. Emissions embodied in wind and solar power plants are not included in this study. In the renewable gas pathway, substituting natural gas with biogas reduces the emission intensity by 78% (from 50.3 to 11 g_{CO2}/MJ) but small biogas related emissions remain. The quantity of those emissions depend on available biogas supply. Achieving net-zero greenhouse gas emissions by mid-century to limit global warming to below 2°C will require additional emission reduction. If negative emission technologies like direct air capture are to be deployed, additional expansion of zero-carbon energy sources will be required.

This analysis highlights the scale of the challenge to addressing greenhouse gas emissions in the building heating sector. The existing natural gas system provides three services that a future low-carbon system will need to replicate. These services include 1) provision of a large quantity of energy that 2) can be stored for long durations at relatively low cost and 3) be dispatched to provide a large quantity of power when cold weather events cause large heat demand. British Columbia's low-carbon hydroelectric system provides those services, but its ability to accommodate additional demand from natural gas substitution is limited. The variable renewable energy sources wind and solar power provide energy, but they lack dispatchability and require separate storage capacity installation. Considering the scale of fossil fuel combustion that will need to be eliminated in all sectors of the economy, enabling the gas system to continue to provide its services via renewable gas adoption may be a cost-effective strategy to mitigating climate change.

6. Future work

The completed study contributes to understanding emission reduction options for the heating sector in Metro Vancouver, and exposes several key research questions that warrant further investigation. First, both transition pathways reduce greenhouse gas emissions by ~ 80%, but emissions will ultimately need to decline to net-zero. Extending the energy system model to include negative emission technologies can inform further mitigation options.

Second, both electricity and renewable gas can substitute natural gas in the building heating sector, but further study is required to understand the impact of simultaneously substituting fossil fuels in several economic sectors. Extending the energy system model to include transportation and industrial energy demands can help identify which substitution provides the most benefit in each sector.

Third, the completed study represents Metro Vancouver as a single node without energy transmission requirements, but fossil fuel substitution will require transmission system upgrades. Increasing the spatial resolution of the energy system model will enable accounting for electricity and gas transmission costs, and reveal cost-effective upgrades needed to accommodate increased electricity demand and hydrogen concentrations.

The interest generated by the completed study, and the relevance of the resulting research questions has led to an extension of this research project. In the coming two years, an expanded research team at the University of Victoria will investigate electrification and power-to-gas alternatives in more detail by conducting further long-term and medium-term modelling, and extending modelling resolution both spatially and temporally.

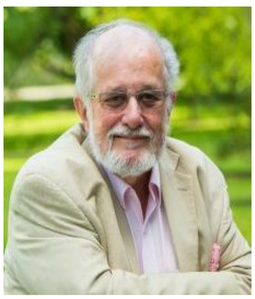
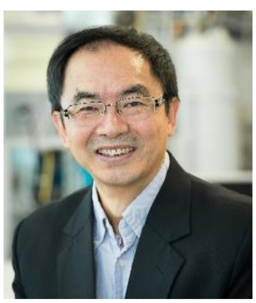
Biographies

Haoqi Wang worked on life cycle environmental analysis and techno-economic analysis of bioenergy systems in British Columbia during his PhD study as a PICS fellow and postdoctoral research at the Department of Chemical and Biological Engineering, University of British Columbia, under the supervision of Xiaotao Bi and Roland Clift. He is now an assistant professor in the College of Materials and Environmental Engineering, Hangzhou Dianzi University, China.



Roland Clift is emeritus professor (founding director) in the Centre for Environment and Sustainability, University of Surrey, UK, and an adjunct professor at the Department of Chemical and Biological Engineering, University of British Columbia. His research interests are in life cycle assessment, industrial ecology and sustainable energy systems. He is a fellow of the Royal Academy of Engineering, UK, and a past member of the UN Intergovernmental Panel on Climate Change (IPCC).



Xiaotao Bi is a professor in the Department of Chemical and Biological Engineering and the director of UBC's Clean Energy Research Centre. His current research focuses on particle technology and fluidized bed reactors for biomass thermo-catalytic conversion, green and sustainable engineering, and integrated assessments of clean energy systems. He is a fellow of the Canadian Academy of Engineering and Engineers Canada.

Executive Summary

The two phases of CleanBC set out strong policy support for further developing renewable energy in the province as a contribution in achieving BC's 2030 Greenhouse Gas (GHG) mitigation target. However, the CleanBC framework lacks strong demand-side measures, to reverse the growth of energy demand in BC. Attempts have been made to reduce energy use in land transportation but action plans for other sectors, especially industry, are lacking. As a result, even with moderate energy demand reduction (10%), the CleanBC framework will not reach the 2030 target. Even if demand is reduced more sharply (25%), the current supply of renewable electricity and bioenergy is still insufficient to meet demand: the additional supply of renewable energy will be immense.

Future demand reduction cannot be predicted with precision, but any reduction reduces emissions. Growth in demand is predicted mainly for heating, mobility, and industrial production. The pursuit of lower cost and higher profit will lead to continuous but slow improvement in energy efficiency. However, decoupling demand from economic and population growth requires transformative change in business models and personal behaviors, and therefore more stringent policy measures.

Electrification is seen as a core strategy for GHG mitigation in BC. However, electricity supply is insufficient to meet the growth in demand inherent in the electrification-centered strategy. Even with Site C and radical demand reduction, about 60 PJ of additional supply will be needed to meet the 2030 target, and 160 PJ for carbon neutrality in 2050. New electricity generation will be needed by 2030 and beyond, comparable in magnitude to the projected output of the current Site C project. This implies installing hundreds of wind turbines and millions of solar panels.

The bioenergy-centered strategy is an alternative to a strategy dominated by electrification; it would dramatically increase demand for bioenergy. As the first step, it must fully exploit existing waste biomass, predominantly woody waste. Even then, roughly 250 and 450 PJ of additional primary bioenergy supply will be needed for 2030 and 2050, respectively. This is well beyond any foreseeable waste supply within BC.

Hence, strategies that rely solely on either electricity or bioenergy will raise demand beyond sustainable and manageable supplies. There is no single 'silver bullet' renewable energy source to meet BC's GHG mitigation targets: it is essential to utilize all the available bioenergy and renewable electricity resources and promote a balanced renewable energy portfolio. The limited time frame to 2030 emphasizes the difficulty of securing the renewable energy needed and the urgency of action to reduce demand. For the long-term target of carbon neutrality, the supply problems emphasize the need for a balanced renewable energy strategy.

Clean Energy Research Centre

Table of contents

1. Background

In 2007, British Columbia introduced the Climate Change Accountability Act to mitigate provincial emissions of greenhouse gases (GHGs). Amendments introduced in 2018 established reduction targets: 40% below 2007 levels by 2030, 60% by 2040, and 80% by 2050. However, policy measures under the act, including the carbon tax and low-carbon fuel mandate, have not stemmed the rise in emissions: in 2019, BC's GHG emissions were 68.6 million tonnes (Mt), 5% above the 65.7 Mt emitted in 2007 [1]. The increase is mainly attributable to fossil fuel consumption - in 2019, 891 PJ of natural gas (NG) and refined petroleum products (RPP) provided 70% of energy supply in BC [2].

The CleanBC Phase 1 plan [3], published in 2018, gave more detail on the 2030 target and announced action plans to mitigate GHG emissions across BC's economy. It was supplemented in 2021 by a Roadmap to 2030 (CleanBC Phase 2 [4]), with quantified reduction targets for heating, mobility, industrial production, and waste management (see Table 3-1 below). CleanBC focuses on electrification, bioenergy, methane emission reduction, and efficiency improvement. Additionally, low-carbon hydrogen is to be promoted for heavy-duty vehicles and heating in buildings and industrial processes [3]. The plan depends on decoupling emissions from economic growth but does not address reducing economy-wide energy demand or matching renewable energy supply to demand. Only three policy actions to reduce demand are included: increasing the carbon tax, reducing distance travelled by light-duty vehicles by 25%, and reducing energy use by heavy-duty vehicles by 10% [4].

Electrification, relying on a low-carbon electricity supply mainly from hydroelectric sources, is a key component of the plan, to be promoted across all sectors. Some electrification technologies, such as heat pumps, electric motors, and electric vehicles, do have efficiency advantages over their fossil fuel counterparts. However, electrification increases the overall demand for electricity, raising the question of whether the supply of renewable electricity in BC will be sufficient.

Furthermore, the potential contribution of bioenergy needs to be examined. CleanBC sees renewable natural gas and liquid biofuels as low-carbon alternatives to natural gas distributed via the grid and fossil transport fuels, with the low-carbon fuel standard expected to be increasingly stringent. However, the plan ignores possible uses for biomass with higher efficiencies than refined biofuels, including low-grade heat for district heating and gasification-combustion to provide high-grade energy for industrial processes.

Against this background, this paper sets out an analysis to investigate pathways to achieve BC's GHG mitigation targets. Future clean energy scenarios to meet BC's GHG mitigation targets are presented in Section 2. Key findings on strategies for promoting and prioritizing clean energy development are presented in Section 3, and the details are included in Part II of this paper series.

2. Future Energy Profile in BC and the Potential Role of Bioenergy and Renewable Electricity

2.1 Baseline future energy demand

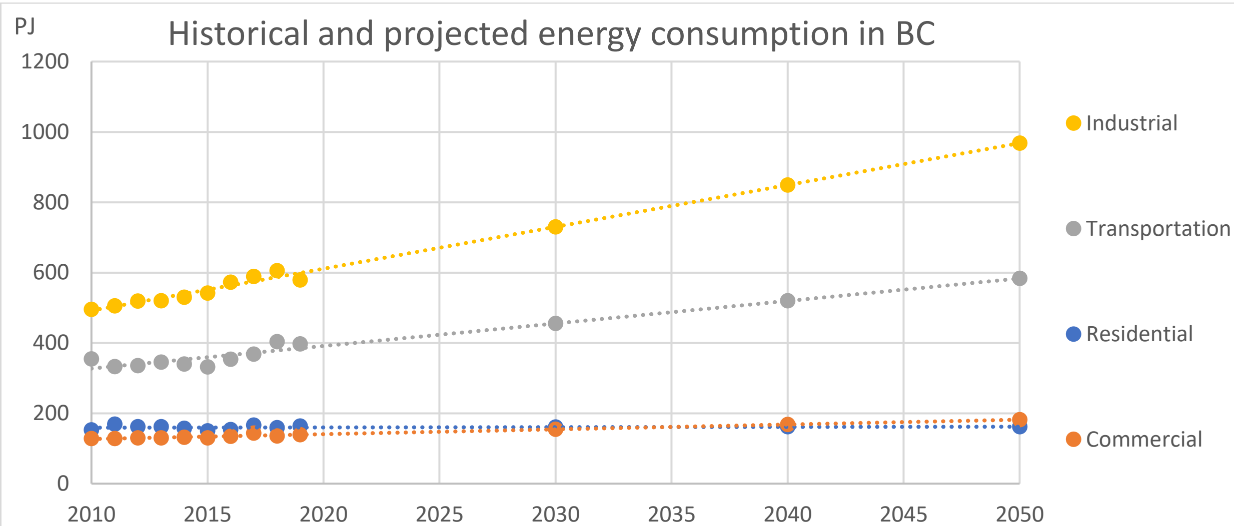

Figure 2-1 Historical and projected energy consumption in BC's different sectors

Baseline future energy demand refers to the anticipated energy demand for "business as usual", reflecting current projections of economic activity, population growth, and moderate efficiency improvement but excluding climate policies. Based on BC's historical energy consumption from 2010 to 2019 [5], baseline energy demand is expected to grow, particularly in the industrial and transportation sectors (see Figure 2-1). This will generate 68.6 Mt of GHGs from fossil fuels in 2030 and 87.4 Mt in 2050 (see Figure 2-2), a severe challenge for GHG mitigation.

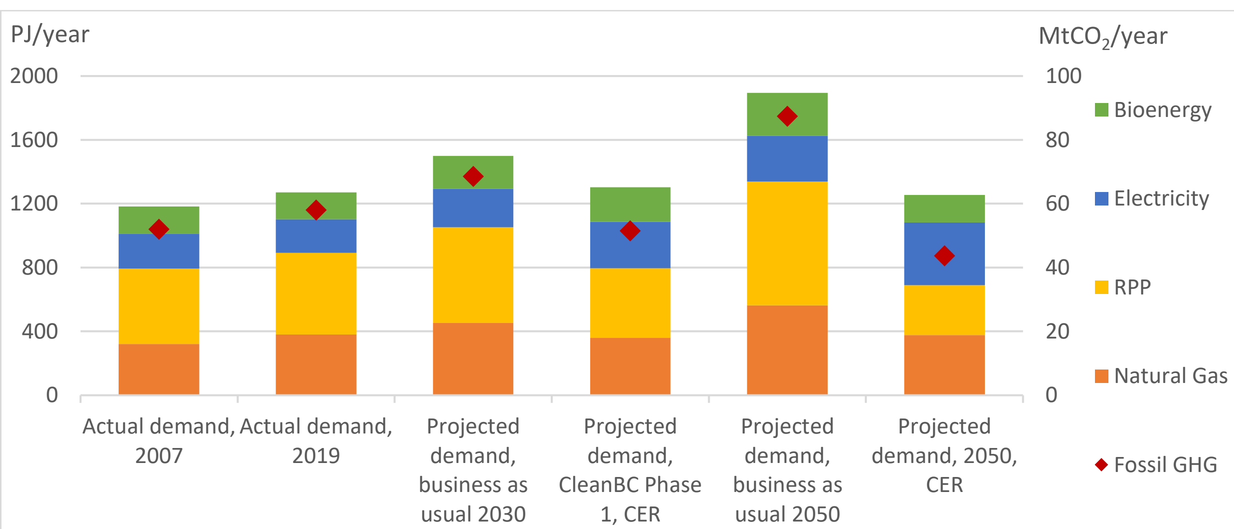

Figure 2-2 Projection for BC's energy demand and GHG emissions from fossil fuels in 2030

The growth in baseline energy demand is associated with industrial production, mobility, and heating in commercial and residential buildings. Canada Energy Regulator (CER) [2] has produced "optimistic" projections for BC, assuming CleanBC Phase 1 is fully implemented, augmented by further policy effort and continuous technological improvement. Even with the optimistic projections, fossil fuel consumption in 2030 will exceed 800 PJ (see Figure 2-2), directly emitting 51.5 Mt of GHGs, far above BC's 2030 target of 38.0 Mt. For 2050, ideally a time frame to approach carbon neutrality, CER's optimistic projection foresees 770 PJ of fossil fuel consumption, directly emitting 43.7 Mt of GHGs. This projection does not include the recently announced CleanBC Roadmap to 2030, but it still shows that meeting BC's GHG mitigation targets depends critically on decoupling energy use from economic growth.

Therefore, possible scenarios for BC to meet its GHG reductions for 2030 and 2050 are explored in the following sections. As a basis for constructing these energy scenarios, the potential in BC for increasing use of biomass, generation and use of renewable electricity, and using hydrogen as an energy carrier has been assessed. The salient conclusions are summarized in Section 3; details are given in the accompanying document "Part II: Clean Energy Strategies for Mitigating Greenhouse Gas Emissions in British Columbia". An important finding is that future energy scenarios must deploy the optimal uses of clean energy, giving the greatest GHG mitigation at the lowest cost, as both bioenergy and renewable electricity will be in short supply.

2.2 Energy scenarios for 2030 target

Energy flows in the different scenarios are represented in terms of Sankey diagrams: the left-hand axis in each case shows the different primary energy sources, the central line shows the forms in which the energy is distributed, and the right-hand axis shows end-use.

2.2.1 Scenario 1: CleanBC with moderate energy demand reduction

As shown in Figure 2-3, economy-wide electrification will substantially increase electricity demand. In addition to BC's current renewable electricity generation capacity and the capacity to be provided by the Site C project, Scenario 1 will require a further 54.1 PJ, which is 9 times the totality of BC's wind and solar capacity, or 2.9 times the capacity of the Site C project. As estimated in Part II of this paper series, the output of one Site C project equals that of 30 km^2 of solar panels or nearly 700 average sized (2.5 MW) wind turbines in BC. The challenges presented by the enormous new demand, limited time frame towards 2030, and intermittency of solar and wind electricity generation are obvious.

Scenario 1 also foresees substantial increase in demand for all forms of bioenergy. The current bioenergy supply refers to wood residues and liquid biofuels currently consumed in BC, as well as wood pellet exports (see Part II). As global bioenergy demands are expected to increase continuously, importing bioenergy will become increasingly difficult and expensive. Therefore, for the reason of energy security, pellets currently exported should be diverted for domestic uses.

Waste streams, mainly unused wood residues and methane from landfill gases and anaerobic digestion of waste, must be prioritized for bioenergy production. However, after fully exploiting the energy potential of these waste streams, an additional supply of 118.8 PJ of liquid biofuels will still be needed, which is equivalent to about 200 PJ of primary bioenergy before conversion and even higher than the current bioenergy supply. If this new bioenergy supply is to be provided within BC, fundamental changes in forest management and residue collection systems will be needed, to ensure thorough recovery and utilization of wood residues, dead trees, and forest thinning, which is also in the interest of wildfire prevention [6]. Planting energy crops on marginal land may also be considered.

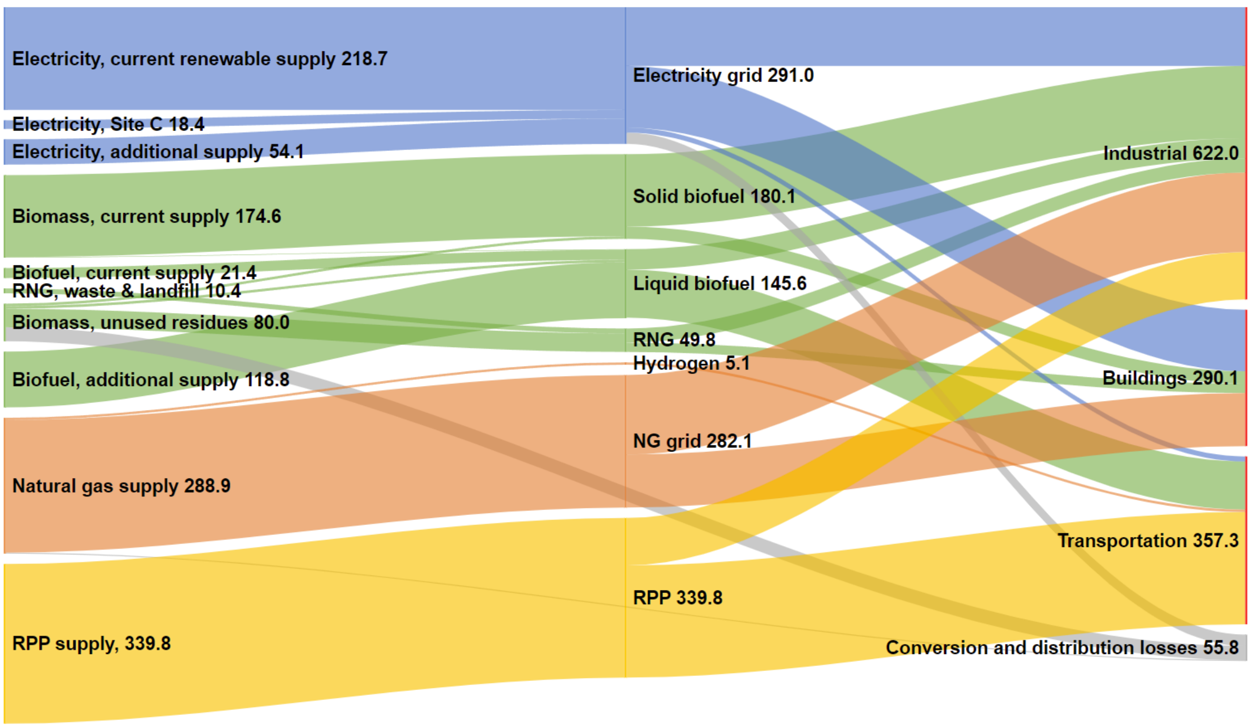

Figure 2-3 Scenario 1 (CleanBC with moderate energy demand reduction)

However, Scenario 1 can only achieve 12.6 Mt of GHG mitigation from energy transformation. As shown in Table 2-1, GHG mitigations across all sectors are far below the sectoral targets. Including the non-energy action plans in CleanBC, such as CCS and methane emission mitigation, the total GHG reduction is estimated to be 15.8 Mt, which is slightly more than half the 2030 target. As the additional renewable energy supply required for Scenario 1 is already enormous, securing even more will be technically and economically unrealistic. Therefore, much deeper reduction of energy demand is necessary across the economy.

Table 2-1 Sectoral GHG mitigations in 2030

	Buildings	Transportation	Industry
Sectoral targets	59-64%	27-32%	38-43%
Scenario 1	31%	29%	20%
Scenario 2	38%	37%	35%
Scenario 3	64%	37%	41%
Scenario 4	64%	37%	41%

2.2.2 Scenario 2: CleanBC with accelerated energy demand reduction

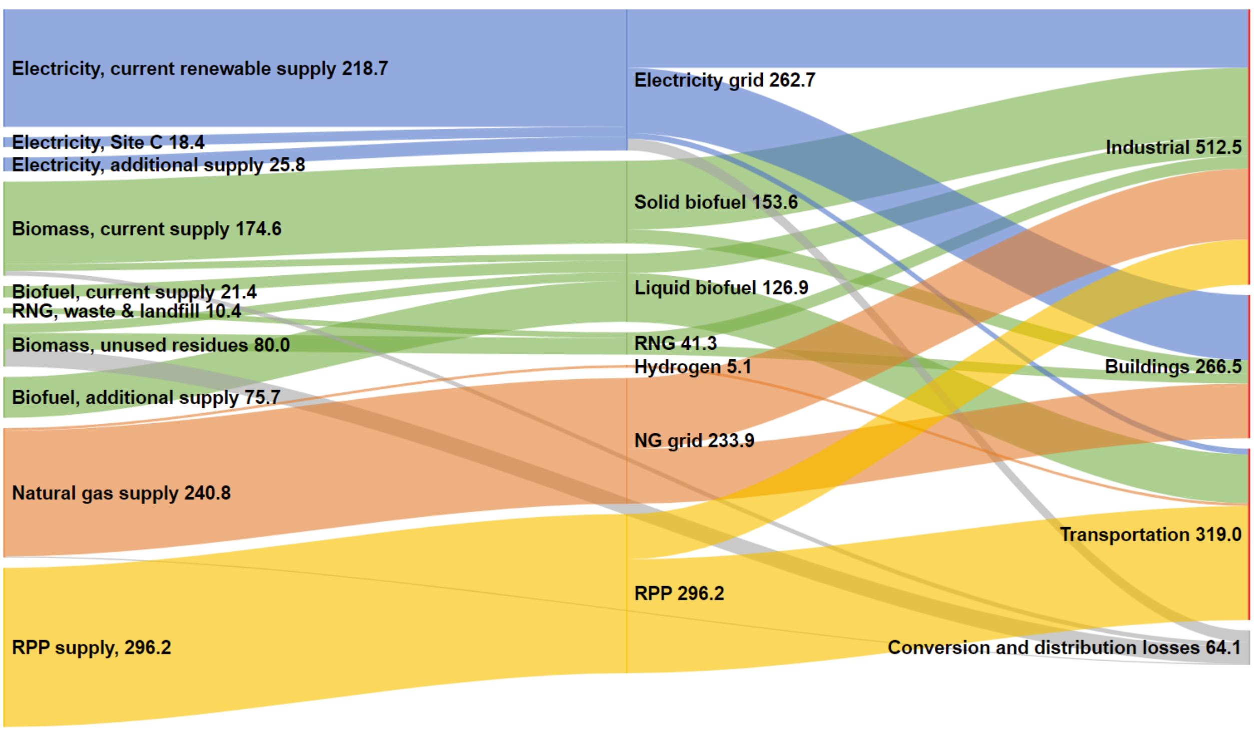

Figure 2-4 Scenario 2 (CleanBC with accelerated energy demand reduction)

Scenario 2 differs from Scenario 1 in assuming deeper reductions in economy-wide energy demand: 25% reduction by 2030 (2.5% annually from 2021). Given the historical rise in energy demand, this assumption is obviously ambitious and optimistic. In addition to reducing energy use in transportation, as laid out in CleanBC Roadmap, use in buildings and industries must be reduced substantially by efficiency improvement plus measures such as modifying buildings to reduce heating and cooling loads and integrating industrial operations to use waste heat.

Comparison between Scenarios 1 and 2 confirms that energy demand reduction is essential to contain renewable energy demand at manageable levels and achieve further mitigation: the additional demands for renewable electricity and biofuels in Scenario 2 are 25.8 and 75.7 PJ, respectively, much smaller than in Scenario 1. The additional renewable electricity could be supplied if the output of wind generation in BC grows by 14% annually, a global average predicted by IEA [7] (See Part II).

Together with non-energy GHG mitigation actions in CleanBC, GHG emissions are reduced by 22.2 Mt, a much greater reduction than in Scenario 1 but still 4.1 Mt short of the 2030 target. In terms of sectoral mitigations, Scenario 2 represents 37% reduction in the transportation sector, fulfilling BC's sectoral target. However, GHG mitigations in buildings and industries are 38% and 35%, slightly lower than the respective sectoral targets. Further actions to achieve the 2030 target are explored in Scenarios 3 and 4.

2.2.3 Scenario 3: Enhanced electrification and Scenario 4: increased use of bioenergy

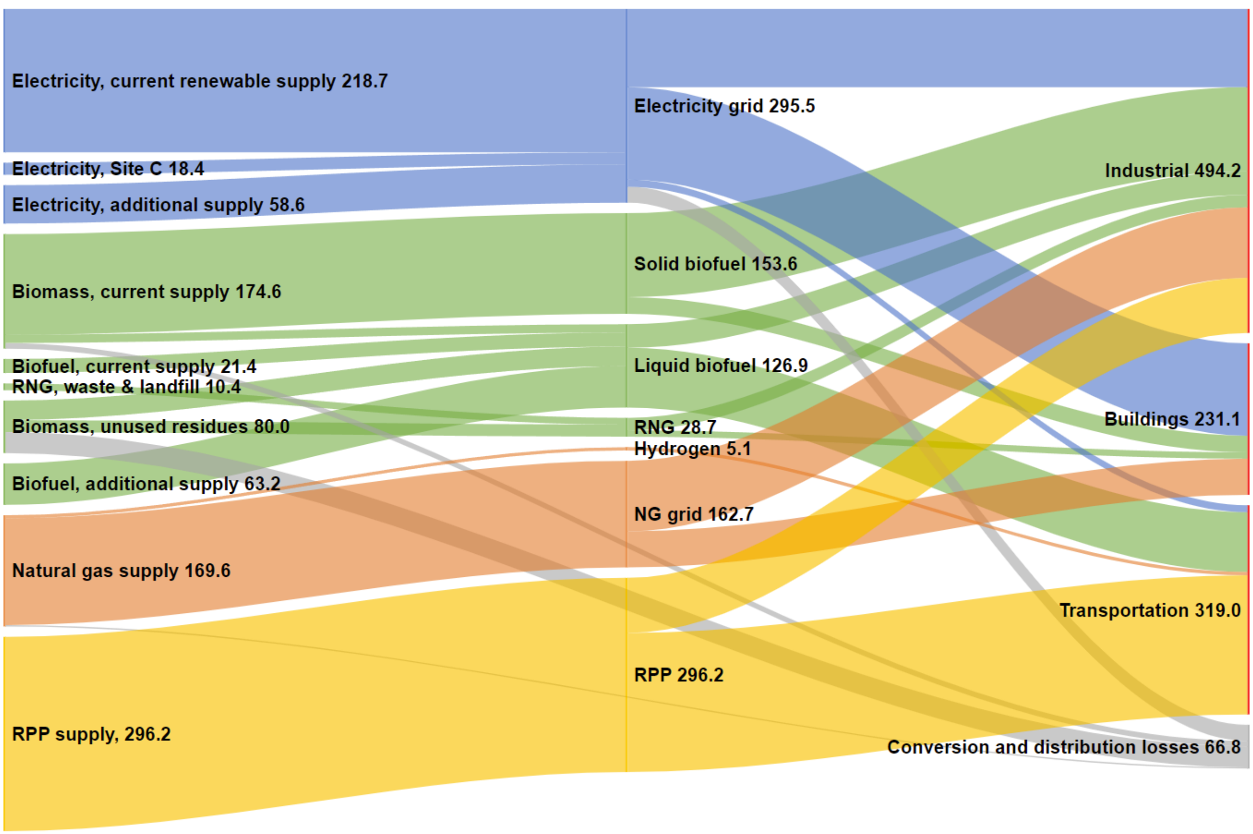

Figure 2-5 Scenario 3: CleanBC with enhanced electrification

Scenarios 3 and 4 build on the assumptions in Scenario 2, i.e., fully enacted CleanBC policies and accelerated energy demand reduction, but explore how the further reductions needed to achieve the GHG mitigation targets for 2030 might be achieved. In line with BC's sectoral mitigation targets, emissions are to be reduced by a further 2.7 Mt (64%) from buildings and 1.4 Mt (41%) from industries.

In Scenario 3, shown in Figure 2-5, the additional reductions are achieved by electrification to further reduce natural gas use, mainly through increased use of heat pumps in buildings and electric motors in industries. This increases demand for low-carbon electricity by an additional 58.6 PJ. Electrification will reduce the overall demand for RPP and natural gas and therefore reduce demand for biofuels to blend into these fossil fuels, so that Scenario 3 requires a slightly smaller additional supply (63.2 PJ) of liquid biofuels than Scenario 2.

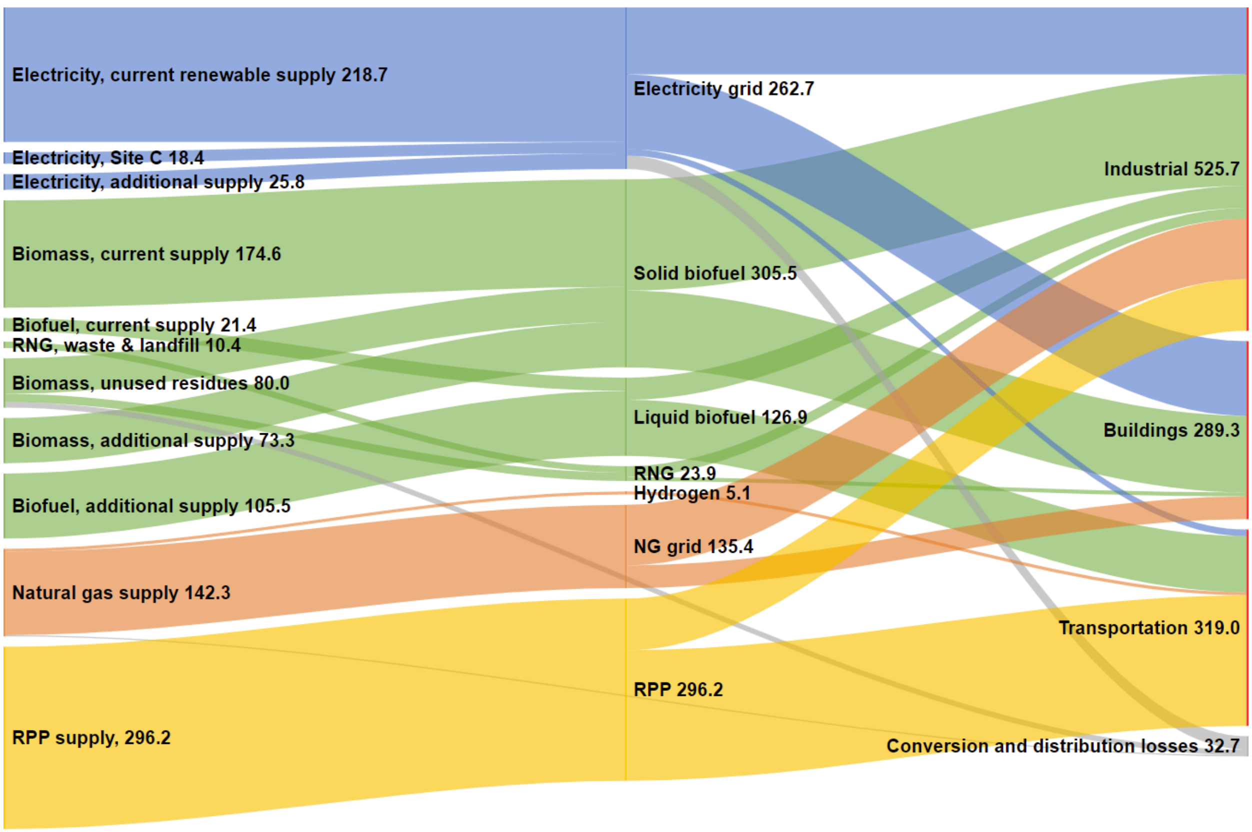

Figure 2-6 Scenario 4: CleanBC with increased use of bioenergy

Scenario 4, shown in Figure 2-6, relies on bioenergy for further GHG mitigation, including biomass-fired district heating systems for buildings and biomass gasification-combustion systems for industries. After fully exploiting the bioenergy potentially available in wood residues, other organic waste and landfill, Scenario 4 requires additionally 73.3 PJ (3.7 million ODT) of solid biomass and 105.5 PJ of liquid biofuels (176 PJ of primary bioenergy before conversion). Securing this additional bioenergy will be an enormous challenge (see Part II).

2.3 Energy scenarios for carbon neutrality in 2050

The time horizon is now extended to 2050 by exploring scenarios to achieve carbon neutrality, building on the CleanBC framework. Accelerated reduction of energy demand is no less indispensable. Therefore, all the scenarios assume that energy demand will decrease by 25% in buildings and 50% in other sectors by 2050. Light-duty vehicles will be 100% electric [4]. Following the BC Hydrogen Strategy, GHG reduction of 7.2 Mt [3] will be achieved through using hydrogen, by replacing diesel fuel in 88% of the heavy-duty vehicle fleet. This will require 50.7 PJ of blue hydrogen. Methane emissions from industries and waste management are assumed to be reduced by 95%. To illustrate the problems, two extreme scenarios are considered – maximum electrification and maximum use of bioenergy – but the most realistic scenarios are likely to lie between the two.

2.3.1 Scenario 5: Carbon neutrality via enhanced electrification

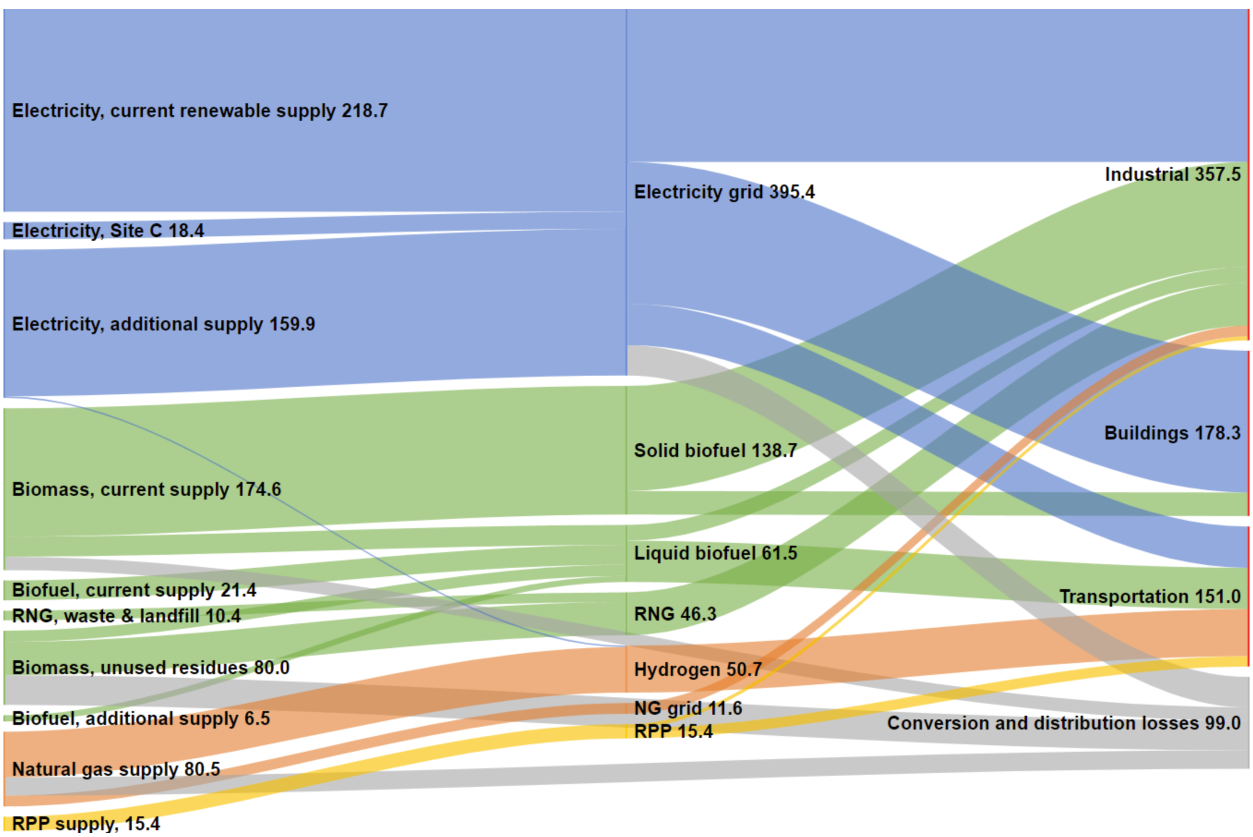

Figure 2-7 Scenario 5 (Carbon neutrality with electrification strategy)

In Scenario 5, shown in Figure 2-7, GHG mitigations beyond CleanBC are assumed to be achieved mainly by electrification, with the most efficient options prioritized in each sector. Heat pumps and EVs eliminate fossil fuel consumption in buildings and transportation, respectively. Electric motors eliminate industrial fossil fuel consumptions for motive power, including RPP for industrial machinery and hauling and natural gas for fluid compression in the oil and gas industry. However, natural gas use in manufacturing is mostly for thermal energy: high-temperature heating and kilns. In the absence of data on use in different applications, it is assumed here that the use of electric motors will displace 70% of natural gas and 80% of RPPs used throughout industry. For the remaining fossil fuel usage, it is assumed that low-carbon fuel standards for liquid fuels and natural gas will be increased to 80%. Taken together, these measures can mitigate GHG emissions from energy by more than 90%. Potential emissions from the remaining fossil fuel uses and non-energy sources are estimated to be 8 Mt, but are assumed to be eliminated by CCS.

As shown in Figure 2-7, 160 PJ of additional renewable electricity supply will be needed for the electrification strategy in Scenario 5, equivalent to the output of nine projects on the scale of Site C. While such dramatic expansion of renewable electricity may be technically possible, the investment needed is huge and action needs to start immediately. If the entirety of the additional supply is provided by intermittent wind and solar generation, the share of intermittent electricity in BC's grid will reach 40% by 2050, leading to difficult but accomplishable challenges to grid management (see Part II). However, in spite of the increase in low carbon fuel standards for liquid and gaseous fuels, the demand for bioenergy will be only slightly above current levels, mostly due to increased electrification and reduced overall energy demand, and should be easily manageable. Most natural gas will be used for hydrogen production; together with CCS at stationary sources, this should be technologically straightforward. Only 27.0 PJ of fossil fuels will be used in conventional industrial applications, with the GHG emissions mitigated by technologies involving direct air capture.

2.3.2 Scenario 6: Carbon neutrality through increased use of bioenergy

In Scenario 6, shown in Figure 3-8, carbon neutrality is achieved through enhanced production and use of bioenergy. Biomass-fired district heating systems, especially sufficiently large to incorporate pre-gasification for lower air emissions [8], and industrial gasification-combustion systems are further promoted to replace 60% of natural gas consumption in buildings and industries, due to their high conversion efficiencies. Low carbon fuel standards are increased to 100% to eliminate fossil fuels. The remaining 6.6 Mt of GHG emissions will be mitigated by CCS. This strategy will require an additional supply of 155 PJ of liquid biofuels (258 PJ of primary bioenergy before conversion) plus 202 PJ of solid biomass. As stated in Section 3.2.1, production of biomass is subject to restrictions of land availability and GHG emissions from land-use change. Therefore, securing such a large additional bioenergy supply sustainably within BC, through utilization of waste biomass and plantation of energy crops, is speculative.

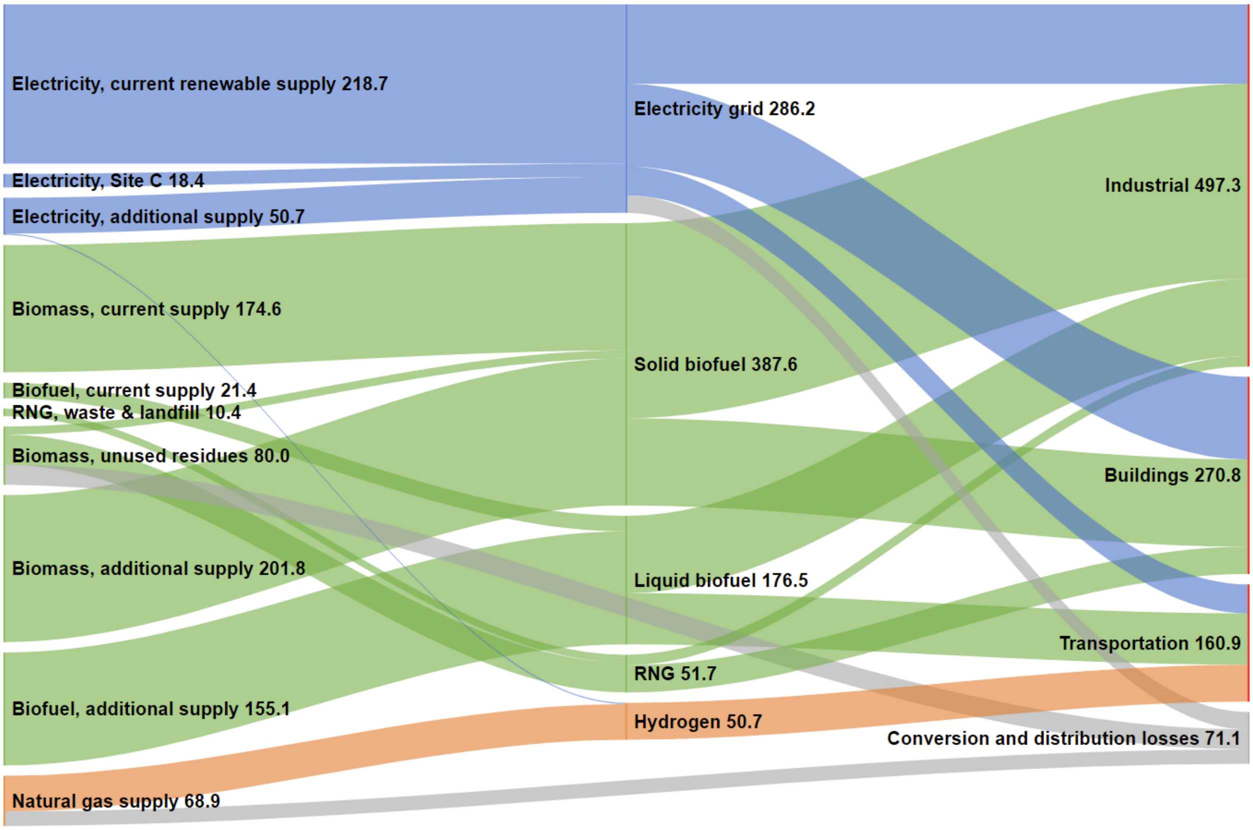

Figure 2-8 Scenario 6 (Carbon neutrality with promotion of bioenergy)

2.4 Discussion

Scenarios 3 and 5 represent maximal use of low-carbon electricity while scenarios 4 and 6 include maximum use of bioenergy. They show that any strategy relying primarily on either electrification or bioenergy faces enormous supply problems. The most realistic ways to decarbonize the energy system beyond the CleanBC action plans will no doubt lie between these extremes. However, the main conclusion remains: all available bioenergy and electricity resources need to be exploited to meet the province's targets.

The various electrification, bioenergy, and hydrogen options differ significantly in the efficiency of energy use. The scenarios all assume that, to minimize primary energy demand, the most efficient technologies are preferred: electric heat pumps and motors, biomass-fired heating system, and hydrogen fuel cells. Actual energy demand will be even higher if less efficient options are deployed: electric resistance heating, refined biofuels, and hydrogen combustion. Similarly, hydrogen is assumed to be produced by the most efficient route: steam-methane reforming (SMR) of natural gas combined with Carbon Capture and Sequestration (CCS). Using electrolysis or biomass gasification would raise future demands for renewable energy even further and diminish the role natural gas can play in a carbon-neutral economy.

Table 2-2 Impact of energy demand reduction on renewable energy needed in addition to supply in 2019, electricity from Site C project and bioenergy from existing waste streams

Demand reduction by 2030		15%	20%	25% (base)	35%	35%
Additional supply (PJ) in Scenario 3:	Electricity	79	69	59	49	38
	Liquid biofuel	96	80	63	47	30
	Solid biomass	0	0	0	0	0
Additional supply (PJ) in Scenario 4:	Electricity	46	36	26	16	5
	Liquid biofuel	122	114	106	97	89
	Solid biomass	100	87	73	60	46
Demand reduction by 2050		40%	45%	50% (base)	55%	60%
Additional supply (PJ) in Scenario 5:	Electricity	221	190	160	129	99
	Liquid biofuel	42	24	7	-11	-21
	Solid biomass	0	0	0	0	-13
Additional supply (PJ) in Scenario 6:	Electricity	83	67	51	35	19
	Liquid biofuel	211	183	155	127	99
	Solid biomass	274	244	202	155	108

Furthermore, all the Scenarios include accelerated energy demand reduction. A sensitivity analysis has been carried out to investigate the significance of reducing overall energy demand. As shown in Table 3-2, for every 5% of further reduction in overall energy demand, the additional renewable electricity supply required to achieve BC's 2030 target can be reduced by 10 PJ, with similar reductions in demand for biomass and biofuels. Demand reductions for the 2050 scenarios are even larger. Therefore, progressive reduction of overall energy demand is essential to meet BC's GHG targets for 2030 and beyond. This challenging task requires substantial efficiency improvement and also behavioral changes induced by more stringent policy measures.

3. Clean Energy Sources for BC

A full assessment of potential sources of low-carbon energy in BC is set out in the accompanying document: "Part II: Clean Energy Strategies for Mitigating Greenhouse Gas Emissions in British Columbia". A summary is provided here.

BC has enormous potential for bioenergy production. Waste biomass available in BC could provide about 20% of the energy currently provided by fossil fuels [9]. The main source is unused wood residues generated during logging and sawmilling; this material is currently destroyed by slash burning, to ensure that it does not provide a potential fuel for wildfires. Trees killed by mountain pine beetle infestation are another source, although long-term availability is uncertain. Waste biomass is available in animal manure, crop residues, and the organic fraction of municipal solid waste (MSW). Energy crops, such as short-rotation coppice, could also be produced [10].

Most of the available biomass is lignocellulosic ("woody"). It can be used directly as fuel for generation of electricity or heat, gasified to produce Renewable Natural Gas (RNG) or liquid fuels including methanol and ethanol, or pyrolyzed to produce a range of liquid biofuels including aviation fuel. Following a general principle, the greatest GHG mitigation with the lowest cost is achieved by the simplest processes: direct use as fuel, including for district and industrial heating [9]. Syngas combustion generates lower health impacts [8]. Converting biomass to refined biofuels has lower efficiency and much higher costs [11].

Animal manure and food waste can be processed into biogas by anaerobic digestion. The gas can be used directly to generate heat and/or electricity or can be upgraded to RNG, and the digestate residue can be used to displace synthetic fertilizers. The greatest GHG mitigation at the lowest cost results from using the biogas in integrated operations combining animal husbandry, glasshouse cultivation and, preferably, mushroom production, following the industrial symbiosis principle [12], [13]. Upgrading the biogas to RNG brings lower GHG benefits at higher cost [13].

It has been demonstrated in Section 2 that even with the Site C project completed and radical energy demand reduction, BC will not have surplus renewable electricity, as future electricity demands will dramatically increase. Other primary energy sources must therefore be explored. Wind energy could make a significant contribution in BC [7]. Solar Photovoltaic production is less favourable in BC [2] but can be deployed in niche applications, such as local uses for charging electric vehicles, as well as in large solar farms linked to the grid. Increasing wind and solar will increase the proportion of intermittent generation in the provincial grid way beyond the present level of 2.5% but, based on experience elsewhere, at least 20% should be readily manageable. Combined heat and power generation, providing dispatchable renewable electricity and low-carbon steam/heat to industrial operations, should be retained and possibly increased.

Given that the demand for renewable electricity is expected to rise in the future, the most effective uses should be prioritised. For land transport, this means powering electric vehicles, which is more energy-efficient than using electricity to produce liquid fuels ("electrofuels"). For industrial applications, replacing natural gas and diesel engines by electric motors is the preferred use. In buildings, the preferred use is in heat pumps to replace resistive and gas-fired heaters.

Hydrogen is an energy carrier that can be produced from different primary energy sources: electricity, by electrolysis of water; biomass, by gasification; or natural gas, by steam methane reforming [3]. Given the scarcity of renewable electricity and biomass in BC and the need to mitigate GHG emissions, "blue" hydrogen, which is produced from natural gas with the CO_2 sequestered, is recommended; this represents the only sizeable use for natural gas consistent with a low-carbon economy. The hydrogen is recommended for powering fuel cell vehicles, preferably heavy-duty ones, to replace internal combustion engines. Direct combustion of hydrogen is not a preferred use because it loses the advantage of fuel cells and is less efficient than direct use of the primary energy from which the hydrogen is produced.

4. Conclusions and Recommendations

The two phases of CleanBC include a full suite of policy measures for promoting renewable energy and reducing methane emissions and thus represent firm steps towards achieving BC's 2030 GHG mitigation target. However, a problem in the CleanBC framework is the lack of comprehensive action to address the growth of energy demand in BC associated with growth in economic activity and population. Even though the CleanBC Roadmap attempts to reduce energy use in the transportation sector, similar action plans in buildings and industries are lacking. Scenario 1 shows clearly that the CleanBC framework, together with moderate demand reduction of 5% by 2030, is unable to reach the 2030 target. In all the other scenarios, rapid demand reduction of 25% by 2030 and 50% by 2050 is assumed, but the current supply of renewable electricity and bioenergy is still far from enough to meet the growing needs. The additional supply of renewable energy needed for BC's GHG mitigation targets will be immense.

The extent of demand reduction achievable in 2030 and 2050 cannot be predicted reliably, but any further demand reduction moves closer to meeting GHG mitigation targets. Naturally driven by desire for lower cost, energy efficiency can be expected to improve continuously but slowly. Decoupling energy demand from economic and population growth needs stringent policy measures to achieve transformational rather than incremental change. Growth in demand in BC is predicted to arise mainly for heating, mobility, and industrial production. Energy consumption for home heating and personal mobility is largely a matter of behavioral change, which may be induced by both voluntary desire for a sustainable future and involuntary policy measures.

Electrification is seen as a core strategy for GHG mitigation in BC. With radical demand reduction and electrification-centered strategy, an additional electricity supply of about 60 PJ will be needed for BC's 2030 target, and 160 PJ for carbon neutrality in 2050. These numbers are obtained from hypothetical scenarios, but show that the current electricity supply is clearly insufficient. The new projects needed will be comparable in magnitude to the output of the Site C project, i.e., hundreds of wind turbines and millions of solar panels, representing both challenges and opportunities for utilizing all the available wind, solar, and hydroelectric generation resources in BC. On the other hand, as electrification progresses, the demand for conventional fuel and consequently biofuels for blending will be expected to peak and decline. By 2050, currently available biomass residues will meet demand for bioenergy if the electrification-centered strategy is implemented.

The bioenergy-centered strategy is an alternative to a strategy dominated by electrification. It would dramatically increase demand for bioenergy. As the first step, it must fully exploit existing waste biomass, including wood residues, agricultural waste, food waste, and landfill gases. In addition to securing sustainable bioenergy supply, this would reduce atmospheric emissions of non-GHG pollutants. Even so, roughly 250 and 450 PJ of additional primary bioenergy supply will be needed for BC's 2030 target and carbon neutrality in 2050, respectively. Provision of such a large quantity of biomass is well beyond foreseeable waste collection from BC's current forestry and agricultural sectors. To further expand bioenergy supply, the sustainability of forest and farmland management and emissions from land-use changes must be carefully investigated.

Hence, strategies that rely solely on either renewable electricity or bioenergy will raise demand for the respective renewable energy beyond sustainable and manageable levels. Therefore, there is no single 'silver bullet' renewable energy source to meet BC's GHG mitigation targets: it is essential to utilize all the available bioenergy and renewable electricity resources and promote a balanced renewable energy portfolio. The limited time frame to 2030 emphasizes the difficulty of securing the renewable energy needed. For the long-term target of carbon neutrality, the supply problems emphasize the need for a balanced renewable energy strategy.

Executive Summary

The potential in BC for increasing use of biomass, generation and use of renewable electricity, and using hydrogen as an energy carrier have been assessed. As demonstrated in Part I of this paper series, both bioenergy and electricity will be in short supply, as further decarbonization efforts are made. Therefore, all renewable energy sources must be used in the ways that give greatest mitigation of Greenhouse Gas (GHG) emissions at the lowest cost.

Waste biomass in BC could provide about 20% of the energy currently provided by fossil fuels, mainly wood residues from logging and sawmilling. Energy crops could also be grown in BC. Lignocellulosic (woody) biomass can be used to generate electricity and heat, gasified to produce Renewable Natural Gas (RNG) or liquid fuels, or pyrolyzed to produce a range of liquid biofuels including aviation fuel. Direct use for district and industrial heating gives greatest GHG mitigation at lowest cost. Pre-gasification combustion generates lower health impacts. Converting biomass to refined biofuels leads to energy losses and increases overall costs. Manure and food waste can be converted into biogas by anaerobic Digestion (AD). Biogas can be used directly to generate electricity and heat or upgraded to RNG. The digestate residue can displace synthetic fertilizers. Integrating AD with agricultural operations gives the greatest GHG mitigation at the lowest cost. Upgrading to RNG has the highest cost.

Even with Site C completed and operating, BC will not have surplus renewable electricity. Other primary energy sources must therefore be explored. Wind energy could be significant. Solar photovoltaic production is less favourable in BC but could be deployed in niche applications. Increasing wind and solar will greatly increase the proportion of intermittent generation but at least 20% should be readily manageable. Cogeneration of heat and power, providing dispatchable electricity and steam/heat for industrial operations, should be retained and possibly increased.

The most effective use of electricity for land transport is to power electric vehicles. Using electricity to produce liquid fuels (“electrofuels”) is much less efficient. For industrial applications, replacing natural gas and diesel engines by electric motors is the preferred use. In buildings, the preferred use is in heat pumps to replace resistive and gas-fired heaters.

Hydrogen can be produced from different energy sources: electricity, by electrolysis of water; biomass, by gasification; or natural gas, by steam methane reforming. Hydrogen produced from renewable energy sources is termed “green” hydrogen, but its application is limited due to scarcity of future renewable electricity and biomass supply. “Blue” hydrogen is made from natural gas with carbon capture, which represents the only major use for natural gas in a low-carbon economy. It should be used in fuel cell vehicles, to replace internal combustion engines which are inherently less efficient. Combustion of hydrogen loses the advantage of fuel cells and is less efficient than direct use of the energy from which the hydrogen is produced.

Table of contents

CERC Clean Energy Research Centre

1. Bioenergy

1.1 Bioenergy potential in BC

BC has enormous potential for bioenergy production from waste biomass: existing wastes and byproducts of existing economic activities do not require additional resources and therefore constitute sustainable bioenergy feedstock. Figure 1 shows the estimated total primary energy in currently unused waste biomass in BC, totaling 190 PJ per year [1], equivalent to 20% of fossil fuel consumption. BC's primary source of waste biomass is its forestry sector. During logging and sawmilling, millions of tonnes of wood residues are generated; most are used domestically for energy production (135 PJ) [2] or exported as pellets (40 PJ) [3], but a considerable amount (80 PJ) remains unused. To prevent wildfires, unused wood residues must be destroyed by slash burning, which generates CH_4, a potent GHG, and other hazardous emissions [4]; converting the residues to bioenergy avoids these emissions as well as displacing fossil fuels. Trees killed by mountain pine beetle infestation are another source of forestry waste biomass [5], but future availability is unpredictable. Waste biomass is also available in animal manure, crop residues, and the organic fraction of municipal solid waste (MSW). The total waste biomass resource could supply a significant part but not the whole of BC's energy demand. The priority for developing the available bioenergy resource is therefore to maximize GHG mitigation while keeping the total costs as low as possible.

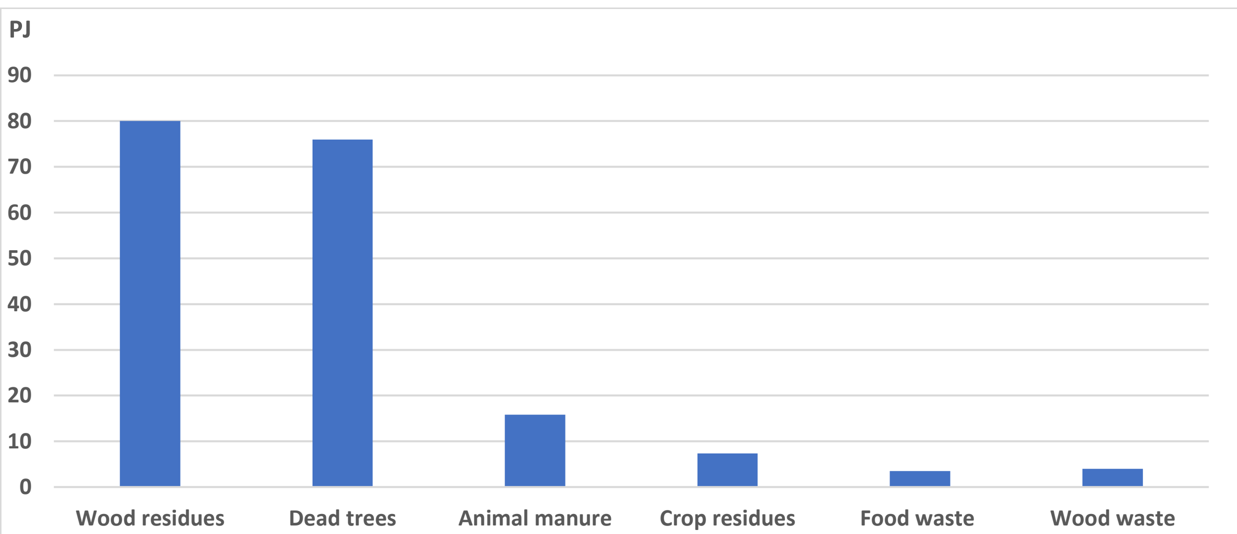

Figure 1 Primary energy in unused waste biomass in BC [1]

Beyond waste biomass streams, additional primary bioenergy could be obtained by expanding timber harvesting and growing energy crops. Short-rotation coppice (SRC) production of biomass should give an annual yield of 16-23 ODT/ha in Canada [6], [7]. However, producing 100 PJ of primary bioenergy would require roughly 250,000 ha, equivalent to 10% of BC's agricultural land [8]. Because the sustainability of these sources is contentious – they involve land-use change and potentially a conflict between food and energy production – they are not considered further here. However, they might be considered in future given that SRC is tolerant of flooding.

Most biomass resources in BC, including wood logs and residues, crop residues, and the woody fraction of MSW, and also SRC product, are lignocellulosic, composed of cellulose, hemicellulose, and lignin. The material can be converted to biofuels and energy by thermochemical processing (see Section 2.1.2). On the other hand, animal manure and food waste contain much more mixed constituents with higher moisture contents and are thus not suitable for thermochemical conversion; instead, anaerobic digestion (AD) should be employed (see Section 2.1.3).

1.2 Utilization of Lignocellulosic biomass

As illustrated in Figure 2, many thermochemical bioenergy conversion technologies start with gasification, a partial oxidation process that converts biomass into syngas, a mixture of mainly H_2, CO, CH_4, and CO_2 [9]. Biomass or biomass-derived syngas can be combusted for heat generation or cogeneration (CHP). Syngas combustion provides higher-grade heating, which can be used to replace natural gas for industrial use, such as in lime kilns in the pulp and paper industry. It also generates lower health impacts [10]. Alternatively, syngas can be synthesized into different biofuels, including methanol, ethanol, and methane (RNG). Biomass can also be pyrolyzed to produce hydrocarbons. An emerging pyrolysis technology is hydrothermal liquefaction (HTL), which turns biomass into a mixture of liquid biofuels including aviation fuel. Due to the nature of biogenic carbon cycle, bioenergy generally has lower GHG emissions than its fossil fuel counterpart [11]. Converting wood residues to bioenergy in BC can achieve additional reductions of GHGs and health impacts by avoiding slash burning [12].

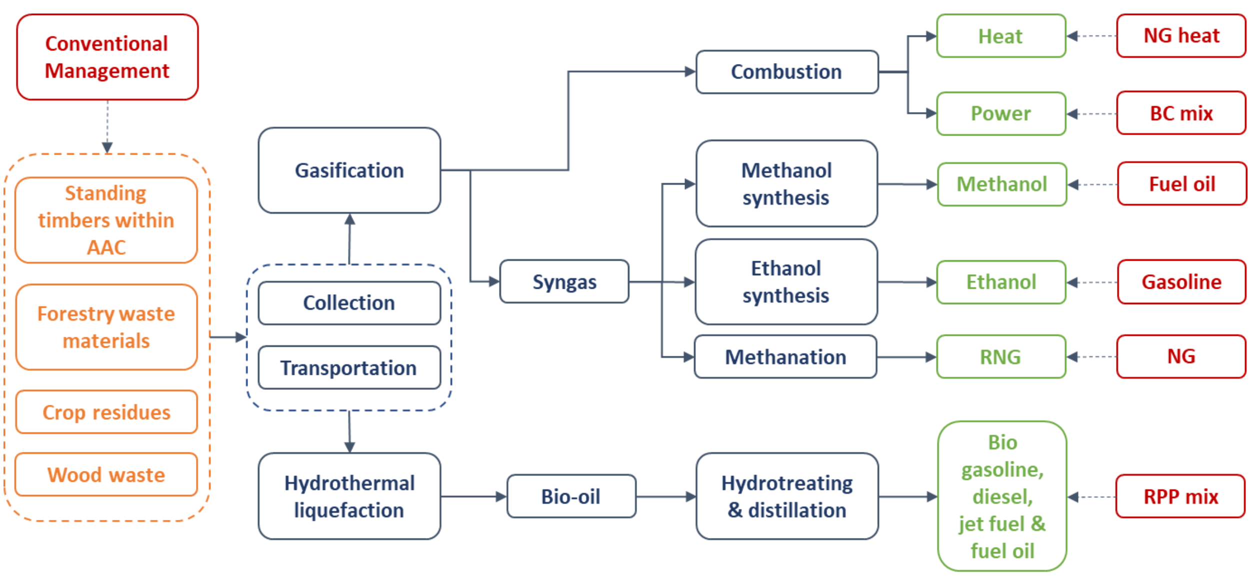

Figure 2 Systems for energy production from lignocellulosic biomass [12]

Conventionally, the carbon footprint of bioenergy is reported per GJ, which underplays the importance of conversion efficiencies. In Figure 3, GHG reduction potential of bioenergy derived from wood residues is compared per ODT biomass, which properly reflects the GHG benefit of utilizing limited biomass supply allowing for conversion efficiency [12]. GHG reduction cost ($/tCOeq) is shown in the ordinate of Figure 3, which represents the total carbon pricing (such as carbon tax and low-carbon fuel credit) needed to make bioenergy economically viable. Biomass-fired heating gives the highest GHG reduction per ODT, with negative reduction cost. Liquid biofuels and RNG have lower GHG mitigation benefits, due to extra energy losses in the conversion processes, but higher reduction costs. Typically, the conversion efficiency of biomass-fired heating can exceed 75%, whereas efficiencies of refined biofuels are below 60% [12]. Biomass-fired CHP has the lowest GHG reduction potential, due to the low carbon intensity of electricity in BC, but this could change in the long term (see Section 2.2.1). For other lignocellulosic biomass, the ranking of bioenergy options remains the same [13]. Overall, biomass-fired heating, in applications including high-pressure steam, kilns, and district heating, should be prioritized.

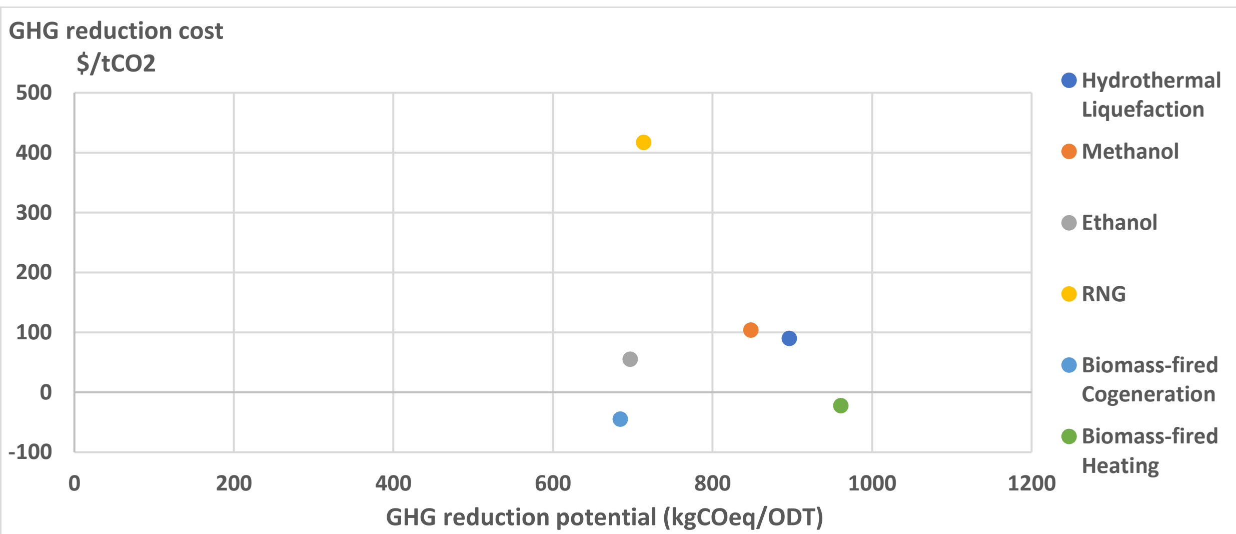

Figure 3 GHG reduction potential and costs of bioenergy produced from wood residues [12]

1.3 Anaerobic digestion

AD can decompose animal manure and food waste into biogas, which typically consists of 60% CH_4, 40% CO_2, and traces of other components. As shown in Figure 4, biogas can be directly combusted for heat production or CHP. Alternatively, it can be upgraded to RNG by removing CO_2 and trace gases. Thus AD can produce renewable energy and reduce the volume of waste. Furthermore, the organic residue of the AD process, namely digestate, retains nutrients in the feedstock. Using digestate as organic fertilizer can achieve additional environmental benefits by displacing synthetic fertilizers and improving nutrient management [14].

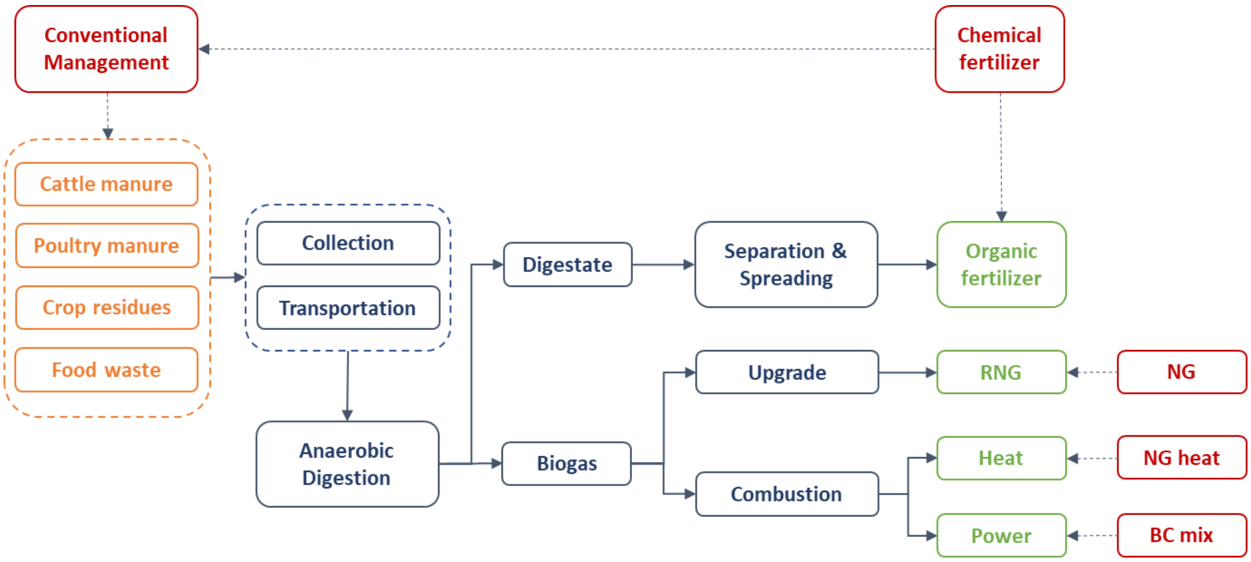

Figure 4 Systems for anaerobic digestion of organic wastes [15]

Figure 5 compares GHG reduction potential and costs of different biogas utilization options. Biogas-fired heating has the highest GHG mitigation potential and the lowest costs. RNG has slightly lower GHG benefits, due to extra energy losses and fugitive CH_4 emissions, but significantly higher costs. Biogas-fired CHP has the lowest GHG benefits but, like direct use of biomass for CHP, this could change in the long term (see Section 2.2.1). Economically, the GHG reduction costs of AD for standalone applications are higher than \$200/tCO_2, well above an ambitious future carbon tax level of \$170/tCO_2 (currently \$45/tCO_2). Such high GHG mitigation costs call for strong financial support from policy measures. Full utilization of the waste streams can generate 5.9 PJ of biogas and RNG [13], which is a small yet indispensable step towards reducing GHG emissions from natural gas consumption.

1.4 System integration for byproduct utilization

Utilization of byproducts from bioenergy conversion enhances the overall GHG mitigation potential and economic viability. For example, digestate residue from AD is rich in nutrients and can be used to substitute synthetic fertilizers [16]. Biochar generated by thermochemical conversion of biomass contains residual carbon and nutrients [17], [18] and can be used as a soil improver. Byproduct utilization may potentially improve the GHG benefits of AD and HTL by 100% and 50%, respectively, and also lead to cost savings [13].

A novel type of AD-centered system can effectively integrate animal, greenhouse, mushroom, and crop farming [15], [19], which are all common agricultural activities in BC. Biogas from AD of animal manure is combusted to heat participating farms. Biogenic CO_2 from combustion of biogas and ventilation of the mushroom farm replaces natural gas consumption for CO_2 enrichment in greenhouses. Digestate is used as growing medium in greenhouse and mushroom farming, in addition to fertilizers for crop farming. Co-digestion can further increase biogas yield and thus improve overall performance of the system. As shown in Figure 5, such integrated AD systems have substantially higher GHG benefits and lower GHG reduction costs than standalone AD options (Section 2.1.3) [15]. They represent an application of agricultural carbon sequestration and circular economy and so fit perfectly into BC's GHG mitigation roadmap [20].

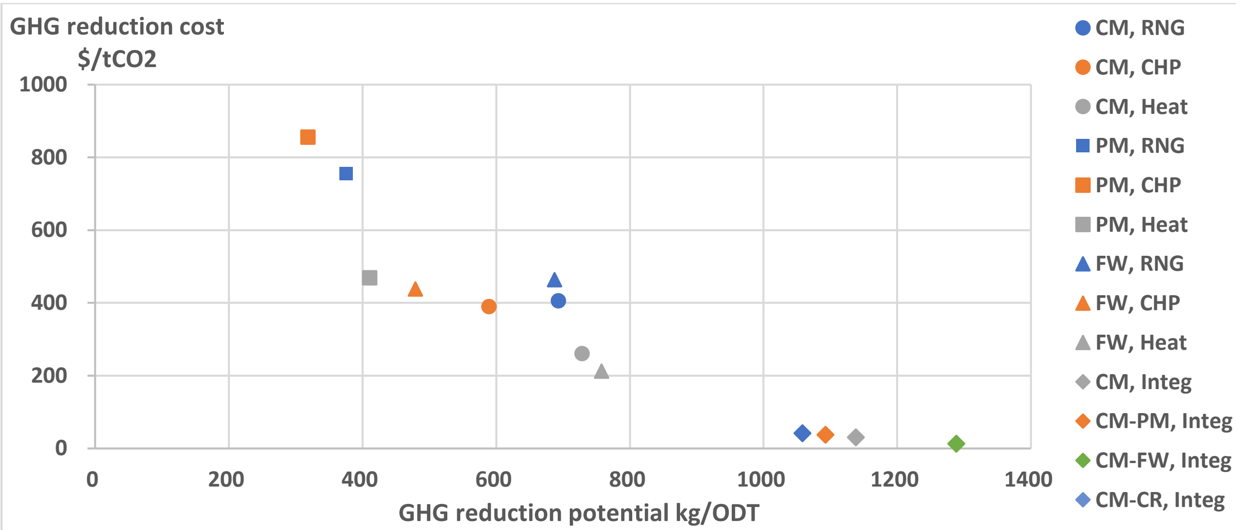

Figure 5 GHG reduction potential and costs of anaerobic digestion of organic wastes in BC [1], [15]**. CM = cattle manure, PM = poultry mature, FW = food waste.**

2. Renewable electricity and electrification

2.1 Renewable electricity sources

Hydroelectric generation is the main electricity source in BC, providing 90% of total supply [21] and expected to grow significantly. The Site C project currently under construction should provide an additional 18.4 PJ annually upon completion, expected in 2025. However, hydroelectric resources are limited, and no data are available on BC's total hydroelectric generation potential. Therefore, electricity from other renewable sources in BC should also be considered.

Biomass, mainly wood residues, fuels 5.5% of total generation in BC [21]. Section 2.1.1 identified the scope to expand the use of biomass, but power generation must compete with other uses of the feedstock. In the near term, with hydroelectricity dominating the mix of sources and the added capacity of Site C, biomass generation yields low GHG benefits and thus attracts little interest in BC [12]. In the long term, the position of biomass generation depends on whether other renewable sources can meet demand.

Wind energy is the third largest source of renewable electricity in BC and is growing: in 2019, .capacity reached 6.1 PJ, providing 2.5% of total generation in the province [21]. The average capacity factor, defined as output divided by maximum capacity, is about 33% in BC. Typical capacity for one wind turbine is 2.5 MW so, to match the output of Site C, about 700 turbines will be needed. Permanent direct land use for onshore turbines is about 3000 m^2/MW capacity, so 2.1 km^2 of land would be required. BC's location enables use of offshore wind turbines, which are more expensive although the additional cost is compensated at least partially by higher capacity factors. Assuming that wind generation in BC grows in line with the annual rate of 14% predicted globally by the IEA [22], annual output could reach 26 PJ in 2030, a substantial addition to future renewable electricity supply.

Solar photovoltaic (PV) generation is a major source of renewable electricity world-wide, but its contribution in BC is nugatory (0.043%) [21]. BC does not have strong solar radiation: average annual output of PV panels in BC is 1200 kWh/kW capacity (corresponding to an average capacity factor of 14%), and each kW capacity requires more than 7 m^2 of panel area [23]. To match the output of Site C would require as much as 30 km^2 of panels so that, if PV is to make a significant contribution in BC, distributed rooftop collectors and large-scale solar farms will all be needed.

Wind and solar generation are intermittent, i.e. not continuous or controllable. The possible proportion of intermittent generation in the grid depends on matching supply and demand, using dispatchable sources – hydroelectric (including pumped storage), biomass, and conventional fossil fuel-based generation. In many European countries, including Germany, Spain, and UK, the total share of wind and solar electricity has approached or exceeded 30% [24], [25], and may realistically increase to 45-50% by 2040 [26]. In US, EU, and China, the share of intermittent electricity is also expected to exceed 20% by 2026 [22]. It is therefore reasonable to expect BC's grid to be able to accommodate far more than the current 2.5% of intermittent generation; 20% appears to be a modest target for 2030, and 40% for 2050.

2.2 Efficiencies of electrification technologies

The most efficient ways to use electricity differ between the applications targeted in CleanBC: buildings, transportation, and industrial production. Energy demand in buildings is mainly for low-grade heat, which can be provided by electric heat pumps or resistance heaters. Heaters merely convert electrical input, whereas output from a modern heat pump can be at least three times the electrical input, giving an efficiency at least three times that of a resistance heater.

For transportation, the immediate option is the electric vehicle (EV). EVs use less than 30% energy per km than internal combustion engine vehicles (ICEVs) of similar size [27]. Electricity can also be used to produce other energy carriers, such as hydrocarbons for ICEVs from captured carbon (Carbon Capture and Utilization, CCU) and hydrogen for fuel cell vehicles (FCVs) by water electrolysis. ICEVs using synthesized hydrocarbons have similar efficiency to those using fossil fuels while FCVs have about twice the energy efficiency of ICEVs [27]. However, converting electricity to other energy carriers involves significant energy losses so that these options have much lower overall efficiency than EVs.

Electrification can reduce industrial energy consumption in two main ways: replacing natural gas and diesel engines by electric motors for motive power, and replacing fossil fuel boilers by electric resistance heaters for high-grade thermal energy. The efficiency of electric motors, defined as motive power output divided by energy input, can reach 85%, whereas the efficiency for natural gas engines is 30-40% [28]. Electric resistance heaters can approach 100% efficiency, whereas the efficiencies of modern natural gas furnaces and boilers are typically around 90% [29]. The efficiency advantage of electric motors is notably higher than that of electric heaters. However, both these applications depend on the availability of low-carbon electricity; if the electricity is generated from fossil fuels, the comparison depends on the application, with direct firing usually preferred for furnaces and boilers due to the inefficiencies in power generation.

3. Hydrogen

3.1 Hydrogen production pathways

Hydrogen is an energy carrier that can be derived from various primary energy sources. In BC, potential hydrogen production pathways include water electrolysis using renewable electricity, biomass gasification, and steam methane reforming (SMR) with or without carbon capture and storage (CCS). Hydrogen produced from low-carbon electricity and biomass is considered as "green hydrogen", which inherits the low carbon intensity of these renewable energy sources. Hydrogen produced by SMR of fossil natural gas coupled with CCS also has low carbon intensity and is termed "blue hydrogen". Hydrogen produced from fossil natural gas without CCS has high carbon intensity and is thus labeled "grey hydrogen". To ensure effective GHG mitigation, BC intends to set a gradually declining carbon intensity threshold for hydrogen [30], which means only green and blue hydrogen should be considered.

In principle, green hydrogen has the advantage of being renewable. However, green hydrogen suffers from additional energy losses during the conversion process and competes with alternative applications for the same renewable energy sources: in the context of limited renewable energy supply (see Section 3), energy used to produce hydrogen is diverted from more beneficial uses. Blue hydrogen is therefore more practical for BC, giving BC's abundant natural gas resources a role in a future carbon-neutral economy and helping relieve the pressure to expand renewable energy supply. However, a low carbon intensity for blue hydrogen depends on curtailing methane emissions from natural gas supply and hydrogen conversion.

3.2 Hydrogen utilization options

Like bioenergy and electricity, the most efficient uses of hydrogen must be identified and prioritized. The two main potential applications are (1) fuel-cell vehicles (FCV) replacing internal combustion engine vehicles (ICEV); and (2) direct combustion for thermal energy replacing combustion of fossil fuels, primarily natural gas for low-grade heating in buildings or high-grade thermal energy in industrial processes. FCVs are twice as efficient as ICEVs of similar size (see Section 2.2.2). On the other hand, combustion of hydrogen has similar efficiency as fossil fuels Therefore, using hydrogen in FCVs displaces more fossil fuels and achieves significantly higher GHG mitigation, and is therefore preferable to direct combustion.

Appendix B

ANNUAL ENERGY DEMAND FORECASTING

Appendix B-1

DEMAND FORECAST – TRADITIONAL ANNUAL METHOD DESCRIPTION AND BUSINESS AS USUAL FORECAST RESULTS

APPENDIX B-1: DEMAND FORECAST - TRADITIONAL ANNUAL METHOD DESCRIPTION AND BUSINESS AS USUAL FORECAST RESULTS

This Appendix provides further background on the Traditional Annual Method of demand forecasting for FEI's residential, commercial and industrial customer groups, and key results from the Business As Usual (BAU) forecast. In this context "business as usual" means that the forecast methods are unchanged and that the trajectories of the forecast elements such as use rates and customer additions are expected to remain consistent with trajectories experienced in the recent 3-10 years for the duration of the planning horizon. In this context "BAU" does not mean that the customers, use rates and demand recorded as of 2019 are expected to remain "flat" for the planning horizon.

FEI's Traditional Annual Method is consistent with the recommendations in the FEI Forecasting Method Study filed as Appendix B2 in FortisBC's 2020-2024 MRP Application. The Forecasting Method Study represented the culmination of a number of years of research and testing of alternative forecasting methods in response to the forecasting directives in Order G-86-15 and accompanying decision related to the FEI Annual Review for 2015 Rates Application. The flow chart presented in Figure B1-1 summarizes the Traditional Annual Method and guides the discussion in this appendix.

Figure B1-1: Data Inputs for the Traditional Annual Method

The BAU forecast for the 2022 LTGRP uses 2019 as the base year. This base year is consistent with the End-use Annual Method for demand forecasting described in Section 4 and Appendix B-3 of the 2022 LTGRP. FEI notes that the following discussion of both the End Use Method and the BAU forecast developed from the Traditional Annual Method applies to the built environment category of demand only.

1.1 RESIDENTIAL AND COMMERCIAL DEMAND FORECAST

1.1.1 Customer Forecast Method

The BAU forecast starts with preparing the customer forecast. FEI notes that the customer forecast method described in this Appendix is used for both the BAU forecast developed using the Traditional Annual Method and the Reference Case and alternative future scenario forecasts developed using the End-Use Annual Method presented in Section 4 and Appendix B-3 of the 2022 LTGRP.

1.1.1.1 Residential Customers

The residential net customer additions forecast was developed based on housing starts data from the Conference Board of Canada (CBOC) as follows:

1) Determine the prior year actual net residential customer additions by region.
2) Based on internal data, proportion the net residential customer additions into single and multi-family additions.
3) Use the CBOC long term growth rates for single and multi-family housing starts to develop the long-term growth rate forecast for both single and multi-family net residential customer additions.
4) Sum up the single and multi-family net residential customer additions.
5) Add the additions to the prior year total customer count, starting with the base year.

1.1.1.2 Commercial Customers

The commercial customer additions forecast is calculated as the average of the net customer additions by region and rate class (RS 2, 3 and 23) for the prior three years. The customer additions forecast is assumed to remain constant for the first five years and then adjusted based on the long term BC STATS household formation forecast for the remaining 15 years. The customer additions are then added to each year of the forecast throughout the planning horizon. Due to rate switching between the large commercial rate schedules (specifically RS 3 and RS 23), forecasting for these two classes was done as a group and then divided between RS 3 and RS 23 based on the 2019 customer distribution.

1.1.1.3 Customer Forecast Uncertainty

The 2022 LTGRP relies on a statistical approach using 95 percent[1] confidence intervals to model customer forecast uncertainty. This approach applies FEI's historical customer

[1] FEI notes that the 95 percent confidence level a common choice in statistics, but that other levels could be used. Choosing a higher confidence level (e.g., 99 percent) results in wider uncertainty bands, while choosing lower levels (e.g., 90 percent) results in narrower bands. Further a 95% confidence level is associated with 1 in 20 year events and aligns with the 20 year forecast horizon of the LTGRP.

fluctuations to perturb the BAU customer forecast into respective high and low customer forecast outcomes. This statistical method serves as a proxy to model the potential impact of economic growth on customer numbers but may also account for other intrinsic factors, such as FEI marketing and promotional campaigns. FEI created a custom script using a statistical programming application with built-in CI functionality connected to FEI billing system databases to complete the CI analysis. Please see Figures B3-2 through B3-6 in Appendix B-3 for the customer forecast and uncertainty bands results.

1.1.1.4 Residential and Commercial Use Rates

Monthly residential and commercial use per customer (UPC) forecasts are developed for each region and rate schedule using weather normalized historic data. As a result of this study, FEI adopted the Exponential Smoothing method (ETS) for the purpose of forecasting residential and commercial use rates, as ETS proved to be the most accurate method for this purpose.

1.1.1.4.1 WEATHER NORMALIZATION OF RESIDENTIAL AND COMMERCIAL USE RATES

Residential and commercial rate schedules (RS 1, 2, 3 and 23) are weather sensitive. A weather normalization process is applied to all actual use rates for these rate schedules. Separate normalization factors are developed for each region, rate schedule and month.

Actual UPC is weather normalized on a monthly basis for each region and rate class by dividing the actual UPC by a normalization factor. The normalization factor is derived from a non-linear regression model that estimates the impact of the monthly weather variation on the load.

The heat sensitivity estimated from the model assumes that the sensitivity varies not only depending on the weather but also on the rate class. For example, the residential rate schedule shows higher sensitivity to weather compared to the commercial rate schedules, and FEI's normalization factors account for the difference.

1.1.1.5 UPC Forecast

Ten years of weather normalized actual use rate data is used to calculate the UPC forecast using ETS, as implemented in Microsoft Excel. Once the use rates are seasonalized and developed for each region and each rate schedule they are entered into Forecast Information System (FIS) software. The amalgamated use rates are calculated using the following relationship:

$$Use\ Rate = \frac{\sum Volume}{\sum Accounts}$$

FIS calculates both the monthly volume and accounts by region and rate class.

UPC trends present in the forecasts implicitly include the impact of broad changes in consumption patterns that might have been caused by such factors as energy efficiency, economic activity, policies and equipment standards up to the time of the most recently available annual usage data. For the purpose of the BAU forecast the trends were then extended out 20 years for the purposes of providing the long term BAU forecast.

1.1.1.6 Preparing the BAU Residential and Commercial Demand

The residential and commercial demand forecasts are the products of the monthly customer forecast and the corresponding monthly use rates forecast at the regional level. The regions and months are then summed to arrive at the amalgamated annual residential and commercial BAU forecast.

1.2 INDUSTRIAL DEMAND FORECAST

FEI utilized the results of the annual industrial customer survey to identify expected changes in industrial customer demand. The survey was conducted as part of FEI's short term demand forecasting process used for gas supply planning, revenue requirements and other BCUC submissions. The intentions of industrial customers over the next five years were held constant over the LTGRP planning horizon consistent with the design philosophy and intended purpose of the Traditional Annual Method and the BAU forecast.

1.3 BAU FORECAST RESULTS FOR RESIDENTIAL, COMMERCIAL AND INDUSTRIAL CUSTOMERS

The following figure shows the BAU forecast for the residential, commercial and industrial rate groups. The BAU forecast represents an extension across the planning period of intrinsic end-use trends from the most recent data. The resulting annual demand forecast is largely flat with moderate growth in the commercial sector.

Figure B1-2: BAU Forecast for Residential, Commercial and Industrial by Rate Groups

1. EXECUTIVE SUMMARY

In the regulatory proceeding reviewing the 2014 Long Term Resource Plan for FortisBC Energy Utilities (2014 FEU LTRP), FEU was asked by the BC Utilities Commission ('the Commission') whether it had compared its end-use forecasting model with forecasting models used by other utilities. The Commission and interveners expressed some reservations about FEU's end-use model including the complexity and associated cost of updating the model. Accordingly, the Commission directed FEU to "provide a detailed analysis of the relative benefits/shortcomings of their particular end-use method as compared to other end-use methods". As a result, in 2016 FEU retained Boreas Consulting (Boreas) to review long-term forecasting practices of North American gas utilities to determine whether there is a preferred method for conducting demand forecasts for use in integrated resource planning activities. Boreas completed a comparison of long-term (over 10 years) annual demand forecasting activities among gas distribution utilities in North America – particularly in Canada, the US Pacific Northwest and California.

Subsequently, in the regulatory proceeding reviewing the 2019 Long Term Resource Plan for FEU, the Commission asked FEU to review the long-term forecasting methods used by other utilities and energy planning entities in North America. As a result, FEU retained Energitix Management & Consulting Corporation (Energitix) to review long-term annual demand forecasting methods used by other utilities and energy planning entities, particularly those in Canada, the US Pacific Northwest, and California. to determine whether there have been any changes in long-term demand forecasting practices of the entities studied in the 2016 Boreas report, as well as other appropriate utilities and energy planning entities.

Energitix completed this work by reviewing publicly available documents from 18 utilities and energy planning entities. These documents primarily consisted of regulatory filings by the utilities and included Integrated Resource Plans (IRPs), Capacity Supply Plans, Energy Efficiency Plans, Rate Applications, and Testimonies. Furthermore, Energitix identified the person and/or people responsible for forecasting at some of these organization and interviewed them to obtain more detailed insight into their forecasting methods. Most of these organizations included organizations that were included in the 2016 study. While information from some of the organizations included in the 2016 study was not available for this study, information from other organizations was obtained and included in this report.

Organizations with forecasting horizons of 10 years or more often use their long term forecast as part of their IRP, which often has a longer-term horizon.

Approximately 64% of the organizations that use long-term forecasts of 10 years or more either use an end-use model or a combination of end-use and econometric model. This compares to 44% in the 2016 study. Furthermore, 22% of the organizations that use long-term forecasts of 10 years or more currently use econometric models but are considering end-use models.

The end-use models are often used to forecast use per customer, while econometric models are used to forecast growth in the number of customers. The rationale being that as energy efficiency and changes to energy and climate change policies become more prevalent, the future energy demand will look significantly different from historic energy demand. As a result, econometric regression models that relay on historic energy demand data are not necessarily suited for forecasting demand that is different from the past, whereas end-use models provide a much more detailed understanding of the impact of efficiency improvements and policy changes on energy demand and long-term forecasts, particularly in new construction and replacement of old equipment. Organizations that are considering switching from econometric models to end-use models are primarily driven by the need to prepare long-term forecasts for a future that could be considerably different from the past.

Some of the leading jurisdictions in energy efficiency policy and regulation have used end-use modeling since the introduction of energy efficiency regulation over 20 years ago and continue to do so. One of the energy planning entities that prepares its own long-term forecasts for the state and the utilities in the state has used end-use forecasting since 1975.

In most cases, annual demand forecasts for residential and commercial customer classes are developed by multiplying the forecasted number of customers in each rate class by the average use per customer for that rate class. Economic forecasts from government agencies or other organizations are used to forecast the growth in number of customers. Average use per customer forecasts are based on either econometric models or end use models. Econometric models often use weather normalized historical consumption data and apply regression modeling to the data to forecast average use per customer. End-use models often use end-use data from end-use surveys to forecast average use per customer based on different end-uses.

End-use models tend to be much more data intensive than econometric models. However, the main driver for using end-use models by most organizations is the ability of end-use models to analyse various scenarios due to energy efficiency policies, codes and standards, and energy policies such as electrification and decarbonization; end-use models provide the level of detail required to assess the impact of energy efficiency standards and regulations as well as different energy policies. Similar to econometric models, the parameters used in end-use forecasting models vary from organization to organization, but in most cases, include energy prices, saturation levels of different end-uses, saturation levels of different energy sources, vintage or age of dwellings, dwelling type, dwelling size, and vintage or age of different end-use equipment. This data is often collected from end-use surveys.

Among the organizations investigated in this study, most organizations with high levels of DSM activity and IRPs use end-use modeling for their long-term forecasting. All end-use models require a medium to high degree of data intensiveness and can examine end-use trends within different scenarios, which in turn allow the organizations to show how changes to model inputs affect the results. Most organizations evaluate the performance of their forecasting model by comparing their forecast to actual energy demand, particularly for the early years of the forecast period. However, because long-term forecasts are based on forecasts of many input parameters, such as whether, energy prices, economic conditions, employment levels, new construction activity, etc. a straight comparison of forecasts to actuals without any adjusting for the input parameters does not necessarily reflect the effectiveness of the forecasting model. Thus, comparison of the forecast results to actuals may be quite resource intensive.

2. Introduction

In the regulatory proceeding reviewing the 2014 Long Term Resource Plan for FortisBC Energy Utilities (2014 FEU LTRP), FEU was asked by the BC Utilities Commission ('the Commission') whether it had compared its end-use forecasting model with forecasting models used by other utilities. FEU provided a high-level description of forecasting models from eight other utilities and characterized their approaches as one of: "top-down", "bottom-up statistical", "bottom-up engineering". In its Decision, the Commission agreed that FEU's intention to discontinue using a traditional method and to move towards an end-use forecasting approach had merit, but expressed reservations about the added expense related to further development of a model for forecasting the annual demand when it is the peak demand forecast that is the primary driver for infrastructure planning purposes. The Commission and interveners also expressed reservations regarding the complexity and associated cost of updating the FEU end-use model, as well as with the lack of testing with historical data to ascertain the accuracy of the model. Accordingly, the Commission directed FEU to "provide a detailed analysis of the relative benefits/shortcomings of their particular End-Use Method as compared to other end-use methods".

As a result, in 2016 FEU retained Boreas Consulting (Boreas) to review long-term forecasting practices of North American gas utilities to determine whether there is a preferred method for conducting demand forecasts for use in integrated resource planning activities.

Subsequently, in the regulatory proceeding reviewing the 2019 Long Term Resource Plan for FEU, the Commission asked FEU to review the long-term forecasting methods used by other utilities and energy planning entities in North America. As a result, FEU retained Energitix Management & Consulting Corporation (Energitix) to review long-term annual demand forecasting methods used by other utilities and energy planning entities, particularly those in Canada, the US Pacific Northwest, and California. to determine whether there have been any changes in long-term demand forecasting practices of the entities studied in the 2016 Boreas report, as well as other appropriate utilities and energy planning entities.

Specifically, FEU desired an update to the 2016 report.

3. FortisBC Model

FEU's end-use forecasting model was developed by a consultant. The model is built on top of the model that was used to develop the Conservation Potential Review (CPR), which allows for applying energy efficiency measures to a reference case.

FEU's long-term annual demand forecast starts by developing a detailed annual demand forecast for the base year. The base year demand forecast is built on demand forecasts for geographic regions, sectors and subsectors, rate classes, and different end-uses. FEU's annual demand forecast considers saturation levels of different end-uses, the market share of natural gas, and energy consumption for various end-uses. The base year forecast is then calibrated against FortisBC's sales, using the most recent data available. A detailed description of FEU's model is provided in FEU's LTRGP.

The forecast is built from the base year by growing the number of customers based on FortisBC's 20-year forecast number of customers by rate class. FEU's end-use model forecasts new customers based on the most recent vintage of buildings and building codes; it incorporates anticipated efficiency improvements (such as natural replacement of furnaces with condensing units), as well as anticipated changes in saturation and gas share for specific end uses.

The model uses saturation levels of different end-uses, natural gas market share, the vintage of buildings, rate class, dwelling type, and number of customers.

4. METHOD

Energitix completed a comparison of long-term (over 10 years) annual demand forecasting activities among utilities and energy planning entities in North America – particularly in Canada, the U.S. Pacific Northwest and California.

Energitix completed this work by reviewing publicly available documents from 18 utilities and energy planning entities. These documents primarily consisted of regulatory filings by the utilities and included Integrated Resource Plans (IRPs), Capacity Supply Plans, Energy Efficiency Plans, Rate Applications, and Testimonies. Furthermore, Energitix identified the person and/or people responsible for forecasting at some of these organization and interviewed them to obtain more detailed insight into their forecasting methods.

5. FINDINGS

Energitix's findings are summarized in this section, with detailed findings included in Appendix II.

As illustrated by Figure 1, 78% of the organizations prepare long-term forecasts of 10 years or more, while 22% prepare forecasts of five years. The organizations with forecasting horizons of less than 10 years often prepare their forecast for supply planning purposes or rate applications, while organizations with forecasting horizons of 10 years or more often use their long-term forecast as part of their IRP, which often has a longer-term horizon.

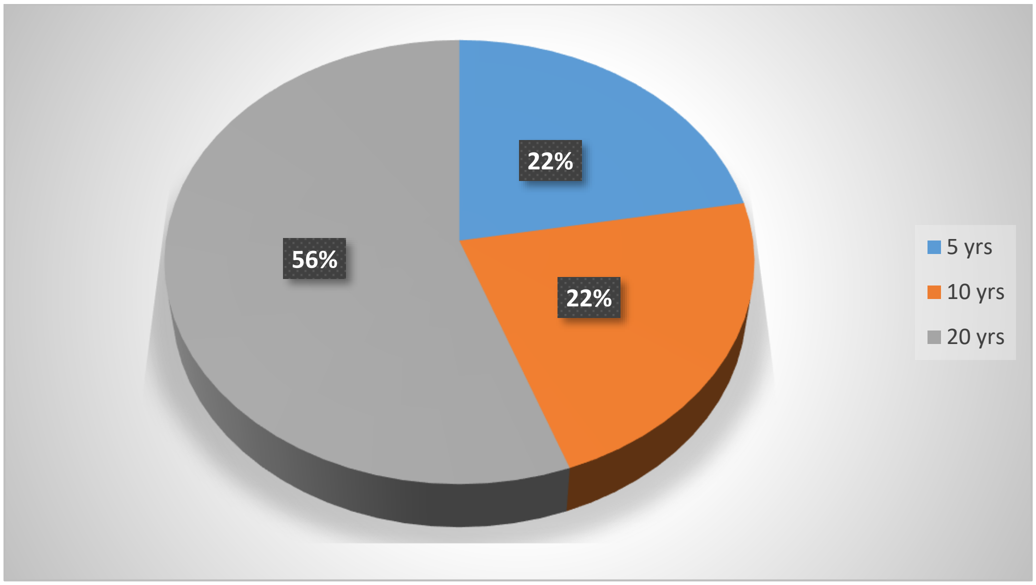

Figure 1. Distribution of Forecast Horizon

As illustrated by Figure 2, approximately 64% of the organizations that use long-term forecasts of 10 years or more either use an end-use model or a combination of end-use and econometric model. This compares to 44% in the 2016 study. Furthermore, 22% of the organizations that use long-term forecasts of 10 years or more currently use econometric models but are considering end-use models.

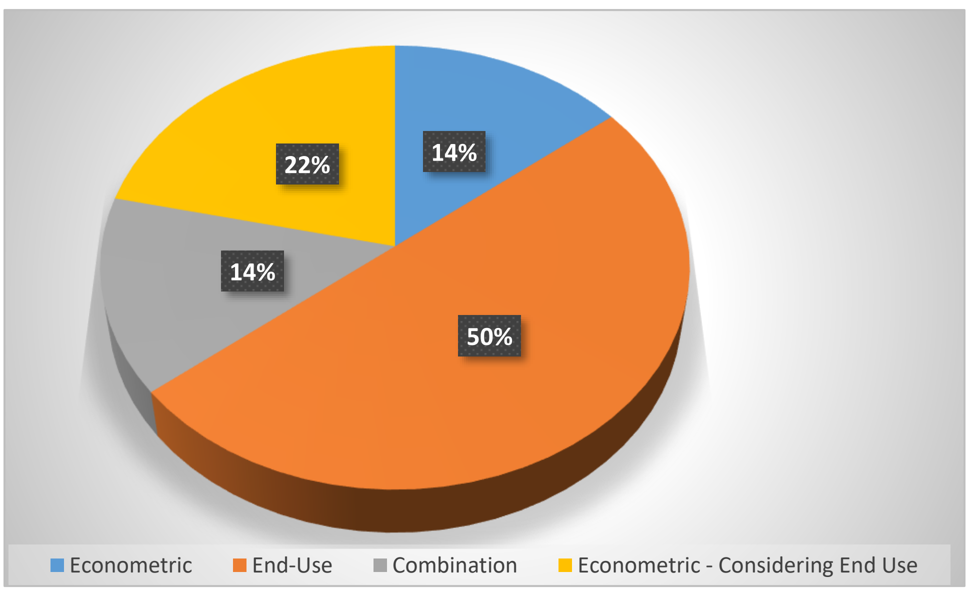

Figure 2. Distribution of Forecasting Method for Organizations w/ Forecast Horizon of Over 10 Years

The end-use models are often used to forecast use per customer, while econometric models are used to forecast growth in the number of customers. The rationale being that as energy efficiency and changes to energy and climate change policies become more prevalent, the future energy demand will look significantly different from historic energy demand. As a result, econometric regression models that relay on historic energy demand data are not necessarily suited for forecasting demand that is different from the past, whereas end-use models provide a much more detailed understanding of the impact of efficiency improvements and policy changes on energy demand and long-term forecasts, particularly in new construction and replacement of old equipment. Organizations that are considering switching from econometric models to end-use models are primarily driven by the need to prepare long-term forecasts for a future that could be considerably different from the past.

Some of the leading jurisdictions in energy efficiency policy and regulation have used end-use modeling since the introduction of energy efficiency regulation over 20 years ago and continue to do so. One of the energy planning entities that prepares its own long-term forecasts for the state and the utilities in the state has used end-use forecasting since 1975.

In most cases, annual demand forecasts for residential and commercial customer classes are developed by multiplying the forecasted number of customers in each rate class by the average use per customer for that rate class. Economic forecasts from government agencies or other organizations are used to forecast the growth in number of customers. Average use per customer forecasts are based on either econometric models or end use models. Econometric models often use weather normalized historical consumption data and apply regression modeling to the data to forecast average use per customer. End-use models often use end-use data from end-use surveys to forecast average use per customer based on different end-uses.

Most organizations build their annual demand forecast for their large industrial customers from individual customer forecasts, which are often based on historical trends with adjustments that are based on customer feedback and future plans and economic forecasts.

The parameters used in econometric forecasting models vary from organization to organization but in most cases include energy prices, GDP growth, population growth, household growth, income, and employment levels. Some econometric models also include an energy efficiency index, which takes into account improvements in energy efficiency standards and building codes.

End-use models tend to be much more data intensive than econometric models. However, the main driver for using end-use models by most organizations is the ability of end-use models to analyse various scenarios due to energy efficiency policies, codes and standards, and energy policies such as electrification and decarbonization; end-use models provide the level of detail required to assess the impact of energy efficiency standards and regulations as well as different energy policies. Similar to econometric models, the parameters used in end-use forecasting models vary from organization to organization, but in most cases include energy prices, saturation levels of different end-uses, saturation levels of different energy sources, vintage or age of dwellings, dwelling type, dwelling size, and vintage or age of different end-use equipment.

This data is often collected from end-use surveys. End-use surveys, therefore, are key in end-use modeling as such surveys provide the input to end-use models.

Irrespective of the type of forecasting model used, most organizations run a number of forecast scenarios. The forecast scenarios typically include a base case, which is the mostly likely scenario, plus a high and low case, which are based on high and low growth. Some organizations also run forecast scenarios to assess the potential impact of energy efficiency codes and standards as well as potential energy policies.

The organizations with long-term forecasts, where the forecast horizons are 10 years or more, provide annual demand forecasts for either every year or every five years during the forecast period.

Most organizations evaluate the performance of their forecasting model by comparing their forecast to actual energy demand, particularly for the early years of the forecast period. However, because long-term forecasts are based on forecasts of many input parameters, such as whether, energy prices, economic conditions, employment levels, new construction activity, etc. a straight comparison of forecasts to actuals without adjusting for the input parameters does not necessarily reflect the effectiveness of the forecasting model. Thus, comparison of the forecast results to actuals may be quite resource intensive. In general, performance of the models is assessed by comparing the long-term average of the adjusted actuals to forecast over several years. The adjustments vary from one organization to another; however, they typically consist of adjusting the forecasted input parameters such weather, energy prices, etc. and using the actuals when actuals are available. This allows the organization to evaluate the forecast model.

Most end-use models are developed by external resources but are operated by internal resources. There are several reasons using external resources to develop end-use models. These include, the expertise and experience required in developing the model and the intensive resources required over a short period of time in developing the model Because econometric models often use regression analysis techniques, they are sometimes developed internally.

Most organizations use their annual demand forecast to develop their peak-day demand forecast. Some of the common methods used in developing peak-day demand forecasts start with the annual demand forecast and apply the load factor of the different customer classes to the average-day demand for the applicable class, apply load shapes for different customer classes or end uses to the annual demand, and adjust the average-day demand for the peak-day weather conditions.

Table 1 summarizes the characteristics of the end-use models for the utilities and organizations that use end-use modeling in their long-term forecasting.

Among the organizations investigated in this study, those with high levels of DSM activity and IRPs use end-use modeling for their long-term forecasting. All end-use models require a medium to high degree of data intensiveness and can examine end-use trends within different scenarios, which in turn allow the organizations to show how changes to model inputs affect the results. This is particularly useful in analysing various scenario such as electrification, decarbonization, changes to energy and climate policy, and energy efficiency regulation.

Table 1. End-Use Model Characteristics

Organization Code	No. of Gas Customers	Utility Ownership	DSM Activity	Degree of Data Intensiveness	Degree of Customization	Ability to Examine End-use Trends/Scenarios	Ability to Show How Changes to Model Inputs Affect Results	Informs both Annual and Peak Demand	Cost to Maintain	Forecast Tested Against Actuals
A	5.9 million	IOU	High	High	High	Yes	Medium	Yes	Moderate	Some
B	873,000	IOU	High	High	High	Yes	Medium	Yes	Moderate	Some
C	1.4 million electric	IOU	High	High	High	Yes	Medium	Yes	Moderate	Some
D	N/A	N/A	High	High	High	Yes	Medium	Yes	Moderate	Yes
G	N/A	Crown	High	High	High	Yes	High	Yes	N/A	Yes
H	285,000	Crown	High	Moderate	High	Yes	Medium	No	Moderate	Yes
K	42,000	IOU	Low	Moderate	High	Yes	High	Yes	Moderate	Some
P	1 million	IOU	Low	Moderate	Moderate	N/A	N/A	No	N/A	N/A
Q	500,000	IOU	Low	Low	Low	Low	Low	No	Low	Yes
R	N/A	Municipal	Low	High	High	High	High	Yes	Low	Some
FEI	1.1 million	IOU	High	High	High	Yes	Yes	No*	Moderate	Not Yet**

Notes:

* Linkage with peak demand is being addressed as part of the ongoing improvement to the forecasting model.

** To date there has not been enough actual history to compare to the end-use demand forecast. Once enough historic data is available, FEI plans to compare end-use demand forecast to actual consumption.

Appendix II. LONG TERM DEMAND FORECASTING PRACTICES

A. Organization A

1. Overview

The company is an investor owned utility. It has the same parent company as another utility company included in this report. The two companies often share forecasting resources. Although each company develops its own forecast, the two companies use the same models to develop their long-term forecasts.

The company is one of the largest natural gas distribution utilities and serves 21.8 million consumers through 5.9 million meters in more than 500 communities, with a service territory encompassing approximately 20,000 square miles.

The company forecasts its use per customer across most sectors and its total annual gas demand across all market sectors, including residential, commercial, and industrial sectors, to decline from 2018 to 2035. The decline in annual demand is due to modest economic growth, mandated energy efficiency (EE) standards and programs, tighter building codes and standards, renewable electricity goals, decline in commercial and industrial demand, and conservation savings linked to Advanced Metering Infrastructure (AMI).

2. Forecasting Method

The company used to use both an econometric model and an end-use model to create its long-term annual demand forecast. A number of years ago, it stopped using the econometric model because the econometric model was based on historic energy use data, which does not allow the company to capture changes in the demand forecast when the "future is different from the past." An end-use model allows the company to forecast future demand under scenarios that are different from historic conditions. The end-use model allows the company to analyse the impact of different energy policies on their annual demand forecast.

The company, currently, uses a bottom up or end-use approach to forecast the use per customer for different sectors in its long-term forecast and the long-term economic outlook for its service territory to forecast the number of customers. Together, the use per customer forecast and the forecasted number of customers are used to develop the annual demand forecast.

The company's forecasting model, EU Forecaster, takes into account the age of the equipment to determine when the equipment is to be replaced. As the model iterates from one year to the next, it distinguishes between the load added due to new meters, changes in the load due to existing customers replacing old equipment with newer, more energy efficient appliances or other equipment in each year. Historical accounts are segmented into the total number of customers in the base year and their distribution among the historical vintages. The model produces a forecast over the planning horizon by applying a forecast of equipment capital costs, energy consumption, and fuel prices to the customer choice parameters. It calculates energy use for each customer type by optimizing the underlying customer choices. EU Forecaster's structure is designed to keep track of energy use for each market segment, each end use and for each vintage as the model steps through the entire forecast time horizon.

The company develops forecasts for residential, small commercial/industrial, large commercial/industrial, and power generation sectors. The forecasts for these sectors are developed from the forecasts for subsectors within these sectors.

The company's previous econometric models produced forecasts that relied on historical data as inputs to regression models. The models were used to explain how changes in the independent variables drove changes in the dependent variable. The models forecasted future demand by extrapolating the same relationship over the forecast period and assumed that there were no structural changes in the relationship between the impendent and the dependent variables into the future. Improvements in energy efficiency were included in econometric models by including an efficiency index as an explanatory variable. This efficiency index was only a proxy that accounted for the downward trend in gas use because of energy efficiency improvements. In prior econometric work, the company used end-use models to develop the energy efficiency index.

3. Forecasting Parameters

The company uses data from end-use surveys conducted by one of the state's energy planning bodies in their forecasting model. The main parameters from the end-use surveys are end-use, market penetration of end-uses, and energy use per end-use.

The parameters used in the forecasting model include:

- Equipment usage equation forecast drivers
- Coefficients describing how usage varies by weather, customer characteristics, prices, and other variables
- Choice forecast drivers, including capital costs for equipment in existing, conversion, and new construction buildings, plus future availability of each equipment type
- Average and marginal market shares for existing, conversion, and new customers
- Fuel, product, or service price forecasts in native units
- Decay functional form indicator and parameters for existing, conversion, and new customers
- Number of existing customers, non-customers on main, and non-customers off main
- Forecast of new construction (economic activity driving demand), capture rates, units per customer, and number of units (i.e., units are a scale of measurement consistent with results of the usage forecast, such as buildings, square footage, apartments, etc.)

- Mean age of end-uses by historical vintage in the baseline (i.e., 0th) year of the forecast used to initialize the age dimension in the turnover/vintage module
- Decay functional form indicator and parameters for equipment (end-uses) in existing, conversion, and new buildings
- Saturation (percentage of customers that have the equipment) independent of market shares
- Total actual sales in base year
- Exogenous parameters that change market shares for existing, conversion, and/or new customers through 'what if' intervention strategies
- Exogenous parameters that adjust product usage through 'what if' convention strategies

The company makes some out of model adjustments to the results from the forecasting model to account for energy efficiency improvements resulting from energy efficiency programs and code changes.

4. Forecast Scenarios

Forecasting scenarios included sensitivity to temperatures and non-cogeneration electric generation.

Core demand forecasts are prepared for two design temperature conditions – average and cold – to quantify changes in space heating demand due to weather. The cold design temperature conditions are based on a statistical likelihood of occurrence of 1-in-35 on an annual basis, with a typical recurrence period of 35 years.

The non-cogeneration electricity generation forecasts are prepared for two hydro conditions – average and dry. The dry hydro case refers to gas demand in a 1-in-10 dry hydro year.

In the future, the company may run more scenarios for electrification if legislation for decarbonization is introduced.

5. Forecast Period and Update Frequency

The company prepares a 20-year forecast of customers, annual demand, peak-day demand every two years. While the company prepares a forecast for each year during the forecast period, they only report forecasts for every year for the first 2 years and in five-year intervals after that.

6. Forecast Evaluation

The company finds evaluating the performance of their long-term forecast to be very difficult as there are numerous assumption and inputs into the model. As a result, there is no formal evaluation process in place. Since the company updates its forecast every two years, it compares the forecast to actuals, when actual annual demand data is available and may adjust the longer term forecast to account for the variance between the forecast and the actual demand.

7. Forecast Resources

The company shares forecasting resources with a sister utility. The team responsible for the long-term forecast includes one person who is responsible for the residential sector, one person who is responsible for the core commercial and industrial sector, one person who is responsible for the large commercial and industrial sector, and a manager. The team also performs other tasks.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company uses their annual demand forecast and apply peak-day design temperature to forecast their peak-day demand.

The peak-day design temperature conditions are based on a statistical likelihood of occurrence of 1-in-35 on an annual basis, with a typical recurrence period of 35 years.

B. Organization B

1. Overview

The company is an investor owned utility. It has the same parent company as company A. The two companies often share forecasting resources. Although each company develops its own forecast, the two companies use the same models to develop their long-term forecasts.

The company is a combination gas and electric utility that provides energy service to 3.6 million people through 1.4 million electric meters and 873,000 natural gas meters, with a service area that spans 4,100 square miles.

The company forecasts its natural gas and electricity demand separately.

The company forecasts its total annual gas demand across all market sectors, including residential, commercial, and industrial sectors, to decline from 2018 to 2035. The decline in annual demand is due to modest economic growth, mandated EE standards and programs, tighter building codes and standards, renewable electricity goals, decline in commercial and industrial demand, and conservation savings linked to AMI.

6. Forecast Evaluation

Please see section 6 in Appendix II.

7. Forecast Resources

Please see section 7 in Appendix II.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

Please see section 8 in Appendix II.

C. Organization C

1. Overview

The company is an investor owned utility. It has the same parent company as company A.

The company is combination gas and electric utility that provides energy service to 3.6 million people through 1.4 million electric meters and 873,000 natural gas meters, with a service area that spans 4,100 square miles.

The company forecasts its natural gas and electricity demand separately.

The company forecasts its total annual electricity demand across all customer classes, including residential, small commercial, large commercial, agricultural, and street lighting. It uses a statistically adjusted end-use model to forecast its annual demand.

2. Forecasting Method

The company forecasts its total annual electricity demand across all customer classes, including residential, small commercial, large commercial, agricultural, and street lighting. It uses Itron's SAE model to forecast its average use per customer in its annual energy demand forecast. The average use per customer is then multiplied by the forecasted number of customers by rate class to the forecast the annual energy demand forecast. The forecasted number of customers by rate class is forecasted using an econometric model.

For the residential and commercial sectors, the model uses saturation and efficiencies for different end-uses, which is obtained from the EIA's regional data from the Annual Energy Outlook. The Annual Energy Outlook data is produced by the National Energy Modeling System (NEMS). The company uses the data from the state's Residential Appliance Saturation Survey (RASS) and Commercial End Use Study (CEUS) to adjust the regional NEMS from the EIA for their service territory.

For the non-weather sensitive industrial sector, agricultural sector and street lighting with static loads, the company uses trend analysis in preparing its long-term forecast.

The company does not breakdown its long-term forecast for the residential and commercial sectors into different subsectors.

The company has been using the current SAE model for approximately 10 years. Prior to using this model, the company used a econometric regression model for long-term forecasting. The company switched to the SAE model from the econometric model because of large changes in energy use due to gains in energy efficiency. While the SAE model is not a full end-use model, the company believes it has the ability to account for changes in gains in energy efficiency, whereas, the econometric model did not capture the changes in energy efficiency into the future.

The company is currently investigating how to use a full end-use model for its long-term forecasting.

3. Forecasting Parameters

Unlike traditional economic models which are based on macro-economic variables, the SAE model contains information about thermal shells, appliance saturations, and energy efficiency changes. This information allows the forecast to adjust with known changes in end-use codes and standards. Explicit assumptions for energy efficiency trends create opportunities for developing scenarios and accounting for energy efficiency programs. Furthermore, detailed end-use projections allow for understanding which end-uses are responsible for forecast growth.

4. Forecast Scenarios

While the company prepares high, medium, and low demand forecast scenarios, only the medium scenario is submitted to the state energy body that prepare the state wide energy demand forecast. The state energy body then aggregates the electricity demand forecast from all utilities to prepare the state wide energy demand forecast.

5. Forecast Period and Update Frequency

The company prepares its 10-year forecast every year for every year during the forecast period.

The company used to update its forecast every two years. However, it now updates the forecast every year because factors that impact electricity demand in their market, such as adoption of photovoltaic (PV) for electricity generation and electric vehicles (EV), are changing at a faster rate.

6. Forecast Evaluation

Since the company updates its forecast every year, it compares the forecast to weather normalized actuals, when actual annual demand data is available; it may adjust the longer term forecast to account for the variance between the forecast and the actual demand.

The company is starting to track the various parameters that may impact their forecast. Some of these include adoption PV for electricity generation and EV.

7. Forecast Resources

The company uses Itron's SAE model to prepare its long-term forecast and has 4 full-time-equivalent staff plus a manager responsible for preparing the forecast.

The company uses a consultant to update the NEMS data, which its internal resources use to update the forecast model.

8. Peak Demand Forecast vs. Annual Demand Forecast

The company's peak demand forecast and its annual demand forecast are related. The annual energy demand forecast is an input into the peak demand forecast. The company used to apply load factor to the annual energy demand forecast to determine its peak demand forecast, however, because of the high adoption of solar PV their mid-day peak demand has moved to late afternoon. As a result, their historical load factor does not provide them with an accurate forecast. The company has, therefore, developed an hourly framework that is calibrated to the annual energy demand forecast and layers in the hourly distributed generation resources to determine load shapes which are then applied to the annual energy demand forecast to forecast the peak demand.

D. Organization D

1. Overview

The organization forecasts energy demand for eight electric utility and four gas utility planning/service areas.

The organization has been responsible for forecasting electricity and natural gas (and other fuels) demand for the state since 1975. These include forecasts of statewide and regional electricity and natural gas consumption, annual and seasonal peak demand, factors contributing to projected demand growth, and the impacts of electricity and natural gas efficiency, load management and other demand response activities.

The forecasts are used in various proceedings, including the state public utility regulator's IRP process and the state's ISO Transmission Planning Process. The state public utility regulator identified the IEPR process as "the appropriate venue for considering issues of load forecasting, resource assessment, and scenario analyses, to determine the appropriate level and range of resource needs for load-serving entities in the state." In addition, the organization provides monthly peak demand forecasts for the resource adequacy process in coordination with the ISO and the public utility regulator.

A critical part of the demand forecast is estimating energy savings from DSM activities. The organization is required to include all such demand reductions which are "reasonably expected to occur" during the forecast period in its forecasts.

2. Forecasting Method

The organization's demand forecasting methodology features an annual electric consumption model, an hourly electric load model, and an annual natural gas consumption model. These models produce forecasts by sector or consumer types. In most sectors, the methodology attempts to simulate individual energy use decisions as they pertain to end-use energy services. Some examples of energy services are the comfort derived from a heated home, the clean dishes from a dishwasher, the illumination from a light fixture, and the evaporation of water from pulp in a paper making machine. Energy in the form of natural gas, electricity (or other fuels) operates machinery to produce the service derived. Therefore, energy demand is a derived demand, not a direct one.

End-use energy consumption estimates can be developed from the application of analytical engineering techniques and econometric techniques for extracting information from customer use data. Early generation end-use models were developed using largely engineering methods. As better data became available, disaggregate econometric techniques were incorporated.

Although the methods to estimate energy efficiency impacts and self-generation have undergone refinement, the energy demand baseline forecast uses the same technical methods as previous long-term demand forecasts, including detailed sector models supplemented with single equation econometric models applied to a revised geographic scheme.

The organization forecasts natural gas demand in the state as part of each IEPR cycle. The organization uses end-use and econometric models structured along utility planning areas for the residential, industrial, commercial, agricultural, transportation, communications, and utilities sectors.

End-use modeling is used for forecasting residential and commercial demand, while econometric/trend modeling is used for forecasting industrial and agricultural demand.

Residential use is forecasted for different building arch-types based. Vintage of the dwellings is used to adjust for changes in building code and standards.

Commercial use is forecasted for different building types by building gross area.

End-use surveys are used to collect average use per appliance, saturation levels, and equipment and building vintages. These are conducted every four to five years.

End-use modeling is used rather than other forecasting techniques because of the ability of the end-use model to better explain how energy is actually used and how various factors effect changes in energy use. For example, models involving different levels of end-use detail are used to characterize how efficiency programs affect both energy requirements and peak demand.

The sectoral groups the organization modeled balance the desire to capture end-use detail with available data resources. Moreover, while the composition of sectoral consumption among the planning areas differs, the same models are used to forecast electricity and natural gas demand. Data from individual planning areas is used in the models to the extent possible. Table 2 lists the end-use and consumer characteristics of each of the sectoral models.

Table 2. Characteristics of Forecast Sectoral Models

Sector	Consumer Type/NAICS Code	End uses Covered
Residential	Residential consumers 3 housing types	24 major appliance and space conditioning categories
Commercial	12 building types 21 NAICS codes	10 equipment and space conditioning categories
Transportation, Communications & Utilities (TCU)	NAICS codes 221, 48 (excluding 48841), 49, 513, 56151, 56152, 562, 62191, and 92811	Consumption is estimated for aggregated of the ten NAICS codes, not for specific end uses
Industrial	Process, extraction, and assembly industries included in NAICS 1133, 21, 23; 31-33, 511, and 516	Thermal processes, HVAC, process steam, and cogeneration.

Sector	Consumer Type/NAICS Code	End uses Covered
Agriculture	Crop production, livestock, and related commodities.	Irrigation pumping, building heating, crop drying

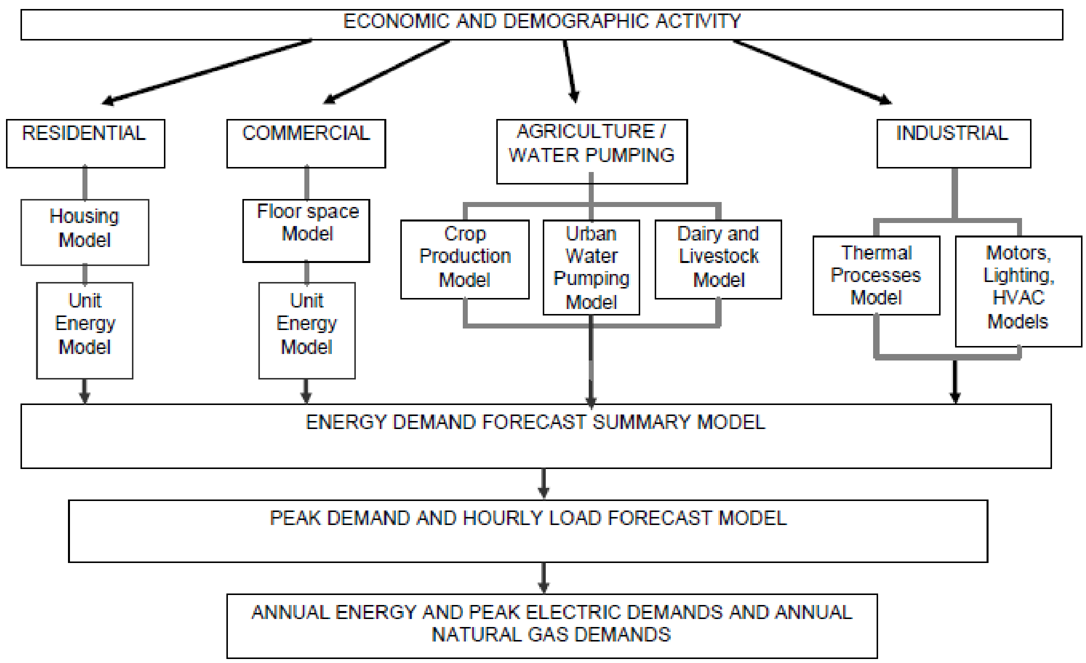
Planning area forecasts are developed by aggregating county data to the planning area level. For example, county-level housing construction, population and income estimates form the basis of a planning-area residential consumption forecast. Each county is apportioned to one or more of sixteen climate zones and each climate zone is assigned to a planning area.

The same models are used to forecast electricity and natural gas demand.

The aggregate demand for energy services increases with growth in economic activity and population and as new energy services become available due to technological development.

In addition, updated forecasts reflect the penetration rates at which more efficient equipment and new energy services come into use. In addition to the energy and peak demand sectoral forecasting models, the organization sometimes develops models that generate the values of economic variables used to drive the energy or peak sectoral models. This work has been necessary because suitable specific variables have not been readily available.

Figure 3 illustrates a schematic diagram of the major elements of the energy and peak demand forecasting models. The results from the energy forecasting models flow directly into the peak demand forecasting model.



Source: California Energy Commission staff, May 2005

Figure 3. Framework for Energy Demand Forecast Models

Residential Energy Demand Forecast Model

The residential model forecasts energy demand for 24 end uses, three housing types and three fuel types.

End-uses include space heaters, air conditioners, refrigerators, color televisions, lighting, water heating, etc. Electricity and natural gas consumption are fully modeled for all relevant end uses, while saturations are maintained for other fuels (principally wood, liquid propane gas, and solar).

Three housing types single-family, multi-family, and mobile homes are modeled; these are further grouped by climate zone. Sixteen climate zones are modeled; these are intended to capture differences in residential energy use for space conditioning across the state's microclimates.

Five vintages of housing construction are used to represent the eras in which building codes and revisions significantly influenced the thermal characteristics of residential buildings.

The residential model forecasts energy demand in three principal components:

1. The number of households of each housing type is forecasted.
2. The saturation of appliances for each of three fuel types is projected
3. The model determines the amount of energy expected to be used by each end-use appliance; this depends, in part, on the age profile of the appliance stock.

Total residential energy consumption is the product of projected households, the number of households possessing a particular appliance, and the yearly average energy use for that appliance, summed over all end uses.

Commercial Energy Demand Forecast Model

The commercial model uses end use intensities (EUIs), which are the energy use estimates per square foot by building type with corresponding end-uses and equipment.

The commercial energy forecasting model is similar to the residential model with respect to the degree of disaggregation. The model first forecasts the amount of building floor-space and vacancy rates for twelve different building types. The model then determines the fraction of floor-space in each building with commercial equipment for each of three fuel types. The nature of the energy-using equipment in each building type determines the commercial end-uses (for example, restaurants contain ovens and stoves, therefore, cooking is a principle end-use for that building type). The amount of energy required per square foot of floor-space is then determined for each fuel type. Total commercial energy demand is the product of these three factors and summed for all end-uses and building types. The model considers the effects of changes in floor space, vacancy rates, energy prices, building and appliance standards, and other major efficiency programs on energy use.

Industrial Energy Demand Forecast Model

The industrial sector is divided into process and assembly groups.

Projections of industrial energy demand for most sectors except extraction industries are driven by forecasts of GDP. For extraction industries, because the volatility of the prices of such commodities as oil, natural gas and precious metals leads to volatility in values of shipments or GDP forecasts of employment are used.

To forecast annual electricity and natural gas demand, the organization used to use the INFORM, developed by the EPRI until 2014. However, because EPRI does not support the model any longer, the organization decided to develop a new model for its 2014 report based on the INFORM method. The INFORM program accounted for energy use trends, price effects, and exogenous improvement in efficiency by end use and industry.

The major end-uses in the model are motors, thermal processes, lighting, HVAC and miscellaneous. The organization used to use the model to forecast demand for electricity, natural gas and other fuels for these five major end-uses over a 12-year period.

The new model forecasts industrial energy demand based on a number of factors, including:

- Projected growth in dollar output or employment for 28 categories
- Projected average industrial rates

- Changes in end-use characteristics, including energy intensities, which measure energy use per dollar of output

The marginal impact of economic growth on energy use in each of the 28 categories is estimated using regression analysis. Estimated coefficients are applied to the appropriate economic indicator to provide “business as usual” forecast for each industrial category. This forecast is adjusted for rate increases, using price elasticities estimated in the sector econometric models. Finally, the forecast is adjusted to account for changes in end-use energy intensity.

Since a full statewide industrial end-use survey has not been completed for more than 20 years, recent data on industrial end-use energy intensities and other characteristics to fully populate the model are not available. As a result, the organization started to populate end-use characteristics in the model using national data and smaller-scale state surveys. However, the organization expects the new model will require a full statewide industrial end-use survey to reach its full potential as a forecasting tool.

Energy Demands Summary Forecast Model

Individual sectoral model energy demand forecasts are processed by the Energy Demands Summary Forecast Model in order to calculate planning area total forecasts. The summary model adjusts the sectoral forecasts for weather and DSM program savings. The results are calibrated using recorded energy consumption.

Energy demand for weather sensitive end-uses is adjusted to accommodate the deviation between actual weather and normal weather for each climate zone in the planning area. After the weather adjustment, minor adjustments are performed to account for DSM programs that have not been incorporated into the input data used in the sectoral models. The final adjustment to the forecasts calibrates the results using recorded energy consumption.

3. Forecasting Parameters

Factors that affect natural gas supply and demand include production, population growth, pipeline capacity, economic outlook, weather, national and global markets, environmental concerns, and the effects of energy policies. Supply and demand, in turn, affect natural gas prices.

Four classes of data are needed as inputs to disaggregated forecast models:

- Consumer characteristics data such as end-use appliance saturations, dwelling size and age, occupants' income and demographic makeup, utility bills for the residential sector, and equipment saturations, hours of operation, etc. for the commercial sector
- Aggregated energy consumption data for the non-residential sectors (most notably the industrial sector) classified by the NAICS codes devised by the federal government

- Disaggregated economic and fuel price projections at a level of detail matching the customer sectors of the energy forecasting models
- Characteristics of demand side management programs

Customer surveys are the principle source of information on consumer characteristics. These surveys are used to collect data on customer electric and natural gas use, which form the core data needed for the end use forecasting models.

A major secondary data source on consumer attributes national census data.

Acquisition of reliable commercial floor-space data remains a difficult and unresolved problem for forecasters.

Monthly consumption data for different NAICS codes are used in the sector models.

Essential inputs into the forecasting models are annual economic and fuel price projections for each planning area for 10 years into the future. Several translation models are used to convert available economic data into the actual "energy driver variables" which are used in the models to forecast energy use. For example, in the commercial sector, the key energy driver is floor space by building type, while the economic variables are employment of various types, taxable sales, and various groupings of population.

The sector-specific economic variables used in developing the forecast are summarized in Table 3.

Table 3. Economic Variables Used in Forecast Models

Sector	Energy Driver	Economic Variable	Constructed Economic Variable
Residential	• Fuel Prices	• Population • Personal income • Households	• Household population • Persons per household • Group quarters • Income per capita
Commercial	• Floor-space, by building type • Fuel prices	• Employment • Retail sales • Population	
Industrial	• Output by industry • Fuel prices	• Output by industry • Employment (extraction sectors only)	
Agriculture	• Crop production • Rainfall • Electricity price • Diesel price • Cooling degree days • Dairy and livestock production	• Personal income • Population • Households	• Total households • Persons per household • Income per capita

4. Forecast Scenarios

The forecast includes three demand cases designed to capture a reasonable range of demand outcomes over the 10-year forecast period. The "high-energy demand case" incorporates relatively high economic/demographic growth, relatively low electricity and natural gas rates, and relatively low committed efficiency program, self-generation, and climate change impacts. The "low-energy demand case" includes lower economic/demographic growth, higher assumed rates, and higher committed efficiency program and self-generation impacts. The "mid" case uses input assumptions at levels between the "high" and "low" cases. It represents a future in which the economy and commercial activity remain consistent with trends experienced over the last several years. The high demand and low demand cases are created by altering assumptions, which move natural gas prices. The assumptions that are varied included economic growth, technology improvements, renewable portfolio standards, coal-fired generation retirements, natural gas supply cost curves, demand, and the production cost environment.

5. Forecast Period and Update Frequency

The forecast provides annual demand forecast for every year over the 10-year forecast period. It is updated every year as part of each IEPR cycle.

6. Forecast Evaluation

The organization evaluates the performance of its forecasts by having an expert panel review the forecasts. It also examines annual demand compared to subsequent actual consumption. In addition, it compares model backcasts, or predictions of historical outcomes, to historical consumption.

7. Forecast Resources

Although the original model was developed externally, the forecasts are prepared by internal resources.

Two full time equivalent (FTE) staff prepare the forecast for both gas and electricity in the residential sector.

One FTE prepares the forecast for both gas and electricity in the commercial sector.

One FTE prepares the forecast for both gas and electricity in the industrial sector.

One FTE prepares the forecast for both gas and electricity in the agricultural sector.

One FTE prepares the forecast summary for both gas and electricity for all sectors.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The organization uses hourly load shapes for each end-use and applies the load shapes to the annual demand forecast from the end-use model to determine the hourly demand for each end-use. It then aggregates all the hourly demand for all end-uses to forecast the peak-day demand.

The organization refreshed its hourly electric end-use load profiles, as well as hourly savings profiles for efficiency measure categories, generation profiles for behind-the-meter solar PV systems, and charging profiles for EV. For future forecasts, these profiles will be combined into a new bottom-up hourly electric load model (HELM 2.0) that will translate the organization's annual end-use consumption forecasts into hourly and peak-load forecasts. In the meantime, the organization continues to leverage its top-down hourly load model (HLM) to forecast annual and monthly peak loads. The HLM has been updated to incorporate the estimated impact of behind-the-meter battery storage, as well as EV charging profiles.

E. Organization E

1. Overview

The company provides natural gas and electricity to approximately 16 million people throughout a 70,000-square-mile service area. The company has approximately 42,141 miles of natural gas distribution pipelines and over 6,400 miles of transmission pipelines. It serves 5.4 million electric customer accounts and 4.3 million natural gas customer accounts.

The company has experienced declining growth rate in its annual demand in the core market and forecasts this decline in annual growth rate to continue primarily due to increasing emphasis on energy efficiency and electrification.

2. Forecasting Method

The company's gas demand forecasts for the residential, commercial, and industrial sectors are developed using econometric models. Forecasts for other sectors (NGV, wholesale) are developed based on market information. Forecasts of gas demand by power plants are developed by modeling the electricity market using the MarketBuilder software.

The company uses the current levels of energy efficiency programs included in its latest IEPR in the forecast.

3. Forecasting Parameters

While variations in short-term gas use depend mainly on prevailing weather conditions, longer term trends in gas demand are driven primarily by changes in customer usage patterns influenced by underlying economic, demographic, and technological changes, such as growth in population and employment, changes in prevailing prices, growth in electricity demand and in electric generation by renewables, changes in the efficiency profiles of residential and commercial buildings and the appliances within them, and the response to climate change.

Because space heating accounts for a high percentage of natural gas use, the company's natural gas requirements for residential and commercial customers are sensitive to prevailing temperature conditions.

Inputs for gas prices and rate assumptions are important for forecasting gas demand; this is especially true for market sectors that are particularly price sensitive, such as industrial or electric generation.

4. Forecast Scenarios

The company develops an alternative forecast of natural gas demand under assumed high-demand conditions. For the high-demand scenario, the company relies on weather conditions that have an approximate 1-in-10 likelihood of occurrence of cold temperature conditions and by considering a year for dry hydro conditions. In previous forecasts, the company used the average of observed temperatures during the past 20 years. However, the company is now building an assumption of climate change into its forecast.

The climate change scenario is developed from work done at the National Center for Atmospheric Research, adjusted to the company's service area.

Despite growth in number of households, total residential demand is expected to decrease due to continuing upgrades in appliance and building efficiencies, conversion to electric appliances, as well as warming temperatures.

Natural gas use per commercial customer is projected to decline over the forecast horizon due to continuing EE and electrification efforts as well as warmer temperatures.

Natural gas requirements for the industrial sector are affected by the level and type of industrial activity in the service area and changes in industrial processes.

Forecasts for the electricity generation sector are subject to greater uncertainty due to future gas prices; the retirement of existing power plants; the timing, location, and type of new generation, particularly renewable-energy facilities; construction of new electric transmission lines; and the impact of GHG policies and regulations on both generation and load.

The company forecasts natural gas demand by power plants and market-sensitive cogenerators using the MarketBuilder software. MarketBuilder enables the creation of economic-equilibrium models of markets with geographically distributed supplies and demands, such as the North American natural gas market.

The company's forecast for 2018-2035 uses the mid-case electricity demand forecast from the 2017 IEPR. The forecast assumes that renewable energy generation will provide 33 percent of the state's retail sales in 2020, 40 percent by 2024, and 50 percent by 2030. Additionally, the company included the impact of electric battery storage at the mandated level. The impact of battery storage may limit gas throughput from peaking electric generators.

5. Forecast Period and Update Frequency

The company prepares a 20-year forecast of customers, annual demand, peak-day demand every two years. While the company prepares a forecast for each year during the forecast period, it reports forecast results for every year for the first five years of the forecast period and at five-year intervals after that.

6. Forecast Evaluation

This information was not available.

7. Forecast Resources

This information was not available.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company uses a 1-in-90-year cold-temperature event as the design criterion for its abnormal peak-day demand forecast. The core market peak-day demand forecast is developed using the observed relationship between historical daily weather and core usage data. This relationship is then used to forecast the core load under peak-day conditions.

F. Organization F

1. Overview

The company is an investor owned utility that serves over 3.4 million customers in over 400 communities.

The company was formed by the merger of two natural gas distribution companies a few years ago. The company has made significant progress in integrating the operations and regulatory processes of the two companies, but there are some aspects of the regulatory process that are still different.

The company produces its forecast by rolling up the demand forecast for each division into one companywide demand forecast. The forecasting methods for both divisions are essentially the same, however, the models have some differences. The company is planning to evaluate its forecasting model and expects to use one model that it will be used to produce a companywide forecast in the near future.

The forecasting models for both divisions are primarily econometric models. The company does not produce a long-term forecast. It prepares a five-year forecast, which is filed with the regulator.

2. Forecasting Method

The company uses econometric models to prepare a five-year forecast, which it files with the regulator. Forecasts are prepared for different rate classes for each division, which are then rolled up to produce a companywide forecast.

Residential and Core Market Commercial

The company uses a separate econometric regression model for the residential and core market commercial customers for each division. One division uses annual data to create an annual demand forecast, while the second division uses monthly data to create monthly demand forecasts, which are rolled up to create the annual demand forecast.

The forecasts are prepared by rate class and by different geographic regions, which represent different climate conditions.

The regression models produce the average user per customer, which is then multiplied by the forecasted number of customers from econometric data.

The residential and core market commercial forecast for one division is derived using forecasted number of customers and normalized average use per customer forecast generated from the average use forecasting models. This econometric model allows the company to produce separate forecast for each rate class. While the model does not use specific end-uses in determining average use per customer, it includes bundles of end-uses grouped together. The model uses historical data to forecast annual demand for each rate class using regression techniques. The model determines average use per customer for each bundle of end-uses which are adjusted for efficiency improvements within the bundle.

The econometric model for residential and core commercial customers for the second division uses actual monthly average use per customer for each rate class for the previous 10 years and runs regression analysis of the data against demographic and econometric indicators. The regression model includes an "efficiency index."

Non-Core Industrial

The company uses bottom-up approach in forecasting for the non-core industrial sector. This approach is similar for both divisions. The company forecasts the demand for each individual customer for the large industrial customers based on data from the customers. The forecast for the medium sized industrial customers is based on the previous year's consumption. The company assumes little change in consumption year over year, unless they have information from the customer that the customer plans to change its natural gas use.

3. Forecasting Parameters

One division uses a number of parameters in its forecasting model. These include natural gas prices, historical annual demand, weather, vintage for residential customers, employment, real GDP, vacancy rates, and time trend

The vintage variable is constructed to reflect the impact that new homes, with more energy efficient gas equipment and enhanced building codes, have on average use.

The time trend, including the dynamic variable in the regression model, captures the historical actual average trend of the sectorial average use, conservation initiatives originated by customers themselves or promoted by government programs, stock turnover, and other historical impact not reflected in the mentioned driver variables.

The second division uses several parameters in its forecasting model, efficiency index, which represents the weighted average appliance efficiency; number of people per household; total gas bill in dollars, and weather.

4. Forecast Scenarios

The company does not run specific scenarios other than the base case. The company runs sensitivity analysis on the major drivers (inputs) of their forecast such as weather and number of customers.

5. Forecast Period and Update Frequency

The company does not prepare a long-term annual demand forecast. It only prepares a five-year forecast, which is updated annually.

The company provides a forecast for each year during the forecast period.

6. Forecast Evaluation

The company evaluates the performance of its forecasting model by comparing forecasted annual demand to normalized actuals using statistical methods such as MAPE to determine if their forecast has any built-in biases. In general, the difference between the forecasted annual demand and actual annual demand has been less than 1% for residential and small to medium commercial customers.

7. Forecast Resources

The company only uses internal resources in preparing its forecast. The forecasting department consists of four FTE dedicated to preparing the long-term forecast.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company applies the load factor for each rate class to the annual demand forecast to determine the peak-day demand forecast for each rate class. It then sums up the peak-day demand for each customer class to forecast the peak-day demand for the system.

G. Organization G

1. Overview

The company is a not-for-profit entity established by the provincial government. The company manages the province's power system so that the province receive power when and where they need it. It plans and prepares for future electricity needs.

2. Forecasting Method

The company uses an end-use model to forecast its annual energy demand by sector and by zone. Demographic and economic drivers are considered in the development of the annual gross forecast, including changes in household formation, commercial floor space, industrial output and energy price. Gross energy demand estimates are computed with the company's model EUF. EUF produces estimates of electricity consumption at the consumer level. The company applies transmission and distribution line losses to convert these energy values to the generator level. Figure 4. illustrates the company's load forecasting process.

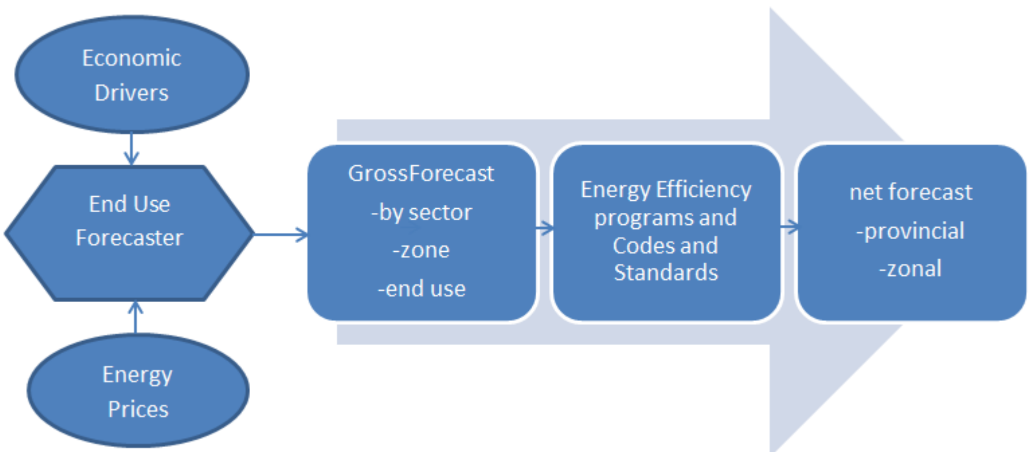


Figure 4. Load Forecasting Process

The EUF model is built at the zonal level with all zones aggregating up to the provincial total. EUF is an end-use model that tracks equipment and building stocks over time and simulates technology acquisition in the economy. The residential, commercial/institutional and industrial sectors are each analyzed separately. A schematic of the EUF model is shown in Figure 5.

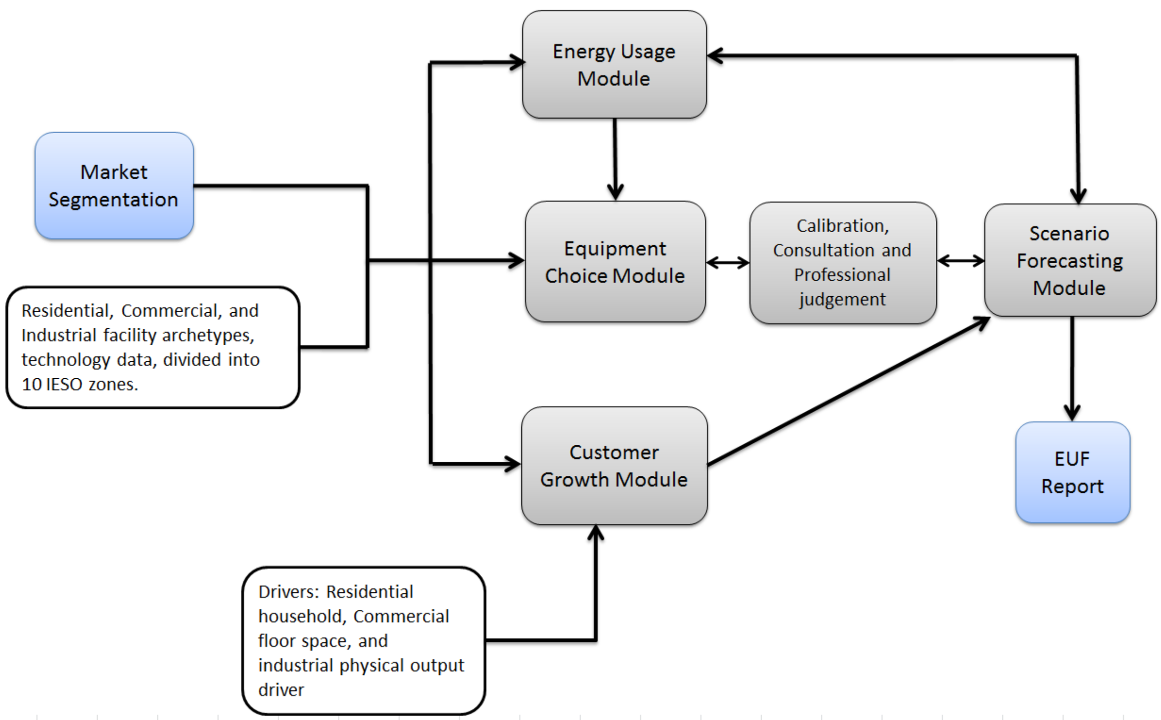

Figure 5. End-Use Forecaster Modules and Structure

There are several primary modules that form the heart of the EUF analytical framework. Figure 4. depicts the relationships between these modules.

- Market Segmentation Module
- Energy Usage Module
- Equipment Choice Module
- Customer Growth Module
- Scenario Forecasting Module

EUF's market segmentation module governs the development of customized market segmentation designs and the population of the model with the necessary data. A consultant supplied the majority of the data characterizing the end-uses as they apply to the province and its sub electric zones. The data includes: building characteristics, equipment saturations, fuel shares, end-use equipment efficiency shares, replacement technology relative efficiencies and capital costs. The company has been in the process of updating the end-use information whenever it becomes available. The market segmentation of the model contains sectors, zones, building types, end uses, fuel types and efficiency levels. Figure 6. shows the details of market segmentation by sector, zone, building type, end use, fuel type and efficiency level.

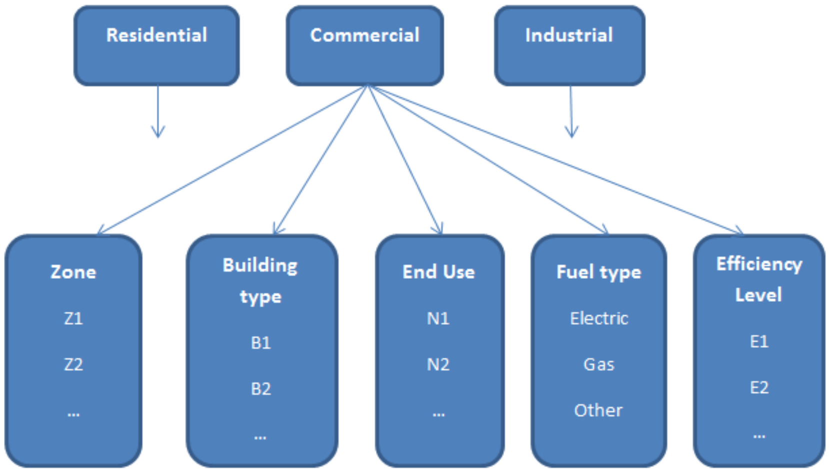

Figure 6. Market Segmentation Data Category

The energy usage module tracks equipment utilization given the stock of equipment, building characteristics, and customer behavior at any moment in time over the forecast horizon. For example, single-family homes may have a discrete set of central air conditioner efficiency choices, with each efficiency level having an associated electric consumption for each year. That consumption can vary in the short run as customers modify behavior that results in changes to the equipment utilization without changing the equipment itself. Factors that can affect consumption in the short run include weather, non-weather seasonal factors, building and customer characteristics, energy prices, disposable income, and other user-specified attributes. These relationships are specified in the Energy Usage Module by combining a forecast of consumption factors or drivers (independent or exogenous variables) with a set of coefficients associated with each exogenous variable.

The customer growth module tracks the number of customers (facilities) present within each vintage, geographic zone, and dwelling type or sub-sector from the market characterization. Customer growth varies over time through a range of factors, including forecasts of population (typically applicable to the residential sector) and square footage of different building types (typically applicable to the commercial sector). As with the energy usage module, these relationships are specified in the Customer Growth module by combining a forecast of customer growth factors or drivers (i.e., independent or exogenous variables) with a set of coefficients associated with each exogenous variable.

The main drivers used in customer growth module, residential household, commercial floor space and industrial physical drivers/activities, are provided either by third-party consultants or the company's in-house analysis.

Equipment stock changes in the model occur in response to new driver growth as well as to end-of-life retirement and replacement of equipment. Increasing saturation and utilization is also considered (e.g. increasing number of computers per household). Equipment acquisition choices are governed by choice equations that consider energy operating costs as well as capital costs. Different technologies are represented by five efficiency choice levels for each end-use. Discount rates by sector vary from 25% to 50%. The choice equations also recognize that price and cost savings are not the only factors that determine consumer action. The choice equation is, therefore, a weighting of financial and non-financial factors.

The equipment choice module analyzes customer choice decisions among competitors and product options. For example, customers choose their end-use equipment based on fuel types and efficiency levels. Purchase decisions are represented by a nested structure of provider (fuel choices) and product (efficiency choices) option choices. See Figure 7.

Choice equations are calibrated against base year new stock acquisition decisions across technology levels. For end-uses with a fuel choice (e.g. domestic water heating), purchase decisions are represented by nested fuel and efficiency option choices.

Short term behavioural response to price that reflects changes in equipment utilization without changing the equipment itself is captured through the use of behavioural price elasticity. The range of the elasticity is from -0.25 to -0.1 and captures behaviour such as lowering thermostats and turning off lights and computer monitors.

The hierarchy of equipment choice module is shown in Figure 7.

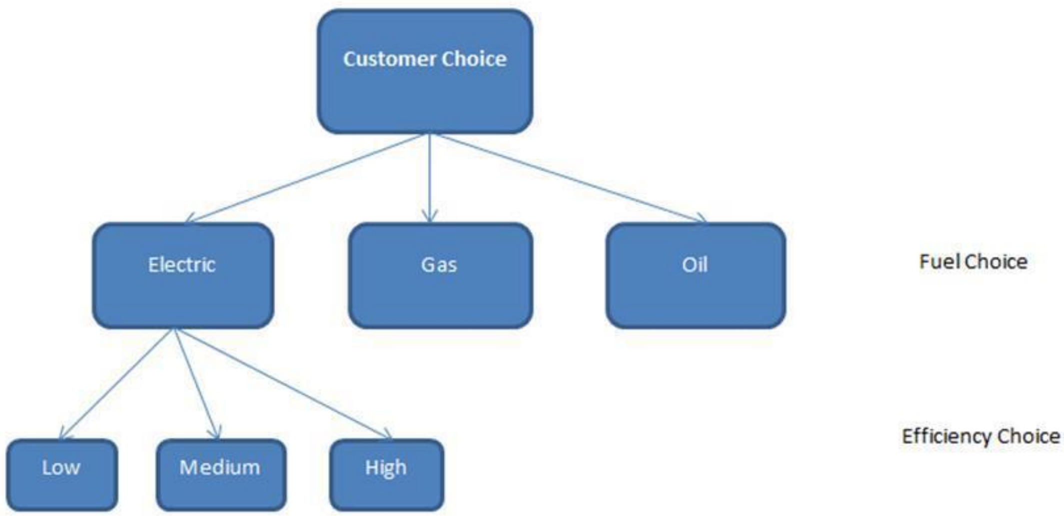

Figure 7. EUF Customer Choice Module Hierarchy

The company uses an end-use level model for a number of reasons, including:

1) The need to capture structural changes in the economy, including the growth and decline of specific industries and change in the relative strength of sectors;
2) The need to address the impact on demand of the penetration of new electricity using technologies;
3) The need to ensure linkages between conservation savings estimates and underlying assumptions of the load forecast;
4) The need to specifically address the impact on peak demand of the growth of different end-uses;
5) Forecasting is done by tracking energy at an end-use and equipment efficiency stock level. This is done so as to allow updates to the codes and standards.

3. Forecast Parameters

The company's EUF uses demographic and economic drivers in the developing its annual gross forecast, including changes in household formation, commercial floor space, industrial output and energy price.

The parameters used in the Market Segmentation Module are shown in Table 4, Table 5, Table 6, Table 7, Table 8, and Table 9.

Table 4. Residential End-Uses

Table 9. Industrial Subsector

Chemical Manufacturing	Transportation & Machinery	Petroleum Refineries
Fabricated Metals	Miscellaneous Industrial	Plastic & Rubber Manufacturing
Food and Beverage	Non-Metallic Minerals	Primary Metals
Mining	Paper Manufacturing	Wood Products

Demand forecasting methodologies vary for each of the other miscellaneous sub-sectors and include adopting study results from third-party consultants, the company's regional resource planning, and consultations with LDCs. These sectors include agriculture, remote communities, street lighting, electricity generator demand, and water treatment facilities.

4. Forecast Scenarios

Scenario Forecasting Module combines the outputs from Energy Usage Module, Equipment Choice Module and Customer Growth Module. It then performs additional calculations regarding turning over equipment at the end of its useful life to produce forecasts for electricity usage.

5. Forecast Period and update Frequency

The company develops a 20-year forecast its annual demand, and peak-day demand for each year during the forecast period.

6. Forecast Evaluation

The company evaluates the performance of it forecasting model by comparing its zonal residential energy forecasts with the annual energy use data from the LDCs by rate class. The company's industrial forecast is also compared with its transmission connected customer trends and market intelligence based on research and consultation with the company's planners, industrial conservation program account managers and others.

Energy consumption trends from NRCan's OEE are also used as check points with respect to provincial end-use energy and sector and subsector consumption trends. Information from NRCan's Survey of Household Energy Use and sales data from Canada Appliance Manufacturers Association are used to check the company's equipment forecasts.

Other various sources are used to check the forecast results including but not limited to: ASHRAE, RECS and CBECS by U.S. EIA, Residential Energy Use Survey conducted by the company's Conservation Division, etc.

7. Forecast Resources

The company uses internal resources to run its forecast. It also uses consultants to provide some of the data required as inputs into its model.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company uses its annual sectoral and zonal gross energy demands to develop its gross hourly demand values through the application of end-use level hourly load shapes. It then corrects its hourly gross peak and energy demand values for projected policy-induced conservation savings (i.e. savings from efficiency codes, standards and incentive programs). The outcome of this derivation is the net hourly load forecast. The net hourly load forecast establishes the amount of electricity that is to be served and forms the starting point for reliability assessment and integrated planning analysis.

H. Organization H

1. Overview

The company is a crown corporation that serves approximately 587,000 electricity customer and 285,000 natural gas customers.

The company used to use a combination of end-use and econometric model to forecast its long-term electricity demand. It switched to a primarily econometric model for electricity demand in the residential sector in 2014 because it wanted to have a better handle on increases in electricity prices and their impact on energy demand. The results from the econometric only and the end-use model were very similar.

The company has used the same model for forecasting its natural gas demand for the past 10 years. This model uses a combination of end-use and econometric model in years with modest electric price increase.

The company's natural gas demand forecast only covers a 10-year period with a focus on the three to five years. This is because the company does not own any transmission assets and can react to changes in demand much faster for the distribution system. The company's electricity demand forecast covers a 20-year period because of the long lead time required for generation and transmission assets.

2. Forecasting Method

The company uses a combination of end-use modeling and econometric modeling for forecasting its annual natural gas demand.

The company uses weather normalized historical usage by rate class.

Future DSM savings are embedded in the company's annual natural gas demand forecast.

The company's annual electricity demand forecast does not include the impact of future DSM savings in the base forecast. However, the company has been reporting its electric DSM savings since 2018.

Residential Customers

The company uses an end-use model to forecast annual natural gas demand for its residential customers.

The company conducts a REUS approximately every five years to collect data, which it then uses in its end-use forecasting model. It uses REUS to collect data on end-use saturation levels, detailed information on newly constructed dwellings, and appliance age distributions and their life expectancy. It uses the results of the REUS together with conditional demand analysis in its forecasting model to forecast the average use per customer. The company uses economic forecasts from external sources to forecast the number of customers.

The end use assumptions used in the model include current usage information and efficiency improvement information. The number of appliances and their estimated usage are multiplied together to calculate an energy forecast for each end use. All uses are then combined to calculate the total use for the residential end-use forecast.

Commercial and Small Industrial Customers

The company uses an econometric model to forecast its annual natural gas demand for its commercial and small industrial customers.

The company forecasts the number of small commercial gas customers based on economic forecasts from external sources. It forecasts the average use per customer based on historical average use per customer for each rate class. Since commercial rate classes are based on annual gas use, the average use per customer for the commercial rate classes is relatively stable. This is because, as customers whose gas use changes move to the appropriate rate class based on their gas use.

Large Industrial Customers

The company forecasts the annual demand for its large industrial customers individually based on information collected on individual operating plans, including short-term expansion or contraction plans. The sources of information include industry news and publications, company prospectuses, and from the company's key and major account advisors.

3. Forecasting Parameters

Residential Customers

The parameters used in the forecasting model include end-use saturation rates, dwelling type, appliance age distribution, and appliance life expectancy, as well as energy prices.

Commercial and Small Industrial Customers

These customers typically supply products to the Provincial, Canadian and US markets. As a result, the company uses Manitoban, Canadian and US GDP forecasts in its model.

Large Industrial Customers

The company forecasts the annual demand for its large industrial customers individually based on information collected on individual operating plans, including short-term expansion or contraction plans.

4. Forecast Scenarios

The company prepares a base case forecast for its natural gas annual demand forecast. In the past, the company used to prepare forecasts under various scenarios but has now moved to probability planning approach.

The company presents a probability-based estimate of how much future actual volumes might vary from forecast. This can be used to produce forecasts with a specific probability of occurrence, or can be used to determine the probability of specific volumes occurring. The company determines the standard deviation and correlation coefficient of historical weather adjusted volume and applies to the forecast to give an estimate of the confidence bands. It used 10% and 90% confidence bands (-/+ 1.28 standard deviations) to represent a low and high scenario. This calculation gives the variability due to economic effects and the year-to-year variation in natural gas use. It does not include variability due to weather which was removed through the use of weather adjusted volumes.

5. Forecast Period and Update Frequency

The company prepares a 10-year annual natural gas demand forecast, which it updates annually and prepares a forecast for each year during the forecast period.

6. Forecast Evaluation

The company evaluates its model regularly by comparing the forecasted annual demand for the first two years of the forecast period to actuals and has found that over the long term after accounting for heating value and weather the absolute average variance is with an acceptable range.

7. Forecast Resources

The company's forecasting team consists of approximately five FTE who prepare the long short-term forecast for both natural gas and electricity.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company prepares both a Peak-Day demand forecast and an Annual Demand Forecast and the Peak-Day demand forecast is primarily used for natural gas purchase planning and cost of service rate allocations.

I. Organization I

1. Overview

The company is a crown corporation and owns and operates a natural gas distribution system that serves over 385,000 residential, farm, commercial and industrial customers through its natural gas distribution systems. One of its subsidiaries, operates a natural gas transmission system with over 14,000 kilometres of high-pressure natural gas pipelines and gas storage sites as well as serves the large industrial customers. The forecasting method for the transmission company is covered in section **Error! Reference source not found.** in this appendix.

2. Forecasting Method

The company does not prepare a long-term annual demand forecast; it only prepares a five-year annual demand forecast.

The company uses a top-down qualitative model to prepare its forecast for each rate class. This model is based on an econometric model that uses economic forecasts from external resources.

The forecast for growth in the number of customers is based on economic forecasts and most recent historical trends.

The forecast for average use per customer for residential and small commercial customers is based on weather normalized historical data, while the annual demand forecast for large commercial customers is based on the annual demand from the previous year.

The company has used this model for many years, as it has provided good results.

3. Forecasting Parameters

The company's econometric model uses a number of parameters, which include average use per customer by rate class economic forecasts from various external resources, input from builders to assess housing starts, and economic and housing starts forecasts from CMHC and Statistics Canada.

4. Forecast Scenarios

The company only develops a base case. While it does not develop any alternative scenarios, if they expect a significantly colder or warmer year than forecasted, they update their demand forecast to update their revenue forecast.

5. Forecast Period and Update Frequency

The company prepares a five-year annual demand forecast annually for every year during the forecast period to align with the company's five-year business plan. The forecast is prepared for each rate class.

6. Forecast Evaluation

The company evaluates the performance of its forecasting model by comparing weather normalized actual annual demand to weather normalized forecasted annual demand. Forecasts are generally within one to two percent of actuals.

7. Forecast Resources

The company uses internal resources to develop its annual demand forecast. It estimates approximately one FTE plus some support from other resources to prepare its forecast. The company, however, uses various external resources to research the econometric data required for the forecasting model.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The peak-day demand forecast is forecasted separately from the annual demand forecast. The peak-day demand forecast is based on the regression analysis of the coldest day in 20 years.

J. Organization J

1. Overview

The company is a fully owned subsidiary of the crown corporation and owns that operates the natural gas distribution system in the province. The company operates a natural gas transmission system with over 14,000 kilometres of high-pressure natural gas pipelines and gas storage sites that supply natural gas to the natural gas distribution company, as well as serve the large industrial customers in the province.

The transmission company uses its forecasts primarily to assess load requirements and urban growth, which may encroach on its assets and result in potential relocation of the assets.

2. Forecasting Method

The company prepares a long-term forecast, which includes the demand from the distribution company and its industrial customers.

Since the company's customers are large industrial customers and the distribution company, its annual demand forecast is based on forecasts provided by its customers. When it receives new service requests, it includes a probability of the customer coming online during the forecast period and includes it in its forecast based on probability.

3. Forecasting Parameters

The company uses forecasts provided by its customers and market intelligence on new customer additions or expansions.

4. Forecast Scenarios

The company develops a most likely case as well as high demand and low demand cases. These scenarios are based on customer feedback and the probability of the customer moving forward with the forecasted changes, if any.

5. Forecast Period and Update Frequency

The company prepares five to 10-year forecasts with results for each year during the forecast period and updates these annually as part of its budget planning cycle. However, most of its forecasts are five-year forecasts. The forecast is prepared for each customer, as the customers are large industrial customers and a distribution company.

6. Forecast Evaluation

The company evaluates the performance of its forecasting model by comparing its forecasted annual demand to its actual throughput. Forecasts are generally within one to two percent of actuals.

7. Forecast Resources

The company only uses internal resources to develop its annual demand forecast. While four people from different departments are involved in preparing the forecast, it estimates approximately one FTE is required to prepare its forecast.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company forecasts the peak-day demand for its customers based on historic customer demand and customer feedback. It uses the annual demand forecast to develop its peak-day demand forecast by applying a load factor coefficient to the annual demand forecast.

K. Organization K

1. Overview

The company provides gas service to approximately 42,000 residential, commercial and industrial customers in more than 16 communities.

The company used an end-use model in its annual demand forecast for the residential sector in its most recent long-term forecast, which was part of its 2019 consolidated resource plan.

The company has experienced declining use per customer in its residential and small commercial sectors, which is likely due to building code improvements and increased appliance efficiencies.

2. Forecasting Method

The company's annual demand forecast is weather normalized. The company uses three different approaches to forecasting annual demand for its three customer classes.

Forecasts for the large industrial and commercial customers are based on the results of a customer survey. The company sends out a survey to its large customers asking for customers to provide a forecast of their gas use. If the customer's forecast is significantly different from its historical trend, the company may adjust the customer's annual demand forecast to align the customer's historical annual demand.

Forecasts for small commercial customers are based on historical trend analysis coupled with forecasted household formations in the company's service area. Historical trend analysis is used to determine the average use per customer, while forecasted household formations is used to forecast growth in the number of commercial customers. The company applied an exponential decline rate extrapolated from the past 10 years of actual use per customer. The company forecasts a decline in use per customer and capture rates for commercial customers to reflect the impact of increased focus on electrification of space heating in the provincial energy plan.

The company uses an end-use model to forecast the average use per residential customer. The model uses a number of parameters to forecast gas use based on type of dwelling and number of appliances. It uses conditional demand analysis to determine the relationship between the various parameters and gas use per residential customer. The number of residential customers used in the forecast is based on forecasted additions to the number of households in the company's service area.

The company uses the results from its REUS, which provides data on the demographic makeup and consumption behavior of its residential customers. It uses this data together with historical customer billing data as key inputs into its residential forecasting model. The model accounts for building code improvements in new homes as well as replacement of appliances with more efficient appliances as customers replace appliances at the end of their useful life. The company uses conditional demand analysis techniques to develop end-use models for single family dwellings (SFD), duplexes (DUP), multi-family dwellings (MFD) such as triplexes and townhouses, apartments and condominiums in vertical subdivisions (VS), and mobile homes (MH). It takes into account various characteristics of natural gas consumption by residential customers such as the distribution of annual demand, the penetration rate and portion of the overall demand of each end-use based on the results of the REUS. The company adjusts its forecast to reflect the impact of increased focus on electrification of space heating in the provincial energy plan.

3. Forecasting Parameters

The company's end-use model uses a number of parameters, which include dwelling type, type of construction, number of gas appliances in the home, type of gas appliances in the home, and behaviour of the residents to forecast the average use per customer.

The company collected this data from its REUS.

4. Forecast Scenarios

The company develops a reference scenario that reflects the current mix of natural gas appliances and insulation in existing construction, and the current mix of SFD and MFD buildings being constructed in its service areas. Forecasts of use per customer for residential and commercial construction reflect changes to the mix of new construction as well as improvements to the energy efficiency of new construction, and building retrofits, that are aligned with the policy actions and targets identified in the provincial energy plan.

In addition to results for the reference scenario, alternative demand scenarios are developed to provide some indication of the sensitivity of the demand forecasts to changes in the assumptions of the reference scenario. The scenarios are referred to as the "Competitive Gas" and "Competitive Electricity" scenarios.

The scenarios are based on changes to the residential and small commercial demand resulting from changes in the penetration of natural gas as the fuel for space and water heating applications in response to the perceptions of customers regarding GHG emissions of natural gas and the relative cost advantage of natural gas over electricity, driven in part through changes to the carbon tax as well as eventual federal and provincial regulations mandating a blend of RNG in natural gas deliveries to end-use customers. The scenarios also reflect varying degrees to which the provincial targets for improved energy efficiency in existing and new construction are met.

The underlying growth in households and small commercial enterprises remains the same in all scenarios, while the capture rates are adjusted to reflect varying degrees of probability that these new households and commercial enterprises become customers of the company.

5. Forecast Period and Update Frequency

The company prepares a 20-year demand forecast and updates its long-term forecast when it files its resource plan. The company expects to file its resource plan with the regulator every five years.

The company prepares a forecast for each year during the forecast period.

6. Forecast Evaluation

The company does not explicitly evaluate the performance of its long-term forecast model by using the actual number of customers in the model and adjusting for different assumptions used in the model, however, it does compare actual annual demand to forecasted annual demand. It has found that the forecasts are reasonable and there are no significant variations.

7. Forecast Resources

The company uses internal resources, which are estimated at approximately one third of an FTE, to develop its long-term forecast.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company determines the design day demand for each of its customer segments based on a mathematical relationship between ambient air temperature and gas consumption that has been determined empirically from historical weather and billed consumption data. The design day demand of residential customers is calculated using the residential end-use model and multiplied by the number of customers forecasted. The design day demand for small and large commercial, and small industrial customers is determined from third- and first-order linear regressions, respectively, of their historical billing and weather data.

As a final step in forecasting peak-day demand, the company sums up the peak-day demand for each customer class to forecast the peak-day demand for the system.

The company used a 50-year period in determining the design day demand.

L. Organization L

1. Overview

The company is an investor owned utility that serves approximately 340,000 electric and 300,000 natural gas customers across 30,000 square miles in four northwestern states.

The company's annual natural gas demand forecasts are developed as part of its IRP. The company develops an annual demand forecast and a peak-day demand forecast.

The company's recent usage data indicated that long-term use per customer has been declining. The company attributes this to a confluence of factors including high unemployment, increased investments in energy efficiency measures, building code improvements, behavioral changes, and heightened focus on consumers managing their household budgets.

2. Forecasting Method

The company currently uses an econometric model to forecast its annual energy demand by rate class. The company sees many benefits in using and end-use forecasting model and is considering an end-use model to forecast its annual energy demand in the future. However, it believes an end-use forecasting model to be more data intensive and costly as the company would have to upgrade their systems. However, the company is currently implementing AMI, which may help in collecting better end-use data.

The company uses the IRP process to develop an annual demand forecast and a peak-day demand forecast. Annual average demand forecasts are used for preparing revenue budgets, developing natural gas procurement plans, and preparing purchased gas adjustment filings. Peak-day demand forecasts are critical for determining the adequacy of existing resources or the timing for acquiring new resources to meet customers' natural gas needs in extreme weather conditions.

The primary drivers of the company's overall demand forecast are customer growth and use per customer.

The company uses a regression model to forecast its use per customer. This produces a reliable forecast because of the high correlation between usage and temperature.

The company also uses 20-year DSM resource forecasts to identify cost-effective savings potential, which are used to reduce demand forecast over the forecast period.

The company forecasts the number of customers for each customer class using national economic forecasts and then drills down into regional economies. The company combines this data with local knowledge about sub-regional construction activity, age and other demographic trends, and historical data to develop its 20-year customer forecasts.

The company forecasts its use per customer using regression modeling. The company develops base and weather sensitive demand coefficients that are combined and applied to HDD weather parameters to determine average use per customer.

The company uses historical daily gas flow data from all of its city gate stations. It uses city gate data over revenue data because of the high correlation between weather and demand. The company's revenue system does not capture daily data; therefore, it could not be used in the daily regression modeling. The company, however, reconciles city gate station data against revenue data to ensure the total demand is properly captured. The company uses three years of historical data in its regression modeling and to derive the use per customer coefficients. The regression modeling is performed for each of the company's service territories and temperature zones.

The company analyzes an alternate planning scenario using the coldest temperature in the last 20 years.

As a final step, the company checks the reasonableness of its coefficient by applying the coefficients to actual customer count and weather data to backcast demand. This compares to actual demand with satisfactory results.

Figure 8 below illustrates the company's method in developing its forecast.

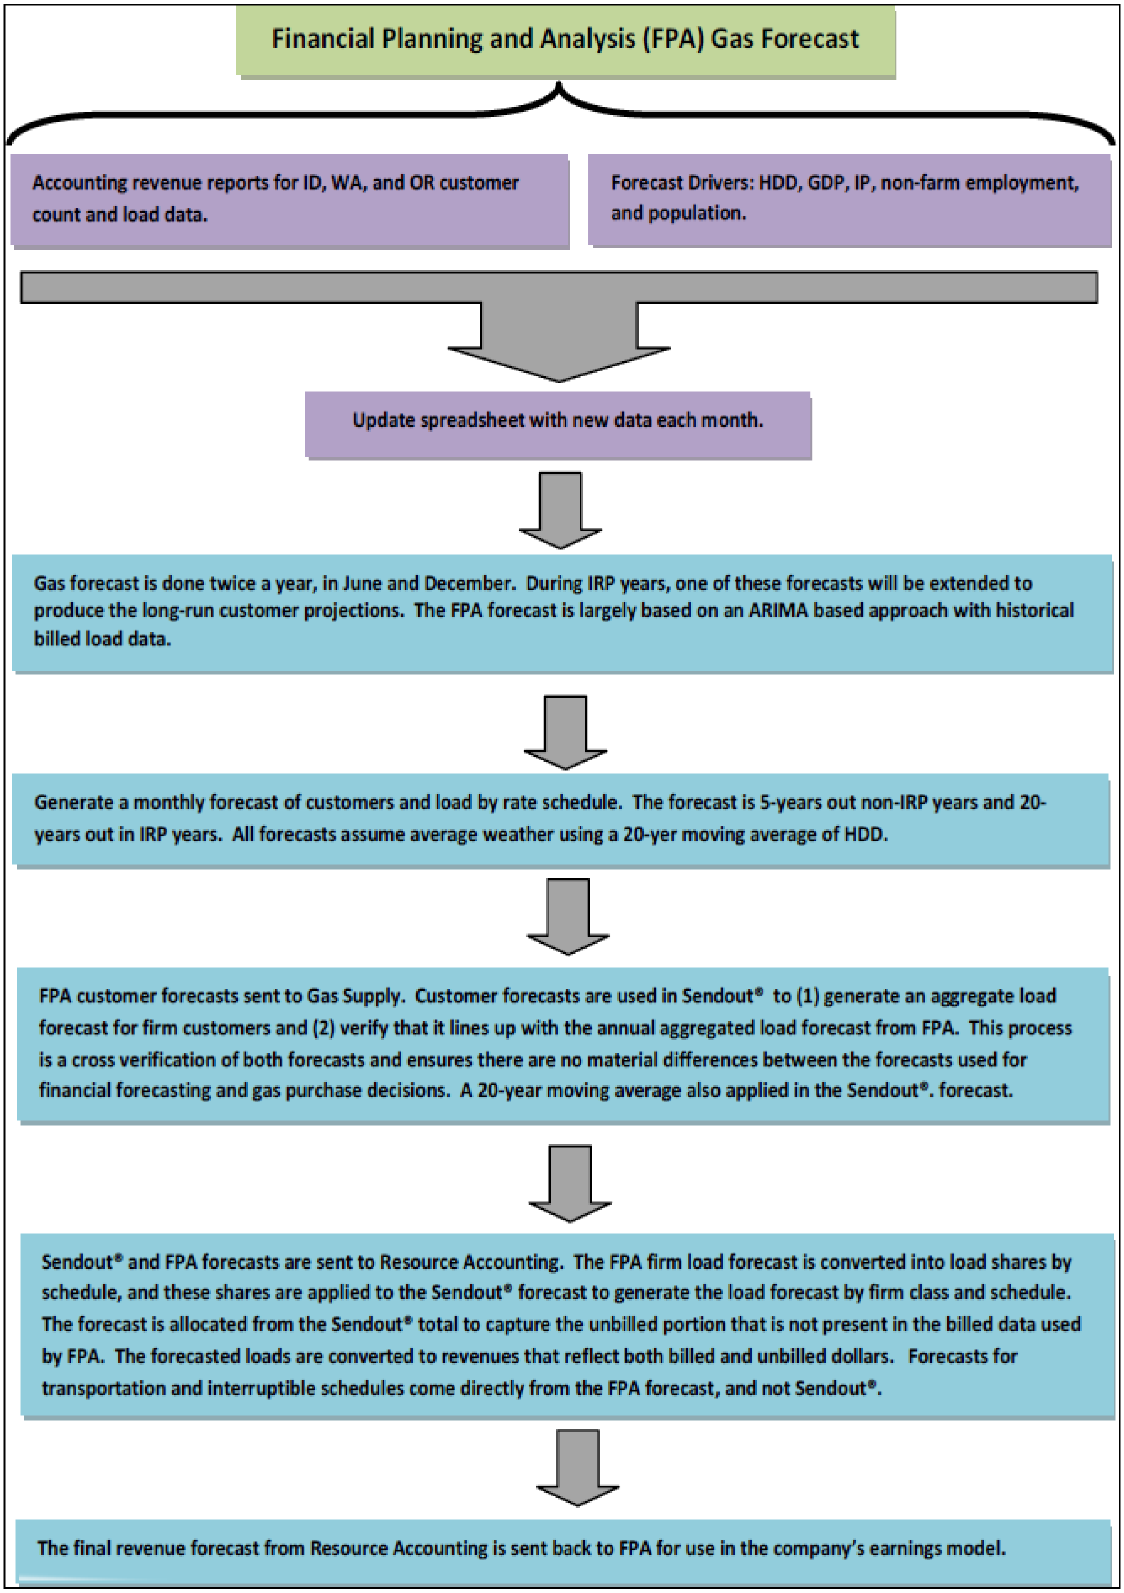

Figure 8. Forecasting Method

3. Forecasting Parameters

The company's econometric model incorporates national economic forecasts and drills down to regional economies. The model uses a number of parameters, which include US GDP growth, national and regional employment growth, and regional population growth expectations. The company combines this data with local knowledge about sub-regional construction activity, age and other demographic trends, and historical data to develop the 20-year forecast of the number of customers rate class.

Weather is the most significant factor influencing demand. Other factors that the company uses include population, employment trends, age and income demographics, construction trends, conservation technology, new uses (e.g. natural gas vehicles), and use-per-customer trends.

The company also analyzes factors that could influence natural gas prices and demand through price elasticity, as customers may adjust consumption in response to changes in price. These include, supply trends, infrastructure trends, regulatory trends, and other trends.

4. Forecast Scenarios

The company recognizes that historical energy use trends may fundamentally change. The company developed a dynamic demand forecasting model that is flexible to changing assumptions. This helps the company examine a range of potential outcomes, such as:

- Identifying key demand drivers behind natural gas consumption;
- Performing sensitivity analysis on each demand driver;
- Combining demand drivers under various scenarios to develop alternative potential outcomes for forecasted demand; and
- Matching demand scenarios with supply scenarios to identify unserved demand.

The company uses a reference case based on historical data and conducts sensitivity analysis on key demand drivers. The company uses this information and input from a technical advisory committee to create several alternate demand scenarios for detailed analysis.

The company groups the demand drivers into two categories:

- Demand Influencing Factors, which directly influence natural gas consumption of core customers.
- Price Influencing Factors, which indirectly influence natural gas consumption of core customers through a price elasticity response.

The company analyzed five demand sensitivities to determine the results relative to the reference case. These include the base case, high price case, low price case, high growth case, and low growth case.

5. Forecast Period and Update Frequency

The company prepares a 20-year annual natural gas demand forecast, which it updates every two years as part of its IRP. It prepares a forecast for each year during the forecast period.

6. Forecast Evaluation

The company evaluates its forecast as a step in its forecasting process, the company checks the reasonableness of the coefficients from its regression model by applying the coefficients to actual customer count and weather data to backcast demand. This compares to actual demand with satisfactory results.

7. Forecast Resources

The company uses SENDOUT for forecasting. The software was purchased and the company has an annual maintenance contract with the vendor, which provides some consulting service. The company uses internal 3 FTE resources to prepare its forecast.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company uses the same model to forecast its peak-day demand forecast and its annual demand forecast. It uses peak-day weather data to forecast its peak-day demand and average annual weather to forecast its annual demand forecast.

M. Organization M

1. Overview

The company serves more than 294,000 customers in 96 communities in two states in Northwest US.

The company developed its latest long-term natural gas demand forecast as part of its 2018 IRP. The company uses an econometric model to develop its demand forecast.

Residential and commercial load growth is primarily a result of increased customer counts.

The forecast is used in short-term (annual budgeting) and long-term (distribution and integrated resource planning) planning processes.

2. Forecasting Method

The company uses an econometric, dynamic, multi-variable, time-series regression model to develop its demand forecast.

The company has made a slight change to its forecasting methodology this year by using a dynamic regression approach to modeling. Dynamic regression is simply an ARIMA term in a standard regression model. The company is also using wind as a predictor for usage, and therefore a coefficient for the demand forecast formula. The company uses statistical analysis software programs R and SAS Analytics. It also uses models that follow a dynamic regression methodology. The company plans to continue improving the customer and demand forecast model through R and SAS.

The company starts demand forecasting process by looking at each city-gate serving firm service. These city-gates are then assigned a weather zone because a significant portion of the company’s customer demand is weather sensitive.

The company forecasts its total annual demand by forecasting its use per customer and number of customers by city gate station and for each rate class. It then multiplies the forecasted use per customer by the forecasted number of customers to determine its annual demand forecast. Figure 9. illustrates an overview of the demand forecasting process.

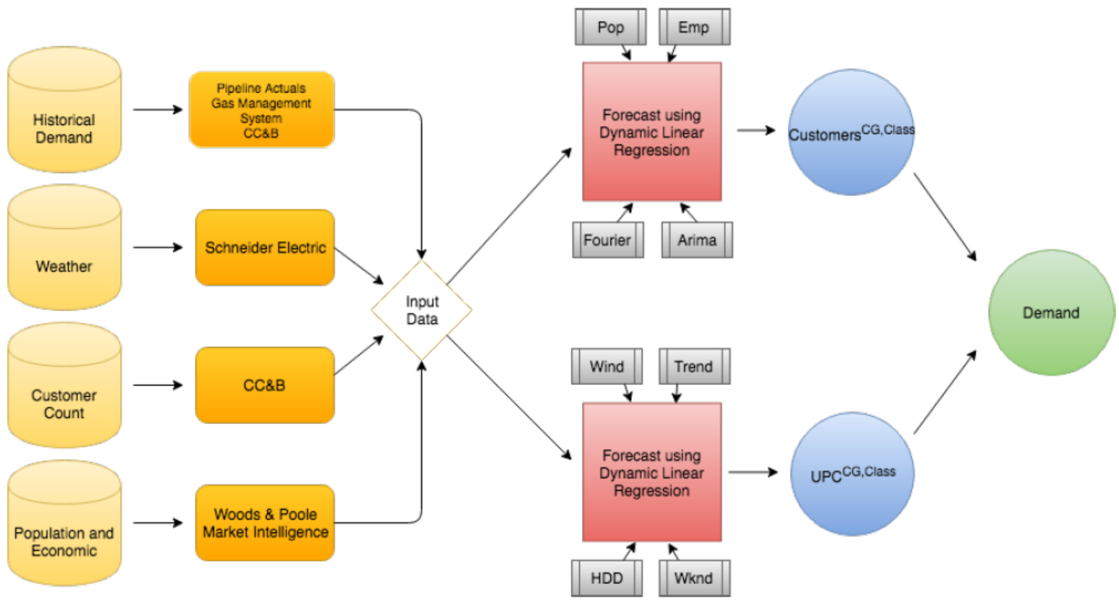

Figure 9. Demand Forecast Process Overview

Customer Growth

Customer count forecasts are designed to reflect both demographic trends and economic conditions both in the short- and long-term. The company uses population and employment growth data at the county level. The data is adjusted when the internal intelligence about a demand area indicates a significant difference on observed economic trends. The company utilizes dynamic regression models for the customer count forecast. Figure 10. illustrates how the company forecasts its number of customers.

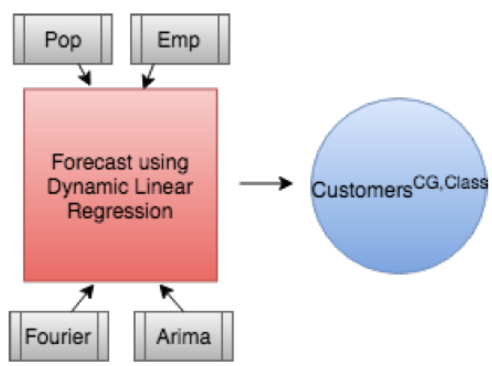

Figure 10. Customer Growth

Use-Per-Customer Forecast Methodology

The company utilizes regression models for the use per customer part of the demand forecast. Sources for the inputs into this model are pipeline actuals, the company's gas management system, and its customer care and billing system. The company develops the use per customer coefficient by gathering historical daily pipeline demand data. The pipeline demand data includes core and non-core usage. The non-core data is backed out using the company's measurement data. The daily data is then allocated to a rate schedule for each city gate by using the customer care and billing system. This data is then divided by number of customers to come up with the use per customer for each day and for each rate schedule at each city gate. Figure 11. illustrates how the company forecasts its use per customer.

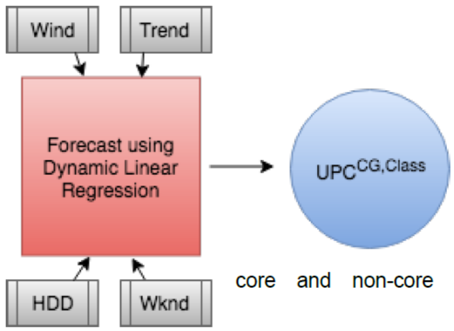

Figure 11. Use Per Customer

The results of the customers count and energy use per customer models are then used to determine the annual gas demand by customer class and district.

These forecasts exclude any saving that may result from the company's energy efficiency programs. The company's energy efficiency and conservation group reviews the forecast and adjusts these forecasts based on the forecasted energy savings from their energy efficiency programs.

The company uses the same model for short term and long-term forecasting.

3. Forecasting Parameters

The company's dynamic regression forecasting model uses a number of parameters. These parameters include a number of econometric parameters such as employment forecast, forecasted number of households, mortgage rates for residential customers, and prime rate for commercial and industrial customers to forecast the number of customers by rate class.

The model uses the forecasted median household income, HDD, and natural gas prices to forecast the average use per customer. The company recently introduced wind data into its forecasting model.

These indicators are used over other indicators as they are the most consistent in returning statistically valid results.

4. Forecast Scenarios

The company stress tests its forecasted annual demand results with high and low scenarios for varying future economic conditions.

These alternative forecasting assumptions refer to changing factors that influence demand. Alternative assumptions include high and low customer growth and a stochastic study of weather using Monte Carlo simulations. These assumptions provide an effective tool for analyzing and stress testing the forecasts. Table 10 shows these scenarios.

Table 10. Growth and Weather Scenarios

Scenario	Weather	Growth	Use per Customer
Base Case	Expected	Expected	Expected
Low Growth	Expected	Low	Expected
Low Growth Stochastic	Monet Carlo Weather	Low	Expected
High Growth	Expected	High	Expected
high Growth Stochastic	Monet Carlo Weather	High	Expected

5. Forecast Period and Update Frequency

The company develops a 20-year forecast of customers, annual demand, and peak-day demand for each year during the forecast period.

The company develops a 20-year forecast of customers, annual demand, and peak-day requirements for use in short (annual budgeting) and long-term (distribution and integrated resource planning) planning processes each year. Updates to the forecasts may be prepared three to four times per year for use in annual budgets, rate cases, and IRP filings. IRPs are prepared every two years.

6. Forecast Evaluation

The company evaluates its forecasting model by using actual weather conditions and actual number of customers in the model and comparing the results to previous forecasts. The company checks its forecast against actual demand and investigates its forecast if there is a variance of +/- 5%. The model has performed well overall.

7. Forecast Resources

The forecasts are prepared internally by the forecasting department which obtains economic forecast reports from external sources and also consults with other consultants as needed.

One person in the forecasting department maintains the models, while others in the energy efficiency and conservation department update the forecast prepared by the forecasting department to reflect impact of energy efficiency programs.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company develops peak-day forecasts in conjunction with its annual demand forecasts to ensure it can meet the demand by its core customers on the coldest days.

The company develops a normal, or expected, future weather year by shaping 30 years of proprietary, historical weather data. HDD values are assigned to each day in the model weather year. To ensure the company will be able to serve its firm customers during extreme weather, the company tests a system weighted peak HDD (the system weighted coldest day in the last 30 years).

The peak-day forecast is developed by adjusting the energy use on the coldest day in in annual demand forecast upwards using the HDD for the coldest day in the past 30 years.

This method assumes that core market load shape does not significantly change throughout the forecast period.

N. Organization N

1. Overview

The company serves more than 750,000 homes and businesses in 140 communities in Northwest US.

The company uses an econometric forecasting model to forecast its annual demand by region and customer class.

The company has used end-use forecasting for some specific studies such as a decarbonization study and a demand response study for its upcoming IRP. While the company's econometric forecasting model has historically performed well, with regulations pushing for decarbonization and direct response programs, which require the company to analyse numerous demand scenarios, the company believes end-use forecasting models are more relevant and the company is considering end-use forecasting models.

2. Forecasting Method

The company uses an econometric forecasting model to forecast its annual demand by region and customer class. It forecasts the total annual demand for residential and commercial customers by multiplying the customer count and annual use per customer. The company's demand forecast process is illustrated in Figure 12.

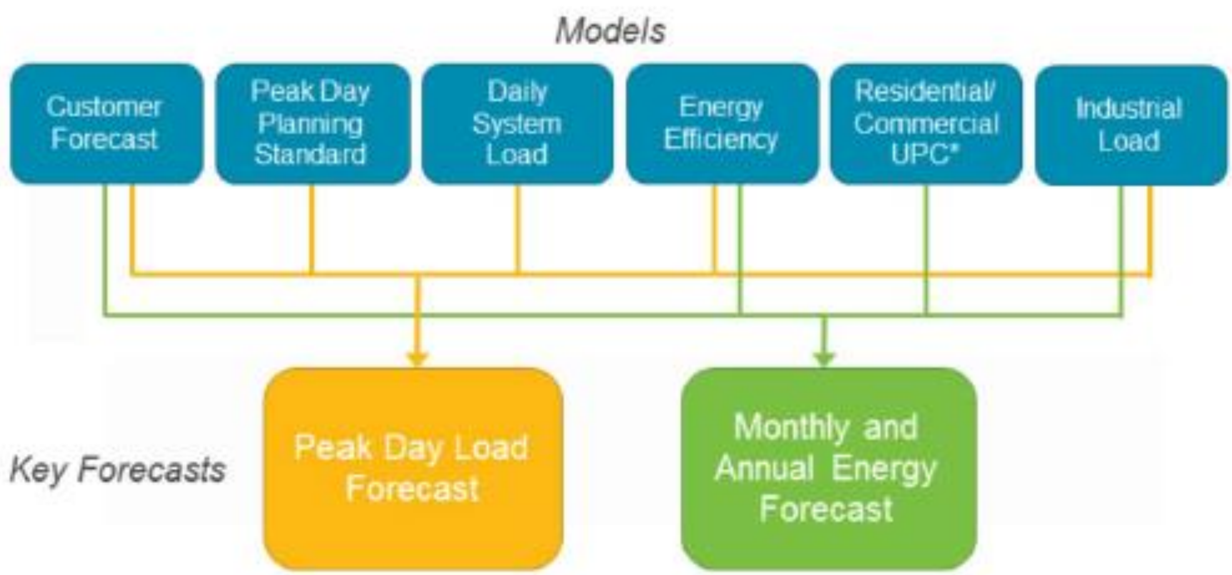

Figure 12. Demand Forecast Process

Customer Forecast

The customer forecast is the starting point of the company's load forecasting and is a key input into both the peak load forecast and the annual energy demand forecast. Customer growth is a primary driver of additional demand—both annually and peak.

The company develops separate customer count forecasts for residential and firm sales commercial customers for each state, as the differs in average annual use and load factor. The company does not forecast the number of industrial customers due to the extreme range of usage levels by these customers.

The company uses annual data in its forecasting model. The company assesses econometric models with alternative autoregressive integrated moving average structures for each forecast. Generally, selecting the structure with the best information. The company also evaluates multiple potential explanatory variables for each customer forecast. These include transformations of values, such as moving averages, leads/lags, and combinations of each.

The company forecasts its number of customers by directly forecasting year-end values of customers directly at the state level.

Use Per Customer Forecast

The company forecasts the annual weather-normalized use per customer for residential and commercial customer classes using billing data, temperature history, and energy efficiency savings projections.

Prior to the 2016 IRP, residential and commercial coefficients along with the industrial demand were used directly to estimate the highest firm sales demand day requirements. In the 2016 IRP, the company transitioned from using the UPC coefficients to using a daily system model to estimate the peak day demand needs. In its latest IRP and the 2016 IRP, UPC has a smaller role in determining system resource needs but is still necessary to forecast total energy demand.

The company forecast its UPC at the state level for the following customer groups:

1) Residential existing customers (current customer base)
2) Residential conversion customers (existing building stock fuel switching)
3) Residential new construction (newly build single and multifamily housing)
4) Commercial existing customers (current customer base)
5) Commercial conversion customers (existing building stock fuel switching)
6) Commercial new construction (newly constructed commercial buildings)

The company applies the forecasted annual energy savings from DSM programs by adjusting the annual usage coefficients such that the reductions match the projected savings for the DSM programs.

The company forecasts the annual demand for its large industrial customers by each customer.

The company has used end-use forecasting for some specific studies such as a decarbonization study and a demand response study for its upcoming IRP. While the company's econometric forecasting model has historically performed well, with regulations pushing for decarbonization and direct response programs, which require the company to analyse various demand scenarios, the company believes end-use forecasting models are more relevant and the company is considering end-use forecasting models.

3. Forecasting Parameters

The company uses some exogenous variables in its econometric customer forecast models. These exogenous variables include housing starts for the residential sector and population growth and non-farm employment for the commercial sector.

The customer forecast is a blend of two different types of forecasts; those developed using econometric methods and those developed using a panel of internal subject matter experts.

An external resource was the source of the forecast value for the exogenous variable used in each of the four customer forecast econometric models used in the 2018 IRP. Because the external resource provides forecasts of US housing starts and of the state's nonfarm employment for 10 years ahead, the company used the long-term forecast of the state's population from the external resource to project US housing starts and the state's nonfarm employment beyond 2027.

4. Forecast Scenarios

The company develops a base case forecast plus high customer count and low customer count cases. The company also analyzes weather uncertainty, gas price uncertainty, cost of compliance uncertainty, and resource costs uncertainty in its stochastic analysis.

The company also develops four additional scenarios based on high and low runs of two separate drivers: carbon policy and deployment ramp rates. These alternative scenarios are shown in Table 11. Scenarios 1 and 2 are based on changes to avoided costs under different carbon policy pricing scenarios. Scenarios 3 and 4 are based on changing deployment ramp rates, both an accelerated and a decelerated case.

Table 11. Additional Alternative Forecast Scenarios

Scenario	Description
Scenario 1	Base Case Ramp Rates / Low CO_2 Carbon Policy Adder Avoided Costs
Scenario 2	Base Case Ramp Rates / High CO_2 Carbon Policy Adder Avoided Costs
Scenario 3	Low Ramp Rates / Reference Case Avoided Costs
Scenario 4	High Ramp Rates / Reference Case Avoided Costs

These scenarios are meant to represent what may be seen on the company's system if savings are achieved faster or slower than the base case, which could be for a wide array of reasons and could be considered 'uncertainty bounds'.

5. Forecast Period and Update Frequency

The company prepares a 20-year annual demand forecast for every year during the forecast period. The company updates the customer count in the forecast annually, while it updates the full forecast every two years as of its IRP.

6. Forecast Evaluation

The company evaluates its forecast for each type of customer using the ARIMA structure selected for that forecast by comparing metrics associated with the errors of out-of-sample forecasts. The company uses three criteria to evaluate these alternative out-of-sample forecasts: MAPE, average error, and RMSE.

The company evaluated four different approaches to forecasting the number of customers. It evaluated its forecasted number of customers using the "levels" and the "components" approach at the state level and load centre level using MAPE, average error, and RMSE. The company refers to the approach in which levels of customers are directly forecast as the "levels" approach and the approach in which components of customer change are forecast as the "components" approach. The company used the "components" approach in recent IRPs, where the components are customer additions due to new construction and customer additions due to conversion from other fuel types, as well as customer "losses."

7. Forecast Resources

The company's forecasts are prepared internally by the forecasting department which includes four economists and one data scientist. The company's forecasting model was also developed internally.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company uses a multi-variable regression model to forecast its peak-day demand forecast for supply and capacity planning. This model uses the same number of customers as the annual demand forecast model. It uses many more variables than the annual demand forecast model. Some of these variables, which are not used in the annual demand forecast include wind, rain, and day of the week.

O. Organization O

1. Overview

The company is an investor owned utility. It serves aapproximately 1.1 million electric and 840,000 natural gas customers with a service territory of approximately 6,000 square miles with a population of approximately 4 million.

The company uses an econometric regression model to forecast its annual demand by rate class and service area.

2. Forecasting Method

The company uses an econometric regression model to forecast its annual demand for both natural gas and electricity by rate class and service area. The rate classes include residential, commercial, and industrial rate classes.

The company forecasts its total annual demand forecast by multiplying the forecasted number of customers in each rate class by the average use per customer for that rate class.

The company's forecasting model produces a forecast based on the historic relationship between energy demand and weather and economic growth.

The company forecasts its use per customer and customer count using econometric equations using sample dates from a historical monthly data series that extends from January 1990 to December 2015; the sample dates vary depending on sector or class. Use per customer is forecast monthly at a class level using several explanatory variables including weather, retail rates, monthly effects, and various economic and demographic variables such as income, household size and employment levels. Some of the variables, such as retail rates and economic variables, are added to the equation in a lagged or polynomial lagged form to account for both short-term and long-term effects of changes in these variables on energy consumption. Finally, depending on the equation, an ARIMA structure is imposed to acknowledge that future values of the predicted variables could be a function of its lag value or the lags of forecast errors.

Similar to use per customer, the company forecasts the customer count equations on a class level using several explanatory variables such as household population, building permits, total employment, or manufacturing employment. Some of the variables are also implemented in a lagged or polynomial distributed lag form to allow the impact of the variable to vary with time. Many of the customer equations use monthly customer growth as the dependent variable, rather than totals, to more accurately measure the impact of economic and demographic variables on growth, and to allow the forecast to grow from the last recorded actual value. ARIMA could also be imposed on certain customer counts equations.

While the company, currently, only prepares a forecast by rate class, it may in the future break down its forecast by subsectors within the broader residential and commercial sectors.

The company is considering moving to an end-use forecasting model because it believes an end-use model is better suited to help with changes in energy policy such as decarbonization. The company is currently running an end-use forecasting model in parallel with its econometric forecasting model to test the reliability and accuracy of the end-use model, but is not ready to move to an end-use model yet.

3. Forecasting Parameters

The company's forecast is based on estimated econometric equations, normal weather assumptions, rate forecasts, and forecasts of various economic and demographic inputs such as income, household size and employment levels.

4. Forecast Scenarios

The company prepares its forecast to model a range of potential economic conditions, weather conditions and potential modeling errors for its IRP analysis. The company also prepares low and high forecasts in addition to the base forecast. The low forecast models lower population and economic growth compared to the base forecast; the high forecast models higher population and economic growth compared to the base forecast. The high and low forecasts are performed using stochastic analysis of the variables.

While the company does not run multiple scenarios, it expects that it will be running many more scenarios in the future to analyse the impact of electrification and other energy policies. The company expects that the end-use model will allow them to analyse multiple scenarios.

5. Forecast Period and Update Frequency

The company prepares a 20-year annual demand forecast for every year during the forecast period. The company updates its forecast every year and files it every two years as part of its IRP filing.

6. Forecast Evaluation

The company evaluates its forecast for each type of customer by comparing its forecast against normalized actual demand.

7. Forecast Resources

The company's econometric forecasting model is run internally with approximately 2 FTEs.

The company's end-use forecasting model is Itron's SAE model. The company's forecasting staff are being trained to run and maintain the model and will be running the model once it is fully implemented. Once the company switches over to the end-use model, it may need additional forecasting resources because of the data requirements of the end-use model.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company's peak-day demand forecast and its annual demand forecast are related. The company uses its annual demand forecast as the starting point for its peak-day demand forecast and applies load shapes for various customer classes to forecast its peak-day demand.

P. Organization P

1. Overview

The company serves more than 1 million natural gas customers in three states.

The company uses statistical methods to forecast its annual natural gas demand in the residential sector. It also studies natural gas consumption for the residential sector by end-use.

2. Forecasting Method

The company uses several statistical methods to analyze and forecast residential gas demand. These methods include univariate and multivariate time series modeling of demand and such explanatory variables as demand history, customer growth and commodity price. The company uses SAS STAT 14.1 and SAS Enterprise Time Series 14.1 software tools for the statistical time series modeling.

The company also studies residential consumption by end-use such as space heating, water heating and cooking with respect to dwelling size, region, appliance efficiencies, and other such variables. This end-use analysis makes extensive use of data collected by the company's energy efficiency experts as they conduct in-home energy audits through the company's energy efficiency programs as well as data from the US EIA and US Census Bureau.

3. Forecasting Parameters

The company's forecasting model uses a number of parameters, which include population growth, personal income growth, employment levels, and housing starts.

4. Forecast Scenarios

The company only provides a base case forecast scenario in its IRP.

5. Forecast Period and Update Frequency

The company prepares a 10-year annual natural gas demand forecast, which it updates every two years as part of its IRP. It prepares a forecast for each year during the forecast period.

6. Forecast Evaluation

This information was not available.

7. Forecast Resources

This information was not available.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company forecasts its peak-day firm customer demand using the coldest design day. Heating degree days, wind speed, the day of the week, and prior-day demand are significant factors in the prediction of daily demand during the winter heating season.

Q. Organization Q

1. Overview

The company serves more than 500,000 natural gas customers in the US Northeast.

The company uses an Excel based econometric model with some consideration for end-use to forecast its annual gas demand by rate class. The forecast is used primarily for revenue forecasting.

2. Forecasting Method

The company uses an Excel based econometric model with some consideration for end-use to forecast its annual gas demand by rate class. The company has used its forecasting model for many years.

It uses an econometric model to forecast the number of customers and the number of customer additions.

The company forecasts its user per customer based on historic energy use data. It further adjusts its use per customer forecast based on its experience and knowledge of its market and customers, particularly for its large industrial customers. The company uses some elements of end-use modeling to forecast its residential use per customer; its residential use per customer is built by forecasting use per customer for customer groups with different end uses. For example, it may forecast annual use per customer for customers with natural gas space heating, customers with natural gas space and water heating, and customers with natural gas space, water, and pool heating. The company forecasts its use per customer for its large industrial customers for each customer and breaks in down into baseload and space heating load.

The total annual demand is forecasted by multiplying the forecasted use customer by rate class by the forecasted number of customers in that rate class.

3. Forecasting Parameters

The company's forecasting model uses historic user per customer data.

The company does not account for energy efficiency and building code changes in its forecast.

4. Forecast Scenarios

The company does not run multiple forecast scenarios because its user per customer is relatively stable. If there is a significant event that impacts their forecast It may run alternative scenarios.

5. Forecast Period and Update Frequency

The company develops a five-year forecast of the number of customers and annual demand for each year during the forecast period to coincide with its five-year business plan cycle. It updates its annual demand forecast annually and its customer count quarterly.

6. Forecast Evaluation

The company evaluates its forecasting model by comparing its forecast to actual energy use in the first few years of the forecast period.

7. Forecast Resources

The forecasts are prepared internally by the forecasting department with two FTEs.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company does not focus on peak demand forecast because it does not impact its revenue forecast.

R. Organization R

1. Overview

The company is the state's largest customer-owned utility. It provides water and electricity service to its customers. As a public utility, it does not operate to earn a profit or to serve the investment needs of stockholders. Instead, it is chartered by the city to serve the interests of its citizens.

The company uses a combination of end-use and econometric forecasting model. Historically, the company only used an econometric forecasting model, but because of the increasing disconnect between the economy and annual energy demand, it has started using an end-use model and will be moving to complete end-use modelling in the near future. The end-use model allows the company to better analyse the impact of various policy changes such as electrification on their load forecast.

2. Forecasting Method

The company uses a combination of end-use and econometric forecasting model.

Historically, the company only used an econometric forecasting model, but because of the increasing disconnect between the economy and annual energy demand, it has started using an end-use model and will be moving to complete end-use modelling in the near future.

The company's forecasting model was developed by a consultant who developed a similar model for the regional power administrator, which markets wholesale electrical power in the region. This allows the company to have connectivity to the regional forecast data.

The company's forecasting model is composed of approximately eight spreadsheets with a detailed database of end-uses for residential, commercial, and industrial sectors. The forecasts are developed by subsector, which are then rolled up to the three major sectors, residential, commercial, and industrial.

3. Forecasting Parameters

The company's forecasting model uses a number of parameters.

For the residential sectors, these parameters include fuel share (gas vs. electric), market saturation levels for different end-uses, building vintage, and equipment efficiency. This data is collected by the company's end use survey. The model then applies load shapes for different end-uses to forecast the use per customer. The company uses econometric methods to forecast the number of customers by subsector.

For the commercial sector, the company has energy use intensities by subsector and based on different end-uses. The forecasting model applies energy use intensities for different end-uses and applies these to the building type to build up the energy use intensity for the building.

4. Forecast Scenarios

The company analyses multiple scenarios to assess the impact of policy changes and legislation on their demand. Some of these scenarios include electrification, fuel switching, carbon tax, increased energy efficiency legislation, and evolving technologies.

5. Forecast Period and Update Frequency

The company develops a 20-year forecast of the number of customers and annual demand for every year during the forecast period. It updates its forecast every year.

6. Forecast Evaluation

The company does not have a formal evaluation process of its forecast. It runs multiple scenarios to see the impact of different scenarios on their forecast.

7. Forecast Resources

The company's forecasting model was developed by a consultant who developed a similar model for the regional power administrator, which markets wholesale electrical power in the region. The forecast is prepared by one FTE.

8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company's annual demand forecasting model builds on hourly demand forecasts. It's peak-day and peak-hour demand forecasts are developed using the same model as the annual demand forecast.

Appendix III. GLOSSARY

AMI – Advanced Metering Infrastructure

ARIMA - Auto Regressive Integrated Moving Average

ASHRAE – American Society of Heating Refrigeration and Air-conditioning Engineers

CBECS – Commercial Building Energy Consumption Survey

CMHC – Canada Mortgage and Housing Corporation

CO_2 – Carbon Dioxide

DSM – Demand Side Management

EIA – Energy Information Administration

EE – Energy Efficiency

EG – Electricity Generation

EIA – Energy Information Administration

EPRI – Electric Power Research Institute

EU – End Use

EUF – End-Use Forecaster

EUI – End Use Intensity

EV – Electrical Vehicle

FTE – Full Time Equivalent

FEU – FortisBC Energy Utilities

GDP – Gross Domestic Product

GHG – Greenhouse Gas

GIRP – Gas Integrated Resource Plan

HDD – Heating Degree Day

HVAC – Heating, Ventilation, and Air Conditioning

IEPR – Integrated Energy Policy Report

IESO – Independent Electricity System Operator

INFORM – Industrial End-Use Forecasting Model

IOU – Investor Owned Utility

IRP – Integrated Resource Plan

LDC – Local Distribution Company

LNG – Liquefied Natural Gas

LTRP – Long Term Resource Plan

LTGRP – Long Term Gas Resource Plan

m^3 – Cubic Metre

MAPE – Mean Absolute Percent Error

MFD – Multifamily Dwelling

MH – Mobile Home

Mscf – Million Standard Cubic Feet

MURB – Multi-Unit Residential Building

NAICS – North American Industry Classification System

NAMGas Model – North American Market Gas-Trade Model

NASA - National Aeronautical and Space Agency

NGV – Natural Gas Vehicle

NOAA – National Oceanic and Atmospheric Administration

NRCan – Natural Resources Canada

OEE – Office of Energy Efficiency

PV – Photovoltaic

RECS – Residential Energy Consumption Survey

REUS – Residential End Use Survey

RMSE – Root Mean Square Error

SAE - Statistically Adjusted End-use

SFD – Single Family Dwelling

TAC – Technical Advisory Committee

UPC – Use Per Customer

UPA – Use Per Account

VS – Vertical Subdivisions

ZNE – Zero Net Energy

Appendix B-3

CRITICAL UNCERTAINTIES AND THEIR FORECAST MODELLING INPUT SETTINGS FOR THE END USE METHOD DEMAND FORECAST SCENARIOS

APPENDIX B-3: CRITICAL UNCERTAINTIES AND THEIR FORECAST MODELLING INPUT SETTINGS FOR THE END USE METHOD DEMAND FORECAST SCENARIOS

1.1 *RESIDENTIAL, COMMERCIAL AND INDUSTRIAL DEMAND CATEGORY*

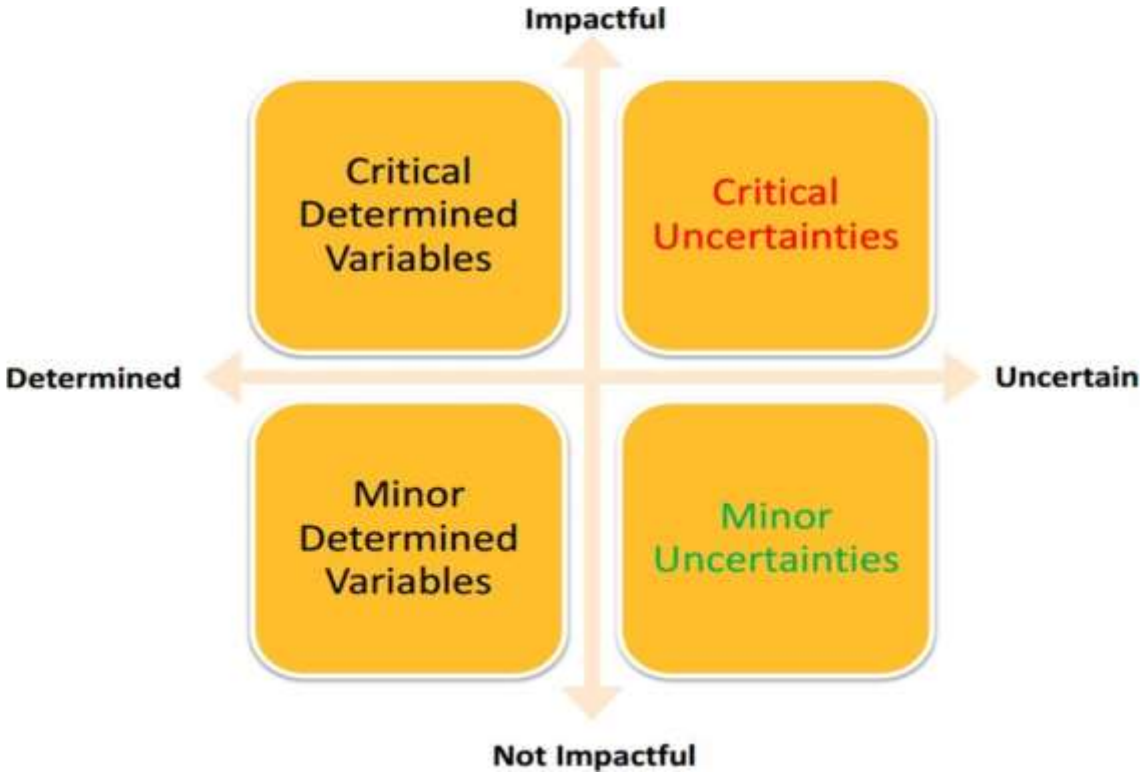
The Reference Case provides a baseline against which forecast demand under six different alternate future scenarios is examined. Since FEI's planning environment for energy services continues to change and present uncertainty, the six future scenarios are intended to provide insight into the impact on demand of a broader range of potential future conditions than has been examined in previous LTGRPs. These six scenarios were developed based on critical uncertainties identified with input from the scenario analysis work for the 2022 LTGRP, both internal FEI stakeholders and members of the external Resource Planning Advisory Group (RPAG), as well as themes that emerged from the 2022 LTGRP's community engagement workshops. The critical uncertainties represent those future conditions that subject matter experts and other stakeholders expect could have the biggest impact on FEI's business.

Following a standard scenario planning approach, FEI's scenario analysis proceeds in four steps:

1. Evaluating planning environment variables and identifying critical uncertainties;
2. Determining the number of outcomes and their broad qualitative boundaries for each selected critical uncertainty;
3. Determining plausible combinations of outcomes for each critical uncertainty and reasonable scenario plotlines; and
4. Populating quantitative data into the outcomes for each critical uncertainty and iterating with internal and external stakeholder feedback.

The first step in the above list intends to focus the scenario analysis by determining which of the manifold variables in the planning environment should be used to alter the Reference Case into various alternate future scenarios. This involves selecting the most impactful and most uncertain variables. Figure B3-1 below illustrates how FEI classified planning environment variables for this first step.

Figure B3-1: Classification of Planning Environment Variables



FEI intentionally held each step separate from the other steps. Selecting critical uncertainties first and then determining their qualitative boundaries before generating the plotlines and populating quantitative data guards against inadvertently favoring certain visions of the future over others by presupposing scenario results rather than focusing on inputs.

The following sections outline the qualitative boundaries of the outcomes of each critical uncertainty, illustrate the actual quantitative trajectories for these outcomes, and discuss how these trajectories impact the end use forecast model.

1.1.1 Qualitative Details on Scenario Critical Uncertainties – Residential, Commercial and Industrial Demand Categories

Table B3-1 below summarizes the outcomes that FEI modelled for each critical uncertainty and briefly discusses any specific attributes that apply to individual critical uncertainties

1 Table B3-1: Summary of Modelled Critical Uncertainty Trajectories for the Residential,
2 Commercial and Industrial Demand Category

Critical Uncertainty	Modelled Trajectories	Comments
Demand-Side Critical Uncertainties – Residential, Commercial and Industrial Demand Category		
Appliance Standards	- Reference - Accelerated	Minimum Energy Performance Standards (MEPS) for energy-using appliances; BC and federal MEPS applicable to the end uses in the LTGRP.
Carbon Price	- Reference - Low - Medium - Planning - High	BC carbon tax applied to natural gas.
Customer Growth	- Reference - Low - High	Number of customer accounts by rate class is forecast by FEI. Confidence intervals based on historical data provide upper/lower settings for scenarios.
Natural Gas Price	- Reference - High - Low	Commodity price for conventionally sourced natural gas relevant to FEI customers.
New Construction Code	- Reference - Accelerated - Delayed	The British Columbia Energy Step Code is the relevant building code for new construction in FEI's service territory. The Step Code energy-requirements were applied to relevant building types and end uses. Code requirements of the City of Vancouver are unique, as the City has its own building code (the Vancouver Building Bylaw) which has more stringent requirements than the provincial code.
Non-Price Driven Fuel Switching	- Moderate electrification - Accelerated electrification - Extensive electrification	Fuel switching caused by signals other than prices such as incentives and policies to encourage customers to switch from natural gas to electricity.
Retrofit Code	- Reference - Accelerated	Estimated impact and timing of a retrofit code based on publicly available information.

The following section discusses the detailed quantitative inputs of each critical uncertainty.

1.1.1.1 Critical Uncertainty Inputs (Quantitative Details) – Residential, Commercial and Industrial Demand Category

1.1.1.1.1 CUSTOMER GROWTH

The 2022 LTGRP provides further analysis to simulate the impact of economic growth on customer counts that relies on a statistical approach using confidence intervals (CI). This approach uses the historical variation in customers to provide high and low uncertainty bands for the BAU customer forecasts. See Appendix B1 for additional information. This statistical method serves as a proxy to model the potential impact of economic growth on customer numbers but may also account for other intrinsic factors, such as FEI marketing and promotional campaigns. Note that rate schedules with fewer customers experience a greater range between their high and low outcomes than larger rate schedules.

Figures B3-2 to B3-6 illustrate the customer number trajectories for key rate schedules.

Figure B3-2: Customer Forecast Parameters – Rate Schedule 1

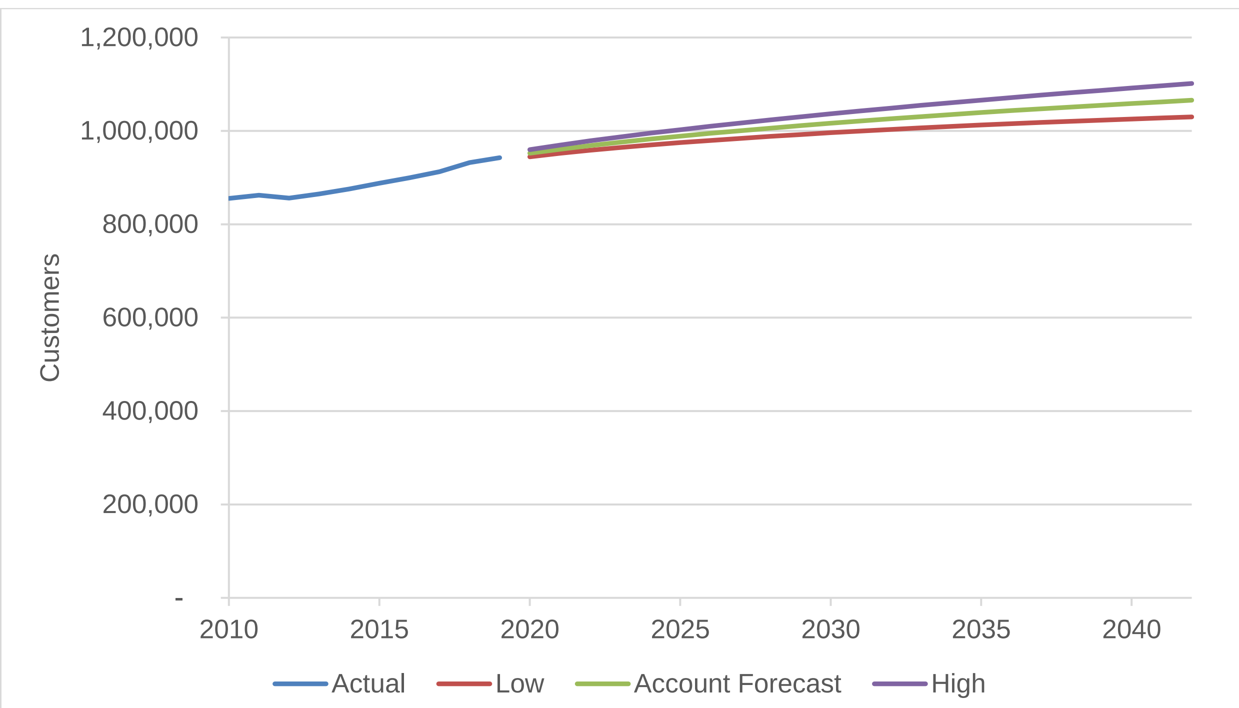


Figure B3-3: Customer Forecast Parameters – Rate Schedule 2

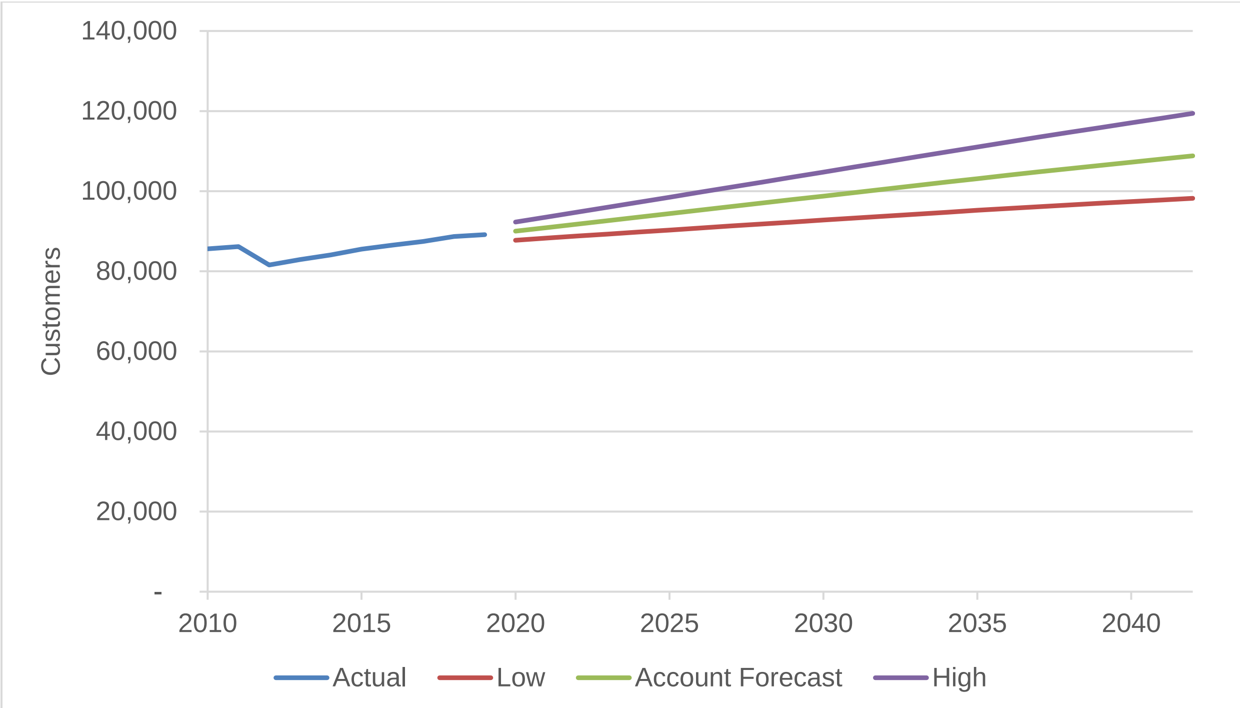

Figure B3-4: Customer Forecast Parameters – Rate Schedule 3

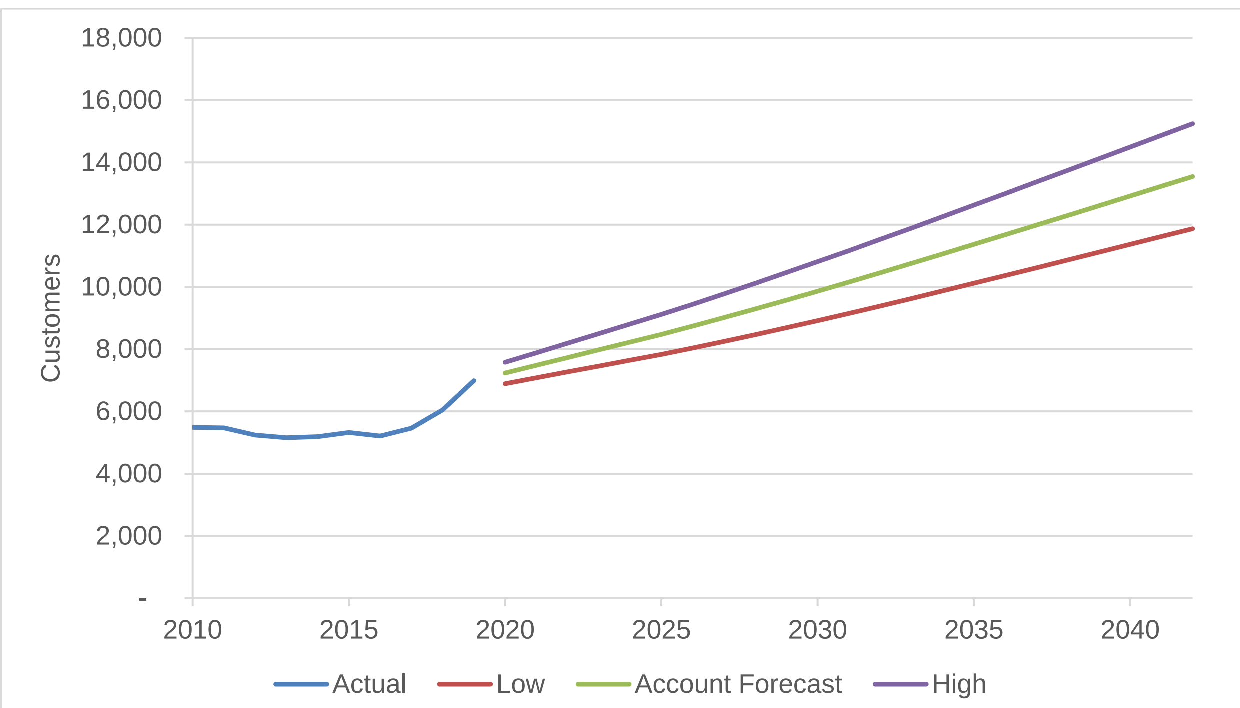

Figure B3-5: Customer Forecast Parameters – Rate Schedule 23

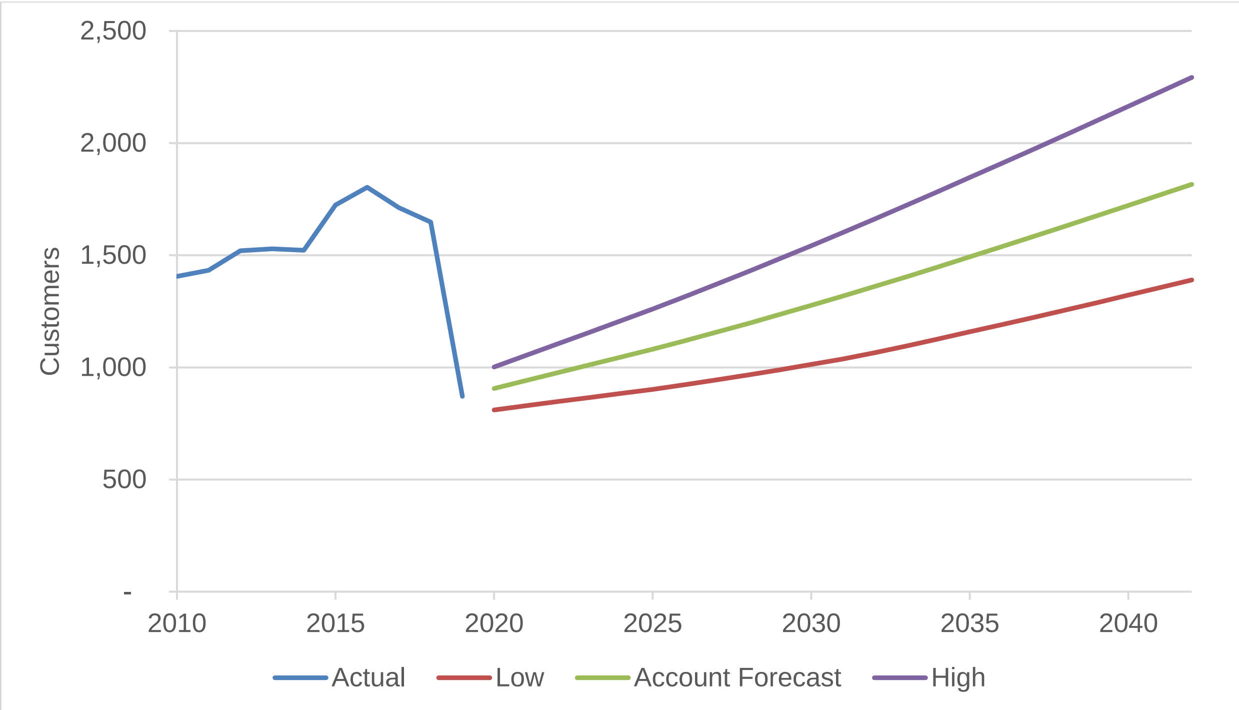

Figure B3-6: Customer Forecast Parameters – Industrial Rate Schedules

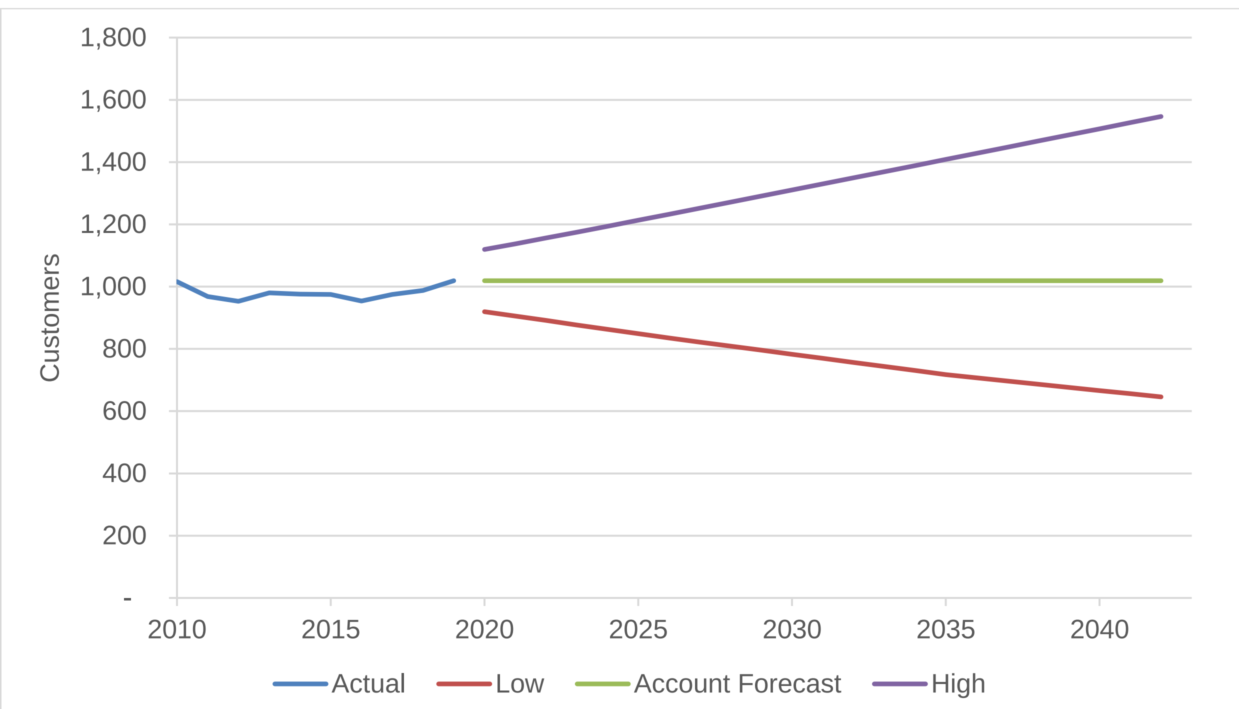


1.1.1.1.2 NATURAL GAS PRICE

FEI relied on forecasts from multiple third-party expert entities to prepare the 2022 LTGRP natural gas price forecast trajectories. The Reference Case natural gas price trajectory represents the same reference trajectory that FEI used for the 2021 CPR. FEI selected this trajectory for the 2022 LTGRP in order to facilitate the 2021 CPR results informing FEI's calibration of the 2022 LTGRP DSM analysis.

The natural gas market price forecasts are based on an average of the market price forecasts provided within the Northwest Power and Conservation Council (NPCC) 2021 Eighth Power Plan (2021 Power Plan)[1] and the long-term North American Gas Market Outlook from IHS Markit (IHS), released in February 2021.

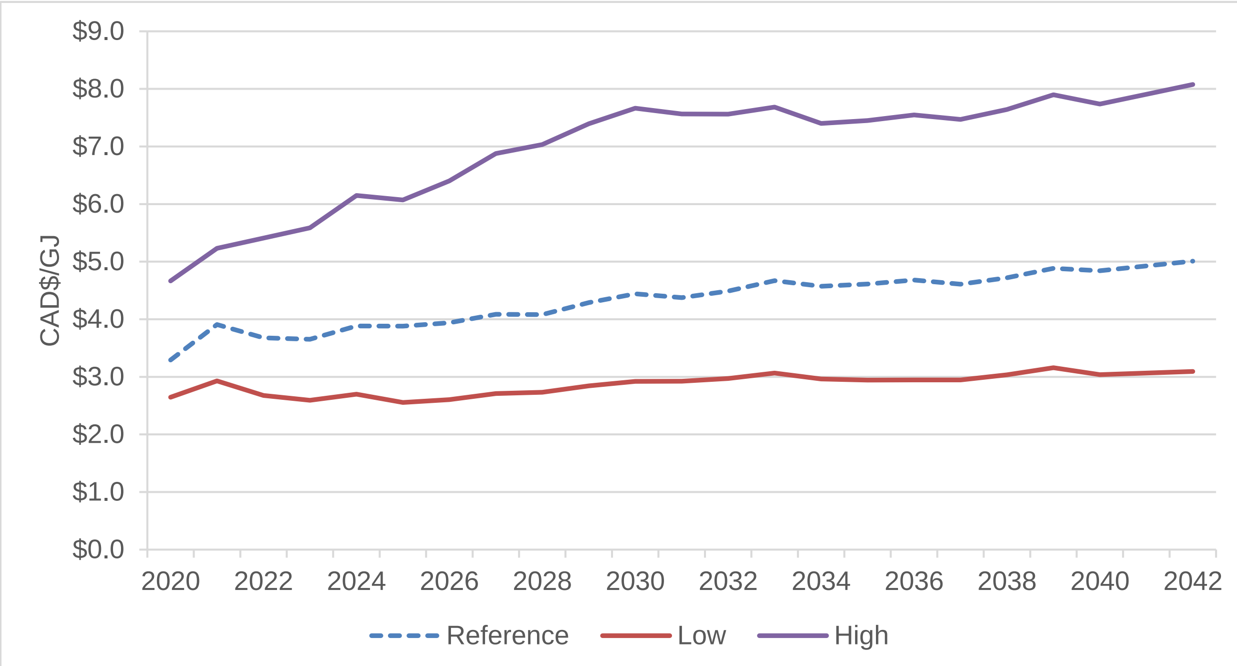
The Reference trajectory is based on expectations for natural gas prices, with prices increasing most years as demand increases due to LNG exports from BC and coal plant retirements in the PNW. The high and low-price trajectories provide reasonable extremes of possible future prices. The high trajectory assumes rapid world economic growth, increasing the demand for natural gas supplies. The low trajectory assumes slow economic growth with reduced demand for natural gas in favour of lower-carbon renewable energy sources.

FEI validated the resulting natural gas price trajectories against a range of existing recent third-party forecasts, including those developed by the International Energy Agency (IEA) and GLJ Petroleum Consultants Ltd. (GLJ).

Figure B3-7 below displays the resulting Reference, High, and Low natural gas price trajectories. The range between High and Low serves as a proxy not only for price changes due to shifting demand-supply conditions, but also potential policy actions that may impact the commodity price, such as upstream GHG reduction initiatives.

[1] https://www.nwcouncil.org/media/filer_public/4b/68/4b681860-f663-4728-987e-7f02cd09ef9c/2021powerplan_2022-3.pdf

Figure B3-7: Setting Options for Natural Gas Price

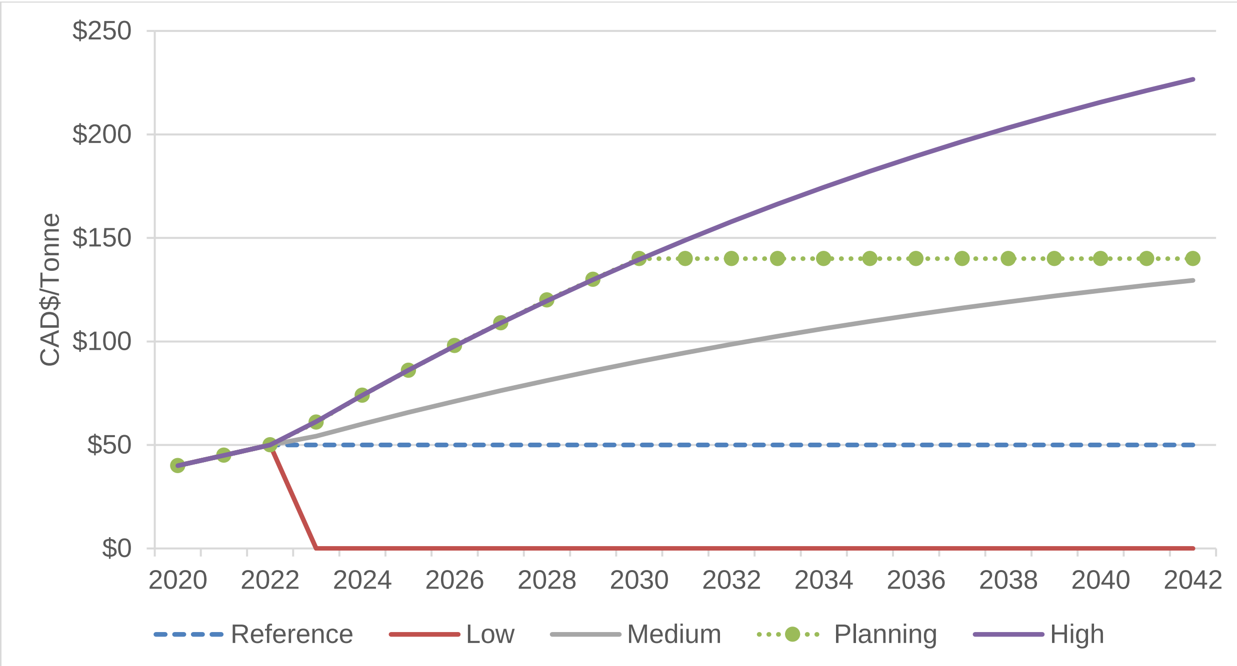


1.1.1.1.3 CARBON PRICE

FEI and FBC collaborated to develop their long-term carbon pricing trajectories by consulting internal and external subject matter experts. The resulting carbon pricing planning trajectory takes into account the Canadian federal carbon pricing backstop mechanism. The trajectories were determined early in the LTGRP planning process and have been validated by the LTGRP RPAG and reviewed by the LTGRP stakeholders (in the RPAG and FEI's community engagement workshops).

Figure B3-8 below displays the 2022 LTGRP's carbon pricing outcomes. The Low trajectory assumes that the carbon tax is removed early in the planning horizon and not replaced by other carbon pricing mechanisms. The Reference trajectory assumes the carbon tax is held constant once the maximum announced value (as of the time the settings were determined) was reached and held constant throughout the planning horizon. The Planning trajectory matches the federal carbon price announcement and grows to $170/tonne in 2030 (in nominal dollars), remaining constant thereafter. The High trajectory maintains this level of annual increase beyond 2030, while the Medium trajectory assumes a lower level of consistent annual increase over the planning horizon. This carbon pricing range intends to account for considerable policy uncertainty in relation to BC provincial, Canadian federal, and wider North American developments (as discussed in Section 2 of the Application).[1]

Figure B3-8: Settings for Carbon Price (2020$ Real)



1.1.1.1.4 CODES & STANDARDS

Codes & Standards accounts for the impact of building codes (for new construction) and retrofit code and appliance standards (for retrofits in existing buildings or appliance installations during new construction) that may prompt customers to switch from gas to another end use fuel type.

New Construction Code

The Reference Case assumptions are based on what was known and enforceable in the market as of 2019.

BC has enacted the BC Energy Step Code, and the provincial Climate Leadership Plan (CLP) declares a goal of net-zero-ready new construction for 2032. The 2022 LTGRP progressively applies two settings in the parametric analysis: accelerated and delayed. These settings are relative to the Reference Case where the accelerated setting contemplates earlier adoption/compliance and the delayed setting contemplates later adoption/compliance.

The 2022 LTGRP scenarios assume a differentiation between the City of Vancouver and all other regions, as the City of Vancouver has adopted by-laws, including its building code and the Vancouver Building Bylaw (VBBL), that are more stringent than those in other municipalities. Table B3-2 below illustrates the assumptions of the settings.

Table B3-2: New Construction Code Settings Assumptions

Setting	Years	Residential Assumptions	Commercial Assumptions
Reference	2020-2042	Step 4 (City of Vancouver)	Step 3 (City of Vancouver)
	2020-2042	Step 3 (all other regions)	Step 2 (all other regions)
Accelerated	2020-2027	Step 4 (City of Vancouver)	Step 3 (City of Vancouver)
	2028-2042	Step 5 (City of Vancouver)	Step 4 (City of Vancouver)
	2020-2027	Step 3 (all other regions)	Step 2 (all other regions)
	2028-2032	Step 4 (all other regions)	Step 3 (all other regions)
	2033-2042	Step 5 (all other regions)	Step 4 (all other regions)
Delayed	For all regions including the City of Vancouver: New buildings perform at discounted rates related to the code-mandated level. Based on industry research of how well BC buildings perform in relation to mandatory new construction performance requirements, the 2017 LTGRP assumed such buildings to perform at 63 and 70 percent of mandated performance, respectively, for residential and commercial buildings. We have applied these de-rated savings to the Reference Case to generate the savings in the delayed case for the 2022 LTGRP.		

Retrofit Code

The 2022 LTGRP applies two settings in the parametric analysis: reference and accelerated. The Reference Case, which is based on known, legally enshrined and mandatory requirements, assumes there would not be an impact for all regions, including the City of Vancouver. Nevertheless, the 2022 LTGRP estimates what the Retrofit Code could look like and when it could be implemented. Based on the research from two documents,[2] the accelerated setting contemplates the Retrofit Code being introduced in 2030, with 1.5 percent of existing buildings each year being retrofitted, so that heat load is reduced by 20 percent for residential customers and 15 percent for commercial customers

Appliance Standards

The Reference Case assumes that the 2019 in-market mandatory or legally enshrined appliance standards continue across the entire forecast period. Scenarios that are subject to the

[2] Canadian Commission on Building and Fire Codes, *Final Report – Alterations to Existing Buildings (April 2020), available at:* *https://nrc.canada.ca/sites/default/files/2020-07/final_report_alterations_to_existing_buildings_joint_CCBFC_PTPACC_task.pdf* and Navius Research, *Supporting the Development of CleanBC: Methodology report for assessing the impacts of CleanBC policies, available at:* https://www2.gov.bc.ca/assets/gov/environment/climate-change/action/cleanbc/supporting-development-cleanbc_methodology-report_navius.pdf

Accelerated outcome assume the introduction of the following additional performance requirements for appliances:

- Gas Storage Water Heater: No change (BC MEPS are already slightly more stringent than Federal MEPS)
    - BC = energy factor must be ≥ 0.70 − (0.0005 × V), and
    - Federal = energy factor must be ≥ 0.675 – 0.00039 Vr.
- HRV: estimated new minimum performance of 50 percent (residential only); likely minimal impact, since there are few homes with HRVs.
- Gas Dryer: likely new testing requirements, but no expected efficiency requirements.
- Gas Range: estimated 10 percent improvement in minimum efficiency level (residential only)
    - Assuming 20 percent of existing ranges are non-conforming, and will be upgraded when they are replaced. Replacement rate is assumed at 1/lifespan or 1/15th per year.
- Windows: new minimum performance of USI 1.61 or ER 25 (residential only)
    - Assuming 20 percent of existing windows are non-conforming, and will be upgraded when they are replaced. Replacement rate is assumed at 1/lifespan or 1/20th per year, and
    - Previous work by Posterity Group found this upgrade has on average a 2.7 percent heating energy savings.
- Commercial Warm Air Furnace: estimated improvement to 85 percent efficiency from 80 percent efficiency
    - Assuming 20 percent of existing commercial furnaces are non-conforming, and will be upgraded when they are replaced. Replacement rate is assumed at 1/lifespan or 1/15th per year, and
    - Commercial furnaces are estimated to make up 37 percent of the gas heating mix in BC.

Non-Price Driven Fuel Switching

In the 2022 LTGRP, non-price driven fuel switching captures gas-to-electricity fuel switching as a function of policies and incentives. This type of fuel switching differs from price-driven fuel switching when the prices of conventional natural gas and carbon cause a change in demand for conventional natural gas.

The non-price driven fuel switching focuses on space and water heating end uses in the residential and commercial sectors, as it is thought that policies and incentives for electrification would focus on these end uses for these sectors. Non-price driven fuel switching is assumed to occur in the industrial sector as well, as there are spillover effects from the electrification of other sectors. Fuel switching in the industrial sector occurs in the end uses that are assumed to be able to switch to electricity.

There are three gas-to-electricity ("G2E") fuel switching settings to serve as inputs to the associated scenarios. These settings were developed to reflect various levels of electrification by the end of the forecast period. The fuel switching assumptions presented in the Pathways Report (Appendix A-2) were reviewed to establish the settings. The "moderate" and "accelerated" settings align with a specific pathway presented in that report, indicated below. Using the Pathways Report as a guide, the 2022 LTGRP estimated gas fuel share reduction targets for 2042. The "extensive electrification" setting explores electrification beyond what was analyzed. The targets were set for reductions in gas fuel share by 2042 relative to the 2019 fuel share for space and water heating end uses in existing residential and commercial buildings. In the case of the City of Vancouver region, separate targets were set, as the City has more stringent building code requirements.

For 2042, a linear interpolation was used to set the following electrification assumptions consistent with the Pathways Report of modelled values in 2050:

- Moderate electrification (aligned with the 'Diversified Pathway'): ~14 percent decline in gas fuel share;
- Accelerated electrification (aligned with the 'Electrification Pathway'): ~56 percent decline in gas fuel share; and
- Extensive electrification: ~67 percent decline in gas fuel share.

1.1.1.2 Critical Uncertainty Impacts on the Forecast Model – Residential, Commercial and Industrial Demand Category

Table B3-3 summarizes how each critical uncertainty impacts the mechanics of the 2022 LTGRP forecast model and discusses the attributes of individual critical uncertainties

Table B3-3: Summary of Critical Uncertainty Impacts on the Forecast Model

Critical Uncertainty	Model Levers	Comments
Demand-Side Critical Uncertainties – Residential, Commercial and Industrial Demand Category		
Appliance Standards	- Natural gas appliance efficiency	See Table B3-1 above.

Critical Uncertainty	Model Levers	Comments
Demand-Side Critical Uncertainties – Residential, Commercial and Industrial Demand Category		
Carbon Price	- Long run natural gas fuel share	This critical uncertainty relies on the same mechanics as the Natural Gas Price critical uncertainty.
Customer Growth	- Residential buildingstock - Commercial floor area - Industrial facilities	See Table B3-1 above.
Natural Gas Price	- Long run natural gas fuel share	Based on a literature review of existing research by FEI and Posterity, the 2022 LTGRP uses -0.380, -0.350 and -0.700 as the long run price sensitivity values for residential, commercial and industrial customers, respectively. Since these are long run values, the 2022 LTGRP forecast model calculates the total fuel share change from these values by the end of the forecast period and subsequently solves for the required annual change rates required to produce the total change. The model ensures that the calculated annual change rates are achievable in relation to the rate of end use equipment replacements.
New Construction Code	- Unit energy consumption in new construction in Residential and Commercial sectors by building type and end use.	See Table B3-1 above.
Non-price Driven Fuel Switching	- Long run natural gas fuel share	See Table B3-1 above.
Retrofit Code	- Unit energy consumption in retrofit projects in Residential and Commercial sectors	See Table B3-1 above.

1.2 LOW-CARBON TRANSPORTATION AND GLOBAL LNG DEMAND CATEGORY

FEI developed four long-term forecast demand settings or trajectories for the CNG segment and LNG segment, based on core end use forecast scenario parameters for this category. These parameters are: (1) GGRR vehicle incentive applications that FEI uses for incentive funding for LCT customers; (2) industry research; (3) policy expected to impact the demand for natural gas as a transportation fuel in the future; (4) the allowed funding period permitted under the GGRR; (5) actual LCT customer additions to date; and (6) the relative price of competing or incumbent fuels such as diesel. Sections 3.4.7.1 and 3.4.7.2 further elaborate on these factors. The settings are:

- **Reference**: the continuation of planning environment conditions and demand trends that existing during the base year (2019) of the demand forecast.
- **Planning**: the expected forecast under the transportation fuelling initiatives being undertaken as part of FEI's Clean Growth Pathway.
- **High**: an upper bound forecast of possible demand from the transportation sector under very favourable conditions for expanding service to this customer group.
- **Low**: a lower bound scenario of possible demand from this sector if future conditions were to be very unfavourable for serving this customer group.

1.2.1 Qualitative Details on Scenario Critical Uncertainties – LCT and Global LNG Demand Category

FEI created the demand forecast settings separately for the CNG segment and LNG segment, as each segment has distinct characteristics and different considerations. CNG is positioned as a fuel for on-road transport applications, such as transit buses, waste haulers and heavy duty on-road trucks. LNG is positioned as a fuel for off-road and high-horsepower applications, such as marine vessels, locomotives, mine haul trucks, and remote industrial power and heat generation applications. Potential also exists for LNG to be exported overseas. Table B3-4 summarizes the critical uncertainty trajectories for the LCT and global LNG Demand Category.

Table B3-4: Summary of Modelled Critical Uncertainty Trajectories for the LCT and Global LNG Demand Category

Critical Uncertainty	Modelled Trajectories	Comments
Demand-Side Critical Uncertainties – LCT and Global LNG Demand Category		
Low-Carbon Transportation (LCT) Demand	- Reference - Planning - Low - High	Supply of CNG for the LCT sector to be used by on-road vehicles. Supply of LNG for the LCT sector to be used by marine vessels.

Critical Uncertainty	Modelled Trajectories	Comments
Demand-Side Critical Uncertainties – LCT and Global LNG Demand Category		
Global Liquefied Natural Gas (LNG) Demand	- Reference - Planning - High	Supply of LNG for export outside of the province.

Each of the settings are described in the subsections below. The links between the core end use forecast parameters and the LCT annual demand forecast settings are qualitative only because LCT is an emerging market with frequent changes in technology and policy in the market. Therefore, with little information to assess trends, FEI made its best assessment based on its understanding of potential market changes. Each CNG and LNG trajectory is considered a setting that is then mapped to the 2022 LTGRP Annual Demand Reference Case and Scenarios, as shown in Table B3-5 and Table B3-6.

Table B3-5: Mapping CNG/LNG Demand Forecast Settings to the 2022 LTGRP Annual Demand Scenarios – Transportation Fuel

CNG / LNG Demand Forecast Setting	Is Applied to this 2022 LTGRP Annual Demand Scenario
Reference	Reference Case
Low	Lower Bound, Deep Electrification, Economic Stagnation
Planning	Diversified Energy (Planning)
High	Upper Bound, Priced-Base Regulation

Table 3-6: Mapping Global LNG Demand Forecast Settings to the 2022 LTGRP Annual Demand Scenarios

Global LNG Demand Forecast Setting	Is Applied to this 2022 LTGRP Annual Demand Scenario
Reference	Reference Case, Price-Based Regulation, Economic Stagnation, Lower Bound
Planning	Diversified Energy (Planning), Deep Electrification
High	Upper Bound

Notes: - Because in the Reference Setting Global LNG Demand drops to zero, there is no "Low" setting.
Tables B3-5 and B3-6 = Tables 4-2 and 4-3 respectively in Section 4 of the 2022 LTGRP

Utilizing the above information, including demand from a number of different market segments that are suited to adopt LNG as a fuel, FEI developed Reference, Low, Planning and High demand forecast settings, described below.

1.2.1.1 LNG Reference Demand Forecast Setting

For the Reference forecast setting, FEI has assumed that incentives supporting LNG infrastructure under the GGRR will be extended to beyond 2030 with development in the short sea market segment as FEI's customers proceed with adoption of additional LNG marine vessels. The Reference setting assumed that there is no growth in trans-Pacific marine vessels adopting LNG as a fuel. As such, the marine bunkering jetty[3] at Tilbury is not constructed and does not apply in this setting. Similarly, completion of the EGP project is not assumed and the addition of Woodfibre LNG demand is not included. A solution to the discontinued 15L road engine for truck fleet customers does not emerge and consumption by these on-road customers will halt by 2026. Over the forecast horizon to 2042 in the Reference setting, FEI has forecast an average growth rate of about 1 percent from 2020 to 2030 and no growth beyond 2030.

1.2.1.2 LNG Low Demand Forecast Setting

For the Low demand forecast setting, FEI assumes that incentives supporting LNG infrastructure under the GGRR are not extended. Further, FEI has projected that short sea LNG demand would slightly increase annually until 2026 based on the current projection of short sea vessel additions. However, this would stabilize thereafter and maintain that volume of consumption for the remainder of the forecast period. This setting assumes that trans-Pacific marine vessels will not be adopting LNG as marine fuel and that a marine bunkering jetty at Tilbury does not get constructed. Additionally, it is assumed that there will not be a solution to the discontinued 15L road engine for truck fleet customers and therefore further decreases the LNG consumption demand for on-road customers. Although it is forecasted that ISO exports will remain consistent at 3PJ per year for the initial two years, it is expected that the ISO export demand will significantly decrease thereafter for the remainder of the planning horizon. There is no growth in LNG demand assumed under this setting through to the end of the forecast period of 2042.

1.2.1.3 LNG Planning Demand Forecast Setting

In the Planning forecast setting, FEI assumes that incentives supporting LNG infrastructure under GGRR will be extended beyond 2030. FEI has assumed that there will be development in the short sea market segment as our marine customers will proceed with adoption of additional LNG marine vessels. In the Planning setting, the marine bunkering jetty at Tilbury is constructed, which will accelerate the adoption of LNG by trans-Pacific marine vessels as facilitated by ship-to-ship bunkering. This setting assumes that there will not be a solution to the discontinued 15L road engine for truck fleet customers and consumption by these customers will halt by 2026. The ISO exports market segment is assumed to increase by 0.68PJ per year from 2021-2042. The Planning setting includes completion of the EGP project resulting in an average of 94.8 PJ annually of LNG from 2025-2042. Moreover, the mining and remote power market segments will grow which will increase LNG demand by an average of 2.9PJ annually from 2024 to 2042.

[3] The proposed Jetty is a non-regulated activity and is not part FEI's initiatives included in the LTGRP.

1.2.1.4 LNG High Demand Forecast Setting

For the High forecast setting, FEI assumes that incentives supporting LNG infrastructure under the GGRR will be extended beyond 2030. As in the Planning setting, the marine bunkering jetty at Tilbury is constructed, accelerating the adoption of LNG by trans-Pacific marine vessels as facilitated by ship-to-ship bunkering. However, in the High setting there is a more aggressive LNG adoption, particularly from the trans-Pacific marine vessels.

The High setting begins to diverge from the Planning setting beginning in 2022 and 2023, as the marine transportation market begins addressing the impending IMO sulphur cap on marine industry emissions. The IMO sulphur cap regulation accelerates a need for gas as an alternative fuel to meet these tighter emissions restrictions.

Similar to the Planning setting, the High setting assumes that the ISO exports market segment increases by 0.68PJ per year from 2021-2042. In addition to the Planning setting expectation, the EGP project will be completed and also result in 94.8PJ LNG annually from 2025-2042. Moreover, the mining and remote power market segments grow, increasing LNG demand by an average of 4.6PJ annually from 2024 to 2042.

In the High setting, it is projected that an introduction of a new high horsepower engine would be available for on-road customers as a solution to the discontinuance of the 15L road engine. It is assumed that this 400 horsepower engine would enable FEI to retain our current on-road customer LNG demand up to 2042.

1.2.1.5 CNG Reference Demand Forecast Setting

The Reference setting assumes that incentives supporting CNG infrastructure under GGRR will be extended beyond 2030, and that the CNG demand from current customers will be consistent throughout the forecast period. The setting forecasts new customer additions, and that all new customer load is expected to grow on average of 3% annually until 2030 at which it will be stagnant thereafter. This setting assumes that CNG engines are continued to be manufactured and improved while the price of CNG vehicles and fuel savings from adopting CNG vehicles are assumed to remain relatively consistent. The Reference setting assumes that the cost difference between diesel and CNG will vary. It is assumed that EV and hydrogen adoption is slow due to technology uncertainty. By 2031, EV technology advancements have progressed which results in limited CNG growth. The Reference setting is forecast to capture 2.5 percent of the demand from the eligible CNG market by the end of the forecast period of 2042.

1.2.1.6 CNG Low Demand Forecast Setting

The Low setting assumes an annual growth rate of about 1 percent per year on average until 2030, at which point it will decrease at 1.9 percent per year until 2042 due to an assumed transition to EV for this setting in the eligible market. In this setting, incentives supporting CNG infrastructure under the GGRR and the BC-LCFS are assumed to end in 2030. Demand from current customers is forecast to remain consistent and, based on demand from new customers, the load will grow on an average of 1 percent annually until 2030 at which point all GGRR stations are completed. In 2030 and beyond, CNG consumption will decrease as adoption of other potential low-carbon fuels increases and existing CNG fleets are replaced. Unlike in the Reference setting, the Low setting assumes that CNG vehicle prices will increase, and medium and heavy duty EV and hydrogen vehicle adoption is accelerated. The Low setting assumes that the acceleration of EV and hydrogen vehicle adoption will result in CNG stations closing and CNG trucks are retired, reducing demand. As a result, the Low setting forecasts a market share of about 2 percent of the eligible market size by 2042.

1.2.1.7 CNG Planning Demand Forecast Setting

For the Planning setting, the incentives supporting CNG infrastructure under the GGRR are expected to be extended beyond 2030 and the BC-LCFS continues beyond 2042. For this setting, demand from current customer base is forecast to remain consistent throughout the forecast period, based on demand from new customers, load is forecast to grow on an average of 2 percent annually until 2030 at which point all GGRR stations are completed. This setting assumes that current customers will continue to renew or replace their CNG vehicles with the same gas equivalent. CNG engines continue to be manufactured and improved and the price of CNG vehicles as well as fuel savings from adopting CNG vehicles is assumed to remain relatively consistent. It is assumed that medium and heavy duty EV and hydrogen vehicle adoption is slow due to delayed development of these heavy and medium duty vehicle technologies and supporting supply chain readiness. The growth of CNG demand is forecast to capture about 2.9 percent of the eligible market by the end of the forecast period of 2042. This level of market capture constitutes a growth rate of approximately 3 percent per year with average demand increase of 15 thousand GJ per year from 2031 to 2042.

1.2.1.8 CNG High Demand Forecast Setting

For the CNG High setting, incentives supporting CNG infrastructure under the GGRR are assumed to be extended beyond 2030 and the BC-LCFS continues beyond 2042. For this setting, current customer load is forecast to be consistent throughout the forecast period while new customer load grows on average at 5 percent annually until 2042. Additionally, the spread between diesel prices and CNG prices increases in favour of CNG, which contributes to higher customer consumption. CNG engines are assumed to continue to be manufactured and improved and the price of CNG vehicles and fuel savings from adopting CNG vehicles are assumed to decrease. The popularity of LCT vehicles continues to increase due to fuel savings over diesel. The High setting assumes that medium and heavy-duty electric vehicle (EV) and hydrogen vehicle adoption is relatively slow, as is the case with the Planning setting.

By 2042, the High setting assumes FEI will capture approximately 5.8 percent of the potential eligible market in BC, which equates to an average annual growth rate of about 5 percent per year or an average demand addition of approximately 100 thousand GJ per year from 2027 to 2042.

1.2.2 Critical Uncertainty Impacts on the Forecast Model – Low-Carbon Transportation and Global LNG Demand Category

Table B3-7 summarizes how each critical uncertainty impacts the mechanics of the 2022 LTGRP forecast model and discusses the attributes of individual critical uncertainties.

Table B3-7: Summary of Critical Uncertainty Impacts on the Forecast Model

Critical Uncertainty	Model Levers	Comments
Demand Side Critical Uncertainties - LCT and Global LNG Demand Category		
Low-Carbon Transportation (LCT) Demand	- Commercial rate schedule demand - Industrial rate schedule demand	See Table B3-1 above.
Liquefied Natural Gas (LNG) Export Demand	- Industrial rate schedule demand	See Table B3-1 above.

1.3 CRITICAL UNCERTAINTIES FOR THE NEW LARGE INDUSTRIAL DEMAND CATEGORY

The New Large Industrial Demand Category is in itself a critical uncertainty in that such demand is either added or it is not. There are only three settings for new large industrial demand:

- High – in which both Woodfibre and a second generic large industrial facility are added to FEI's demand in 2025 and 2028, respectively.
- Planning – in which only Woodfibre is added to FEI's demand in 2025.
- Reference – in which no new large industrial facilities are added to FEI's demand over the planning horizon.

The high setting is applied only to the Upper Bound Scenario. The planning setting is applied to the Diversified Energy (Planning) and the Deep Electrification Scenarios. The Reference setting is applied to all other scenarios.

1.4 CONCLUSION

In response to the complex and partially uncertain planning environment discussed in Section 2 of the LTGRP, FEI has built on the end use forecast method scenario analysis from the 2017 LTGRP and identified a range of critical uncertainties to account for potential changes in the planning environment across the forecast period. These uncertainties include customer growth, natural gas prices, the carbon price, Codes & Standards, non-price driven fuel switching, and the impact of emerging markets, such as LCT and the potential impact of LNG export. FEI used a rigorous process for developing the inputs for each critical uncertainty and for implementing these into the 2022 LTGRP forecast model. In doing so, FEI drew on the expertise of its internal LTGRP working groups, its forecast consultant (Posterity Group), and the experience of stakeholders in the RPAG and across FEI's community engagement workshops. The resulting critical uncertainty data accounts for a wide range of possible alternate future scenarios and enables FEI to account for planning environment risks in its 2022 LTGRP analysis. The critical uncertainties also serve as signposts for FEI to evaluate which future scenarios may be unfolding as it proceeds through the planning horizon.

HIGH-LEVEL ASSESSMENT OF THE EFFECTIVENESS OF THE TRADITIONAL AND END USE METHODS

APPENDIX B-6: HIGH LEVEL ASSESSMENT OF THE EFFECTIVENESS OF THE TRADITIONAL AND END USE METHODS

In the Decision and Order G-39-19 related to the 2017 Long Term Gas Resource Plan FEI was directed to include a high-level assessment of the effectiveness of the Traditional and End Use Models compared to actual results.

Measuring the effectiveness of the long-term forecasting method in a scenario analysis context goes far beyond how accurately the method predicted the actual outcome in a given year, since by its very nature forecasting cannot predict the outcome of all uncertainties. A complete evaluation of a long-term forecasting method includes how well the forecast model can explore different future outcomes and how useful it is for the organization employing the method to analyze and understand the nature of future uncertainties, discuss these uncertainties and potential future outcomes with stakeholders, and inform the decisions the organization needs to make. On these parameters, the end use annual demand forecast method employed by Posterity Group on behalf of FEI has performed well, having enabled FEI to examine a broad range of uncertainties across different future scenarios, to understand the degree to which these uncertainties will impact future demand, to discuss these uncertainties and findings with stakeholders, and to identify a future scenario on which to plan shorter-term actions.

Nevertheless, the following discussion presents a review of LTGRP forecast annual demand against actuals for each year of the forecast that is available from the 2014, 2017 and 2022 LTGRP models. As shown below the 2014 and 2017 Reference Case and BAU forecasts performed well in the initial years of their forecast horizon. Residential and industrial demand increased after the publication of the 2017 forecasts and actual demand has remained above forecast since then. The 2022 Reference Case and BAU forecasts reflect the increased demand, and both extend the demand trend observed in recent years.

Figure B6-1: Comparing the Reference Case Forecasts with Actuals

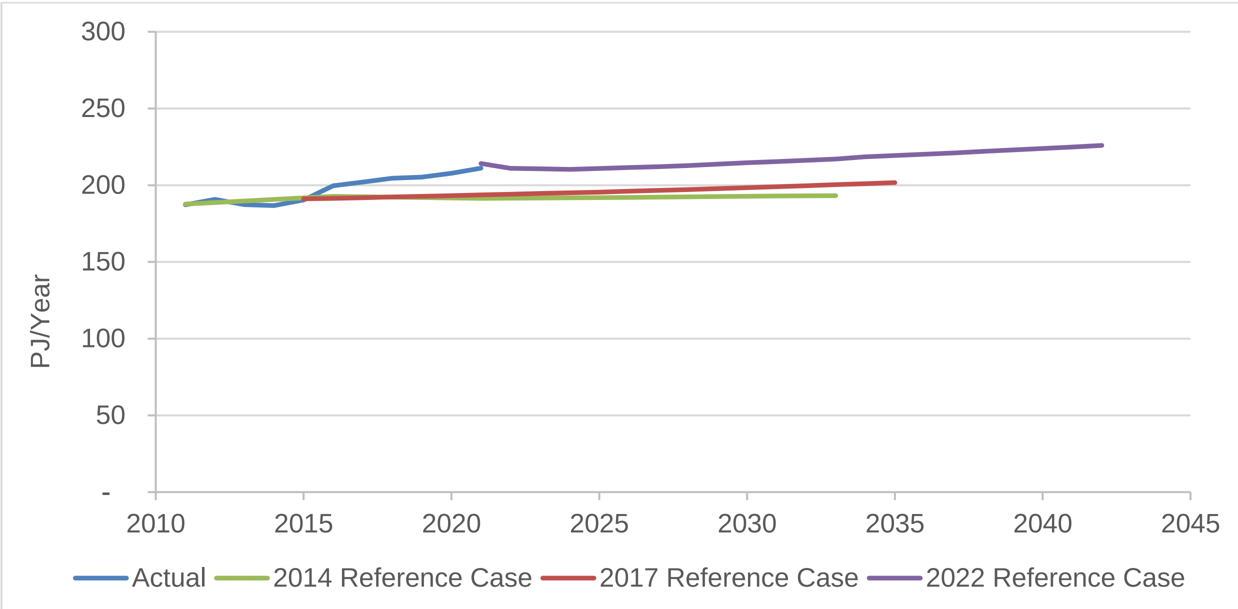

Figure B6-2: Comparing the BAU Forecasts with Actuals

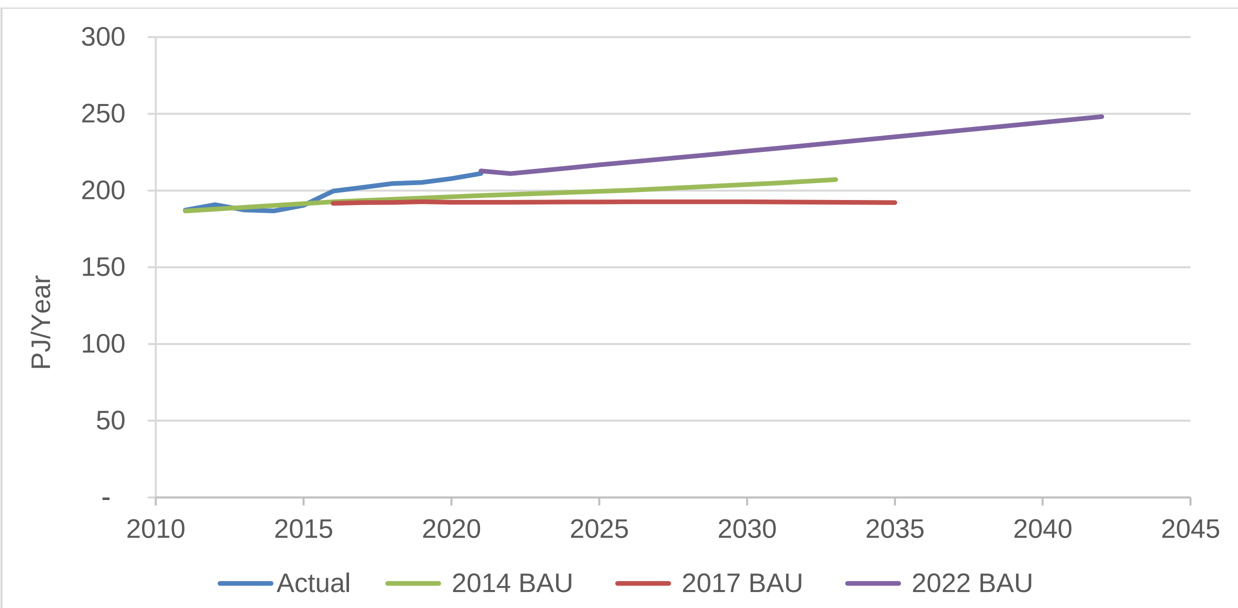

For the period up to 2021, the 2014 and 2017 BAU forecasts and Reference Case forecasts performed similarly. FEI notes that the BAU forecast, as used in this context, is to check the reasonableness of the end use method Reference Case (as the starting point for alternate future scenarios), regardless of how either forecast compares to actual results.

As noted above, the end use method provides features critical for long term planning that cannot be achieved using the traditional method. Figures B6-1 and B6-2 demonstrate that the results from the two methods are comparable in the early years of the forecast, and therefore it is reasonable to use the extended capabilities of the end use method to examine future scenarios.

Executive Summary

Background and Objectives

The 2021 Conservation Potential Review (CPR) is the review of energy efficiency opportunities available among FortisBC's residential, commercial, and industrial natural gas customers.

The CPR will support two of FortisBC Energy Inc's (FEI) major regulatory filings in 2022: the long-term gas resource plan (LTGRP) and the Demand Side Management (DSM) plan. For this CPR, Posterity Group reviewed estimated technical, economic, and market potential natural gas savings in FEI's service territory over a 20-year period. The CPR is an important guiding document for ongoing conservation and energy management program development and support at FortisBC.

FEI has also retained Posterity Group to produce the load forecast of natural gas demand of FEI's customers to support the 2022 LTGRP filing. The base year and reference case forecast developed by Posterity Group is common to both the LTGRP and CPR. As a result of the integrated nature of the two projects, the LTGRP project is frequently referenced in this document.

Findings Summary

- This study has found significant cost-effective and market achievable natural gas savings throughout the study period 2020-2040, and in all sectors and segments.

  Across all sectors, and using the MTRC screen, medium market potential savings are estimated at approximately 8 PJ, or 4% of reference consumption in 2025, rising to 24 PJ, or 10% of reference consumption in 2040.

  This estimated 24 PJ savings by 2040 includes potential savings from Residential, Industrial, and Commercial sectors of 9.9 PJ, 8.6 PJ, and 5.8 PJ respectively.

- In the ***residential sector***, only a small number of measures are cost-effective based on the TRC test, most being low-cost retrofit measures. Measures that pass the MTRC screen only become more important in the residential sector as the study period progresses.
  - The opportunities for equipment replacement measures, especially space heating measures, are much smaller relative to previous studies. This is primarily due to increasingly higher federal and provincial minimum energy performance standards (MEPS) for furnaces, which have caused DSM opportunities to become increasingly scarce.
  - In terms of percentage of reference case consumption forecast, more residential opportunities are available in the domestic hot water end use than the space heating end use throughout the study period. In absolute terms, savings potential for DHW measures (4 PJ by 2040 in the medium market potential scenario, MTRC screen) approaches that of space heating measures (5 PJ by 2040 in the medium market potential scenario, MTRC screen).

- *Commercial sector* savings show the most variance between the high and medium market potential scenarios. Using the MTRC screen, by 2040 the difference in potential between the medium and high market scenarios is 11.6 PJ.

  Gas heat pumps (GHPs) and efficient new construction are major contributing factors to this difference. These measures have high technical and economic potential, but future uptake is uncertain. For example, in the medium scenario, GHPs are modeled as an innovative technology with low forecasted growth. In the high scenario, they are modeled as an innovative technology with high forecasted growth, especially in the second half of the study period (2030-2040).
- The *industrial sector* is estimated to have the largest cost-effective savings potential on the TRC economic screen relative to other sectors. However, industrial customers require shorter payback periods relative to commercial and residential customers. Achieving savings from industrial measures that are cost-effective but have longer customer payback periods may be challenging and/or more expensive due to higher incentives and program costs.

Scope

Timing: The base year for this study is the 2019 calendar year, where the reference case forecast is from 2020 to 2040 with results calculated for each intervening year.

Regions: This study divides the FortisBC gas regions in British Columbia into six: City of Vancouver, Lower Mainland (excluding Vancouver), Vancouver Island, Northern BC, Southern Interior, and Whistler.

Sectors: The study addresses three sectors: residential, commercial, and industrial. The LTGRP also includes transportation in its scope. EX 1 shows the breakdown of each sector (except transportation), which are organized into segments.

EX 1 – CPR Segments

Residential	Commercial	Industrial
• Single Family Detached/Duplexes • Single Family Attached/Row • Mobile/Other Residential	• Apartments – Medium • Apartments – Large Food Retail • Hospital • Hotel – Medium • Hotel – Large • Non-Food Retail – Medium • Non-Food Retail – Large • Nursing Home • Office – Medium • Office – Large • Other Commercial • Restaurant • School – Medium • School – Large • University/College • Warehouse	• Agriculture (includes greenhouses[1]) • Chemical • District energy providers • Fabricated Metal • Food & Beverage • Other Manufacturing (includes transportation[2] and other industrial) • Mining • Non-metallic Mineral (includes cement) • Pulp & Paper – Kraft • Pulp & Paper – TMP • Utilities • Wood Products

End uses vary and are described in more detail in Section 2 of this report. The residential sector is also broken down into vintages that define the time periods when the dwellings were constructed.

Approach

The CPR model was developed using Posterity Group's Navigator™ Energy and Emissions Simulation Suite. Data was collected from various sources for the analysis and inputted to the model.

The CPR followed these key steps to perform the analysis:

1. **Determine the current (Base Year) customer base and their energy consumption.**
    a. Collect and review data on the building stock in FortisBC's service territory, including end use surveys and previous CPRs.
    b. Develop energy use models of each building or facility type (segments) and model energy consumption by end use.

1 Cannabis included in agriculture segment since there is not enough data at FEI to create a cannabis-specific forecast.
2 In the 2015 CPR, 'transportation' pertained to facilities that supported the transportation sector.

c. Collect and review actual base year (2019) energy use and billing data of FortisBC's customers.
d. Use the billing data to calibrate the base year energy consumption in each sector's energy model.

2. Develop reference case energy consumption forecast.

   a. Collect and review data on all factors that will affect energy use trends over the study period (2020 to 2040 in this study's case).
      i. This includes analyzing and modelling natural improvements in building energy use intensities (e.g. from natural replacement of furnaces with new, higher efficiency ones at replacement time).
      ii. Other factors are existing building demolition / renovation trends, rate of new building stock construction, baseline energy efficiency of new buildings and equipment, and known changes to policies and codes and standards that will impact the energy use of buildings.
   b. Use this data to develop an energy consumption forecast model for each sector.
   c. Calibrate the reference case based on FortisBC's own account forecasts and industrial survey information at the region and rate class level.

3. Characterize energy conservation measures.

   a. Select a set of energy conservation measures for each sector. Measures range from mature, widely known measures that are currently part of FortisBC's program portfolio (e.g. commercial condensing boilers) to innovative or enabling technologies (e.g. smart residential water heater controllers). Behavioural measures are also considered (e.g. thermostat setback).
   b. For each measure, review and collect data on energy savings, costs, useful life, and the baseline equipment or technology that it should be compared with (if applicable).
   c. Use the data to characterize the technology's energy savings potential, cost-effectiveness, and financial attractiveness.
   d. Use the data as inputs to the energy model for each sector.

4. Estimate technical savings potential.

   a. For each measure, determine its technical applicability (i.e. how many buildings or facilities can this measure be applied to, considering only technical barriers).
   b. Determine the measures' current market penetration (i.e. how many buildings or facilities have already installed a measure).
   c. Estimate the measures' reference adoption – their natural rate of uptake in the absence of incentives or utility program intervention.

   d. Input all data into the energy model for each sector and develop a hypothetical estimate of the technically feasible energy savings potential within FortisBC's service territory.[3]

5. Estimate economic savings potential.
   a. Screen each measure for cost-effectiveness from FortisBC's perspective by determining whether the benefit to cost ratio of each measure is 1.0 or above (pass) or if it is below 1.0 (fail) for two cost effectiveness tests: TRC and MTRC.
   b. Update the technical potential model with only the TRC-passing measures, removing measures that are not cost-effective.
   c. Estimate the economic savings potential of all cost-effective measures applied to all technically feasible buildings in the customer base.[4]
   d. Repeat steps 5b and 5c using the MTRC screen. This study presents findings from two economic (and subsequent market potential) models: One with TRC as the economic screen and one with MTRC.

6. Estimate market savings potential.
   a. Based on existing research, develop sets of "generic" adoption curves based on customer payback acceptance and typical market diffusion patterns.[5]
   b. Apply these generic curves to each measure in the economic potential model to develop "simplified market potential" estimates at the measure level.
   c. This data is input into the TRC economic potential model to develop a simplified market potential.
   d. Develop a more realistic market potential for each measure by soliciting feedback from FortisBC and its external stakeholders on the simplified market potential.[6]
   e. Revise the simplified market potential model based on this feedback to develop a realistic market potential scenario (referred to in this study as "medium market potential").
   f. Perform sensitivity analysis by varying incentive levels to model "low" and "high" market potential scenarios.
   g. Repeat steps 6c to 6f using the MTRC economic potential model to estimate low, medium, and high market potential scenarios using the MTRC economic screen.

---

3 See Exhibit 2 for an overview of the constraints considered in the technical potential scenario, and the difference between different potential scenarios.
4 See Exhibit 2 for an overview of the constraints considered in an economic potential scenario.
5 Generic adoption curves primarily consider two things: the current market penetration of the measure, and its simple payback. Based on these factors, the curves are applied to each measure to estimate generic participation rates as a percentage of economic potential.
6 This process includes selecting representative, high-impact measures and adjusting their generic participation rates using historical program data, local market knowledge, and industry insights/feedback, then extrapolating these calibrated participation rates to other similar measures within each sector.

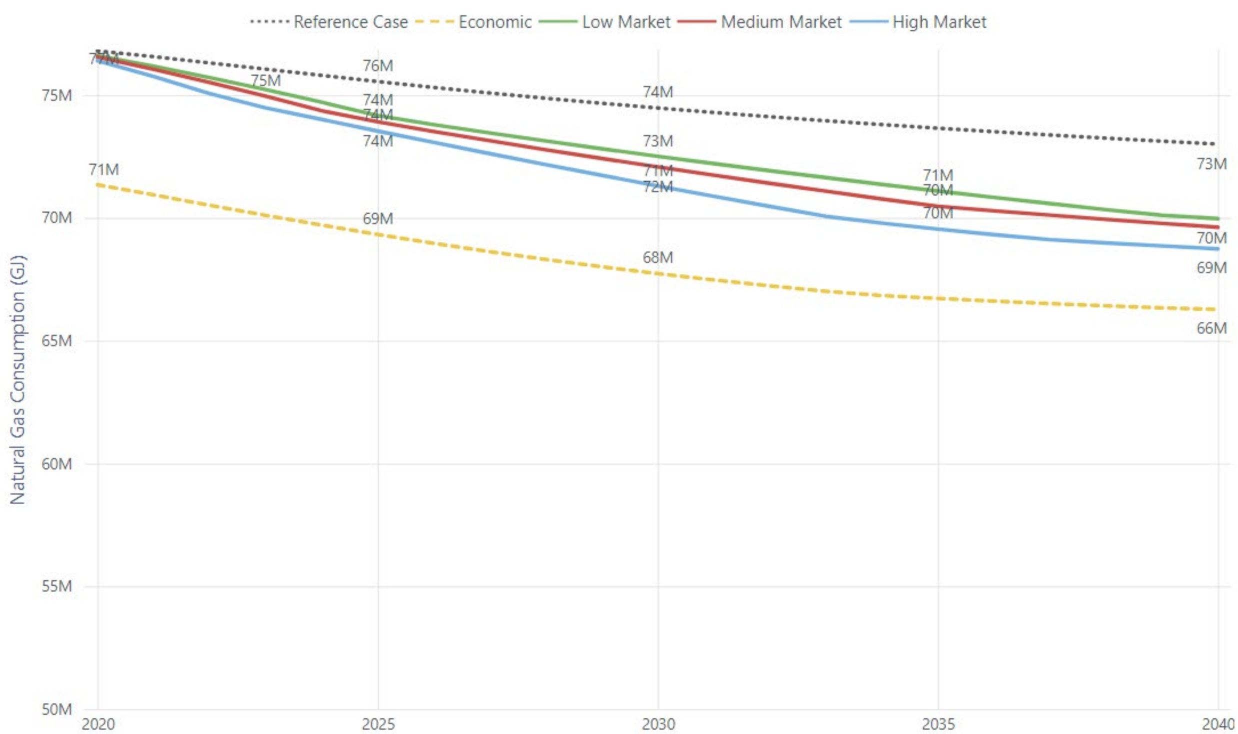
7. **Estimate other energy and non-energy benefits of the potential energy savings.**
    a. Greenhouse gas emissions savings.
    b. Impact of energy conservation measure investments and energy bill savings on provincial employment.

Results and Findings

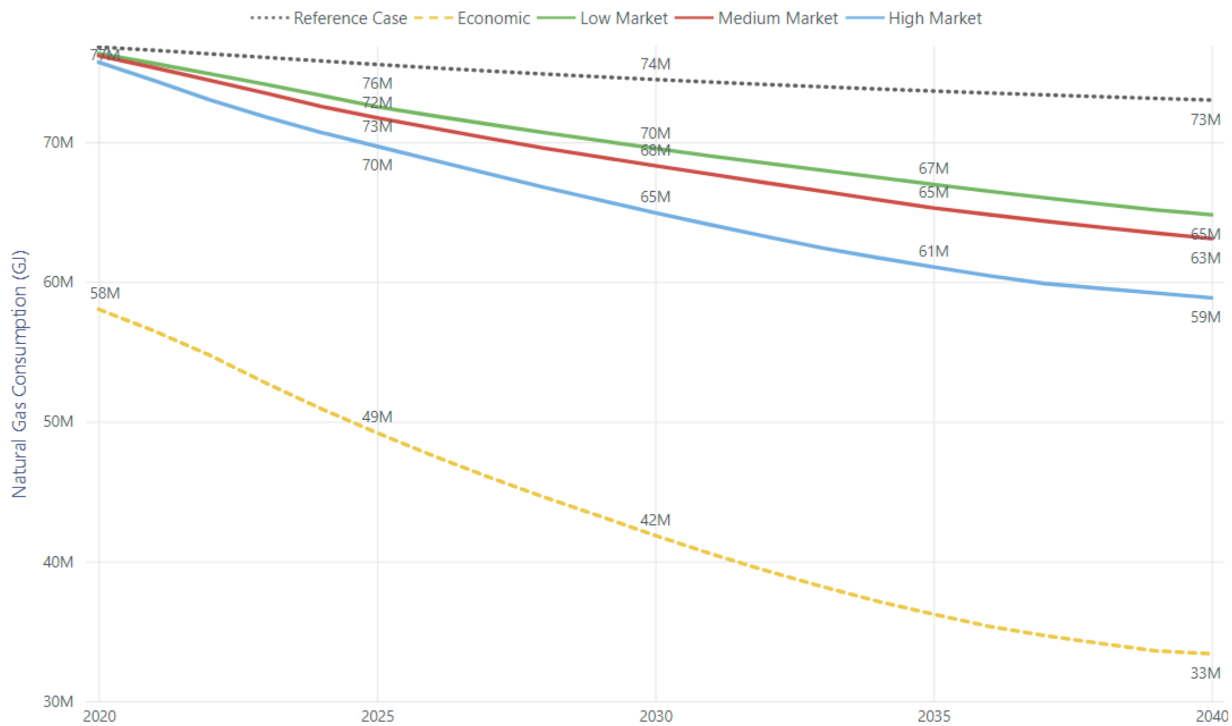
Residential

EX 2 (TRC) and EX 3 (MTRC) show the forecasted gas consumption under the three market potential scenarios for the commercial sector. The reference consumption is forecasted to drop to 73 PJ in 2040 from 77 PJ today. The residential low, medium, and high market TRC potential consumption levels are estimated to be 70 PJ, 69.6 PJ, and 69 PJ by 2040. For MTRC, the potential consumption levels are estimated to be 65 PJ, 63 PJ, and 59 PJ, respectively.

EX 2 – Market Potential Consumption (GJ) Forecasts – Residential, TRC



EX 3 – Market Potential Consumption (GJ) Forecasts – Residential, MTRC



EX 4 (TRC) and EX 5 (MTRC) show the incentive and non-incentive spending required to achieve the medium and high market potential. Medium and high market incentives are 50% and 100% of measures' incremental costs, respectively. The tables show the total and incremental savings from the new measures installed every year.

EX 4 – Medium and High Market Incentive Costs and Natural Gas Savings – Residential, TRC

Year	Medium Market Incentive Cost	Medium Market Non-Incentive Cost	Medium Market Total Costs	Medium Market Potential Savings (GJ)	Medium Incremental Savings (Year-over-Year, GJ)	High Market Incentive Cost	High Market Non-Incentive Cost	High Market Total Costs	High Market Potential Savings (GJ)	High Incremental Savings (Year-over-Year, GJ)

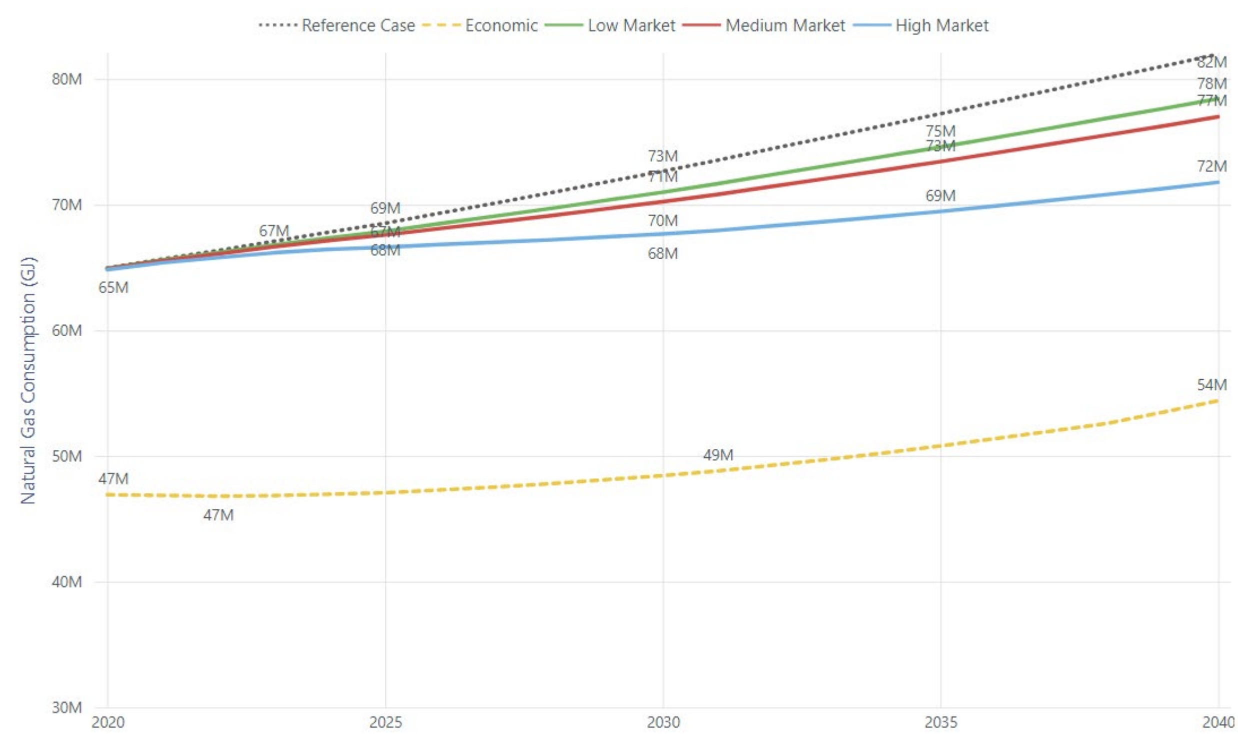
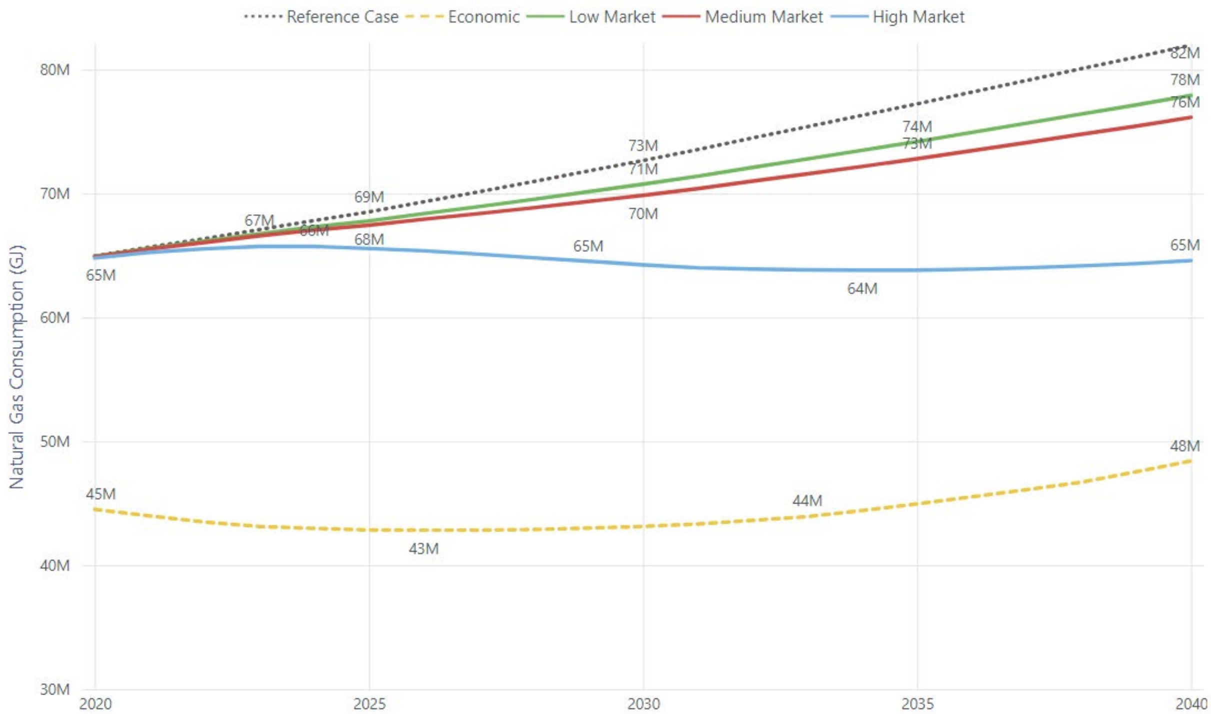
Commercial

EX 6 (TRC) and EX 7 (MTRC) show the forecasted gas consumption under the three market potential scenarios for the commercial sector. The commercial low, medium, and high market TRC potential consumption levels are estimated to be 78 PJ, 77 PJ, and 72 PJ by 2040, while reference consumption is forecasted to reach 82 PJ. The commercial low, medium, and high market MTRC potential consumption levels are estimated to be 78 PJ, 76 PJ, and 65 PJ by 2040, while reference consumption is forecasted to reach 82 PJ.

EX 6 – Commercial Market Potential Consumption (GJ) Forecasts – Commercial, TRC



EX 7 – Commercial Market Potential Consumption (GJ) Forecasts – Commercial, MTRC



The incentive and non-incentive spending in the MTRC scenario required to achieve the medium and high market potential are shown in EX 8 and EX 9. Medium and high market incentives are assumed to be 50% and 100% of measures' incremental costs, respectively. The tables show the total and incremental savings from the new measures installed every year.

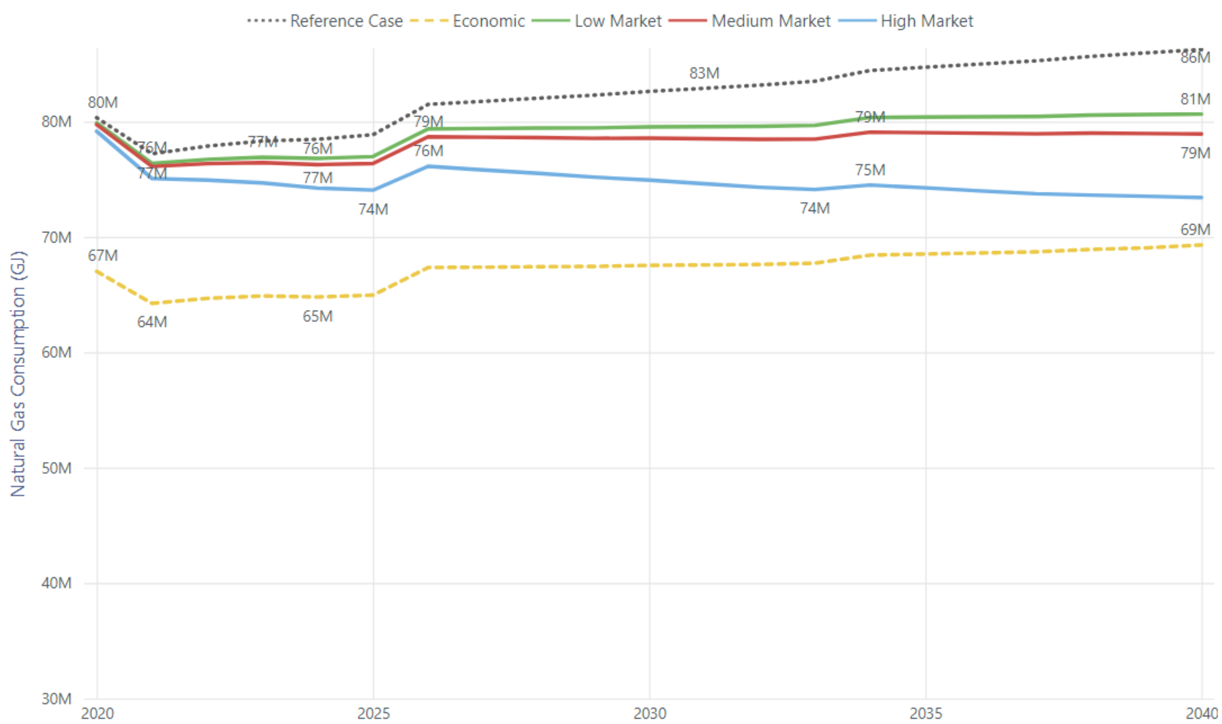
Industrial

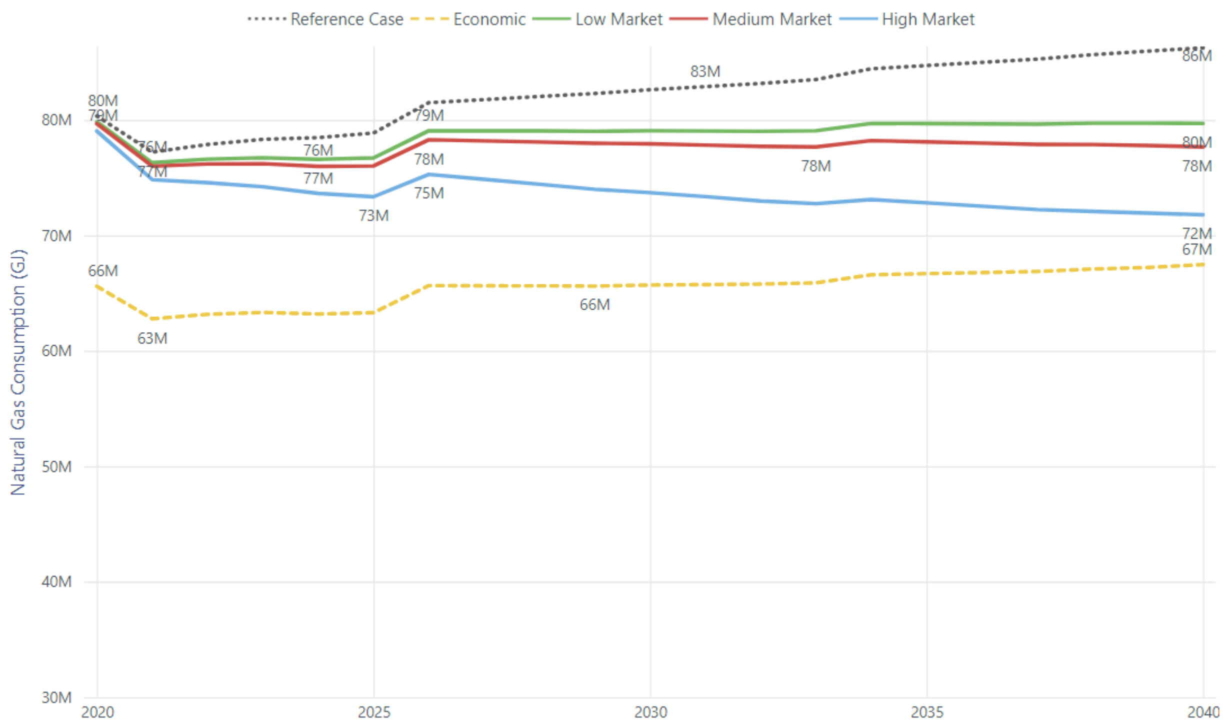
The market potential consumption results are shown in EX 10 and EX 11. The results for the TRC and MTRC screens appear quite similar because of the 39 measures included in the assessment, 34 pass the TRC and 38 pass the MTRC.

The industrial low, medium, and high market TRC potential consumption levels are estimated to be 81 PJ, 79 PJ, and 73 PJ by 2040, while reference consumption is forecasted to reach 86 PJ. The industrial low, medium, and high market MTRC potential consumption levels are estimated to be 80 PJ, 78 PJ, and 72 PJ, by 2040.

EX 10 – Market Potential Consumption (GJ) Forecasts – Industrial, TRC



EX 11 – Market Potential Consumption (GJ) Forecasts – Industrial, MTRC



EX 12 (TRC) and EX 13 (MTRC) show the incentive and non-incentive spending required to achieve the medium and high market potential. Medium and high market incentives are assumed to be 50% and 100% of measures' incremental costs, respectively. The tables show the total and incremental savings from the new measures installed every year.

EX 12 – Medium and High Market Incentive Costs and Natural Gas Savings – Industrial, TRC

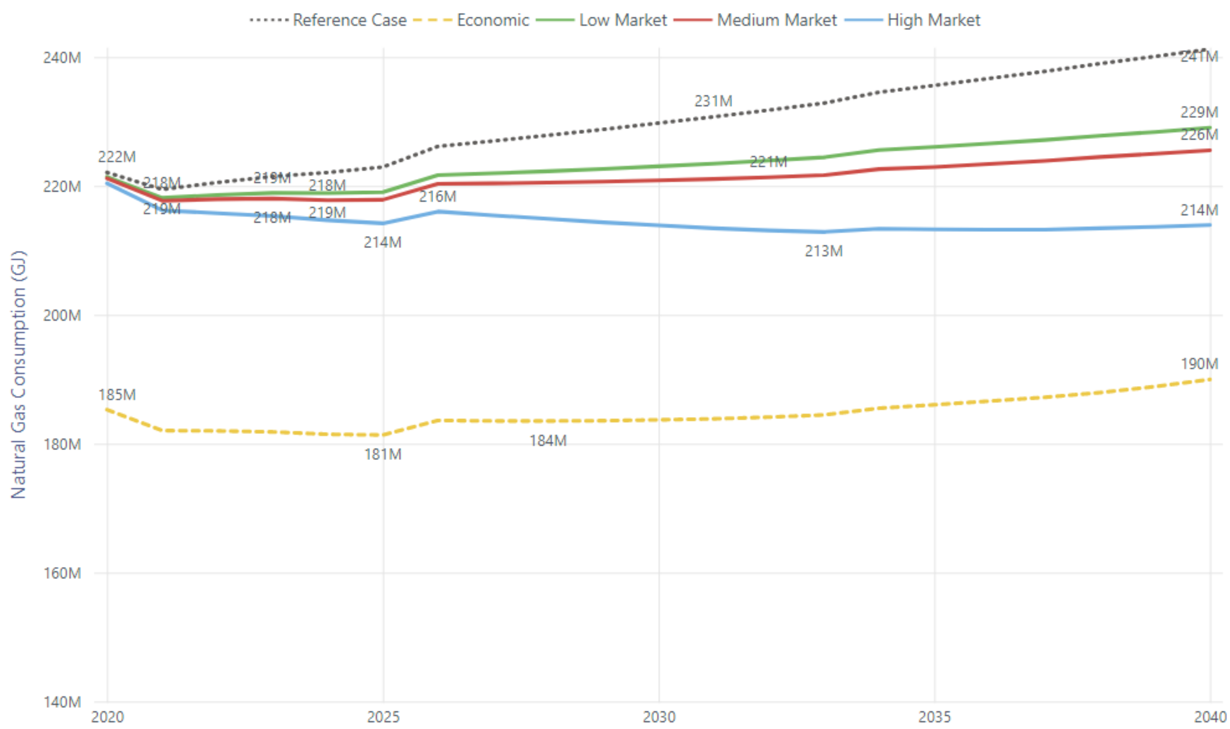
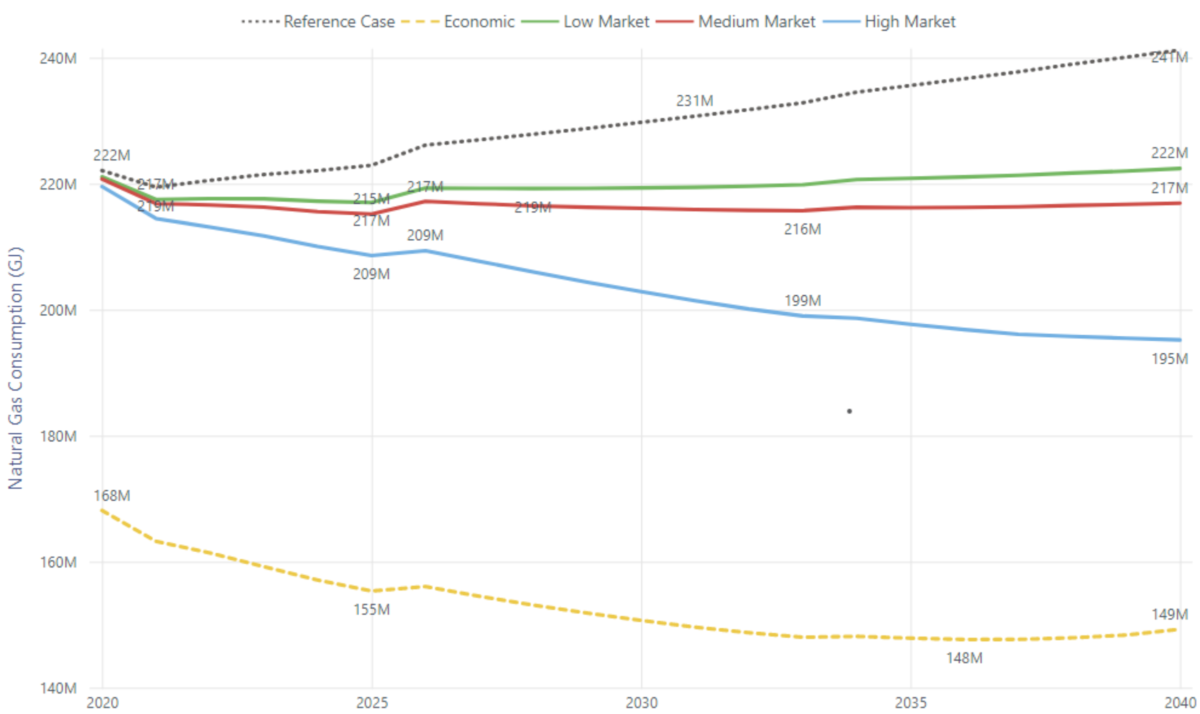
Portfolio

EX 14 (TRC) and EX 15 (MTRC) show the forecasted total natural gas consumption under the three market potential scenarios. The reference consumption is forecasted to increase to 241 PJ in 2040 from 222 PJ today. The total low, medium, and high market TRC potential consumption levels are estimated to be 229 PJ, 226 PJ, and 214 PJ. The low, medium, and high market MTRC potential consumption levels are estimated to be 222 PJ, 217 PJ, and 195 PJ.

EX 14 – Market Potential Consumption (GJ) Forecasts – All Sectors, TRC



EX 15 – Market Potential Consumption (GJ) Forecasts – All Sectors, MTRC

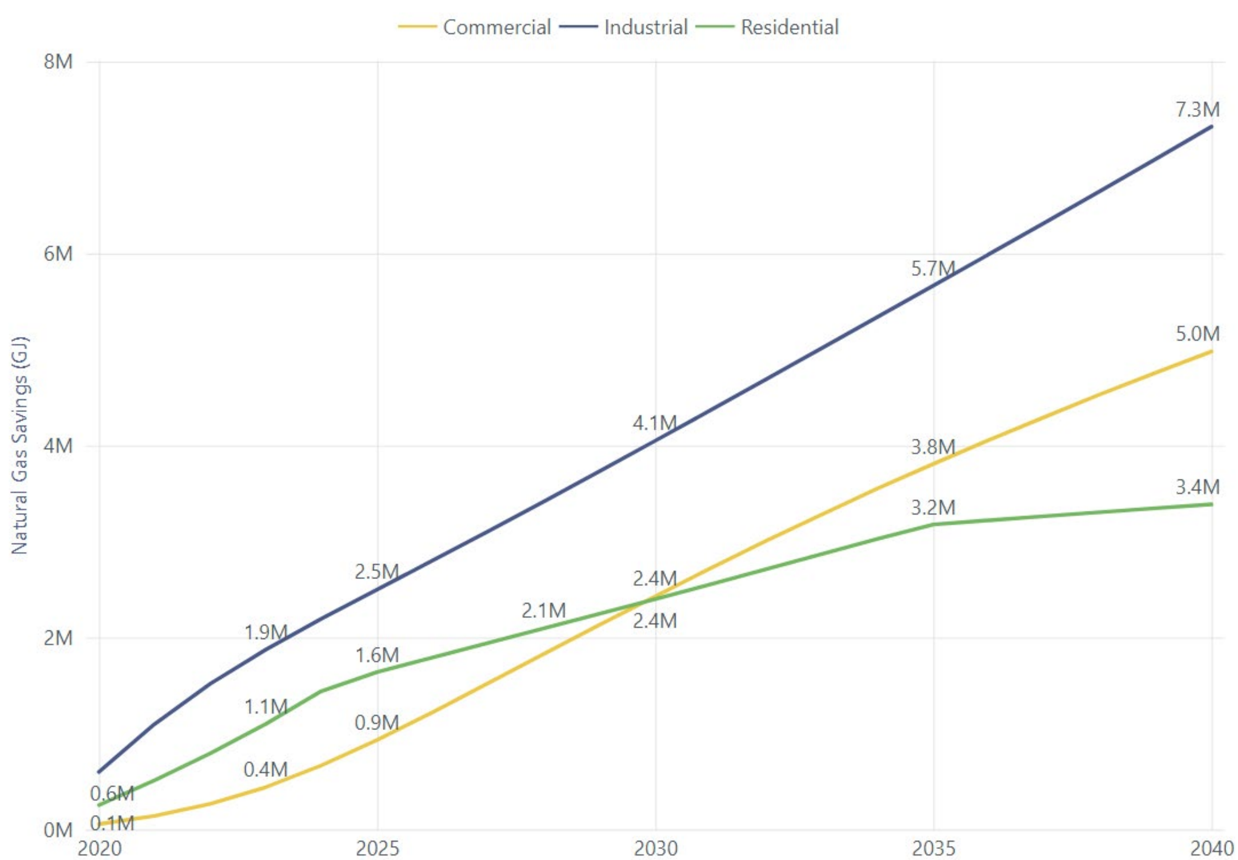


The medium market potential savings from the commercial, industrial, residential sectors are plotted together in EX 16 (TRC) and EX 17 (MTRC).

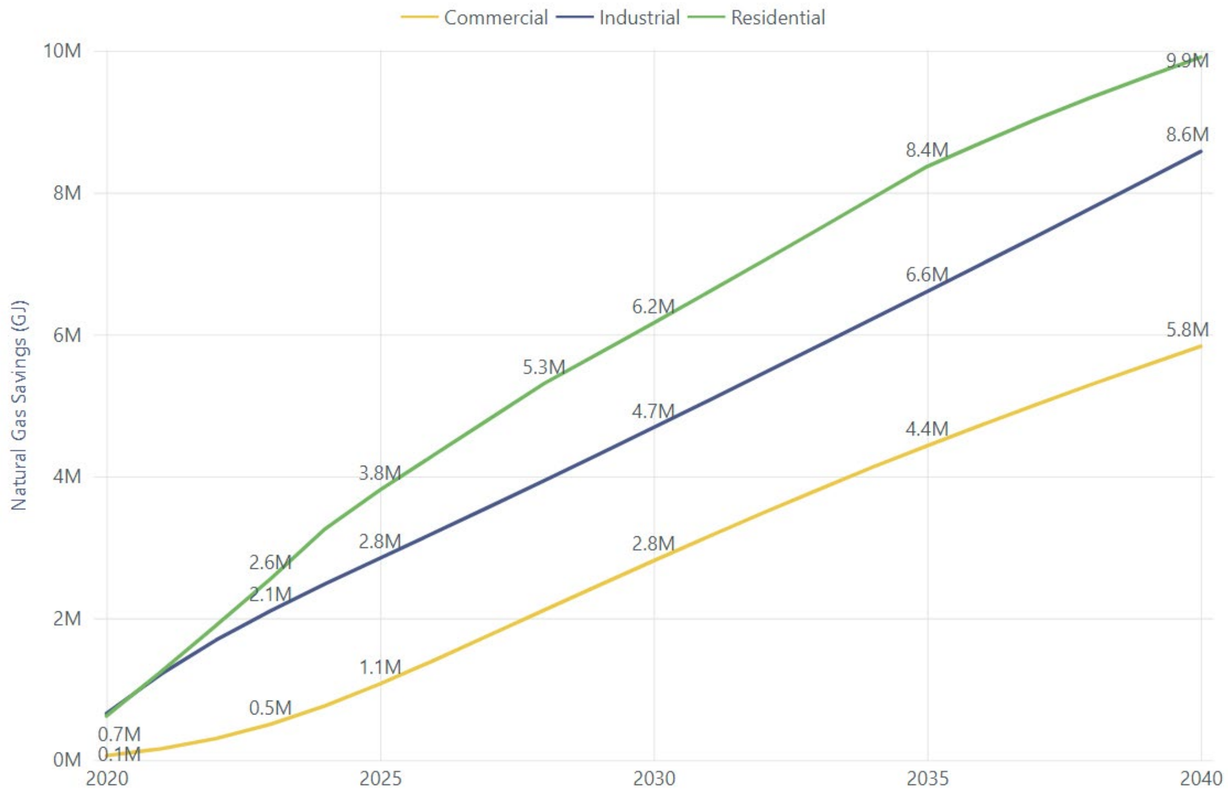
By 2025, the TRC medium market scenario for the industrial sector is expected to have the most savings potential, followed by residential and then commercial sectors. By 2030, the commercial sector overtakes residential. This is because there are only 14 residential measures that pass the TRC, and almost all of them are retrofit measures that can be implemented early in the study period. By 2040, potential savings from industrial, commercial, and residential sectors are estimated to be 7.3 PJ, 5.0 PJ, and 3.4 PJ.

Under the MTRC medium market scenario, the residential sector is estimated to have the most savings potential for the entire study period, followed by the industrial and then commercial. By 2040, potential savings from residential, industrial, and commercial sectors are estimated to be 9.9 PJ, 8.6 PJ, and 5.8 PJ.

EX 16 – Medium Market Potential Savings (GJ) – All Sectors, TRC



EX 17 – Medium Market Potential Savings (GJ) – All Sectors, MTRC



EX 18 (TRC) and EX 19 (MTRC) show the incentive and non-incentive spending required to achieve the medium and high market potential. Medium and high market incentives are assumed to be 50% and 100% of measures' incremental costs, respectively. The tables show the total and incremental savings from the new measures installed every year.

EX 18 – Medium and High Market Incentive Costs and Natural Gas Savings – All Sectors, TRC

Year	Medium Market Incentive Cost	Medium Market Non-Incentive Cost	Medium Market Total Costs	Medium Market Potential Savings (GJ)	Medium Incremental Savings (Year-over-Year, GJ)	High Market Incentive Cost	High Market Non-Incentive Cost	High Market Total Costs	High Market Potential Savings (GJ)	High Incremental Savings (Year-over-Year, GJ)

1 Introduction

1.1 Background and Study Goals

The 2021 Conservation Potential Review (CPR) is the review of energy efficiency opportunities available among FortisBC's residential, commercial, and industrial natural gas customers.

The CPR will support two of FortisBC Energy Inc's (FEI) major regulatory filings in 2022: the long-term gas resource plan (LTGRP) and the Demand Side Management (DSM) plan. For this CPR, Posterity Group (PG) reviewed estimated technical, economic, and market potential natural gas savings in FEI's service territory over a 20-year period. The CPR is an important guiding document for ongoing conservation and energy management program development and support at FortisBC.

FEI has also retained Posterity Group to produce the load forecast of natural gas demand of FEI's customers to support the 2022 LTGRP filing. The base year and reference case forecast developed by Posterity Group is common to both the LTGRP and CPR. As a result of the integrated nature of the two projects, the LTGRP project is frequently referenced in this document.

1.2 Report Organization and Results Presentation

This Report

The 2021 CPR has been prepared as <u>a single report that contains results for three sectors: residential, commercial, and industrial.</u> The report has been structured as follows:

Section 1 provides an overview of the CPR scope and definitions of key terms and acronyms.

Section 2 presents the overall steps taken and approach followed to complete this CPR. This section is applicable to all three sectors.

Section 3 presents the **residential** sector results. These include findings on base year and reference case energy forecasts, measure analysis, technical potential, economic potential, and market potential.

Section 4 presents the **commercial** sector results, following the same format as Section 4.

Section 5 presents the **industrial** sector results, following the same format as Section 4.

Section 6 presents aggregate portfolio-level results covering all three sectors. These include market potential, greenhouse gas emissions impacts, and employment impacts.

Presentation of CPR Potential Results

There are five deliverables included in the CPR report:

- **This report**, which presents the conservation potential results for the residential, commercial, and industrial sectors.
- **Method Appendices Document** that includes all method-related memos that were shared between the study and client team through the course of the project, compiled into a stand-alone document.
- **CPR Data Visualization Tool** that provides a dashboard built using Power BI, with access provided to the FortisBC project team and sector leads. During project execution, this

dashboard was used to facilitate detailed review of draft potential analysis outputs. In its final form, it can be used by FortisBC staff to explore output data for the purposes of DSM planning, program research and program design.

- **Market Potential Model Outputs** that include raw model output that has been organized into Excel workbooks with built-in tables and graphs and provided with this report. There are two workbooks per sector: one using TRC as the economic screen and one with MTRC.
- **Measure Analysis Workbooks** that provide final versions of the workbooks containing measure assumptions for each sector have been shared for reference.

1.3 Caveats and Limitations

Forecasting and modelling are a key part of this CPR study. Both activities require extensive research and more importantly, require assumptions, engineering estimates and the professional judgement of the study team. The study team strove to ensure that these assumptions are in line with the FortisBC team's knowledge of their customer base and are made with the best information available. However, given the nature of forecasting, the results in this report should be considered as estimates.

All potential scenarios in this report are estimated in relation to a "business as usual" reference case scenario. The CPR reference case incorporates FortisBC's account forecast, observed customer consumption trends, and industrial customer demand survey results. By incorporating these sources, the reference case implicitly includes the effects of current policy, but does not adjust for potential future policy changes. Scenarios with specific regulation/policy drivers, including high electrification, are not assessed within the scope of the CPR. High electrification scenarios have been modelled separately, in support of FortisBC's LTGRP.

2 Study Scope

This section defines some common terms used in this study and an overview of what is covered in this CPR.

2.1 Definition of Terms

Accounts – Number of FEI customer accounts. This report refers to 'accounts' rather than customers, as one customer could have multiple accounts.

Benefit/Cost Ratio – Expresses the attractiveness of a measure relative to its costs. A measure with a ratio of 1 or higher has benefits that outweigh its costs. For this study, two measure cost tests were used, both expressed as a Benefit/Cost ratio. These tests, the Total Resource Cost (TRC) test and the Modified Total Resource Cost Test (MTRC), are defined below.

Early Replacement – The act of replacing equipment prior to failure, while it has some remaining useful life. Contrast with "Replace on Burnout (ROB)", below.

End Use, Sub-End Use – The final purpose for which energy is being used. For example, space heating, domestic hot water (DHW), or industrial process heat. In the CPR model, end uses are occasionally further divided into smaller subcategories referred to as Sub-End Uses. For example, Residential DHW is further divided by into shower DHW, washer DHW, dishwasher DHW, and other DHW to facilitate analysis of measures that apply to a specific portion of the und-use energy.

Energy Conservation Measure (ECM, or Measure) – An equipment, technology, or a behavior that results in reduction of energy use in a dwelling, building, or facility.

Fuel Share – Ratio of a specific end use load that is met by a particular fuel. For example, if 90% of single-family dwelling space heating load is met by natural gas equipment, the natural gas fuel share for space heating in single-family dwellings is 90%.

Full Cost Measure – A measure whose benefit/cost ratio is evaluated on the basis of its full cost, as opposed to their incremental cost between the measure and a less-efficient "baseline" alternative. See "Retrofit (RET)" below for further explanation.

Gas-Heated Dwelling, Non-Gas-Heated Dwelling – In the residential sector, a dwelling that primarily uses gas for space heating heat (>50% of the fuel share for space heating) is considered a gas-heated dwelling. A dwelling that has a natural gas space heating fuel share <50% is considered a non-gas-heated dwelling. Gas-heated dwellings may have other fuels serving the space heating end use, but gas comprises at least 50% of the fuel share.

GJ – Gigajoule, or one billion joules. The unit of energy used by FortisBC for billing purposes.

Incremental Cost Measure – A measure whose benefit/cost ratio is evaluated on the basis of its incremental cost relative to a less-efficient alternative. See definition of "Replace on Burnout (ROB)" for further explanation.

Modified Total Resource Cost (MTRC) – A modified version of the TRC test that includes an alternate avoided cost and an adder for non-energy benefits. Per section 4(1.1)(a) of the province's DSM Regulation, the MTRC test incorporates the avoided cost of electricity – BC Hydro's marginal cost of acquiring electricity generated from clean or renewable resources, called the Zero Emission Energy Alternative (ZEEA) - rather than the marginal cost of new gas supply.

Participation or Participation Rate – The rate or percentage of buildings or end users that take part in a utility's program. This is a measurement of customer uptake of a measure and is an input to determine market potential.

Region – In this CPR, FEI's gas service territory is divided into six regions: City of Vancouver, Lower Mainland excluding Vancouver ("Lower Mainland x Vancouver"), Vancouver Island, Northern BC, Southern Interior, and Whistler.

Replace on Burnout (ROB) – One of two primary measure replacement types. Replace-on-burnout measures are typically time, labor, and cost intensive and are applied at the end of the useful life of the underlying equipment. For example, boiler replacements are typically evaluated as replace on burnout. ROB measures are typically evaluated on the basis of their incremental cost relative to a less-efficient, code-compliant alternative. Contrast with "Early Replacement", above and Retrofit (RET) below.

Retrofit (RET) – One of two primary measure replacement types. Retrofit measures are typically less costly measures that can be installed at any time. For example, a communicating thermostat or low-flow showerhead. RET measures are typically evaluated on their full costs. Contrast with "Early Replacement" and "Replace on Burnout (ROB)" above.

R-Value – A measure of a material's resistance to heat flow. In the context of building science, R-value is used to measure the effectiveness of insulation for building envelope components (e.g. attic insulation). The higher the R value, the better the measure's ability to insulate.

Saturation – For most end uses, Saturation is the extent to which an end use is present in a region, and segment. For some specific end uses that are associated with appliances, Saturation is defined as the average number of appliances per Unit.

Sector – Grouping or category of customers or buildings by customer type: residential, commercial, and industrial.

Segment – Grouping or category of buildings (e.g., single-family detached in residential, large offices in commercial). Segments reflect the main purpose of the building and helps to differentiate between energy use intensity or patterns across building types within a sector.

Simple Payback – The duration of time to recover the cost of a project based on cumulative savings, without taking into account the time value of money. In the context of energy conservation measures, savings are accrued based on the value of energy savings. Simple payback is calculated from the perspective of the end user and is presented as a number of years. For example, a measure that costs $600 and results in energy savings valued at $200 annually has a simple payback $600 / $200 = 3 years.

Size Factor – The change in average number of units per account. This is primarily used to reflect the forecast change in production volumes in industry.

Step Code – Compliance path in British Columbia Building Code (BCBC) for achieving energy efficiency in new construction beyond the minimum code requirements.

Stock Average Efficiency – Average efficiency of equipment serving the tertiary load for that end use.

Tertiary Load – The useful energy delivered to an end use. In the context of the CPR, tertiary load is the amount of energy required to be delivered as an end use service, for example, heat delivered by a furnace to a residential dwelling.

Total Resource Cost (TRC) – A metric for evaluating the cost-effectiveness of an energy conservation measure based on both the participants and utility's costs and benefits.

Unit Energy Consumption (UEC) – The amount of energy used by each end use per unit.

Units – The sector-specific unit of analysis: dwellings in the residential sector, square metres in the commercial sector, and production capacity in the industrial sector.

Vintage – A grouping of facilities based on their age.

2.1.1 Acronyms

BAS	Building Automation System
C&EM	Conservation and Energy Management
CCE	Cost of Conserved Energy
CEUS	Commercial End Use Survey
CPR	Conservation Potential Review
DHW	Domestic Hot Water
DIY	Do-It-Yourself
DSM	Demand Side Management
ECM	Energy Conservation Measure
EECAG	Energy Efficiency and Conservation Advisory Group
EUI	Energy Use Intensity
FEI	FortisBC Energy Inc.
GJ	Gigajoule
HE	High Efficiency
HVAC	Heating, Ventilation, and Air Conditioning
LTGRP	Long Term Gas Resource Plan
MUA	Make Up Air
NAICS	North American Industry Classification System
NEW	New Construction
O&M	Operation and Maintenance
PJ	Petajoule, i.e. 1 million gigajoules
RET	Retrofit
REUS	Residential End Use Survey
ROB	Replace-on-burnout
RTU	Remote Terminal Unit
TAC	Technical Advisory Committee
TMP	Thermomechanical Pulping – an industrial Pulp & Paper segment term
TRM	Technical Resource Manual
UEC	Unit Energy Consumption
ZEEA	Zero Emission Energy Alternative

2.2 CPR Coverage

2.2.1 Timing

The base year for the CPR Study is the 2019 calendar year. The reference case forecast is for 2020 to 2040. Results are calculated for each intervening year.

2.2.2 Regions

The CPR divides the FortisBC gas regions in British Columbia (BC) into six:

- City of Vancouver
- Lower Mainland excluding Vancouver ("Lower Mainland x Vancouver")
- Vancouver Island
- Northern BC
- Southern Interior
- Whistler

A segment is a grouping or category of buildings, such as a single-family Detached dwelling in Residential, or large offices in Commercial, for example. Segments reflect the main purpose of the building and help to differentiate between energy use intensity or patterns across building types within a sector.

2.2.3 Sectors, Segments, and End Uses

The 2021 CPR covers three sectors: residential, commercial, and industrial.[7] Each sector is unique and has important differences which are reflected in how inputs and outputs are organized. Please see the supporting Method Appendices Document for details of how the sector model was developed. Exhibit 1 presents the specific way each sector is organized into segments, energy end uses, and building vintages in the CPR model.

7 The LTGRP includes these three sectors as well as transportation.

Exhibit 1 – CPR Segments, End Uses, & Vintages by Sector

	Residential	Commercial	Industrial
Segments	• Single Family Detached/Duplexes • Single Family Attached/Row • Mobile/Other Residential	• Apartments – Medium • Apartments – Large • Food Retail • Hospital • Hotel – Medium • Hotel – Large • Non-Food Retail – Medium • Non-Food Retail – Large • Nursing Home • Office – Medium • Office – Large • Other Commercial • Restaurant • School – Medium • School – Large • University/College • Warehouse	• Agriculture (includes greenhouses[8]) • Chemical • District energy providers • Fabricated Metal • Food & Beverage • Other Manufacturing (includes transportation[9] and other industrial) • Mining • Non-metallic Mineral (includes cement) • Pulp & Paper – Kraft • Pulp & Paper – TMP • Utilities • Wood Products

8 Cannabis included in agriculture segment since there is not enough data at FEI to create a cannabis-specific forecast.
9 In the 2015 CPR, ‘transportation’ pertained to facilities that supported the transportation sector.

	Residential	Commercial	Industrial

End Uses[10]	• Clothes dryer
	• Cooking
	• Domestic hot water[11]
	  ○ Dishwasher DHW
	  ○ Washer DHW
	  ○ Shower DHW
	  ○ Other DHW
	• Fireplace
	• Other gas uses (outdoor fireplaces, patio heaters)
	• Pool & spa heaters
	• Space heating
		• Cooking
		• Domestic Hot Water
		• Other[12]
		• Pools, Spas & Hot tubs
		• Space Heating
			• Direct-fired heating
			• Direct Consumption of Gas in Process[13]
			• Heat Treating
			• Kilns
			• On-Site Power Generation[13]
			• Other[12]
			• Ovens
			• Petrochemical Refining and Process Heating
			• Process Boilers
			• Product Drying
			• Space Heating [includes HVAC air heating and HVAC boilers]
			• Water heaters

Vintages[14]	• Pre-1950 • 1950-1975 • 1976-1985 • 1986-1995 • 1996-2005 • 2006-2015 • Post-2015 (Existing) • New	• Existing • New	• Existing • New

10 All-electric end uses, such as clothes washer, lighting or plug loads, are not included in the reported results therefore are excluded from the End Uses row of this table.
11 In some cases, end uses are broken out into sub-end uses to facilitate CPR measure analysis. DHW can be reported at the end use or sub-end use level in the CPR.
12 The 'other' end use is a catch all for equipment that account for a small portion of consumption in the sector. In the commercial sector, examples of 'other' equipment are patio heaters and laundry dryers.
13 No CPR measures are applied to this end use; included for tracking purposes only.
14 The residential sector segments are divided into vintages that define time periods when residential dwellings were built. 'New' residential dwellings do not appear until the first year of the reference case.

3 Study Approach

This section presents the major steps that were taken to complete this CPR. Subsequent sections present the process for completing each CPR step in further detail.

For this study, Posterity Group developed a common base year and reference case model (steps 1 and 2 below) for the CPR and FortisBC's 2022 LTGRP.

3.1 Major CPR Analysis Steps

1. **Determine the current (Base Year) customer base and their energy consumption.**
    a. Collect and review data on the building stock in FortisBC's service territory, including end use surveys and previous CPRs.
    b. Develop energy use models of each building or facility type (segments) and model energy consumption by end use.
    c. Collect and review actual base year (2019) energy use and billing data of FortisBC's customers.
    d. Use the billing data to calibrate the base year energy consumption in each sector's energy model.
2. **Develop reference case energy consumption forecast.**
    a. Collect and review data on all factors that will affect energy use trends over the study period (2020 to 2040 in this study's case).
        i. This includes analyzing and modelling natural improvements in building energy use intensities (e.g. from natural replacement of furnaces with new, higher efficiency ones at replacement time).
        ii. Other factors are existing building demolition / renovation trends, rate of new building stock construction, baseline energy efficiency of new buildings and equipment, and known changes to policies and codes and standards that will impact the energy use of buildings.
    b. Use this data to develop an energy consumption forecast model for each sector.
    c. Calibrate the reference case based on FortisBC's own account forecasts and industrial survey information at the region and rate class level.
3. **Characterize energy conservation measures.**
    a. Select a set of energy conservation measures for each sector. Measures range from mature, widely known measures that are currently part of FortisBC's program portfolio (e.g. commercial condensing boilers) to innovative or enabling technologies (e.g. smart residential water heater controllers). Behavioural measures are also considered (e.g. thermostat setback).
    b. For each measure, review and collect data on energy savings, costs, useful life, and the baseline equipment or technology that it should be compared with (if applicable).
    c. Use the data to characterize the technology's energy savings potential, cost-effectiveness, and financial attractiveness.

   d. Use the data as inputs to the energy model for each sector.

4. **Estimate technical savings potential.**
   a. For each measure, determine its technical applicability (i.e. how many buildings or facilities can this measure be applied to, considering only technical barriers).
   b. Determine the measures' current market penetration (i.e. how many buildings or facilities have already installed a measure).
   c. Estimate the measures' reference adoption – their natural rate of uptake in the absence of incentives or utility program intervention.
   d. Input all data into the energy model for each sector and develop a hypothetical estimate of the technically feasible energy savings potential within FortisBC's service territory.[15]
5. **Estimate economic savings potential.**
   a. Screen each measure for cost-effectiveness from FortisBC's perspective by determining whether the benefit to cost ratio of each measure is 1.0 or above (pass) or if it is below 1.0 (fail) for two cost effectiveness tests: TRC and MTRC.
   b. Update the technical potential model with only the TRC-passing measures, removing measures that are not cost-effective.
   c. Estimate the economic savings potential of all cost-effective measures applied to all technically feasible buildings in the customer base.[16]
   d. Repeat steps 5b and 5c using the MTRC screen. This study presents findings from two economic (and subsequent market potential) models: One with TRC as the economic screen and one with MTRC.
6. **Estimate market savings potential.**
   a. Based on existing research, develop sets of "generic" adoption curves based on customer payback acceptance and typical market diffusion patterns.[17]
   b. Apply these generic curves to each measure in the economic potential model to develop "simplified market potential" estimates at the measure level.
   c. This data is input into the TRC economic potential model to develop a simplified market potential.
   d. Develop a more realistic market potential for each measure by soliciting feedback from FortisBC and its external stakeholders on the simplified market potential.[18]

---

15 See Exhibit 2 for an overview of the constraints considered in the technical potential scenario, and the difference between different potential scenarios.
16 See Exhibit 2 for an overview of the constraints considered in an economic potential scenario.
17 Generic adoption curves primarily consider two things: the current market penetration of the measure, and its simple payback. Based on these factors, the curves are applied to each measure to estimate generic participation rates as a percentage of economic potential.
18 This process includes selecting representative, high-impact measures and adjusting their generic participation rates using historical program data, local market knowledge, and industry insights/feedback, then extrapolating these calibrated participation rates to other similar measures within each sector.

e. Revise the simplified market potential model based on this feedback to develop a realistic market potential scenario (referred to in this study as "medium market potential").
f. Perform sensitivity analysis by varying incentive levels to model "low" and "high" market potential scenarios.
g. Repeat steps 6c to 6f using the MTRC economic potential model to estimate low, medium, and high market potential scenarios using the MTRC economic screen.

7. **Estimate other energy and non-energy benefits of the potential energy savings.**[19]

a. Greenhouse gas emissions savings.
b. Impact of energy conservation measure investments and energy bill savings on provincial employment.

---

19 Due to uncertainty regarding measure-level impacts on regional and system peak demand, detailed analysis of the system peak impacts from energy efficiency measures has not been undertaken as part of the CPR.

POSTERITY GROUP

Exhibit 2 – Difference Between Technical, Economic, and Market Potential

Constraints	Description	
Technical applicability	Is the measure compatible with the current systems in place in the building or facility? Are there any technical constraints that will prevent installation in specific buildings or facilities? If not, then the measure's hypothetical energy savings can be included in the technical potential. Example: If this is a furnace-related measure, do I have a forced air heating system in my building?	Technical Potential
Cost-Effectiveness	In addition to the technical constraints above: From the utility's perspective, are the energy savings that result from installing the measure financially attractive? Do they provide a return on investment (i.e., the capital and installation costs) based on the economic screen the utility is required to use? If yes, then the measure's hypothetical energy savings can be included in the economic potential.	Economic Potential
Market-related	In addition to the technical and economic constraints above: Are there any constraints related to the market, logistics, or the target customers? Is the measure readily available in the market? Are customers aware of the measure? Realistically, how many customers will have the willingness or interest to install the measure given its costs and benefits? How would the customers' willingness change if the incentives to install these measures increased?	Market Potential *(this study's ultimate objective)*
Utility-related *(out of scope for this study, as this is typically a program design activity)*	In addition to all the constraints above: What are the utility's constraints around encouraging the uptake of this measure? How much budget does the utility have to spend on a program and incentives for a measure? How many resources can a utility allocate to delivering a program realistically?	Program Potential

3.2 Base Year Energy Use Model Development

The CPR model is developed in the following sequence for each sector:

- Base Year (2019): the first year of a forecast period and is based on historical data provided by FEI.
- Reference Case (2020-2040)[20]: forecast of natural gas consumption over a twenty-year (2020-2040) period based on exogenous conditions that follow a "business-as-usual" scenario.

The base year and reference case was modelled for each sector using Posterity Group's Navigator™ Energy and Emissions Simulation Suite. This section provides an overview of the model structure and the process to develop the base year and reference case.

Exhibit 3 defines the six parameters that provide the structure for the model used for the CPR.[21]

Exhibit 3 – 2021 CPR Model Parameters

Parameter	Definition
Accounts[22]	Number of FEI customer accounts.
Units	The basis for how energy consumption is expressed. The unit of analysis is unique to each sector: dwellings in the residential sector, square metres in the commercial sector and production capacity in the industrial sector.
Size Factor	The change in average number of units per account. This is primarily used to reflect the forecast change in production volumes in industry.
Saturation	For most end uses, saturation is the extent to which an end use is present in a region, and segment.[23] For some specific end uses that are associated with appliances, Saturation is defined as the average number of appliances per Unit.
Fuel Share	The percentage of the energy end use that is supplied by each fuel.
Unit Energy Consumption (UEC)	The amount of energy used by each end use per unit.

20 Note that the LTGRP forecast period is 2020-2042. The LTGRP will not be filed until 2022 and requires a twenty-year reference case.
21 Some of the model parameters are adjusted when necessary to reflect a distinct characteristic of a sector. Any adjustments are explained in this document.
22 PG uses 'accounts' instead of customers in this document as one customer could have multiple accounts.
23 A segment is a grouping or category of buildings (e.g., single-family detached in residential, large offices in commercial). Segments reflect the main purpose of the building and helps to differentiate between energy use intensity or patterns across building types within a sector.

Once each parameter of the model is populated with the applicable data, energy consumption is calculated for a specific end use for each region, segment, and vintage each year using the following equation:

$$Consumption = Units * Saturation * Fuel\ Share * Unit\ Energy\ Consumption$$

Exhibit 4 presents the detailed steps that the team took to calibrate the base year energy consumption in the CPR model with FortisBC's actual customer energy use.

Exhibit 4 – Base Year Calibration Steps for All Sectors

Step	Description
1	Compile and analyze available data on FortisBC's existing building stock by segment, including consultation of Residential End Use Survey (REUS), Commercial End Use Survey (CEUS) and relevant third-party data.
2	Develop detailed technical descriptions of the existing building stock at the subsector, end use, and end use equipment level. For each sector, detailed regional and subsector assumptions regarding fuel shares, end use penetrations, equipment saturations and equipment efficiency levels are aggregated in Excel workbooks as inputs into the Navigator™ model under step 4.
3	Compile utility billing data by subsector and region.
4	Create sector model inputs and generate preliminary results.
5	Adjust input assumptions for end uses with greater uncertainty until the results closely match the actual utility billing data.

The results of the base year energy consumption model are presented in Section 4.2 (residential), Section 5.2 (commercial), and Section 6.2 (industrial).

3.3 Reference Case Forecast Development

As explained in Section 3.2 Base Year Energy Use Model Development, the reference case begins with the base year values and forecasts natural gas use based on exogenous conditions that follow a "business-as-usual" scenario. The reference case for the CPR is intended to represent the baseline from which calculation of new potential can be calculated. It considers current energy consumption patterns and known future changes, including expected customer growth, current and known future changes to codes and standards, and natural replacement of equipment at end of life. The reference case does not account for potential changes in fuel share or end use saturations, except those that would occur incidentally because of different rates of new construction for different types of buildings or in the different regions.

The reference case starts with actual 2019 consumption, which includes all DSM activity up to that point. The subsequent years of the reference case incorporate natural conservation, such as the natural turnover of furnaces and other appliances. It does not include conservation from DSM activities carried out after 2019.

Exhibit 5 – Reference Case Development Steps for All Sectors

Step	Description
1	Compile and analyze available data on FortisBC's new building stock by segment and gather forward-looking estimates of demolition rates.
2	Develop detailed technical descriptions of the new building stock at the subsector, end use, and equipment level.
3	Compile data on forecast levels of construction, demolition and natural (non-utility-influenced) efficiency within the existing and new (post 2020) buildings stock.
4	Create sector model inputs and generate gas use forecasts by adding accounts to match forecast construction levels in cooperation with FortisBC Load Forecasting staff.

The results of the reference case energy consumption forecasts are presented in Section 4.3 (residential), Section 5.3 (commercial), and Section 6.3 (industrial).

3.4 Measure Characterization

In this CPR activity, energy conservation measures were selected and analyzed. The team started with developing a list of measures to consider, then finalized this list in collaboration with FortisBC and external stakeholders. For each measure, the team collected and reviewed information on energy savings, costs, useful life, and the baseline equipment or technology that it should be compared with (if applicable). This data was used to characterize the technology's energy savings potential, cost-effectiveness, and financial attractiveness to the utility and the end user.

3.4.1 Development of Measures List

Under this task, the study team reviewed existing energy efficiency measure analysis and program assumptions, assessed gaps and developed a measure list for input by FortisBC staff.

The team started by reviewing the 2015 CPR measure analysis, existing FortisBC Conservation and Energy Management (C&EM) program assumptions, and publicly available resources, especially Technical Resource Manuals (TRMs) from other utilities. Previous measure analysis and prefeasibility studies completed by FortisBC were also reviewed.

Measures range from mature and widely known to innovative or enabling technologies. Several behavioural measures (e.g. thermostat setback) are included as well. The team also developed "mature market" versions of several innovative technologies, such as gas heat pumps. These mature market measures assumed that within two to five years, various measures that are currently at an early stage of market entry would have lower costs, improved energy performance, or both. This approach allowed the study team to include these measures in subsequent analysis at a point after the first forecast year (2020) consistent with best estimates of market entry.

The study team solicited feedback on the measures list from both FortisBC as well as external stakeholders, the CPR Technical Advisory Committee (TAC). Ultimately, more than 180 measures were shortlisted for inclusion in this CPR: 70 in residential, 72 in commercial, and 40 in industrial. For comparison, the 2015 CPR included 97 measures: 45 residential, 36 commercial, and 16 industrial.

3.4.2 Energy Performance and Costs of Selected Measures

Under this task, the study team collected and reviewed information on each selected measure's energy savings, costs, useful life, and other relevant information. The analysis used several types of data sources to gather and establish this information: FortisBC's TRMs, previous FortisBC measure analysis (e.g. 2015 CPR, pre-feasibility studies), TRMs and literature from other jurisdictions, as well as the study team's own technical analysis and building modelling.

Using a typical FortisBC TRM template as guidance, the team developed one Excel-based measure analysis workbook per sector in which all measure data was recorded. The intent of these workbooks was to have each measure's metrics and assumptions easily reviewable, referenceable, and reusable by the FortisBC team. Exhibit 6 shows an example of a measure from the workbook.

Measures were characterized in a way that was consistent with FortisBC's measure TRM templates:

- Type of replacement (Retrofit or Replace on Burnout)
- Cost basis on which the measure should be evaluated – full or incremental
- Energy performance metrics and savings (% against end use and absolute)
- Technical applicability to various segments and / or vintages

- Cost of Conserved Energy (CCE) and simple payback metrics
- Cost-effectiveness on TRC and MTRC scales
- Ability to enter previous program results and customer enrollment (participation) rates, specific regional and segment subtleties

Exhibit 6 – CPR Measure Characterization Workbook Example: Residential Communicating Thermostat

MEASURE SUMMARY		NOTES	DATA SOURCES
Measure Description	Installation of a communicating (also often referred to as "smart," advanced, wi-fi or connected) thermostat to replace a manually operated or conventional programmable thermostat. Thermostat must be on the ENERGY STAR® list of Smart Thermostats and be able to: - Work as a basic thermostat in absence of connectivity to the service provider. - Give residents some form of feedback about the energy consequences of their settings. - Provide information about HVAC energy use, such as monthly run time. - Provide the ability to set a schedule. - Provide the ability to work with utility programs to prevent brownouts and blackouts, while preserving consumers' ability to override those grid requests.		
Measure Type	Controls		
Baseline Condition Description	The baseline condition is an assumed mix of manual and programmable thermostats.		
Calculation Method Description	Space heating and cooling savings estimated based on review of MN and Mid-Atlantic TRMs assumptions for ENERGY STAR® qualifying communicating thermostats. Also reviewed FortisBC's SLT pilot study results. See general notes and sources section below for additional details.		
Measure Applicability	Applies to existsing homes where a manual or programmable thermostat previously existed.		

APPLICABILITY					
Affected Natural Gas End-Uses	Space Heating				You can select up to 2 end-uses affected by this measure. Leave second one blank if not
Affected Electricity End-Uses	Space Cooling				You can select up to 2 end-uses affected by this measure. Leave second one blank if not
Applicable Codes / Standards	n/a				
Meets DSM Definition	Yes				
Meets Tech Innovation Definition	Yes				
Applicable Years	**First:**	2020	**Last:**	2040	

MODEL INPUT ASSUMPTIONS				
Measure Specifications	**Base Case**	**Upgrade Case**	**Notes**	**Data Sources**
Effective Useful Life (years)	12	12	FortisBC's EUL estimate is high compared to other TRMs (e.g., Mid-Atlantic TRM states 7.5 years, MN TRM states 10 years). 12 years is still in a reasonable range, so did not change it.	1, 6, 7

RESULTS (SPECIFIC TO A GIVEN REGION, SEGMENT AND VINTAGE)			
Region	Whistler	Segment Sheet Row #	Change the selections in light blue to see the results specific to a region, segment and vintage.
Segment	SFD/Duplex	82	
Vintage	Post-2015	Comm T-Stat - Segment	

Costs	**Base Case**	**Upgrade**	**Increme**	**Units**	**Notes**	**Data Sources**
Capital	$ -	$ 250	$ 250	per thermostat	FortisBC's estimate of $250 per connected thermostat seems reasonable compared to costs listed in other TRMs.	1, 6, 7
Installation	$ -	$ -	$ -	per thermostat		
O&M	$ -	$ -	$ -	per thermostat		

Energy Savings (%)	**Space Heating**	**Notes**	**Data Sources**
Natural Gas (%)	6%	Estimating 6% savings based on MN and Mid-Atlantic TRMs.	1,7
	Space Cooling		
Electricity (%)	8%	Estimating 8% savings based on MN and Mid-Atlantic TRMs.	1,7

Energy Use (Absolute)	**Base Case**	**Upgrade**	**Saving**	**Units**
Natural Gas	51.9	48.8	3.1	GJ /year
Electricity	515.3	474.1	41.2	kWh /year
Water	-	-	-	m3 /year

Financial Metrics		**Units**
Simple Payback	8.86	years
NPV of Avoided Utility Costs (TRC)	244.94	$ / yr
NPV of Avoided Utility Costs (mTRC)	897.46	$ / yr
Cost of Conserved Energy (CCE)	6.69	$ / GJ

Cost Effectiveness		**Units**
Measure TRC	1.0	total
Measure mTRC	4.1	total

The final measures and their information can be found in Section 4.4 (residential), Section 5.4 (commercial), and Section 6.4 (industrial).

3.5 Technical Potential Forecast Development

The technical potential forecast includes the installation of all conservation measures that are technically feasible. This exercise is hypothetical in nature and is used to provide the team with a starting point on which to develop the economic and market potential. Refer to Exhibit 2 for an overview of the differences between the potential scenarios.

Technical potential estimates ignore all non-engineering and financial constraints, such as cost-effectiveness and the willingness of end users to adopt measures. This is done to estimate the theoretical maximum amount of energy use that could be captured by energy efficiency measures. In this study, the following assumptions were made:

- Retrofit (RET) measures that are technically feasible are applied immediately (that is, in the first year of CPR study period, 2020).
- Replace on burnout (ROB) measures that are technically feasible are implemented at the rate of failure of the underlying baseline equipment, to better match in-market replacement rates. However, there are ROB measures that have “Early Replacement” versions (e.g. early replacement of a commercial boiler) that are treated the same way as RET measures.
- New construction measures that are technically feasible are implemented immediately as new buildings are added to the stock each year.

Development of the technical potential involved the following steps:

- Select the measures to be included from the Measure Analysis Workbook.
- Determine each measure’s technical applicability (i.e. what portion of buildings can a measure be applied to considering only technical constraints) and current market penetration (i.e. what portion of buildings have already installed a measure).

  This information is gathered from various data sources and literature review, including FortisBC’s Residential End-Use Survey (REUS), Commercial End-Use Survey (CEUS), and industrial datasets. The percentage of technically applicable customers that have already adopted a measure are excluded from the technical potential.
- Estimate reference adoption – the natural rate of adoption of a measure. For example, if 2% of the technically eligible customers are expected to implement a measure each year without any utility intervention, reference adoption is 2%. These customers are excluded from the technical potential.
- Apply measure information to the model. For each measure, the following inputs are required: measure’s description, the baseline equipment it affects, incremental or full costs, energy savings information, the total proportion of accounts or dwellings under different segments and vintages that the measure is applicable to, and the pre-retrofit and post-retrofit energy consumption.
- Determine the order that measures should be applied against the baseline energy end-use, and whether these measures are applied in series (in which case measure impacts

"cascade") or in parallel (in which case measure impacts are directly additive). This is an important feature of Posterity Group's modelling software that serves two purposes:

- It avoids overestimation and double counting of savings in instances where measures are not additive. For example, assume there is a reference-case house that uses 100 GJ of natural gas for the space heating end use. An air sealing measure is applied to this house, and it is expected to save 20% of space heating energy. A communicating thermostat can also be installed – it is expected to save 5% of total remaining space heating natural gas use.
- If both measures are applied to the same house, the air sealing measure would reduce the overall heating load, reducing the absolute potential savings for the thermostat. In other words, the thermostat saves 5% of 80 GJ (post-air-sealing consumption), not 5% of 100 GJ. Total natural gas savings in this example are 20 GJ + 4 GJ = 24 GJ.
- It avoids applying two mutually exclusive technologies to the same building. For example, a typical single-family house can be upgraded to a new high-efficiency furnace, or a new high-efficiency boiler, but almost never both. Additionally, there are many upgrade measures that apply to the same end use and baseline equipment. The model's cascade feature ensures that only one appropriate upgrade measure is applied to an eligible account or building.

- Run the model to calculate technical potential – this includes savings from all retrofit measures that can be immediately applied, savings from replace-on-burnout measure at their natural rate of replacement, and savings from new construction measures.

The results of the technical potential forecasts can be found in Section 4.5 (residential), Section 5.5 (commercial), and Section 6.5 (industrial).

3.6 Economic Potential Forecast Development

Economic potential is the subset of technical potential that is financially cost-effective. Cost-effectiveness is determined by screening each measure with the benefit/cost ratio test required by the utility's regulatory authorities. Economic potential considers the cost of the efficiency measures themselves, ignoring market constraints and programmatic barriers. Using economic screening, measures that have a benefit/cost ratio of greater than 1.0 under either the Total Resource Cost Test (TRC) or modified TRC (MTRC) "pass" the screening test and are included in the economic potential. Measures that score below 1.0 are not considered cost-effective and are excluded from future analysis.

Retrofit (RET) measures are evaluated on the basis of their full costs including capital, labor and maintenance costs. This is because the baseline for a retrofit measure is typically "do-nothing": the customer has the option to not install the measure, in which case they would not incur any costs.

Replace on burnout (ROB) measures are evaluated on the basis of their incremental costs – the cost difference between the high-efficiency measure versus the baseline, less-efficient option. This is because the baseline for a replace on burnout measure is typically "do something" because the underlying base equipment has reached the end of its useful life.

New construction measures were also evaluated based on their incremental costs.

Two economic models were developed for each sector – one with TRC as the economic screen and one with MTRC.

Development of the economic potential scenarios involved:

- Determining how measures should be assessed based on their replacement type: retrofit (immediate replacement at full cost), replace on burnout (end of life replacement at incremental cost), or new construction (immediate installation at incremental cost).
- Running the technical potential model using the TRC economic screen – this produces the subset of measures that are cost-effective in terms of TRC (i.e. they have a TRC benefit/cost ratio 1.0 or higher).
- Rerunning the technical potential model using the MTRC economic screen – this produces the subset of measures that are cost-effective in terms of MTRC (i.e. they have an MTRC benefit/cost ratio of 1.0 or higher).

The results of the economic potential forecasts are presented in Section 4.6 (residential), Section 5.6 (commercial), and Section 6.6 (industrial).

3.7 Market Potential Forecast Development

Market potential refers to the subset of the economic potential that is likely to be realized based on expected customer uptake. To be included in the market potential forecasts, customers must have the knowledge of various measures that are economically attractive to the utility and must have the willingness and means to adopt them.

The Low, Medium, and High market potential scenarios in this CPR estimate how customers' adoption rates would change as the simple customer payback varies based on varying incentive levels.

For this study, the market potential forecast was developed in two phases: first a Simplified Market Potential was developed using standard relationships between measure awareness, customer payback and measure uptake. Next, that simplified model was refined based on input from FortisBC staff, local market experts and other external stakeholders to develop a FortisBC-specific Market Potential.

Development of the market potential involved the following steps:

- Develop Simplified Market Potential.
  - At the measure level, this potential estimate was based on standard curves estimating the relationship between measure awareness, measure payback, and measure uptake consistent with the approach taken in the 2015 CPR.
  - Analysis included the development of a library of payback-acceptance and market diffusion curves, and their application to each measure based on attributes such as capital cost and reference market penetration.
  - These curves were then applied at three incentive levels: 25% 50%, and 100% of incremental cost to develop generic measure participation rates at the three spending levels.
- Market Potential Consultation and Workshops.

  This step consisted of two workshops for each sector:
  - Three sector-specific workshops engaging FortisBC Conservation & Energy Management program personnel, discussing and gathering input on the Simplified Market Potential participation rates based on prior program experience and known barriers and factors promoting uptake.
  - Three subsequent workshops attended by both FortisBC staff and members of Fortis BC's CPR Technical Advisory Committee[24] aimed at gathering external input on the Simplified Market Potential participation rates based on local market knowledge and capacity.

24 The Technical Advisory Group was made up of various external stakeholders including industry professionals, environmental nongovernmental organization representatives, and municipal/provincial government staff, and industry organization representatives.

- **Develop Market Potential.**
  - Based on the results of these consultations, updated measure uptake assumptions were developed and re-run through the model. This produced a Market Potential, meant to be the "expected" outcome from DSM programs at a typical incentive level (50% of incremental cost) and a sensitivity analysis at 25% and 100% of incremental cost.
  - The Low, Medium, and High market potential scenarios in this report assume that measure incentive levels will be 25%, 50% and 100% of incremental costs, respectively. For example, assume that a high-efficiency furnace may cost $200 more than a standard furnace, meaning the furnace would have an incremental cost of $200. In the medium scenario, this measure's hypothetical incentive from FortisBC would be $100. The other $100 would be paid by the end user.
  - In all scenarios, the non-incentive program costs are assumed to be 15% of the incentive cost.[25] In the example above, FortisBC's non-incentive spending would be $15. FortisBC's total cost for providing the measure to an end user would be $115.

25 Non-incentive program costs include activities such as program administration, communications, and research & evaluation. These costs have been estimated at 15%, a figure that is consistent with typical industry practice and the assumptions included in the 2017 CPR. Actual non-incentive program costs are dependent on several factors including program design, administrative structure, and evaluation requirements. For the purposes of this analysis, non-incentive spending that is not associated with specific measures or programs (including conservation education and outreach, and portfolio-level enabling activities) are not considered.

4 Residential Sector Results

This section presents the residential sector results and key findings, including:

- Base year (2019) natural gas use
- Reference case consumption forecast (2020-2040)
- Energy conservation measures evaluated in this CPR
- Technical potential savings
- Economic potential savings
- Market potential savings and scenarios

4.1 Residential Segments, End Uses, Vintages

The residential sector is divided into three segments, seven major energy end uses, and eight housing vintages. The residential domestic hot water (DHW) end use is subdivided into four as shown in Exhibit 7.

Exhibit 7 – Residential Sector Segments, End Uses, and Vintages

	Segments (3)	End Uses[26] (7)	Vintages[27] (8)

Residential Sector	• Single Family Detached/Duplexes
	• Single Family Attached/Row
	• Mobile/Other Residential
		• Clothes dryer
		• Cooking
		• Domestic hot water[28]
		  ○ Dishwasher DHW
		  ○ Washer DHW
		  ○ Shower DHW
		  ○ Other DHW
		• Fireplace
		• Other gas uses (outdoor fireplaces, patio heaters)
		• Pool & spa heaters
		• Space heating
			• Pre-1950
			• 1950-1975
			• 1976-1985
			• 1986-1995
			• 1996-2005
			• 2006-2015
			• Post-2015 (Existing)
			• New

26 All-electric end uses, such as clothes washer, lighting or plug loads, are not included in the reported results therefore are excluded from the end uses row of this table.
27 The residential sector has vintages to define time periods when residential dwellings are built. Existence Categories also apply to the residential vintages, as there is conversion of existing dwellings into new homes (i.e., renovations). 'New' residential dwellings do not appear until the first year of the reference case.
28 The DHW end use has been broken out into sub-end uses to facilitate CPR measure analysis. DHW can be reported at the end use or sub-end use level in the CPR.

4.2 Base Year Natural Gas Use

This section profiles the base year (2019) natural gas consumption for the residential sector. The following exhibits summarize how natural gas is used in the residential sector by segment, end use, vintage, and region, respectively.

Natural gas consumption in the residential sector base year is highest:

- In single-family detached (SFD)/duplex segment (~90% of consumption)
- For space heating end use (~62%)
- In the Lower Mainland excluding Vancouver region (~55%)
- In homes built between 1950 and 1975 (26%)

Exhibit 8 – Residential Natural Gas Consumption (GJ) in 2019 by Segment

Segment	Natural Gas Consumption (GJ)	% of Total
SFD/Duplex	69,593,368	90.3%
Attached/Row	5,609,684	7.3%
Mobile/other	1,888,575	2.4%
Total	**77,091,627**	**100.0%**

Exhibit 9 – Residential Natural Gas Consumption (GJ) in 2019 by End Use

Parent End Use	Natural Gas Consumption (GJ)	% of Total
Space Heating	48,159,206	62.5%
Domestic Hot Water (DHW)	13,800,150	17.9%
Fireplace	11,367,123	14.7%
Other Gas Uses	1,779,960	2.3%
Cooking	1,252,716	1.6%
Pool & Spa Heaters	509,960	0.7%
Clothes Dryer	222,511	0.3%
Total	**77,091,627**	**100.0%**

Exhibit 10 – Residential Natural Gas Consumption (GJ) in 2019 by Region[29]

Region	Natural Gas Consumption (GJ)	% of Total
Lower Mainland x Van	42,239,373	54.8%
Southern Interior	14,848,987	19.3%
City of Vancouver	9,339,690	12.1%
Vancouver Island	5,832,901	7.6%
Northern BC	4,564,223	5.9%
Whistler	266,452	0.3%
Total	**77,091,627**	**100.0%**

Exhibit 11 – Residential Natural Gas Consumption (GJ) in 2019 by Vintage [30]

Segment Vintage	Natural Gas Consumption (GJ)	% of Total
1950-1975	19,633,614	26.1%
1986-1995	12,634,000	16.8%
1976-1985	10,907,142	14.5%
1996-2005	10,070,375	13.4%
Pre-1950	9,196,994	12.2%
2006-2015	7,805,930	10.4%
Post-2015	4,954,997	6.6%

29 Recall that the 2019 actuals from FEI were based on FEI's billing system premise city and mapped by PG into the regions included in the study coverage.
30 "Mobile" has been excluded from the vintage results in this report; "mobile/other" appears in the segment results. The sample sizes for mobile dwellings in the REUS were too small to reliably divide the segment into vintages.

4.2.1 Accounts

Base year residential natural gas accounts are presented in Exhibit 12 by segment, region, and vintage. As shown in the table, the largest number of residential accounts in 2019 were:

- SFD / duplex type homes (806k out of 933k total)
- In Lower Mainland x Vancouver region (463k out of 933k total)
- Homes built between 1950 and 1975 (210k out of 933k total)

Exhibit 12 – Number of Residential Dwellings in 2019

Segment	City of Vancouver	Lower Mainland x Van	Northern BC	Southern Interior	Vancouver Island	Whistler	Total
SFD/Duplex	**80,641**	**395,571**	**40,486**	**180,309**	**106,270**	**2,527**	**805,804**
1950-1975	20,353	99,839	10,219	45,509	26,822	639	**203,381**

All	2,024	9,928	8,459	12,764	2,706	179	**36,060**
Total	**94,303**	**462,585**	**51,894**	**203,090**	**117,653**	**2,846**	**932,371**

4.2.2 Tertiary Load

Tertiary load is the useful energy delivered to an end use, or end use energy requirement: heat delivered by a furnace to a house, for example. This differs from natural gas consumption which is impacted by equipment efficiency: in the furnace example, consumption is equal to the tertiary load divided by seasonal efficiency of the furnace.

4.2.3 Unit Energy Consumption

As explained in Exhibit 3, unit energy consumption (UEC) is the end-use energy per unit (a "unit" in the residential sector is a dwelling). Fuel share is the percentage of the energy end use that is supplied by each fuel.

This section presents UEC by end use for dwellings that have gas as the predominant heating fuel and dwellings that have fuels other than gas as the predominant heating fuel[31] (referred to as "gas-heated" and "non-gas-heated" dwellings for simplicity). Tertiary loads for gas-heated and non-gas-heated dwellings are modelled identically for all end uses, except for space heating. Based on market research, non-gas-heated dwellings in FortisBC's service territory have been shown to have slightly lower space heating loads, meaning that they are somewhat smaller, better insulated, heated to a lower temperature, or some combination of these three.

This section also presents *stock average efficiency*, the average efficiency of equipment serving the tertiary load for that end use. UEC by end use is calculated by dividing unit tertiary load with stock average efficiency.

Exhibit 13 presents the 2019 modelled values for unit tertiary load, stock average efficiency and UEC values for all end uses (DHW sub-end uses are shown separately in Exhibit 14) for gas-heated and non-gas-heated SFD dwellings in the Lower Mainland excluding Vancouver region.

Exhibit 13 – 2019 Modelled UEC Values by End Use, Gas and Non-Gas-Heated SFD/Duplex Dwellings in the Lower Mainland

	Unit Tertiary Load (GJ/Dwelling/Yr.)	Stock Average Efficiency (%)[32]	UEC
Predominantly Gas-Heated Dwellings			
Clothes Dryer	3.9	86%	4.6
Cooking	2.9	51%	5.7
Fireplace	7.3	50%	14.5
Other Gas Uses	2.3	100%	2.3
Pool & Spa Heaters	23.7	86%	27.7

31 "Predominant heating fuel" represents if a building primarily uses gas for heat (>50% of the fuel share for space heating is from gas) or other fuels (>50% of fuel share for space heating is from fuels other than gas). In this report, we refer to this as 'gas-heated' and 'non-gas-heated' dwellings to simplify the text. Note that gas-heated dwellings can have other fuels supplying space heating, but gas is at least 50% of the fuel share.
32 Average stock efficiencies are only used to calculate tertiary load and are not used in the measure savings calculations or elsewhere in the modelling.

	Unit Tertiary Load (GJ/Dwelling/Yr.)	Stock Average Efficiency (%)[32]	UEC
Space Heating	59.1	85%	69.4
Domestic Hot Water	12.0	62%	19.5
Predominantly Non-Gas-Heated Dwellings			
Clothes Dryer	3.9	86%	4.6
Cooking	2.9	51%	5.7
Fireplace	7.3	50%	14.5
Other Gas Uses	2.3	100%	2.3
Pool & Spa Heaters	23.7	86%	27.7
Space Heating	55.8	85%	65.5
Domestic Hot Water	12.0	62%	19.5

Exhibit 14 presents the 2019 modelled values for unit tertiary load, stock average efficiency, and UEC values for the DHW sub-end uses. As DHW gas consumption does not vary by the predominant heating fuel in the dwelling, the table does not differentiate by gas versus non-gas-heated dwellings. The values are specific to the SFD/Duplex segment in the Lower Mainland excluding Vancouver ("LML") region.

Exhibit 14 – 2019 Modelled UEC Values for DHW Sub-End Uses, SFD/Duplex Dwellings in the LML

	Unit Tertiary Load (GJ/Dwelling/Yr.)	Stock Average Efficiency (%)	UEC
Other DHW	2.3	62%	3.7
Dishwasher DHW	1.4	62%	2.3
Shower DHW	6.5	62%	10.5
Washer DHW	1.8	62%	2.9

4.2.4 Average Natural Gas Use per Dwelling

The following exhibits present average annual natural gas consumption per account by end use. Included in the exhibits are:

- UEC: the amount of energy used by each end use per unit (the "unit" in the residential sector is typically a dwelling, with some minor exceptions described below).
- Fuel Share: the percentage of the energy end use that is supplied by each fuel (in this case, natural gas).
- Saturation: For most end uses, saturation reflects the extent to which an end use is present in a region, and segment. In the residential sector, cooking, space heating, DHW, and 'other gas uses' have a saturation of 100% as these end uses are assumed to be present in all residential dwellings.

  Three end uses – clothes dryers, fireplaces, and pool & spa heaters – are not present in every residential dwelling. In these cases, saturation is used to show the average number of appliances per dwelling supplying those end uses, and the "unit" referred to in the UEC is one equipment unit: a fireplace for example. In the exhibits below, saturation for these three end uses is not 100%: greater than 100% means that the average residential dwelling has more than one appliance related to that end use (e.g., fireplaces) and less than 100% means that the average residential dwelling has less than one (therefore no) appliances related to that end use (e.g., pool & spa heaters).

Average annual gas consumption per unit is calculated by multiplying these three variables together; therefore, they are included in the exhibits below.

Exhibit 15 presents the modelled average annual gas use per residential dwelling by end use (DHW sub-end uses are presented separately in Exhibit 16) for gas and non-gas-heated dwellings, respectively. Note that these values are specific to the SFD/Duplex segment and the Lower Mainland excluding Vancouver ("LML") region.[33]

Exhibit 15 – 2019 Modelled Average Annual Gas Use Per Dwelling by End Use, Gas and Non-Gas SFD/Duplex Heated Dwellings in the Lower Mainland

	UEC	Fuel Share	Saturation	Average Annual Gas Use (GJ/yr.)
Predominantly Gas-Heated Dwellings				
Clothes Dryer	4.6	6%	104%	0.3
Cooking	5.7	29%	100%	1.6
DHW	19.5	87%	100%	17.0
Fireplace	14.5	95%	110%	15.1
Other Gas Uses	2.3	100%	100%	2.3
Pool & Spa Heaters	27.7	26%	9%	0.7
Space Heating	69.4	93%	99%	63.8
Total Annual Consumption for an Average Residential Customer in LML				**100.8**
Predominantly Non-Gas-Heated Dwellings				
Clothes Dryer	4.6	7%	104%	0.4
Cooking	5.7	35%	100%	2.0
DHW	19.5	58%	99%	11.2
Fireplace	14.5	96%	121%	17.0
Other Gas Uses	2.3	100%	100%	2.3
Pool & Spa Heaters	27.7	10%	9%	0.2
Space Heating	65.5	17%	95%	10.8
Total Annual Consumption for an Average Residential Customer in LML				**43.9**

33 Note that the average annual natural gas use for all residential customers within FortisBC's service territory is approximately 90 GJ per year.

Exhibit 16 presents the modelled average annual gas use per residential dwelling by DHW sub-end use for gas and non-gas-heated dwelling, respectively. Note that these values are specific to the SFD/Duplex segment and the Lower Mainland excluding Vancouver region.

Exhibit 16 – 2019 Modelled Average Annual Gas Use Per SFD/Duplex Dwellings in the LML by DHW Sub-End Uses and Predominant Heating Fuel

	UEC	Gas Fuel Share	Saturation	Average Annual Gas Use (GJ/dwelling/yr.)
Predominantly Gas-Heated Dwellings				
Other DHW	3.7	87%	100%	3.3
Dishwasher DHW	2.3	87%	100%	2.1
Shower DHW	10.5	87%	100%	9.2
Washer DHW	2.9	87%	100%	2.5
Predominantly Non-Gas-Heated Dwellings				
Other DHW	3.7	58%	100%	2.2
Dishwasher DHW	2.3	58%	100%	1.4
Shower DHW	10.5	58%	100%	6.0
Washer DHW	2.9	58%	100%	1.7

4.3 Reference Case Natural Gas Use

This section profiles the reference case forecast (2020-2040) natural gas consumption for the residential sector.

Overall gas consumption is forecasted to decline by approximately 5% by 2040 (as shown in Exhibit 19) compared to 2020 consumption, with an average annual decrease of about 0.25%. While the forecast shows an increase in the number of residential accounts (as seen in Exhibit 18), the growth in accounts is less than the decrease in usage per account, so the net result is that consumption declines.

Exhibit 17 – 2020 vs 2040 Residential Gas Consumption (GJ) by Segment

Segment	2020	2040	Change
SFD/Duplex	69,263K	65,033K	-6%
Attached/Row	5,646K	6,046K	7%
Mobile/other	1,891K	1,927K	2%
Total	**76,801K**	**73,006K**	**-5%**

The following exhibits present how natural gas is forecasted to be used from 2020 to 2040 by segment, end use, and region, respectively. (Section 4.3.1 focuses on consumption from existing and new dwellings over the reference case). These exhibits illustrate forecasted trends in consumption over the reference case, including:

- Many consumption patterns evident in the base year are expected to persist throughout the reference case: natural gas is predominately used in the SFD/Duplex segment, in the Lower Mainland excluding Vancouver region, and for space heating throughout the study period.
- In 2020, post-2015 residential dwellings are forecasted to account for approximately 9% of consumption. By 2040, this vintage is projected to use about 38% of consumption.

Exhibit 19 – 2020 vs 2040 Residential Gas Consumption (GJ) by End Use

Parent End Use	2020	2040	Change
Space Heating	47,864K	43,877K	-8%
Domestic Hot Water (DHW)	13,680K	12,445K	-9%
Fireplace	11,407K	11,710K	3%
Other Gas Uses	1,844K	2,728K	48%
Cooking	1,268K	1,453K	15%
Pool & Spa Heaters	514K	556K	8%
Clothes Dryer	224K	238K	6%
Total	**76,801K**	**73,006K**	**-5%**

Exhibit 20 – 2020 vs 2040 Residential Gas Consumption (GJ) by Region

Region	2020	2040	Change
Lower Mainland x Van	41,954K	38,521K	-8%
Southern Interior	14,828K	14,406K	-3%
City of Vancouver	9,275K	8,502K	-8%
Vancouver Island	5,915K	6,830K	15%
Northern BC	4,557K	4,425K	-3%
Whistler	271K	322K	19%
Total	**76,801K**	**73,006K**	**-5%**

4.3.1 Reference Case Natural Gas Use: Existing versus New Residential Dwellings

Exhibit 21 illustrates the expected increase in consumption from new residential dwellings over the reference case, from 2% in 2020 to approximately 33% in 2040, compared to existing dwellings.

Exhibit 21 – 2020-2040 Gas Consumption (GJ) by New and Existing and Segment

Existing/New	2020	2040	Change
Existing	**75,137K**	**48,621K**	**-35%**

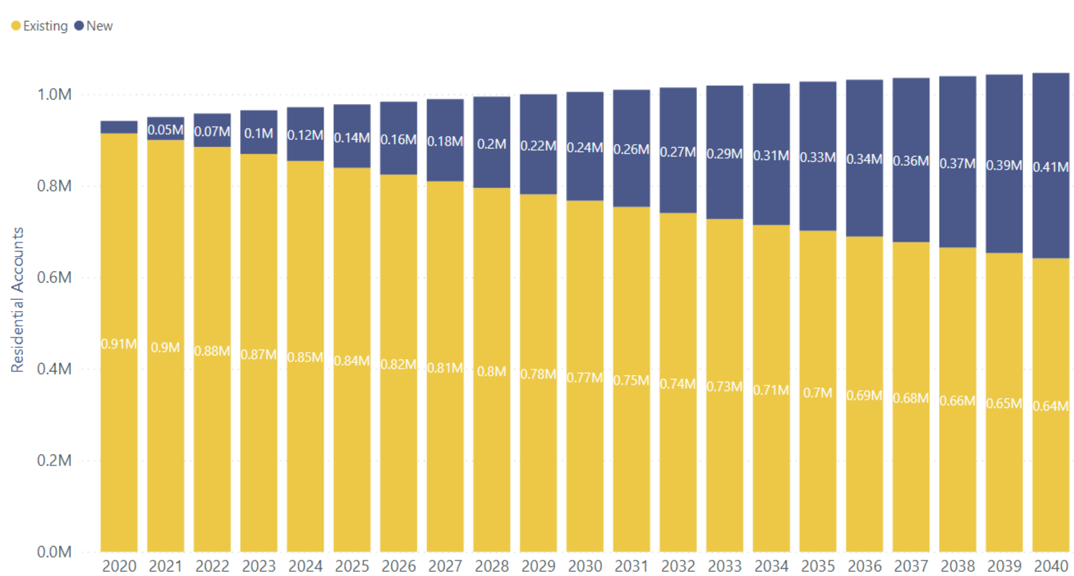
Despite the reference case showing a 5% decrease in residential sector gas use from 2020 to 2040, residential accounts are expected to grow by approximately 11% from 2020 to 2040, from 932,000 to 1,047,000. The portion of FEI accounts from new residential dwellings is forecasted to increase over the reference case from 3% in 2020 to almost 40% in 2040, with new construction contributing approximately 400,000 new accounts, and approximately 290,000 existing dwellings being demolished over the reference case period. This represents 30% of the existing dwellings being demolished between 2020 and 2040, a demolition rate of approximately 2% per year. Slightly countering this trend is the inclusion of some conversion customers, which are existing homes to which gas service is extended sometime after their construction. In most regions, conversion customers are a small fraction of new connections.

Exhibit 22 – 2020 vs 2040 Residential Gas Accounts Forecast by Existing and New Vintage



4.4 Measure Assessment

4.4.1 List of Measures

The list of residential measures that were included in this CPR are presented in Exhibit 23. The measures are divided into categories by end use and measure type.

Please see the MS Excel file entitled "Res_Measure Analysis Workbook" for a description of each measure and a full analysis.

Measures were classified in five measure type categories:

- Building Envelope (also referred to as "envelope measures")
- Equipment
- Controls
- Energy Management (including behavioral measures)
- New Construction – all new construction measures were placed in a separate category

New construction measures are analyzed using a whole-building approach, represented by the Step 3 - Step 5 BC Energy Step Code measures listed below. See Appendix M of the CPR method for the modelling approach used to assess residential Step Code measures.

Exhibit 23 – Residential Sector Conservation and Energy Management Measures

Space Heating – Building Envelope	Water Heating – Equipment
Attic Duct Insulation Attic Insulation Basement or Crawlspace Insulation Comprehensive Air Sealing Comprehensive Draft Proofing Exposed Floor Insulation High Performance Windows and Doors Manufactured Homes Duct Sealing Manufactured Homes Floor Insulation Wall Insulation	Connected Water Heater Controller Drain Water Heat Recovery Faucet Aerator Gas Heat Pump – Domestic Hot Water High-Efficiency Condensing Gas Tankless Water Heater High-Efficiency Condensing Gas Water Heater High-Efficiency Storage Gas Water Heater Low Flow Showerhead Pipe Wrap Solar Water Heating System Thermostatic Restrictor Shower Valve Water Heater Tune-Up

Combination System - Type 1 and 2 Combination System - Type 1 and 2 Early Retirement Combination System - Type 3 Gas Heat Pump Combination System – Type 1 and 2	Deep Energy Retrofits[34] ENERGY STAR Manufactured Home Home Energy Report

[34] Note that analysis that forms the technical, economic and market potential is based on individual measures rather than on "packages of measures" or program delivery approaches. Measures packaged in comprehensive programs such as FortisBC's Rental Apartment Efficiency program, Social Housing Retrofit Support program and deep energy retrofits were assessed within this analysis individually but not also collectively as a program package.

4.4.2 Results

Exhibit 24 shows measure-level results for the residential sector in order of decreasing cost effectiveness.

Measures were assessed based on their replacement type: **retrofit** (immediate replacement at full cost), **replace on burnout** (end of life replacement at incremental cost), or **new construction** (immediate installation at incremental cost).

The TRC and MTRC are presented at the measure-level and exclude program costs and free ridership.

Key findings of the measure assessment for the residential sector include:

- Of the 65 measures included in the analysis, only 14 pass the TRC screen. Substantially more, 54 measures, pass the MTRC screen.
- The most attractive water heating measures (i.e. measures with the highest TRC) include faucet aerators, pipe wrap and low flow showerheads.
- The most attractive space heating measures are certain building envelope (walls, attic duct, and basement) insulation measures, high-efficiency fireplaces, and communicating thermostats.
- Other building envelope measures, such as attic, floor insulation and air sealing measures do not pass the TRC (i.e. TRC is less than 1.0).
- Gas heat pumps combination systems and the mature market version of DHW gas heat pumps pass the MTRC. Neither pass the TRC.
- Most Step Code new construction measures pass the MTRC but neither pass the TRC.

Exhibit 24 – Residential Sector Results: Sector Averages (Sorted by High to Low MTRC)

4.5 Technical Potential

This section provides an overview of the technical potential savings results for the residential sector. Overall results are presented below, followed by measure level results and supply curves for the TRC and MTRC results.

As shown in Exhibit 25, almost half of the residential technical potential (24 PJ) would be available in 2021 and would increase to 43 PJ in 2040. This indicates that a large amount of the potential, approximately 19 PJ, would come from replace on burnout measures over the next two decades. The forecasted natural gas consumption for the residential sector is included for reference.

Exhibit 25 – Residential Technical Potential Savings (GJ)

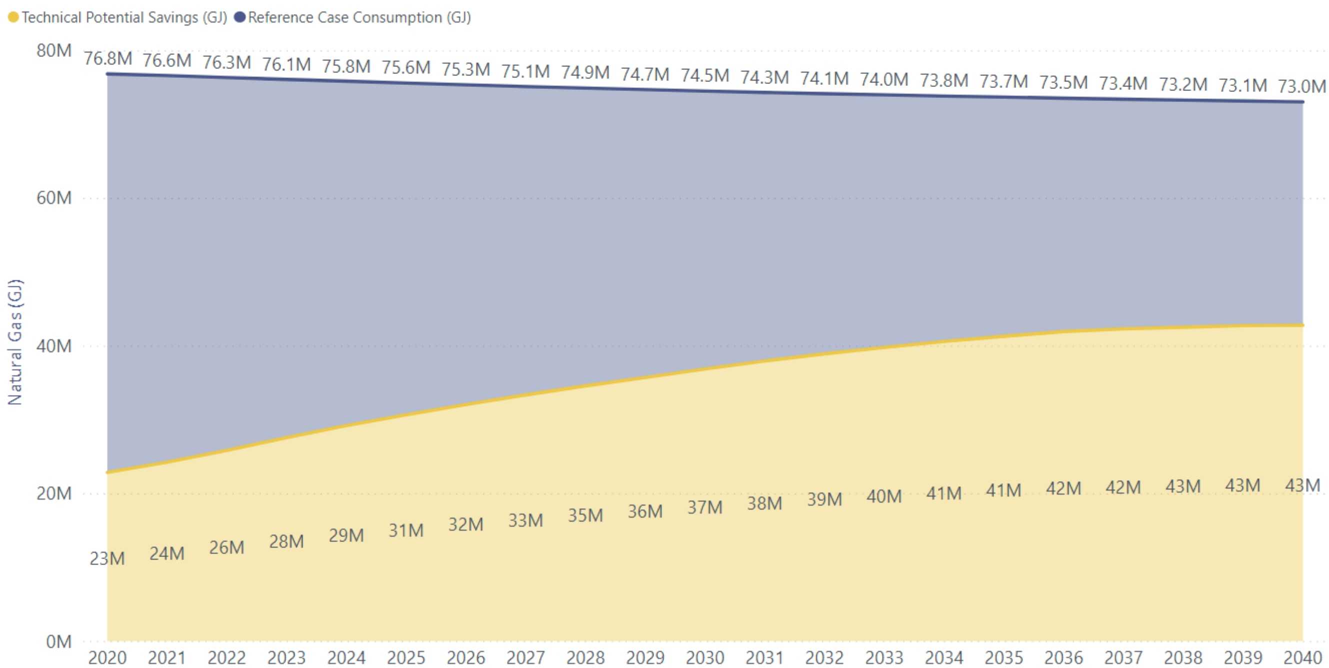

Exhibit 26 – Technical Savings Potential as a Percent of Residential Reference Case Consumption (%)

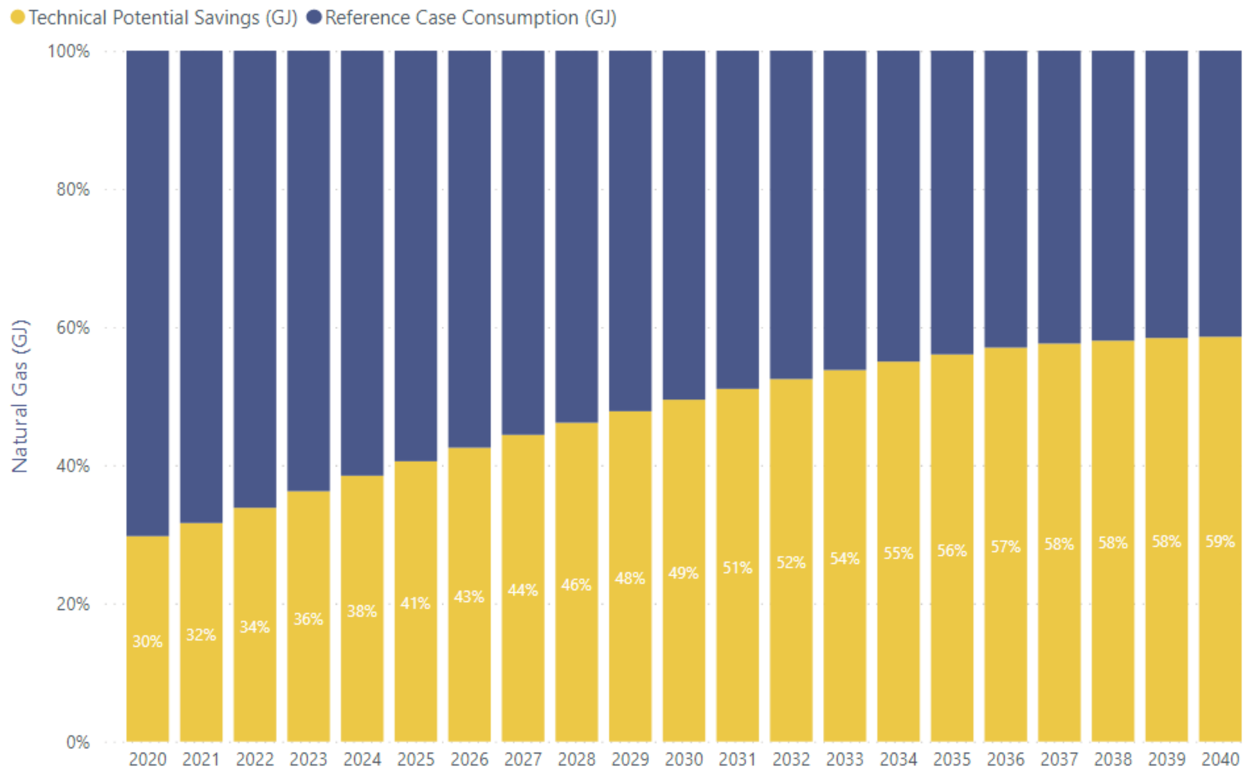

As shown in Exhibit 26, the technical potential savings is about 32% of residential reference case consumption in 2021 and increases to 59% by 2040, further indicating a that a substantial portion of the potential is expected to come from replace on burnout measures.

The technical potential savings by 2025 broken down by measure (only showing the top 25) are presented in Exhibit 27. The top three measures are all space heating measures (including gas heat pumps), followed by Step 4 new construction.

Exhibit 27 – Technical Potential – Annual Gas Savings from Top 30 Residential Measures in 2025 (GJ)

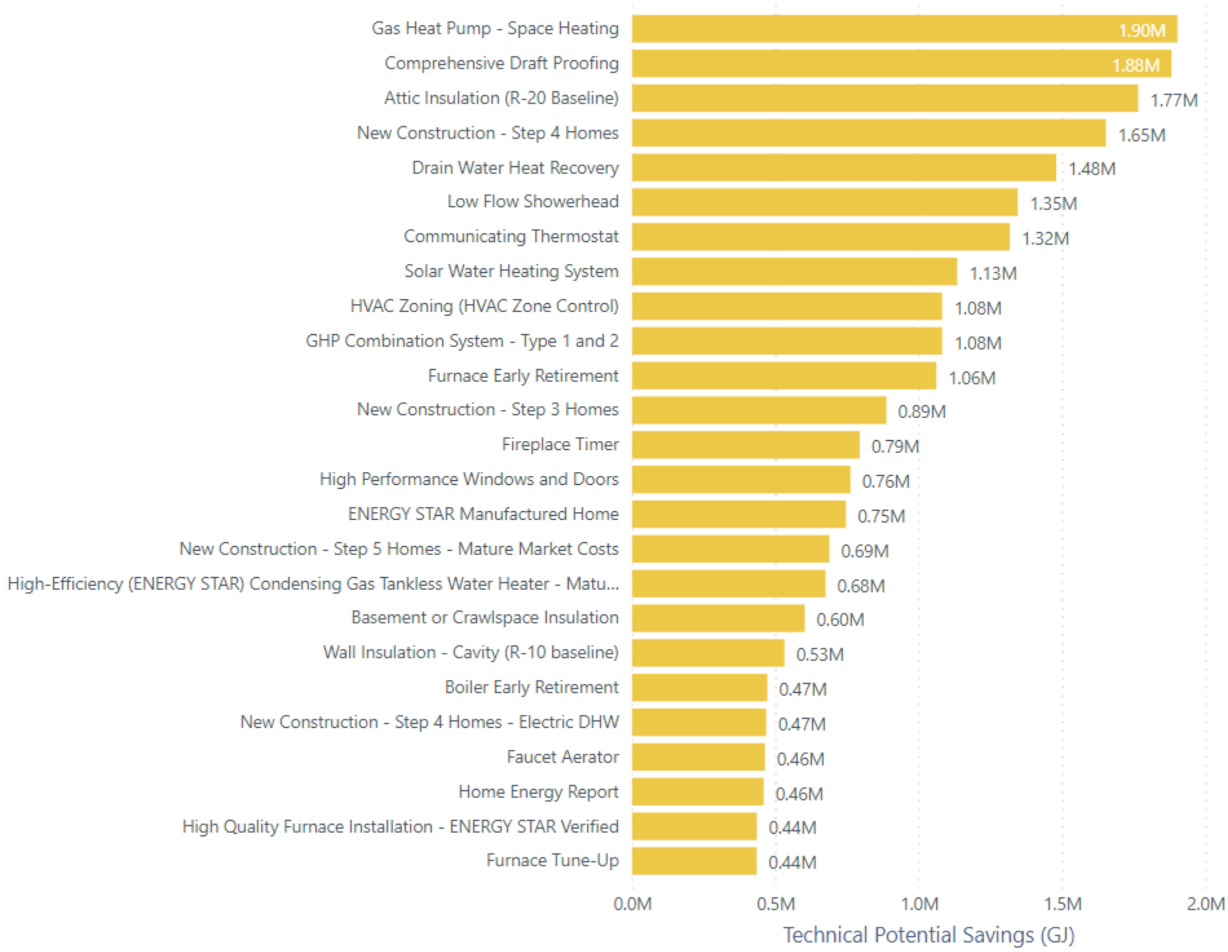

Exhibit 28 shows the cumulative residential sector technical potential savings in 2040 arranged as a supply curve, with measures ordered by decreasing TRC ratio from left to right. The graph shows that roughly 16% (around 7 out of 43 PJ) of the residential sector's technical potential by 2040, comes from measures with a TRC of 1.0 or higher. Approximately 1.5 PJ of savings come from measures with a TRC ratio of greater than 2. These are shown in aggregate.

Exhibit 28 – Residential Sector: Technical Potential Supply Curve – TRC

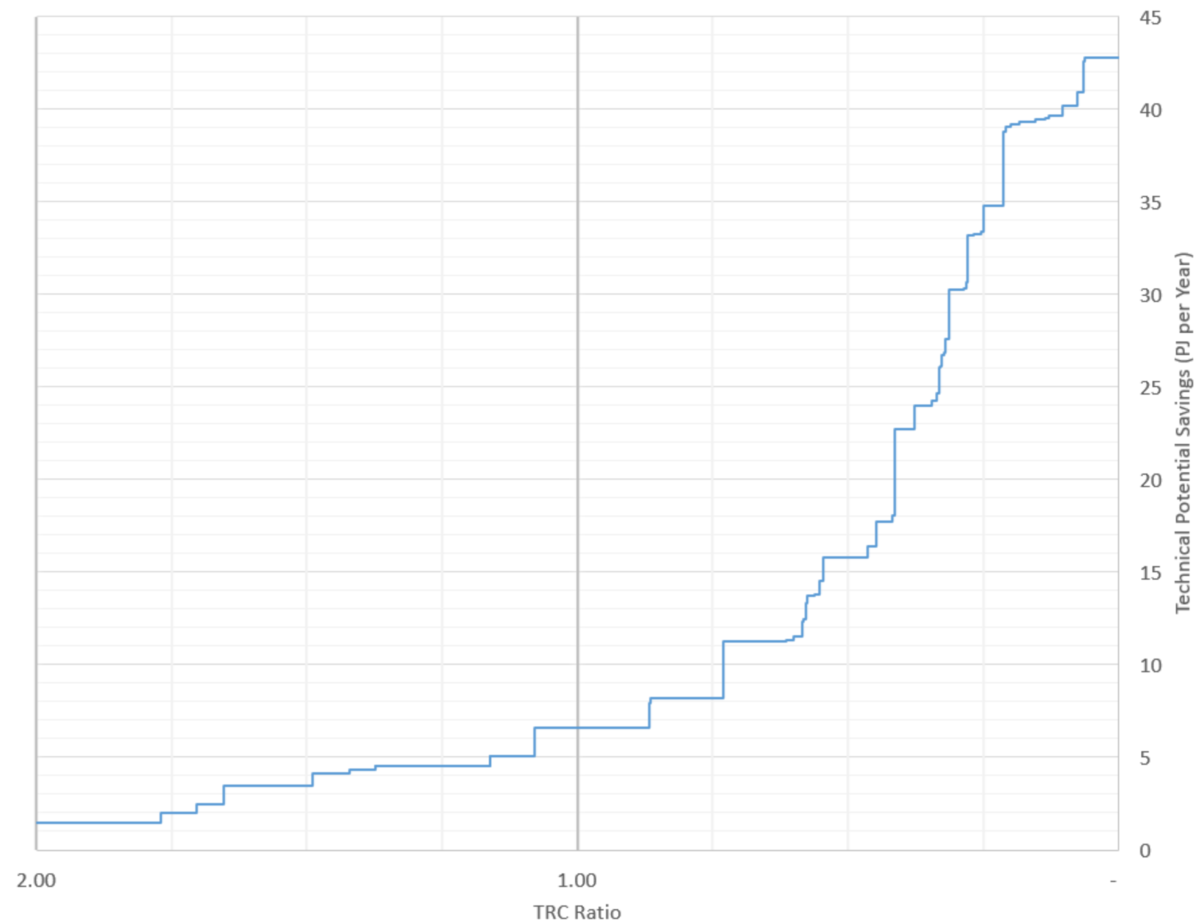

Exhibit 29 shows a similar supply curve, but with measures ordered by decreasing MTRC ratio from left to right. The graph shows that 90% (around 39 out of 43 PJ) of residential sector's technical potential by 2040 comes from cost-effective measures with an MTRC of 1.0 or higher. Approximately 16 PJ of savings come from measures with an MTRC ratio of greater than 2. These are shown in aggregate.

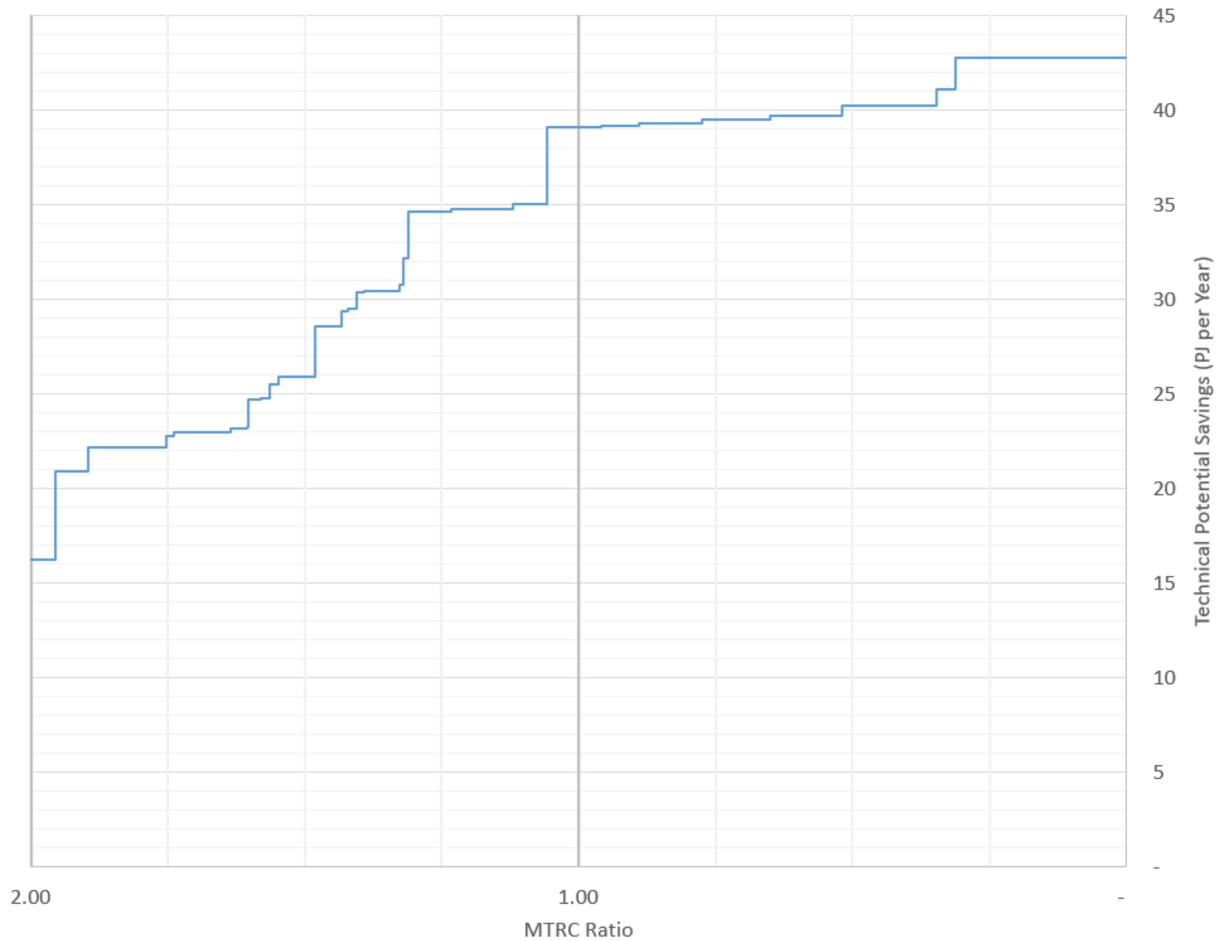
Exhibit 29 – Residential Sector: Technical Potential Supply Curve – MTRC

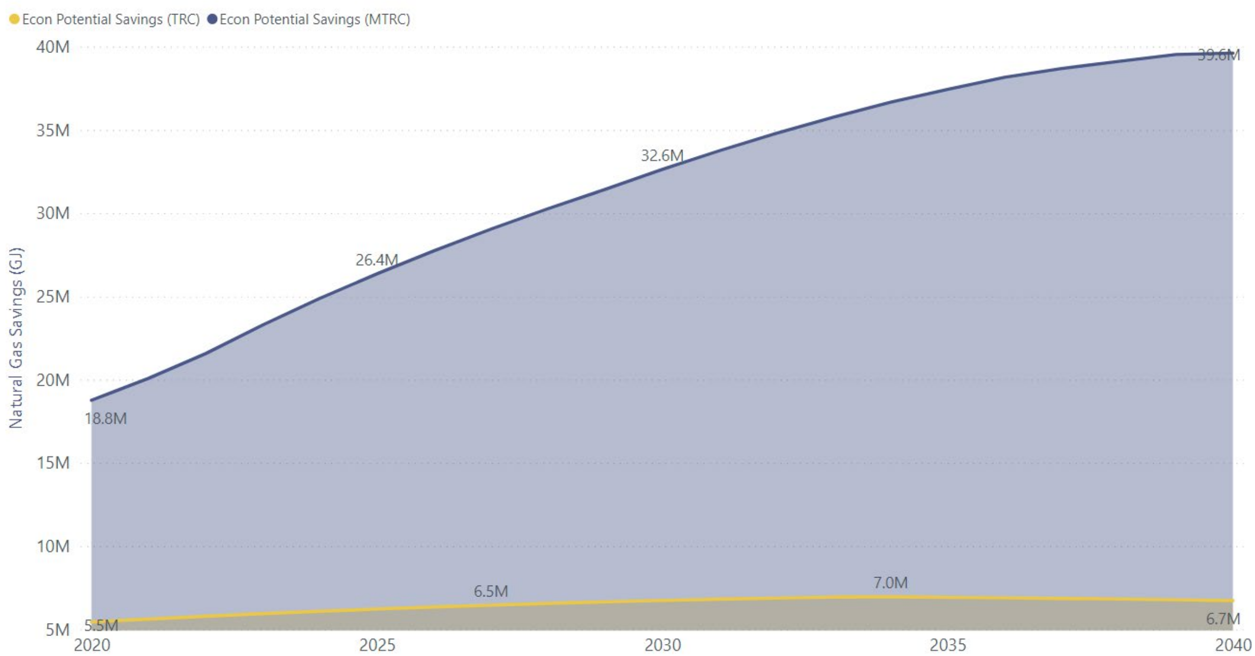


4.6 Economic Potential

This section provides the economic potential savings results for the residential sector from 2020 to 2040. We conducted two economic potential assessments: one using a TRC screen that includes measures with a TRC ratio of 1.0 and above, and one using an MTRC screen that includes measures with an MTRC of 1.0 and above. Outputs of both economic models are presented in this section.

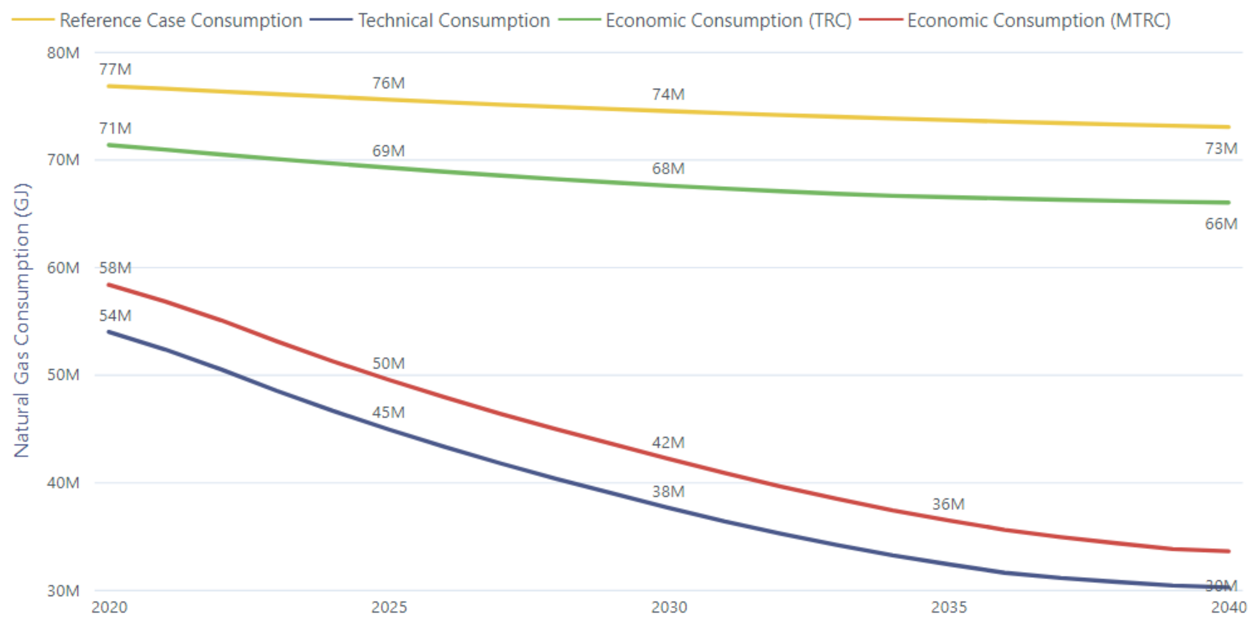
The residential sector economic potential savings with a TRC screen and with an MTRC screen are shown in Exhibit 30. As mentioned earlier, of the 65 measures included in the assessment, only 14 pass the TRC screen whereas 54 measures pass the MTRC screen. Those 40 measures that pass the MTRC but fail the TRC make up the difference between the two economic potential scenarios. This difference in economic potential in 2025 is roughly 20 PJ. In 2025, 24% of the MTRC economic potential comes from measures that pass the TRC as well. By 2040, that ratio is only 17%.

Exhibit 30 – Economic Potential Savings (GJ) – Residential, TRC and MTRC



The forecasted gas consumption under the technical potential, economic potential with a TRC screen, economic potential with an MTRC screen, and reference case scenarios for residential sector are shown in Exhibit 31.

Exhibit 31 – Economic Potential Consumption (GJ) Forecasts – Residential, TRC and MTRC



Results by Region

The TRC and MTRC economic potential savings in 2025 are presented by region in Exhibit 32 and Exhibit 33 respectively. The largest economic potential savings (3 PJ to 14 PJ depending on economic screen) are estimated to occur in the Lower Mainland outside of the City of Vancouver. The percentage of consumption captured by economic potential is uniform across all regions – around 8% under TRC screen and 34% under MTRC.

Exhibit 32 – Economic Potential Savings by Region in 2025 – Residential, TRC

Region	Ref Case Consumption (GJ)	Economic Potential Savings (GJ)	% of Consumption
Lower Mainland x Van	40,757K	3,303K	8%
Southern Interior	14,701K	1,343K	9%
City of Vancouver	9,007K	853K	9%
Vancouver Island	6,280K	421K	7%
Northern BC	4,517K	385K	9%
Whistler	290K	26K	9%
Total	**75,552K**	**6,331K**	**8%**

Northern BC	4,517K	1,522K	34%
Whistler	290K	87K	30%
Total	**75,552K**	**26,034K**	**34%**

Results by Segment and Vintage

The TRC and MTRC economic potential savings in 2025 are presented by segment and vintage in Exhibit 34 and Exhibit 35 respectively. As expected, older single-family dwellings present the most opportunities for economic potential under both economic screens. However, in the MTRC economic potential, the largest percentage of consumption is captured by the post-2015 vintage. This implies a sizeable potential contribution by Step Code new construction measures.

Exhibit 34 – Economic Potential Savings by Segment and Vintage in 2025 – Residential, TRC

Results by End Use

The TRC and MTRC economic potential savings in 2025 are presented by segment in Exhibit 36 and Exhibit 37 respectively. The largest amounts, in absolute savings, are expected to be captured under the space heating end use (2.7 PJ or 17.5 PJ depending on the economic screen). In terms of the percentage of reference case consumption captured by economic potential, domestic hot water captures the largest share in both economic screens (18% TRC, 51% MTRC). Although small in absolute savings, pool and spa heater end use has an economic potential ratio of 76% savings under the MTRC screen.

Exhibit 36 – Economic Potential Savings by End Use in 2025 – Residential, TRC

Parent End Use	Ref Case Consumption (GJ)	Economic Potential Savings (GJ)	% of Consumption
Space Heating	46,600K	2,710K	6%
Domestic Hot Water (DHW)	13,205K	2,347K	18%
Fireplace	11,549K	1,247K	11%

Total	**75,552K**	**26,034K**	**34%**

The TRC and MTRC economic potential savings in 2040 are presented by end use in Exhibit 38. The difference is drastic – around 32 PJ. This is due to the large number of measures that pass the MTRC but fail the TRC. The biggest difference between the economic screens stem from measures that affect space heating.

Exhibit 38 – Economic Potential Savings by End Use in 2040 – Residential, TRC and MTRC

Parent End Use	Economic Savings (GJ) - TRC	Economic Savings (GJ) - MTRC	Difference (GJ)
Space Heating	3,382K	27,738K	24,356K

Results by Measure

The TRC economic potential savings by 2025 broken down by measure are shown in Exhibit 39, sorted by decreasing potential. The savings breakdown by end use is shown in Exhibit 40. Space heating savings make up 42% of the economic potential, domestic hot water 38% and fireplace measures 20% of the savings.

Exhibit 39 – Residential Economic Potential (TRC) – Annual Gas Savings from All TRC-Passing Measures in 2025 (GJ)

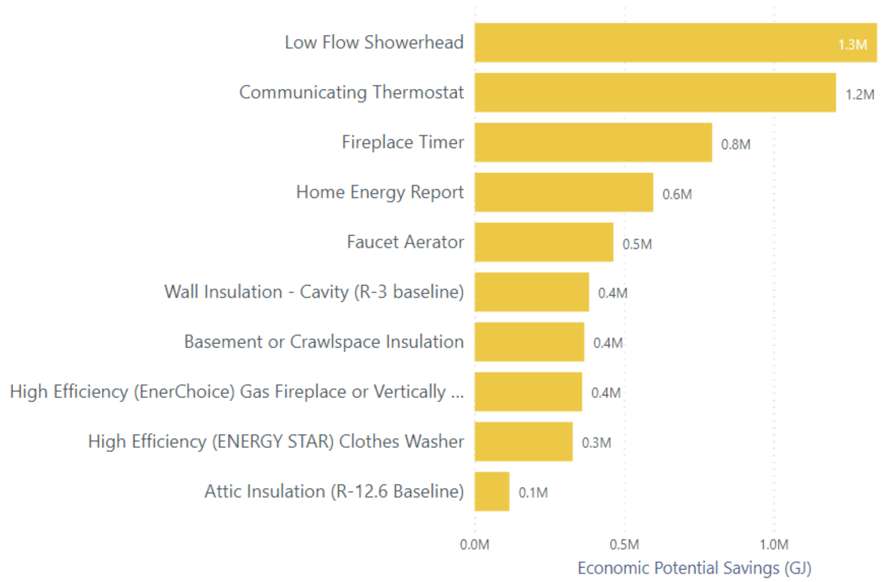

Exhibit 40 – Economic Potential in 2025 (GJ) By End Use – Residential, TRC

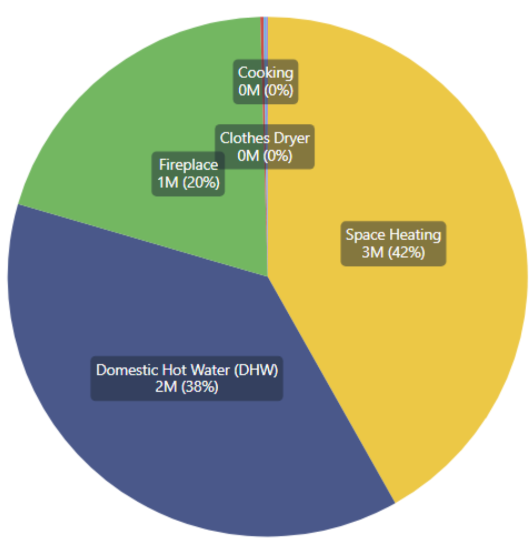

The economic potential savings by 2025 broken down by measure (showing only the top 25 measures) are presented in Exhibit 41. The savings breakdown by end use are presented in Exhibit 42. Space heating measures and their savings makes up the majority (68%) of the MTRC economic potential.

Exhibit 41 – Residential Economic Potential (TRC) - Annual Gas Savings from Top 25 MTRC-Passing Measures in 2025 (GJ)

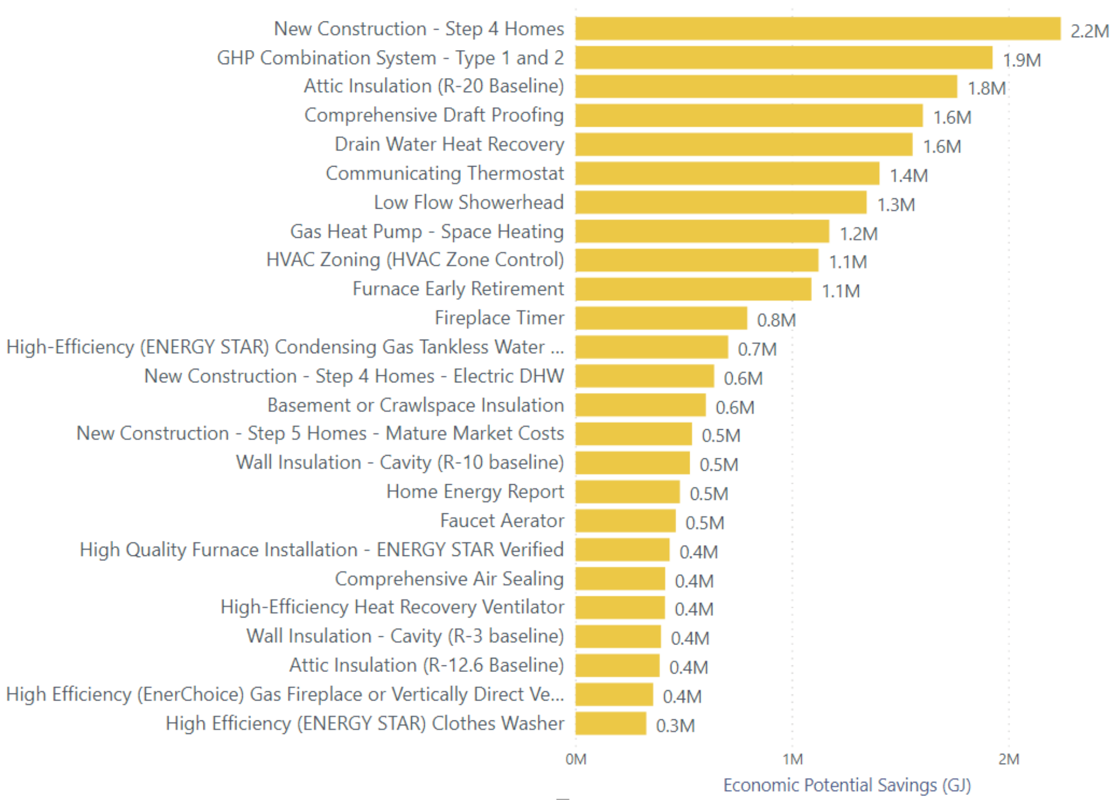

Exhibit 42 – Economic Potential (GJ) in 2025 By End Use – Residential, MTRC

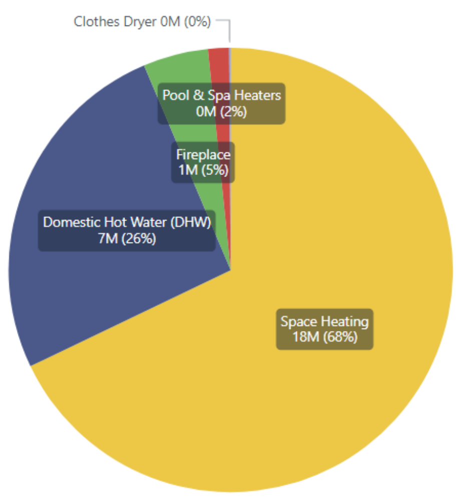

4.7 Market Potential

This section provides an overview of the low, medium, and high market potential results for the residential sector.

Low, medium, and high scenarios assume that measure incentive levels will be 25%, 50% and 100% of incremental costs, respectively. For example, assume that a high-efficiency furnace may cost $200 more than a standard furnace, meaning the furnace would have an incremental cost of $200. In the medium scenario, this measure's hypothetical incentive from FortisBC would be $100. The other $100 would be paid by the end user. In all scenarios, the non-incentive program costs are assumed to be 15% of the incentive cost. In the example above, FortisBC's non-incentive spending would be $15. FortisBC's total cost for providing the measure to an end user would be $115.

The market potential savings results, with a TRC screen and with an MTRC screen, are shown in Exhibit 43 and Exhibit 44, respectively. The medium market potential using the MTRC screen is almost three times the market potential using TRC screen.

By 2040, the residential low, medium, and high market TRC potential savings are estimated to be 3 PJ, 3.4 PJ, and 4.3 PJ, respectively. By 2040, the low, medium, and high market MTRC potential savings are estimated to be 8.2 PJ, 9.9 PJ, and 14.2 PJ, respectively.

Exhibit 43 – Market Potential Savings (GJ) – Residential, TRC

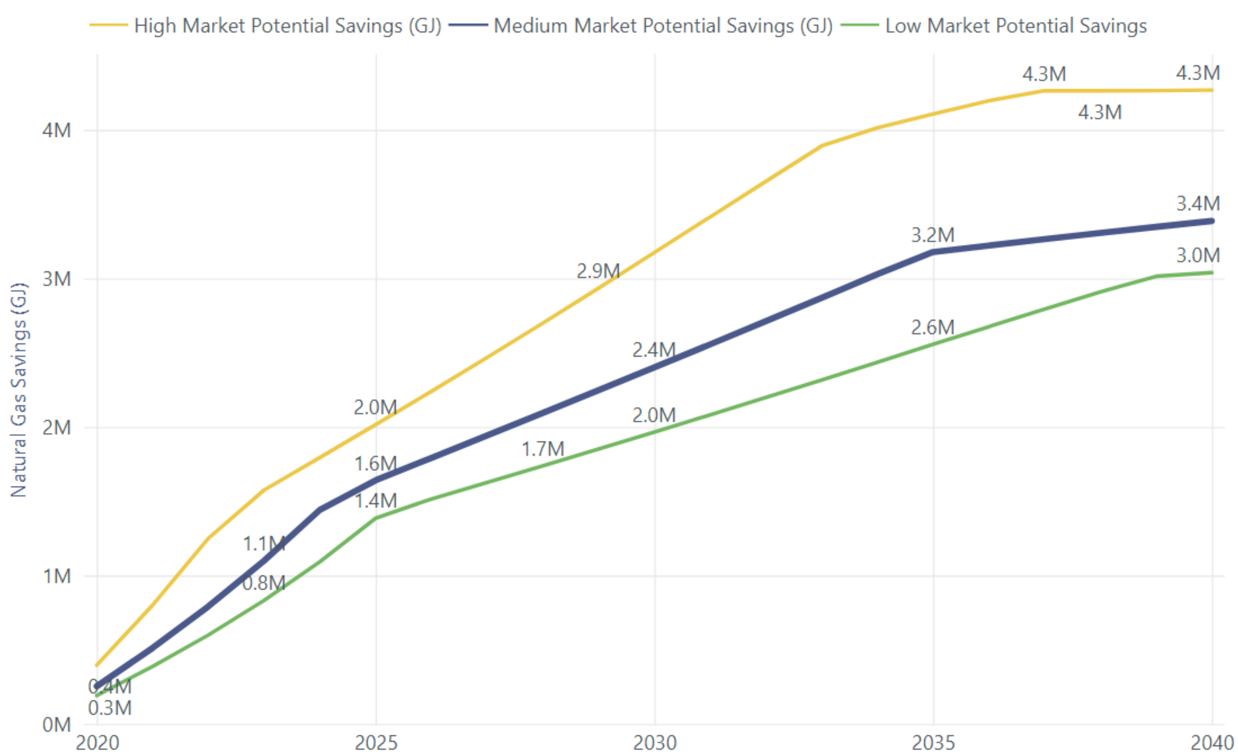

Exhibit 44 – Market Potential Savings (GJ) – Residential, MTRC

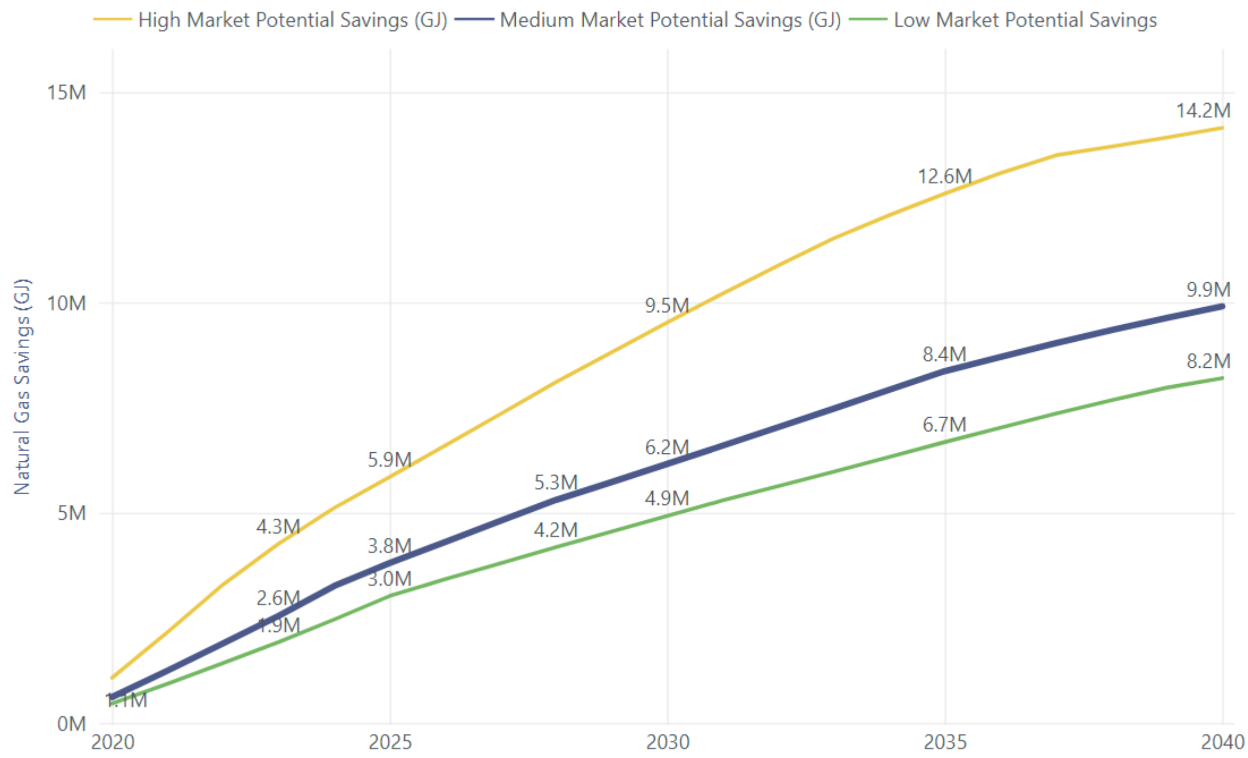

The forecasted residential gas consumption under the three market potential scenarios relative to reference case scenario is shown in Exhibit 45 (TRC) and Exhibit 46 (MTRC). The reference consumption is forecasted to drop to 73 PJ, from 77 PJ today. By 2040, the residential low, medium, and high market TRC potential consumption levels are estimated to be 70 PJ, 69.6 PJ, and 69 PJ, respectively. By 2040, the low, medium, and high market MTRC potential consumption levels are estimated to be 65 PJ, 63 PJ, and 59 PJ, respectively.

Exhibit 45 – Market Potential Consumption (GJ) Forecasts – Residential, TRC

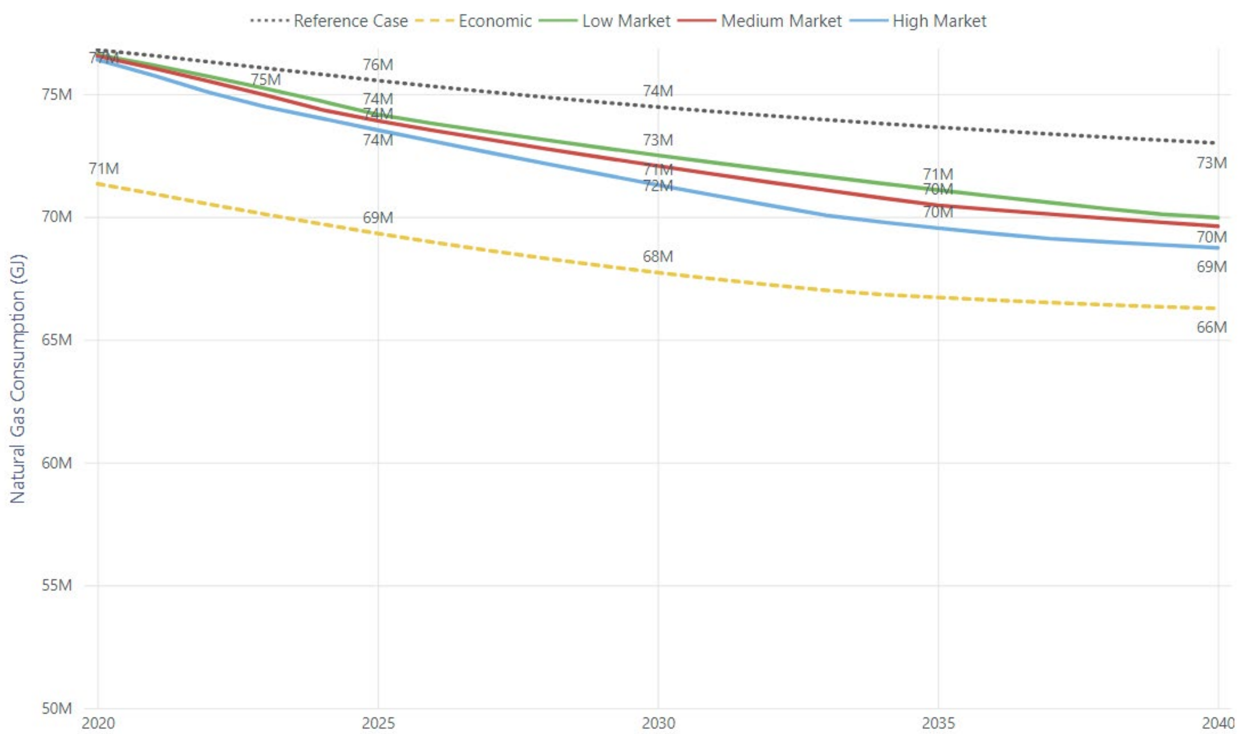

Exhibit 46 – Market Potential Consumption (GJ) Forecasts – Residential, MTRC

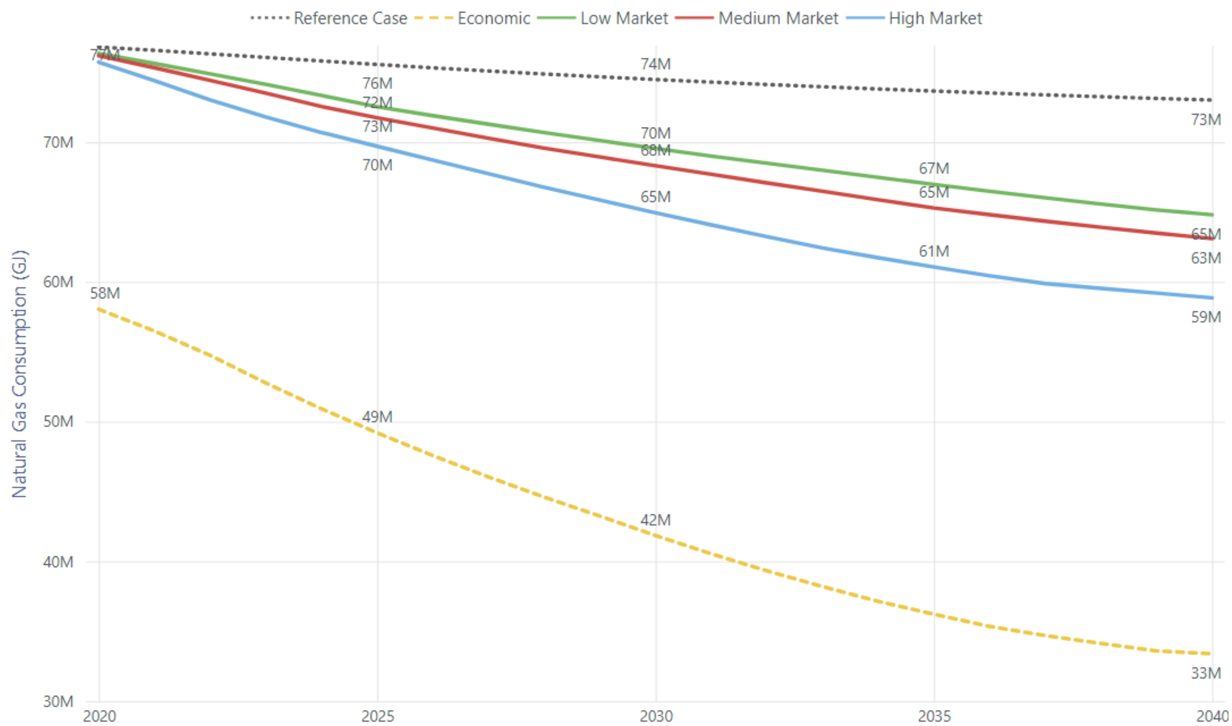

The remainder of this section presents detailed results of the medium market potential scenario only. Similarly detailed results of the low and high market potential scenarios can be found on the Power BI dashboard and the Excel workbooks.

Results by Region

The medium market potential savings for 2025 are presented by region in Exhibit 47 and Exhibit 48 using TRC and MTRC screen, respectively. Medium market potential savings in 2025 are estimated to be 2% of reference case consumption in all regions with TRC screen, and 5% with MTRC. The largest portion savings is expected to be in the Lower Mainland x Vancouver region.

Exhibit 47 – Medium Market Potential Savings by Region in 2025 – Residential, TRC

Region	Ref Case Consumption (GJ)	Medium Market Potential Savings (GJ)	% of Consumption
Lower Mainland x Van	40,757K	876K	2%
Southern Interior	14,701K	339K	2%

Results by Segment and Vintage

The TRC and MTRC economic potential savings in 2025 are presented by segment and vintage in Exhibit 49 and Exhibit 50 respectively. Single-family dwellings present the most market potential under both economic screens.

Exhibit 49 – Medium Market Potential Savings by Segment and Vintage in 2025 – Residential, TRC

Segment	Ref Case Consumption (GJ)	Medium Market Potential Savings (GJ)	% of Consumption
SFD/Duplex	**67,869K**	**1,503K**	**2%**

Results by End Use

The TRC and MTRC medium market potential savings in 2025 are presented by segment in Exhibit 51 and Exhibit 52 respectively. In the TRC potential, the largest amount of absolute savings in 2025 are expected to be from domestic hot water (DHW) end use. These savings are roughly 6% of the DHW end use reference case consumption in that year. In the MTRC potential, the largest absolute savings in 2025 come from space heating end use, even though these savings amount to only 4% of the end use reference case consumption. When evaluating percentages, DHW has a larger potential (11% of the end use consumption in that year). Although small in absolute savings, pool and spa heater end use has the potential of capturing 17% savings under the MTRC screen.

Exhibit 51 – Medium Market Potential Savings by End Use in 2025 – Residential, TRC

Parent End Use	Ref Case Consumption (GJ)	Medium Market Potential Savings (GJ)	% of Consumption
Domestic Hot Water (DHW)	13,205K	757K	6%
Space Heating	46,600K	621K	1%
Fireplace	11,549K	246K	2%

The TRC and MTRC medium market potential savings in 2040 are presented by end use in Exhibit 53. MTRC market potential is almost three times the TRC market potential. The biggest difference between the two economic screen scenarios comes from measures that affect space heating.

Exhibit 53 – Medium Market Potential Savings by End Use in 2040 – Residential, TRC and MTRC

Parent End Use	Medium Potential Savings (GJ) - TRC	Medium Potential Savings (GJ) - MTRC	Difference (GJ)
Space Heating	1,154K	5,049K	3,895K

Results by Measure

The medium market potential savings in 2025 of the top 15 residential measures are shown in Exhibit 54. The top measures in the TRC medium market potential are shown on the left and top measures in the MTRC scenario are shown on the right. Home energy reports and low flow showerheads top the list in both scenarios. More space heating measures contribute to savings in the MTRC screen, as evident from the measures list and the end use breakdown difference in Exhibit 55. The sixth measure on the MTRC list on the right side of Exhibit 54 is High-Efficiency (ENERGY STAR) condensing Gas Tankless Water Heater.

Exhibit 54 – Medium Market Potential (TRC on Left, MTRC on Right) - Top 14 Residential Measures in 2025 (GJ)

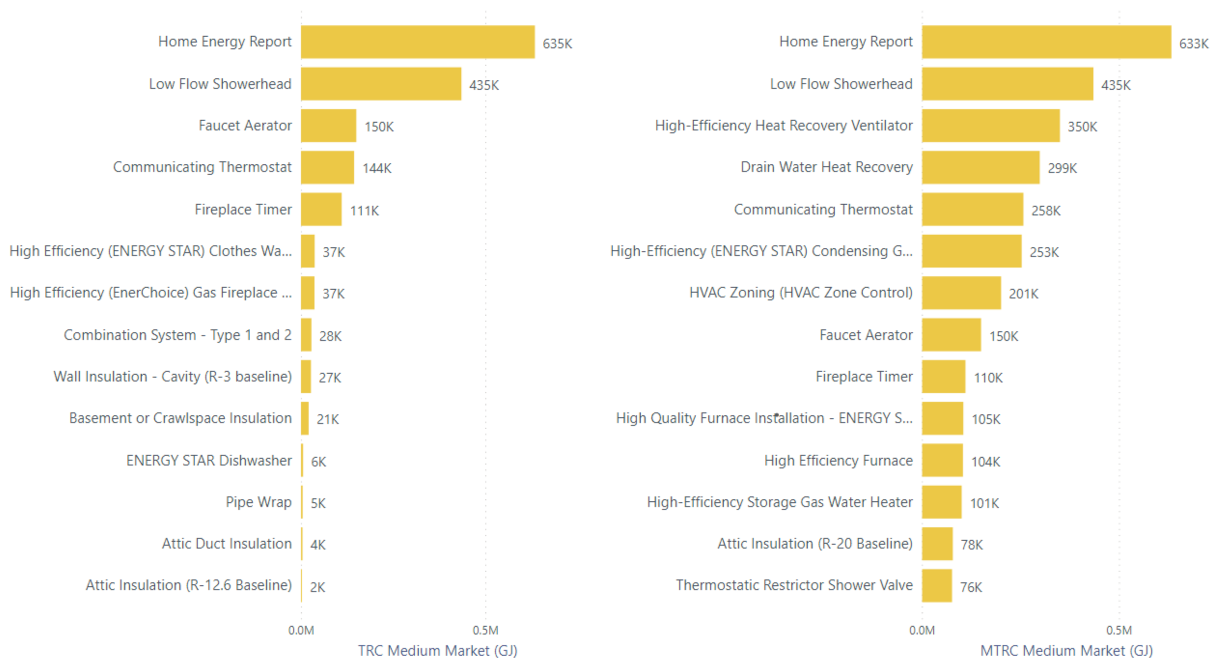

Exhibit 55 – Medium Market Potential (TRC on Left, MTRC on Right) – Savings by End Use in 2025 (%)

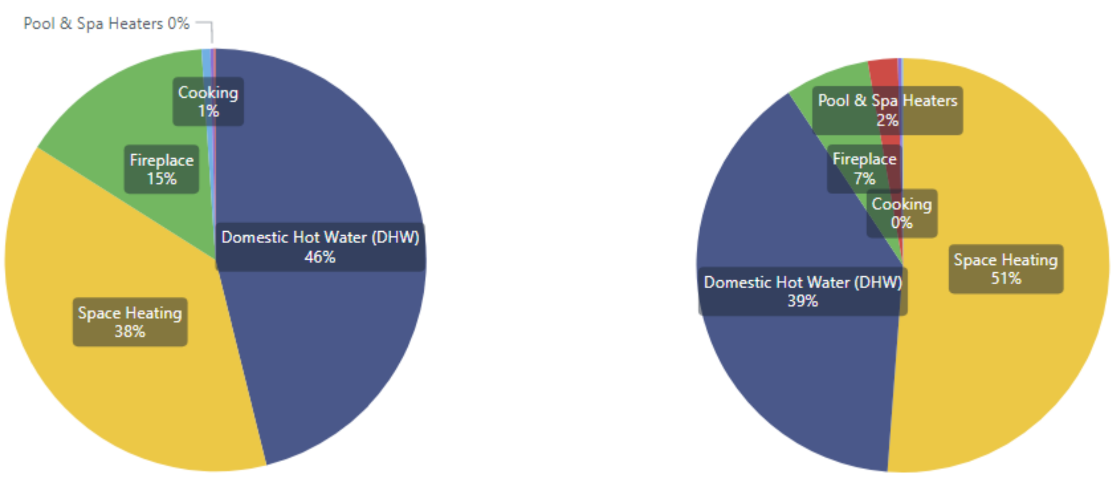

4.7.1 Incentive and Non-Incentive Spending

The incentive and non-incentive spending required to achieve the medium and high market potential are shown in Exhibit 56 (TRC) and Exhibit 57 (MTRC). Medium and high market incentives are assumed to be 50% and 100% of measures' incremental costs, respectively. In both medium and high scenarios, non-incentive costs are estimated to be 15% of incentive costs. The tables also show the total as well as incremental (that is, savings from new measures installed in a year) savings every year.

5 Commercial Sector Results

This section presents the commercial sector results and key findings, including:

- Base year (2019) natural gas use
- Reference case consumption forecast (2020 – 2040)
- Energy conservation measures evaluated in this CPR
- Technical potential savings
- Economic potential savings
- Market potential savings and scenarios

5.1 Commercial Segments and End Uses

In this CPR, the commercial sector is divided into 17 segments, five energy end uses, and two vintages.

Exhibit 58 – Definition of Commercial Sector Segments, End Uses, and Vintages

	Segments (17)	End Uses[35] (5)	Vintages (2)
Commercial Sector	• Apartments – Medium • Apartments – Large • Food Retail • Hospital • Hotel – Medium • Hotel – Large • Non-Food Retail – Medium • Non-Food Retail – Large • Nursing Home • Office – Medium • Office – Large • Other Commercial[36] • Restaurant • School – Medium • School – Large • University/College • Warehouse	• Cooking • Domestic Hot Water • Other[37] • Pools, Spas & Hot tubs • Space Heating	• Existing • New

35 All-electric end uses, such as clothes washer, lighting or plug loads, are not included in the reported results therefore are excluded from the End Uses row of this table.
36 The "other" segment includes facilities that do not fit into any of the other segments.
37 The "other" end use is a catch all for equipment that account for a small portion of consumption in the sector. In the commercial sector, examples of 'other' equipment are patio heaters and laundry dryers.

5.2 Base Year Natural Gas Use

This section profiles the base year (2019) natural gas consumption for the commercial sector. Please see Appendix A in the CPR Method Appendices document for how commercial NAICS codes were categorized into segments.

The following exhibits summarize how natural gas is used in the commercial sector by segment[38], end use, and region, respectively.

Natural gas consumption in the commercial sector base year is highest:

- In the apartment (31%), other (19%) and office (11%) segments
- In the space heating (56%) and water heating (31%) end uses
- In the Lower Mainland excluding Vancouver ("Lower Mainland x Vancouver") (48%) and the City of Vancouver (21%) regions

Exhibit 59 – 2019 Commercial Natural Gas Consumption (GJ) by Segment

Segment	Consumption (GJ)	%
Apartment	19,568K	31%
Other	12,201K	19%
Office	7,084K	11%
Restaurant	4,271K	7%
Warehouse	4,231K	7%
Nonfood Retail	3,587K	6%
Hospital	3,067K	5%
Hotel	2,553K	4%
School	2,271K	4%
University/College	1,987K	3%
Nursing Home	1,665K	3%
Food Retail	1,453K	2%
Total	**63,938K**	**100%**

38 Several commercial segments are further segmented by size (large or medium/small) including apartment, hotel, nonfood retail, office and school. The "other" segment includes facilities that do not fit into any of the other segments.

Exhibit 60 – 2019 Commercial Natural Gas Consumption (GJ) by End Use

Parent End Use	Consumption (GJ)	%
Space heating	35,556K	56%
Water heating	19,619K	31%
Food Service	4,800K	8%
Other	3,384K	5%
Pools; Spas & Hot Tubs	579K	1%
Total	**63,938K**	**100%**

Exhibit 61 – 2019 Commercial Natural Gas Consumption (GJ) by Region

Region	Consumption (GJ)	%
Lower Mainland x Van	30,920K	48%
City of Vancouver	13,507K	21%
Southern Interior	9,153K	14%
Vancouver Island	6,881K	11%
Northern BC	2,809K	4%
Whistler	667K	1%
Total	**63,938K**	**100%**

5.2.1 Accounts

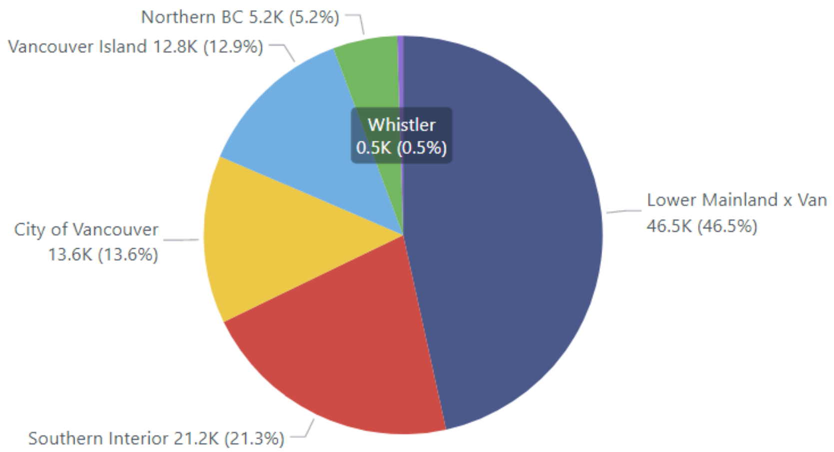
Base year commercial natural gas accounts are presented by segment in Exhibit 62 and by region in Exhibit 63. As shown in these exhibits, in 2019 the greatest number of commercial natural gas accounts were in:

- The other (30%), apartment (27%), office (13%), and nonfood retail (11%) segments
- The Lower Mainland excluding Vancouver region (47% of accounts)

Exhibit 62 – 2019 Commercial Natural Gas Accounts by Segment

Segment	Accounts	%
Other	29,520	30%
Apartment	26,813	27%
Office	13,359	13%
Nonfood Retail	11,211	11%
Restaurant	6,701	7%
Warehouse	4,289	4%
Food Retail	1,857	2%
School	1,713	2%
Hospital	1,640	2%
Hotel	1,534	2%
Nursing Home	660	1%
University/College	524	1%
Total	**99,821**	**100%**

Exhibit 63 – 2019 Commercial Natural Gas Accounts by Region



5.2.2 Tertiary Load

Tertiary load is the useful energy delivered to an end use. In the context of the CPR, tertiary load is the amount of energy required to be delivered as an end use *service*: heat delivered by a boiler to a square meter of office space, for example. This differs from consumption of natural gas which is impacted by the efficiency of the equipment: in the boiler example, consumption is equal to the tertiary load divided by the seasonal efficiency of the boiler.

5.2.3 Unit Energy Consumption

Recall that unit energy consumption (UEC) is the amount of energy used by each end use per unit (a "unit" in the commercial sector is square meter of floor area) and fuel share is the percentage of the energy end use that is supplied by each fuel.

This section presents a sample calculation of UEC for the space heating end use. Along with UEC values is *unit tertiary load*, which is the average tertiary load, by end use, per square meter, and *stock average efficiency*, which is the average efficiency of equipment serving the tertiary load for that end use. These values are included in the table because UEC by end use is calculated by dividing unit tertiary load with stock average efficiency. Values are presented for one segment, region and end use as an example.

Exhibit 64 presents unit tertiary load, stock average efficiency and UEC values for space heating in large offices in the Lower Mainland excluding Vancouver region.

Exhibit 64 – 2019 Space Heating UEC values by End Use, Large Offices in the Lower Mainland

	Unit Tertiary Load ($GJ/m^2.yr.$)	Stock Average Efficiency (%)	UEC ($GJ/m^2.yr.$)
Space heating	0.3	80%	0.3

5.2.4 Average Natural Gas Use per Building

The following exhibit presents average annual natural gas consumption per m^2 for space heating. Included in the exhibit is:

- UEC: the amount of energy used by each end use per unit. The "unit" in commercial sector is square meter of floor area.
- Fuel Share: the percentage of the energy end use that is supplied by each fuel (in this case, natural gas).
- Saturation: reflects the extent to which an end use is present in a region, and segment.

Average annual gas consumption per unit is calculated by multiplying these three variables together; therefore, they are included in the table below. Values are presented for one segment, region and end use as an example.

Exhibit 65 presents average annual gas use for space heating per large office in the Lower Mainland excluding Vancouver ("LML") region.

Exhibit 65 – 2019 Average Annual Space Heating Gas Use Per m^2, Large Offices, LML

	UEC	Fuel Share	Saturation	Average Annual Gas Use ($GJ/m^2.yr.$)
Space heating	0.3	75%	100%	0.25

5.3 Reference Case Natural Gas Use

This section profiles the reference case forecast (2020-2040) natural gas consumption for the commercial sector.

Overall gas consumption in the commercial sector is forecasted to increase over time: consumption in 2040 is expected to be approximately 26% higher than consumption in 2020, with an average annual increase of about 1% from 2020 to 2040. Consumption patterns from 2019 base year are expected to persist throughout the reference case. Natural gas is expected to continue to be used largely in apartments, other and office segments (as shown in Exhibit 66), for space heating (Exhibit 67) and in the Lower Mainland excluding Vancouver region (Exhibit 68).

The forecasted increase in commercial gas consumption can be explained by the following trends:

- There is a forecasted increase in the number of commercial accounts, as seen in Exhibit 69. The growth in accounts is somewhat counterbalanced by a decrease in usage per square meter. However, the decrease in usage per square meter is less than 0.5% per year on average while the increase in floor area due to account growth is more than 1.5% per year. The net result is consumption is forecasted to increase by about 1% per year.
- FortisBC has observed ongoing growth in commercial accounts in recent years with little change in usage per customer. The growth we have estimated is somewhat less than the historical trend, because of our assumed improvement in efficiency. We expect growth in commercial consumption to be further reduced by the future Step Code changes.

Exhibit 66 – 2020 vs 2040 Commercial Gas Consumption Forecast (GJ) by Segment

Segment	2020	2040	Change %
Apartment	19,968K	24,618K	23%
Other	12,440K	15,991K	29%
Office	7,205K	9,086K	26%
Restaurant	4,373K	5,743K	31%
Nonfood Retail	3,634K	4,701K	29%
Warehouse	4,215K	4,639K	10%
Hotel	2,540K	3,628K	43%
Hospital	3,082K	3,437K	12%
School	2,320K	3,319K	43%
Nursing Home	1,713K	2,608K	52%
Food Retail	1,478K	2,194K	48%
University/College	1,986K	2,009K	1%
Total	**64,953K**	**81,973K**	**26%**

Space heating and water heating end uses are expected to grow slower than other end uses, as shown in Exhibit 67. This also implies a slight decline in their ratio to overall building consumption by 2040. This decline is largely driven by:

- Improved new construction practices and more stringent equipment performance standards.
- Natural replacement of space heating and water heating equipment at the end of life. It is assumed that 50% of those replacing such equipment would adopt space heating equipment that was 85% efficient and water heating equipment that was 80% efficient. As a result, the average consumption per square meter for these two end uses was assumed to be declining slightly with time.

Exhibit 67 – 2020 vs 2040 Commercial Gas Consumption Forecast (GJ) by End Use

Parent End Use	2020	2040	Change %
Space heating	36,063K	45,300K	26%

5.3.1 Commercial Reference Case Natural Gas Use: Existing versus New Buildings

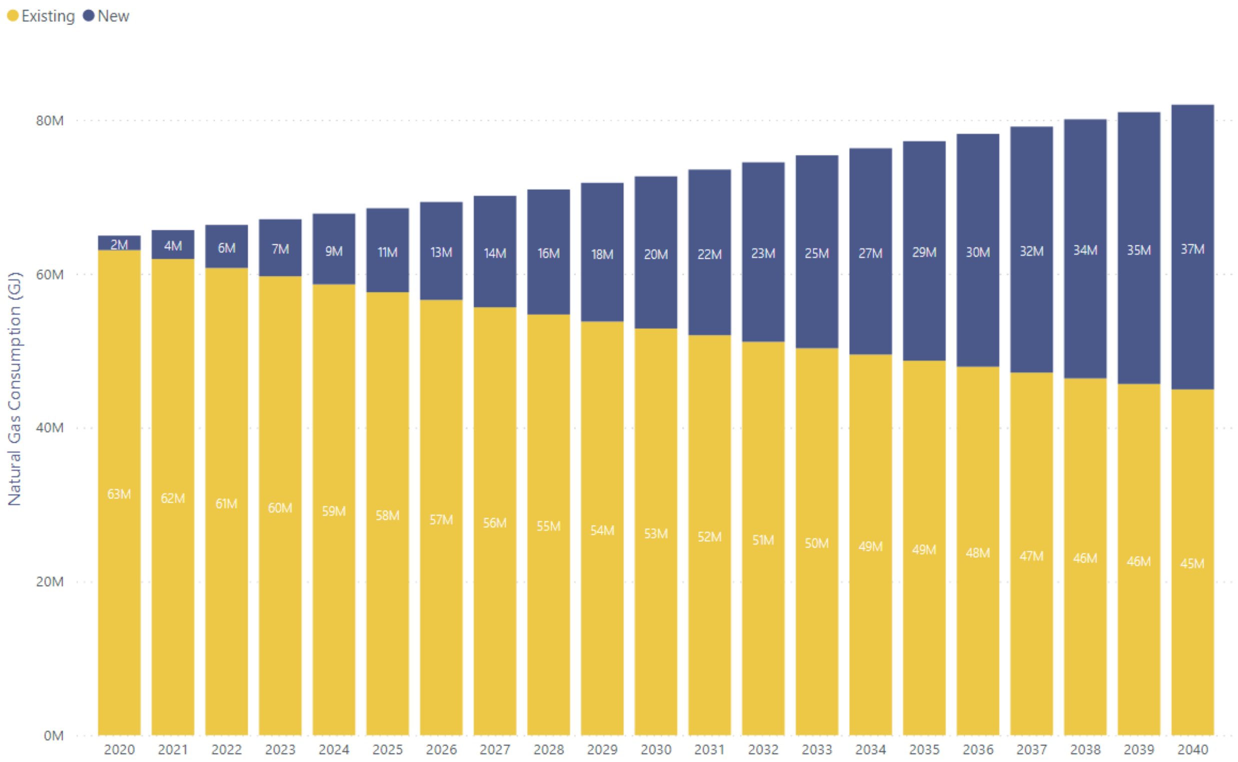
This section compares the consumption in existing versus new commercial facilities in the reference case forecast. Estimated new construction rates are drawn from rate-class level estimates developed by FEI and are applied by segment. Demolition rates are estimated at approximately 2% of floor area per year and held constant across segments. It is assumed that existing commercial buildings that are demolition are replaced by newly constructed buildings. This results in a forecasted commercial gas account increase of 23% by 2040, as shown in Exhibit 70.

In 2020, natural gas consumption from new buildings was roughly two million GJ, or 3% of the total commercial sector consumption. By 2040, new buildings are forecasted to use 37 million GJ (45% of total sector), as shown in Exhibit 71.

Exhibit 70 – 2020 vs 2040 Commercial Gas Accounts Forecast by Existing and New Vintage

Existing/New	2020	2040	Change %
Existing	97,844	65,843	-33%
New	3,144	58,167	1,750%
Total	**100,988**	**124,010**	**23%**

Exhibit 71 – 2020 vs 2040 Commercial Gas Consumption Forecast (GJ) by Existing and New Vintage



5.4 Measure Assessment

5.4.1 List of Measures

The list of commercial measures that were included in this CPR are presented in Exhibit 72. The measures are divided into categories by end use and measure type.

Please see the MS Excel file entitled "Com_Measure Analysis Workbook" for a description of each measure and a full analysis.

Measures were classified in five measure type categories:

- Building Envelope
- Equipment
- Controls
- Energy Management (including behavioral measures)
- New Construction – all new construction measures were placed in a separate category

New construction measures are analyzed using a whole-building approach, represented by the Step 2 - Step 4 BC Energy Step Code measures listed below. See Appendix O of the CPR Appendices document for the modelling approach used to assess these measures.

Exhibit 72 – Commercial Sector Conservation and Energy Management Measures

Refrigeration Waste Heat Recovery
Rink De-Aerator
Solar Air Preheating
Steam to Hot Water Conversion

[39] Note that analysis that forms the technical, economic and market potential is based on individual measures rather than on "packages of measures" or program delivery approaches. Measures packaged in comprehensive programs such as FortisBC's Rental Apartment Efficiency program, Social Housing Retrofit Support program and deep energy retrofits were assessed within this analysis individually but not also collectively as a program package.

5.4.2 Results

Exhibit 73 shows measure-level results for the commercial sector in order of decreasing cost effectiveness. Measures were assessed based on their replacement type: **retrofit** (immediate replacement at full cost), **replace on burnout** (end of life replacement at incremental cost), or **new construction** (immediate installation at incremental cost).

The TRC and MTRC are presented at the measure-level and exclude program costs and free ridership.

Key findings of the measure assessment for the commercial sector include:

- Of the 71 measures included in the assessment, 46 pass the TRC screen and 69 pass the MTRC screen.
- New Construction Step 2 and 3 pass the TRC screen and Step 4 does not.
- Gas heat pumps (Combination type) pass the TRC.
- Aerosol-applied air sealing passes TRC screen, with significant potential for energy savings in existing buildings (especially MURBs).

5.5 Technical Potential

This section provides an overview of the technical potential savings results for the commercial sector. Overall results are presented below, followed by measure level results and supply curves for the TRC and MTRC results.

As shown in Exhibit 74, the majority of the commercial technical potential (24 PJ) would be available in 2021 and would increase to 35 PJ in 2040. This indicates that a lot of the available potential (around 11 PJ) would come from replace on burnout measures over the next two decades. The forecasted natural gas consumption is included for reference.

Exhibit 74 – Commercial Technical Potential Savings (GJ)

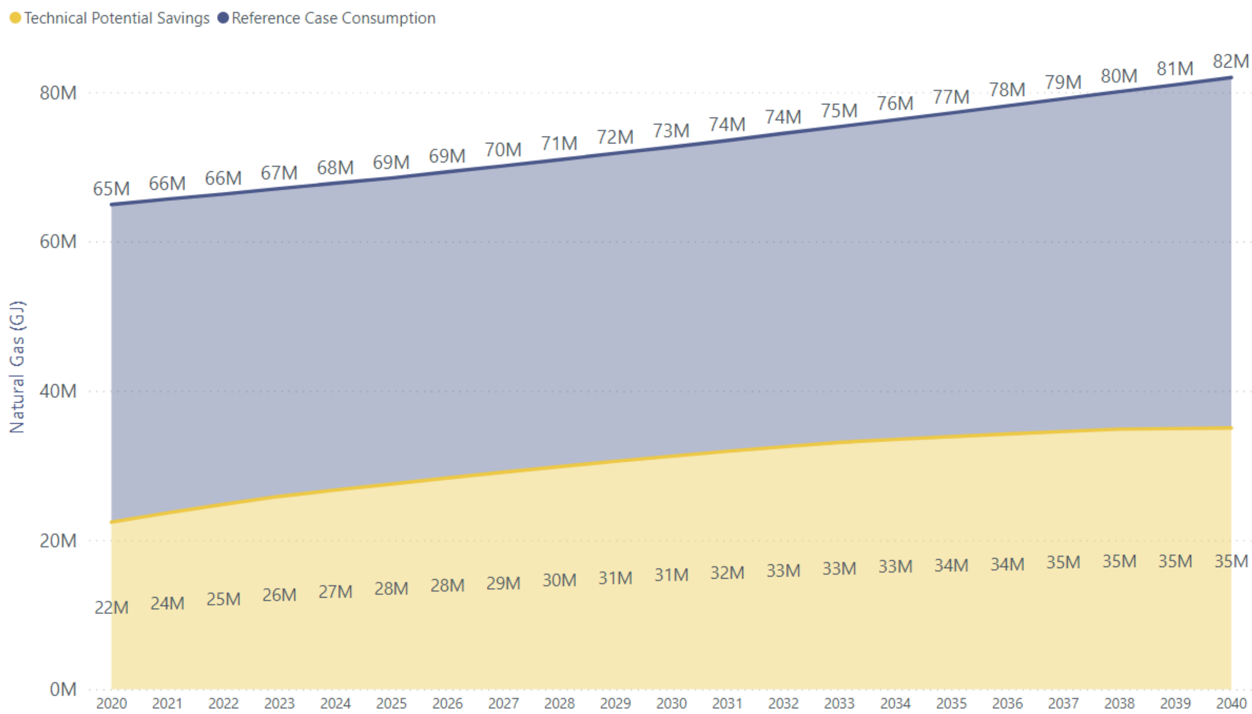

Exhibit 75 – Technical Savings Potential as a Percent of Commercial Reference Case Consumption (%)

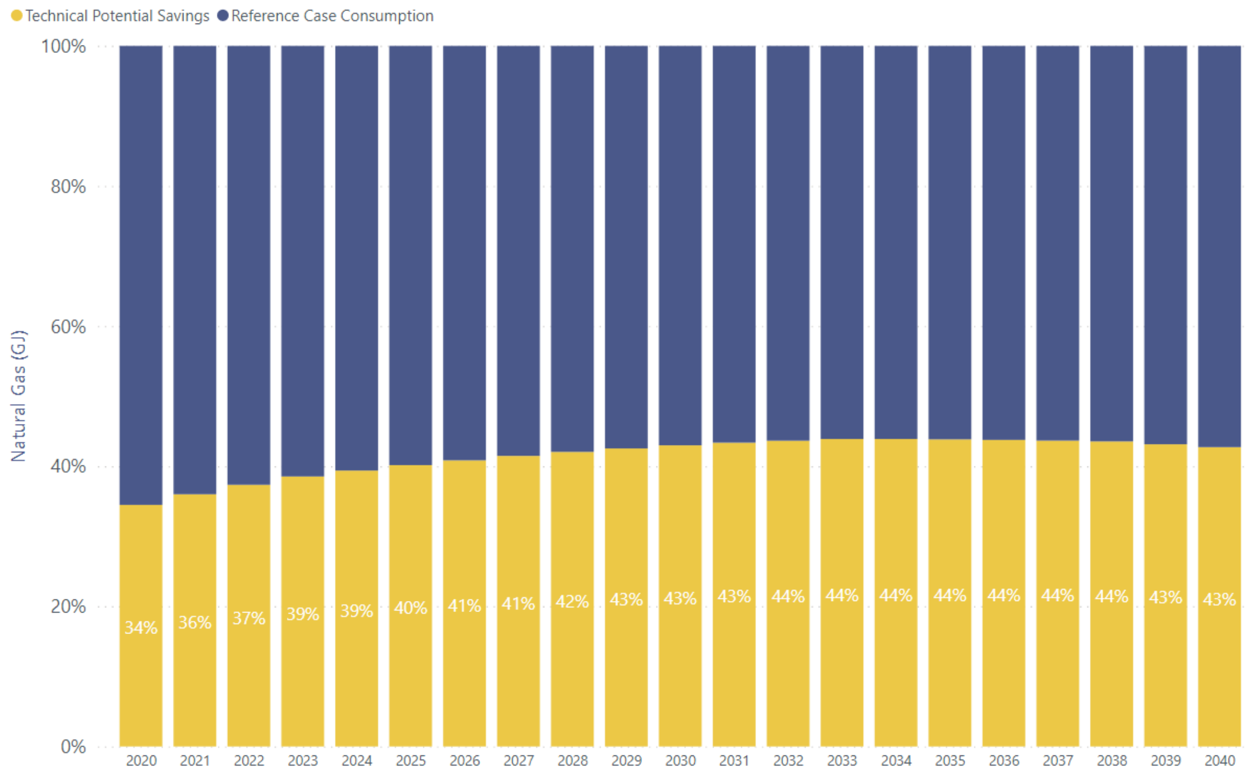
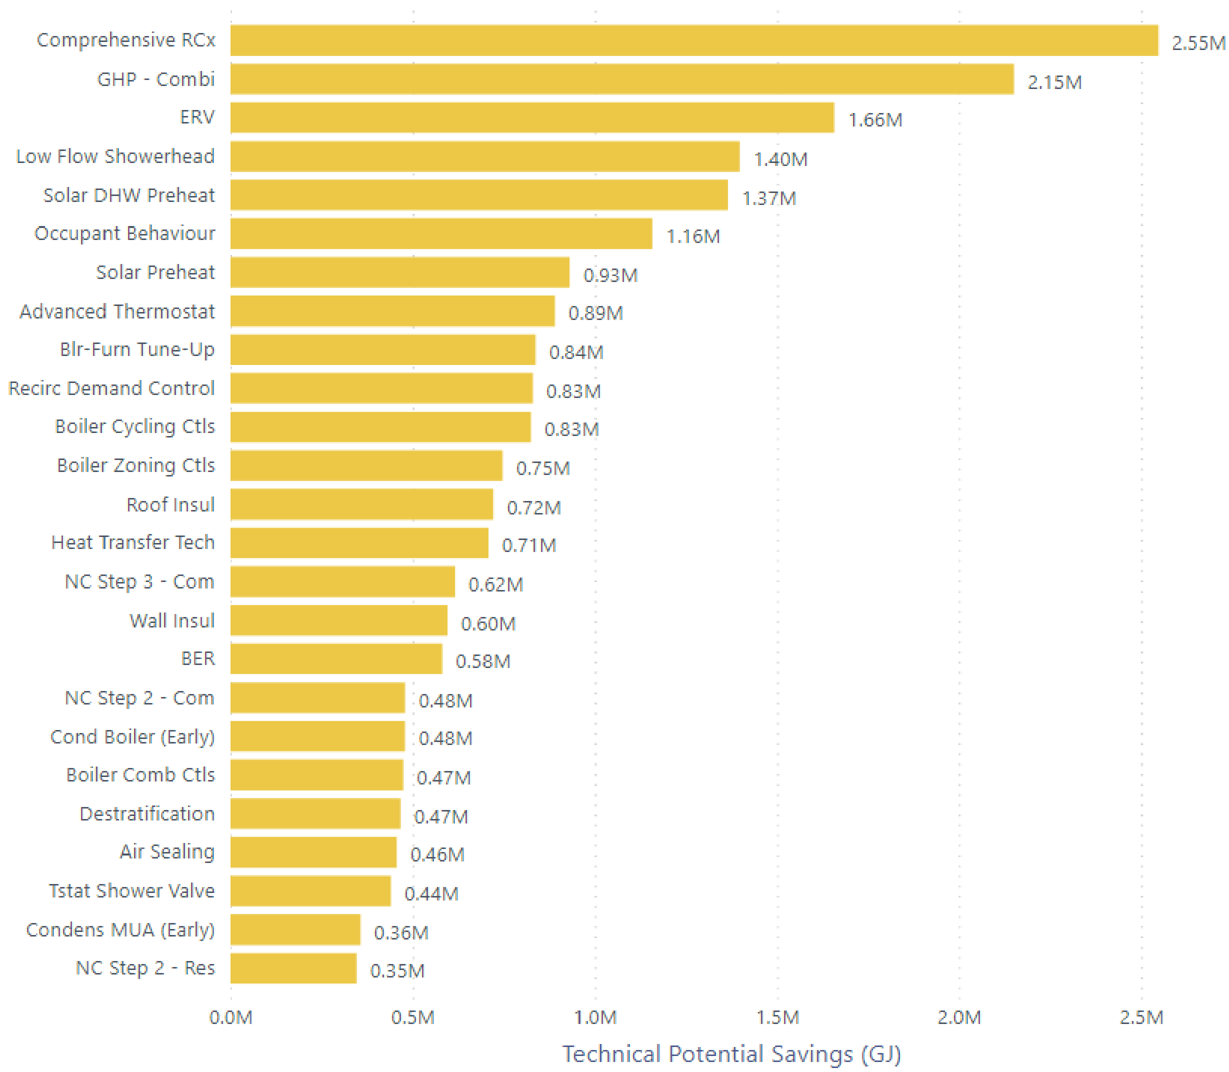


As shown in Exhibit 75, the technical potential savings is about 36% of commercial reference case consumption in 2021 and increases to 43% by 2040, further indicating a fairly balance mix of potential from both retrofit and replace on burnout measures.

The technical potential savings in 2025 broken down by measure (only the top 25 measures are shown) are presented in Exhibit 76. From the top 5 measures that are expected to contribute the majority of the technical potential savings, only Solar DHW Preheat does not pass the TRC test. This means that the rest (the top 4) will also be expected to contribute largely to economic potential savings, as described in the following section.

Exhibit 76 – Technical Potential - Top 25 Commercial Measures in 2025 (GJ)

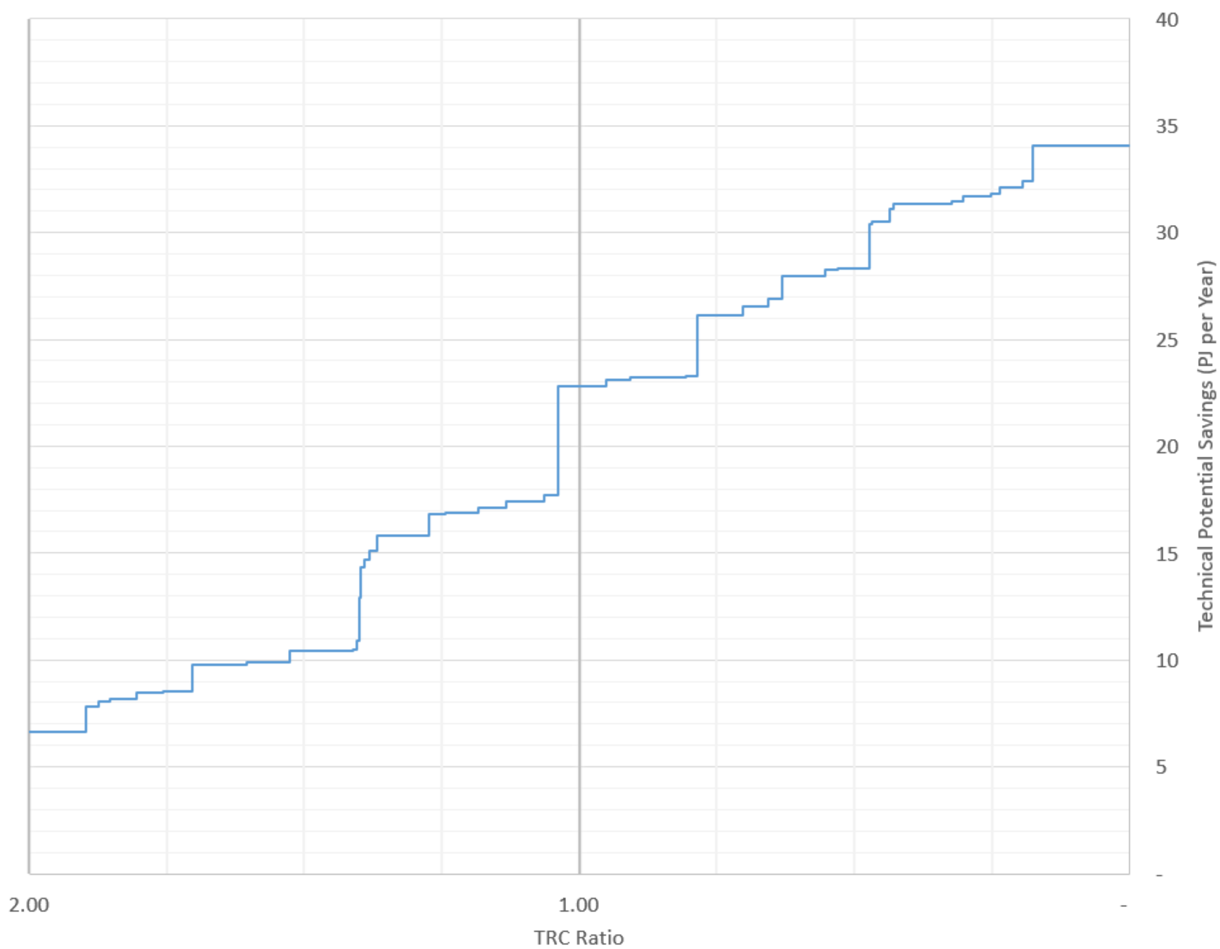


The cumulative commercial sector technical potential savings in 2040 are presented in Exhibit 77 as a supply curve, with measures ordered by decreasing TRC ratio from left to right.

As shown, approximately 68% of the commercial sector technical potential savings (approximately 23 of 34 PJ) comes from measures with a TRC of 1.0 or higher.

Approximately 7 PJ of savings come from measures with a TRC ratio of greater than 7. These are shown in aggregate.

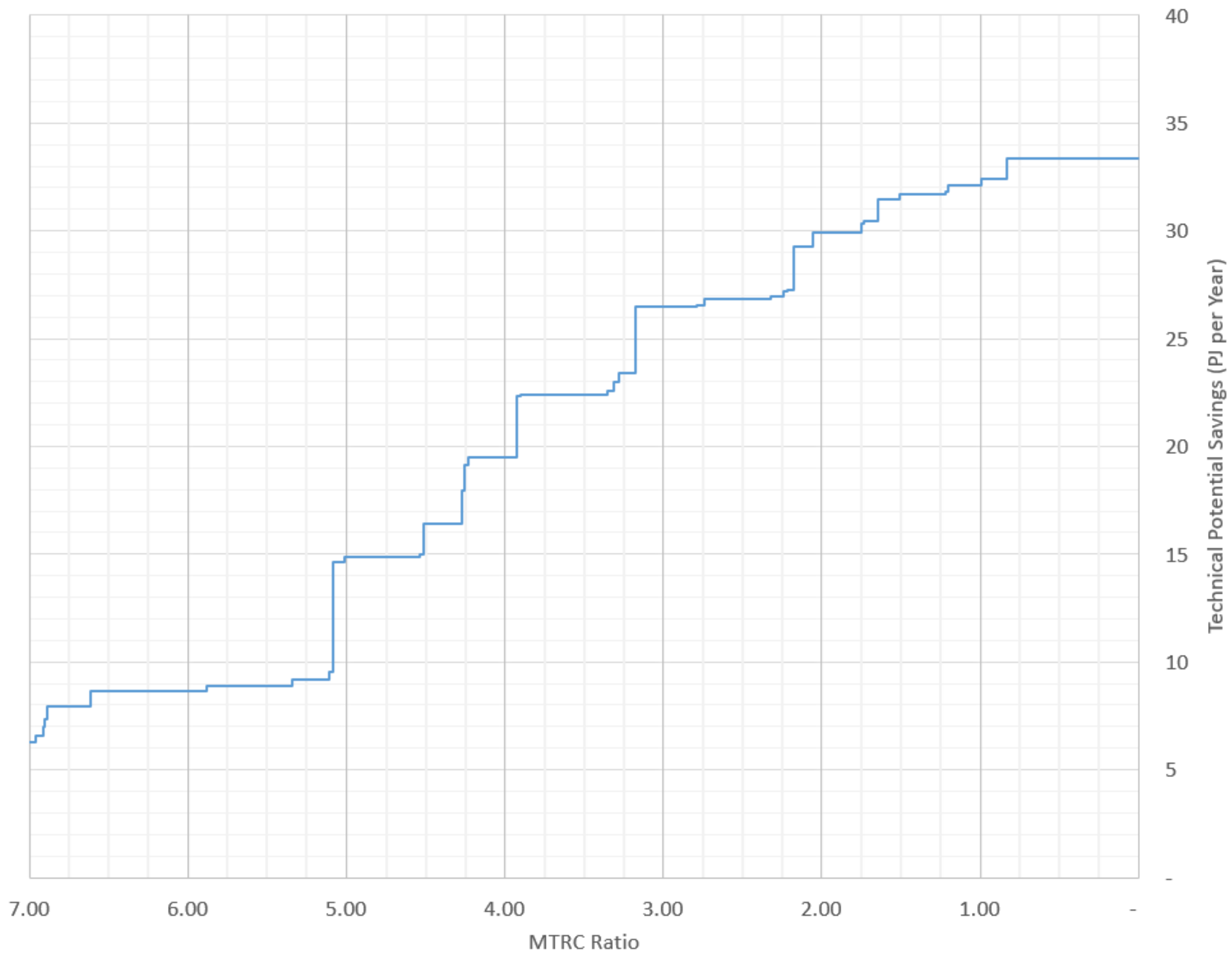
Exhibit 77 – Commercial Sector: Technical Potential Gas Supply Curve in 2040 – TRC Ratio



Similar to Exhibit 77, the cumulative commercial sector technical potential savings in 2040 are presented in Exhibit 78 as a supply curve, with measures ordered by decreasing MTRC ratio from left to right.

As shown, approximately 95% of the commercial sector technical potential savings (approximately 32 of 34 PJ) by 2040, comes from measures with an MTRC of 1.0 or higher. Approximately 6 PJ of savings come from measures with an MTRC ratio of greater than 7. These are shown in aggregate.

Exhibit 78 – Commercial Sector: Technical Potential Supply Curve – MTRC Ratio

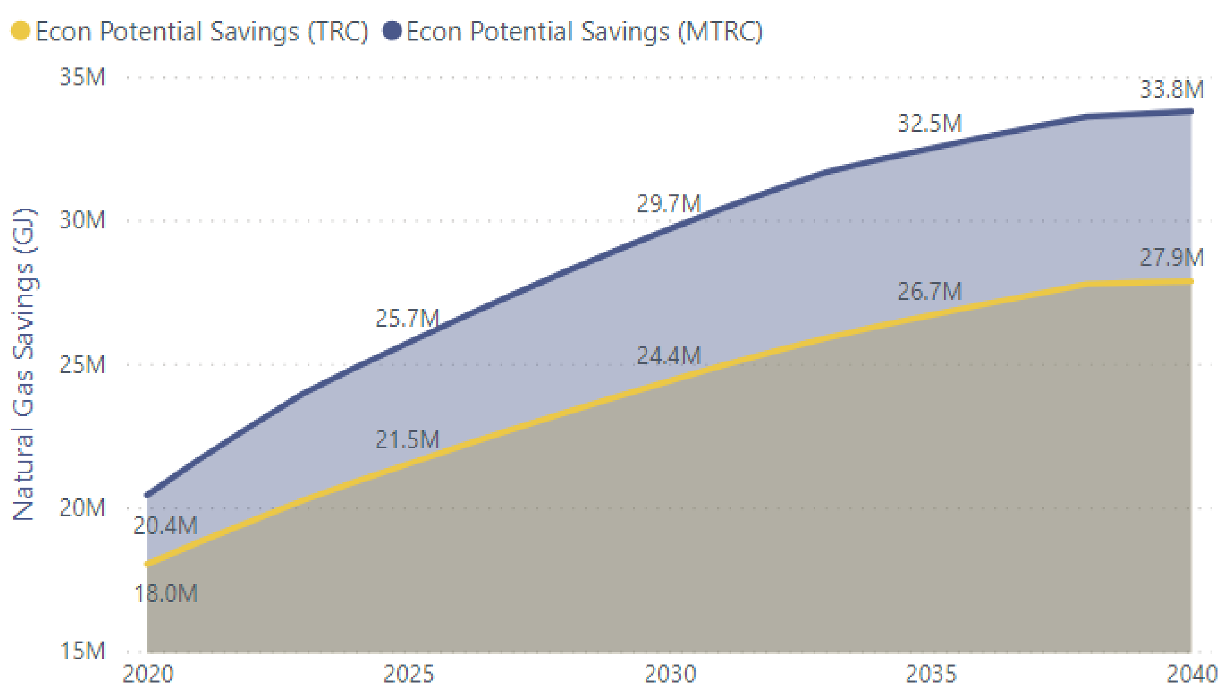


5.6 Economic Potential

This section provides the economic potential savings results for the commercial sector from 2020 to 2040. We conducted two economic potential assessments: one using a TRC Screen that includes measures with a TRC ratio of 1 and above, and one using an MTRC screen that includes measures with an MTRC of 1 and above. Outputs of both economic models are presented in this section.

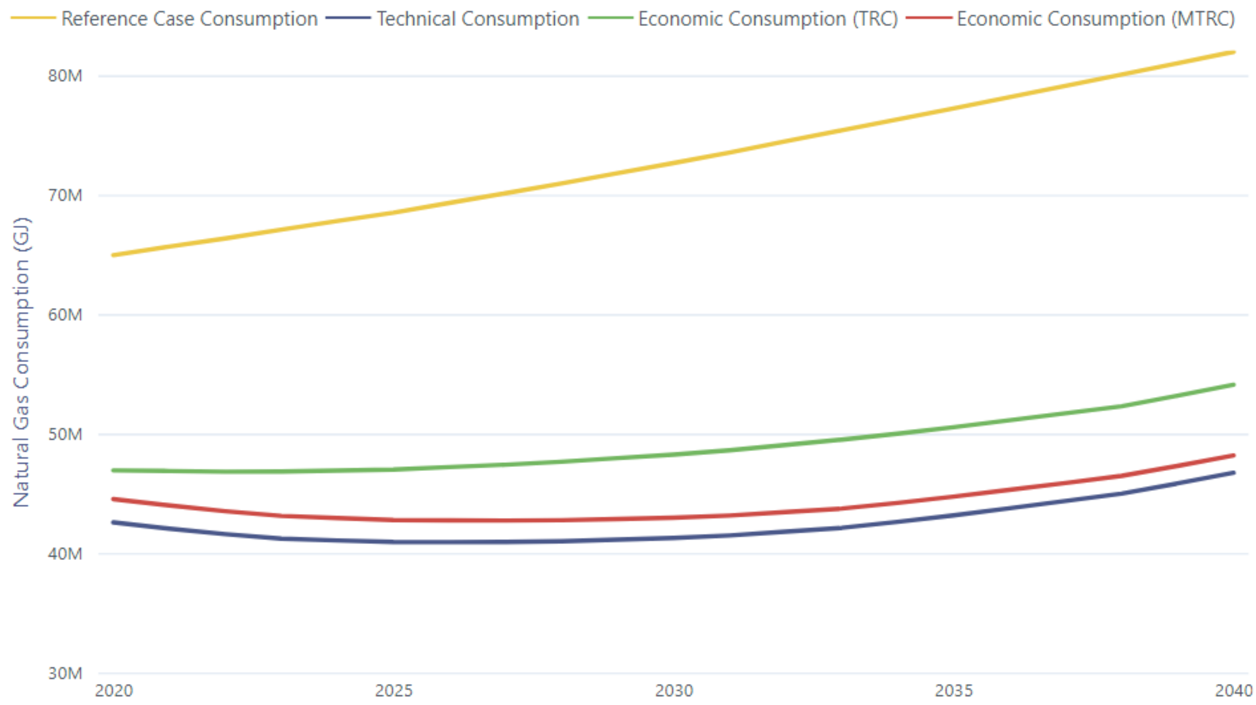
The commercial sector economic potential savings with a TRC screen and with an MTRC screen are shown in Exhibit 79. As mentioned earlier, of the 72 measures included in the assessment, 52 pass the TRC screen and 70 pass the MTRC screen. The 18 measures that that pass the MTRC but fail the TRC make up the difference between the two economic potential scenarios. The difference in economic potential in 2025 is around 4.2 PJ. Another way to look at it that the 84% of the MTRC economic potential comes from measures that pass the TRC as well.

Exhibit 79 – Economic Potential Savings (GJ) – Commercial, TRC and MTRC



The forecasted gas consumption under the technical potential, economic potential with a TRC screen, economic potential with an MTRC screen, and reference case scenarios for the commercial sector are shown in Exhibit 80. The slight uptick at the beginning of the curves is due to the implementation of the retrofit measures. The rest of the curves follow the shape of the reference case curve, as the replace on burnout measures are implemented at equipment end of life.

Exhibit 80 – Economic Potential Consumption (GJ) Forecasts – Commercial, TRC and MTRC



Results by Region

The TRC and MTRC economic potential savings in 2025 are presented by region in Exhibit 81 and Exhibit 82 respectively. The largest economic potential savings (10 PJ to 12.6 PJ depending on economic screen) are estimated to occur in the Lower Mainland outside of the City of Vancouver. Although small in absolute savings, the largest percentage of savings is expected to be captured in northern BC (more than 39% of reference case consumption).

Exhibit 81 – Economic Potential Savings by Region in 2025 – Commercial, TRC

Region	Consumption (GJ)	Economic Potential Savings (GJ)	Economic %
Lower Mainland x Van	33,493K	10,254K	31%
City of Vancouver	14,237K	4,418K	31%
Southern Interior	10,124K	3,322K	33%

Total	**68,513K**	**25,731K**	**38%**

Results by Segment

The TRC and MTRC economic potential savings in 2025 are presented by segment in Exhibit 83 and Exhibit 84 respectively. The largest amounts of savings are expected to occur in apartments, other, and office segments. In both economic scenarios, the highest percentage of savings are expected to be captured offices, schools, university colleges.

Exhibit 83 – Economic Potential Savings by Segment in 2025 – Commercial, TRC

Segment	Consumption (GJ)	Economic Potential Savings (GJ)	Economic %
Apartment	20,961K	6,496K	31%

Nonfood Retail	3,888K	1,273K	33%
School	2,549K	1,268K	50%
Hotel	2,800K	1,038K	37%
Restaurant	4,666K	989K	21%
University/College	1,752K	879K	50%
Nursing Home	1,940K	718K	37%
Food Retail	1,633K	551K	34%
Total	**68,513K**	**25,731K**	**38%**

Results by End Use

The TRC and MTRC economic potential savings in 2025 are presented by segment in Exhibit 85 and Exhibit 86 respectively. The largest amounts, in absolute savings, as well as the highest percentage of savings relative to reference case consumption, are expected to be captured under the space heating end use (40% to 49% depending on the economic scenario).

Exhibit 85 – Economic Potential Savings by End Use in 2025 – Commercial, TRC

Parent End Use	Consumption (GJ)	Economic Potential Savings (GJ)	Economic %
Space Heating	37,973K	15,088K	40%
Water heating	20,913K	6,218K	30%
Food Service	5,322K	205K	4%
Other	3,674K	0K	0%
Pools; Spas & Hot Tubs	632K	0K	0%
Total	**68,513K**	**21,511K**	**31%**

Exhibit 86 – Economic Potential Savings by End Use in 2025 – Commercial, MTRC

Parent End Use	Consumption (GJ)	Economic Potential Savings (GJ)	Economic %
Space Heating	37,973K	18,543K	49%
Water heating	20,913K	6,707K	32%
Pools; Spas & Hot Tubs	632K	274K	43%
Food Service	5,322K	205K	4%
Other	3,674K	0K	0%
Total	**68,513K**	**25,731K**	**38%**

The TRC and MTRC economic potential savings in 2040 are presented by end use in Exhibit 87. The difference of almost 6 PJ is mostly a result of more space heating measures being included in the MTRC scenario. A small but interesting change is the pools, spas, and hot tubs end use, which contributed no savings under the TRC scenario, but has 219K GJ of economic potential under the MTRC.

Exhibit 87 – Economic Potential Savings by End Use in 2040 – Commercial, TRC and MTRC

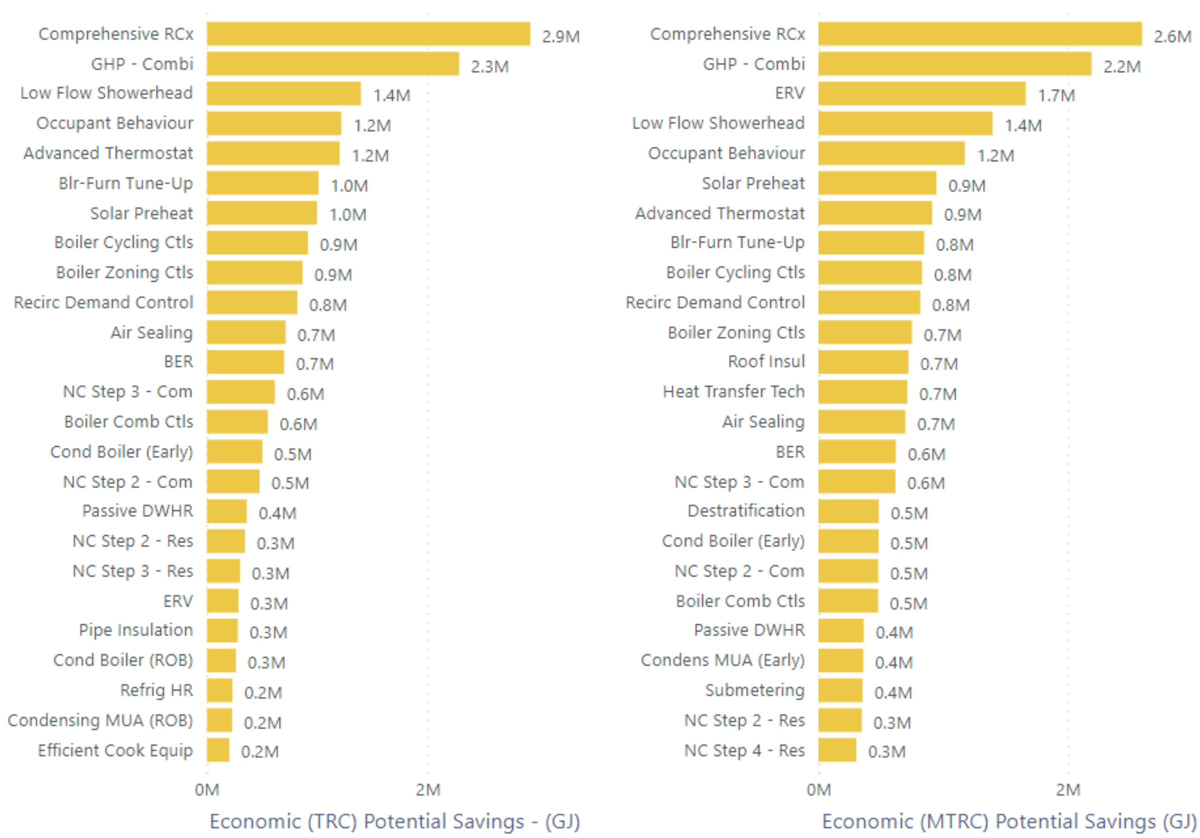
Parent End Use	Economic Savings (GJ) - TRC	Economic Savings (GJ) - MTRC	Difference (GJ)
Space Heating	19,735K	24,646K	4,910K
Water heating	7,822K	8,609K	787K
Food Service	313K	313K	0K
Pools; Spas & Hot Tubs	0K	219K	219K
Other	0K	0K	0K
Total	**27,870K**	**33,786K**	**5,916K**

Results by Measure

The economic potential savings in 2025 broken down by measure (only the top 25 measures are shown) are presented in Exhibit 88. The top measures in the TRC economic potential are shown on the left and on the MTRC scenario is shown on the right. Comprehensive recommissioning and combination gas heat pumps top the list in both scenarios. The MTRC scenario list on the right is almost similar to the top technical potential measures presented in Exhibit 76.

The main differences between the TRC and MTRC list are that the energy recovery ventilators (ERVs) become one of the top measures under MTRC. Other notable additions to the MTRC scenario include heat transfer technologies and roof insulation measures.

Exhibit 88 – Economic Potential (TRC on Left, MTRC on Right) - Top 25 Commercial Measures in 2025 (GJ)



5.7 Market Potential

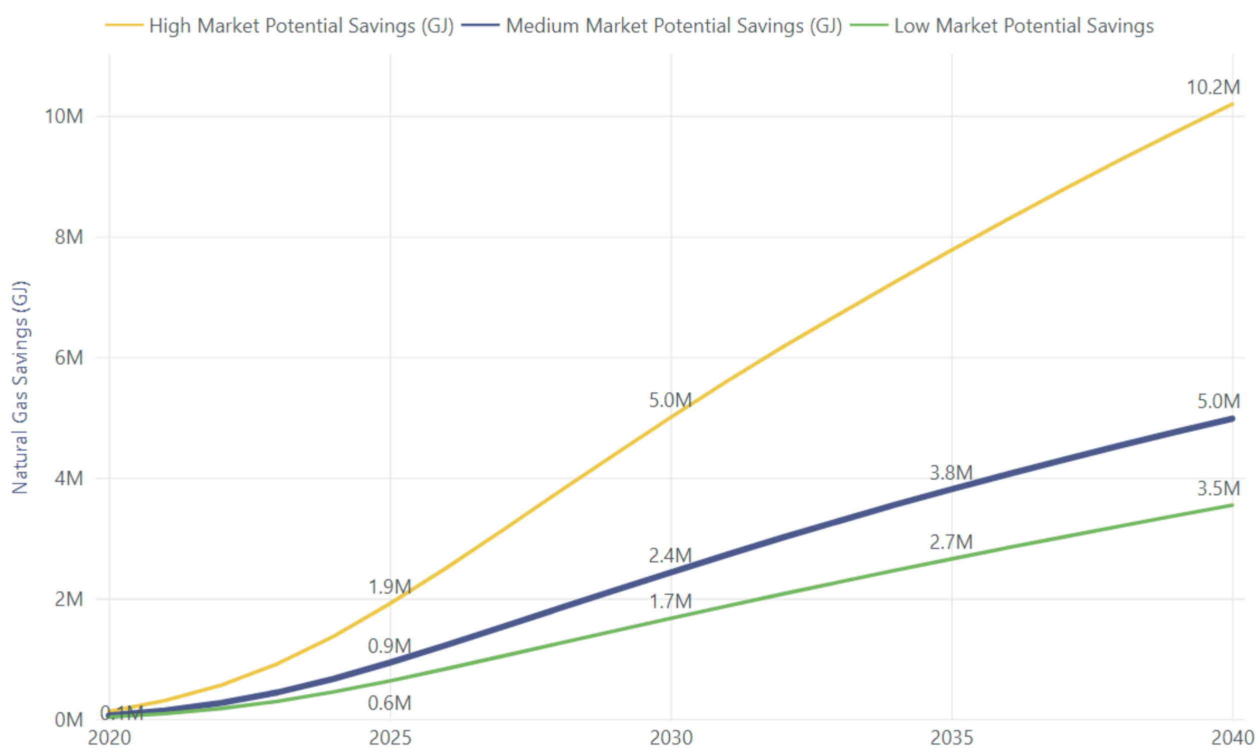
This section provides an overview of the low, medium, and high market potential results for the commercial sector.

Low, medium, and high scenarios assume that measure incentive levels will be 25%, 50% and 100% of incremental costs, respectively. For example, assume that a high-efficiency furnace may cost $200 more than a standard furnace, meaning the furnace would have an incremental cost of $200. In the medium scenario, this measure's hypothetical incentive from FortisBC would be $100. The other $100 would be paid by the end user. In all scenarios, the non-incentive program costs are assumed to be 15% of the incentive cost. In the example above, FortisBC's non-incentive spending would be $15. FortisBC's total cost for providing the measure to an end user would be $115.

The market potential savings results, with a TRC screen and with an MTRC screen, are shown in Exhibit 89 and Exhibit 90, respectively. The medium, or realistic, market potential scenarios under both economic screens are close, as the majority of the measures pass both screens.

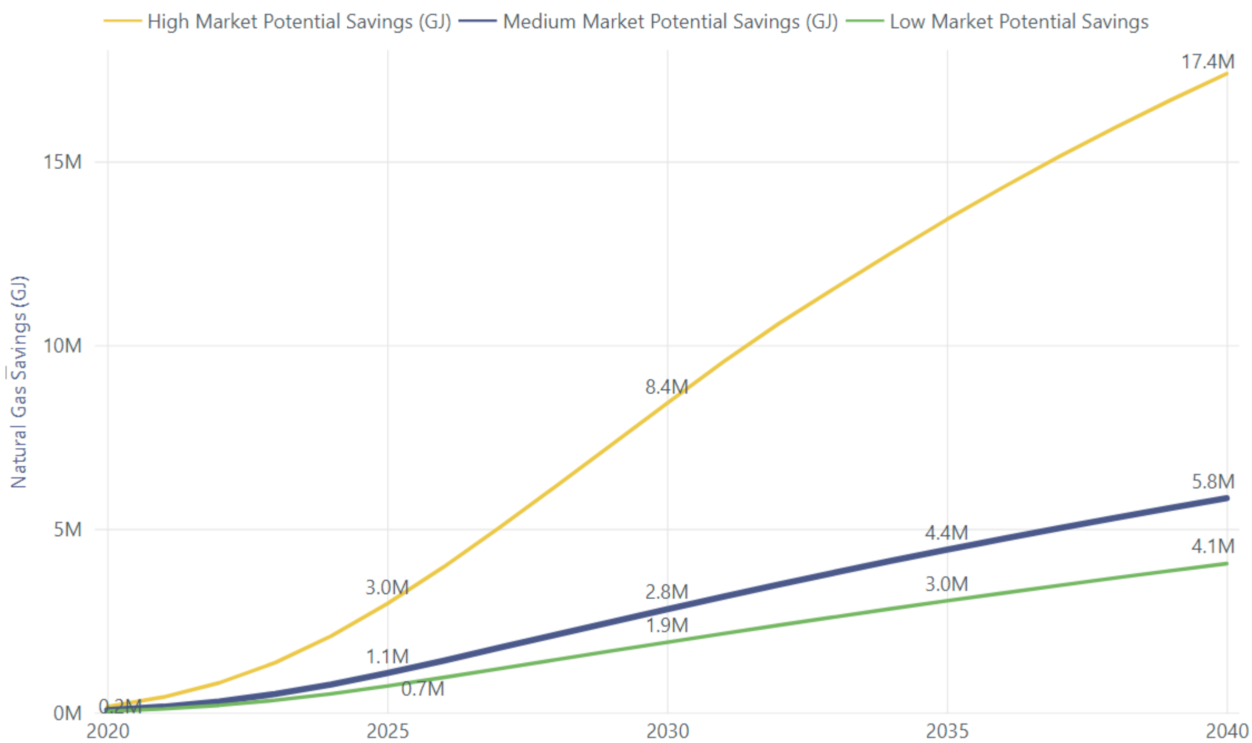
By 2040, the commercial low, medium, and high market TRC potential savings are estimated to be 3.5 PJ, 5 PJ, and 10.2 PJ, respectively.

Exhibit 89 – Market Potential Savings (GJ) – Commercial, TRC



By 2040, the commercial low, medium, and high market MTRC potential savings are estimated to be 4.1 PJ, 5.8 PJ, and 17.4 PJ, respectively.

Exhibit 90 – Market Potential Savings (GJ) – Commercial, MTRC



The high market potential scenario is much higher than the medium market potential in the MTRC scenario. By 2040, the difference in potential between the medium and high market MTRC scenarios is 11.6 PJ. In this case, gas heat pumps (GHPs) are a major factor contributing to the difference:

- For all measures, medium and high scenarios assume that measure incentive levels will be 50% and 100% of incremental costs, respectively.
- In addition to this, gas heat pumps were given different adoption curves in the two scenarios.
- In the medium market scenario, GHPs are modeled as an innovative technology with no current market penetration and low forecasted growth.
- In the high scenario, they are modeled as an innovative technology with no current market penetration, but with high forecasted growth, especially in the second half of the study period (2030-2040).

The difference in MTRC medium and high potential scenarios by 2040, broken down by measure, is shown in Exhibit 91. Only the top 10 measures that contribute to the difference are presented. Gas heat pumps top the list by a sizeable margin, but New Construction Step Code measures and energy recovery ventilators also influence the difference. For comparison, Exhibit 92 shows the difference in TRC medium and high potential scenarios - the absence of gas heat pumps is noticeable here.

Exhibit 91 – Top 10 Commercial Measures Contributing to Difference in Medium and High Market Potential Scenarios (Using MTRC Screen) by 2040

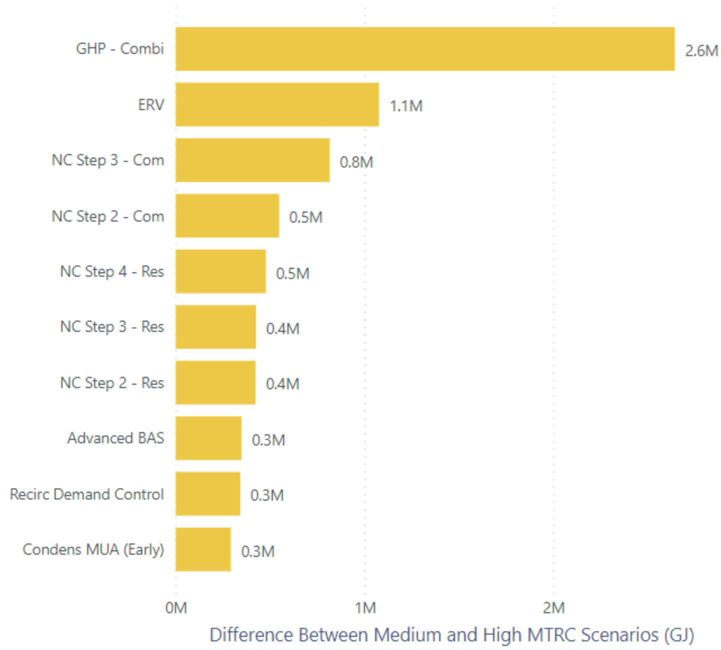


Exhibit 92 – Top 10 Commercial Measures Contributing to Difference in Medium and High Market Potential Scenarios (Using TRC Screen) by 2040

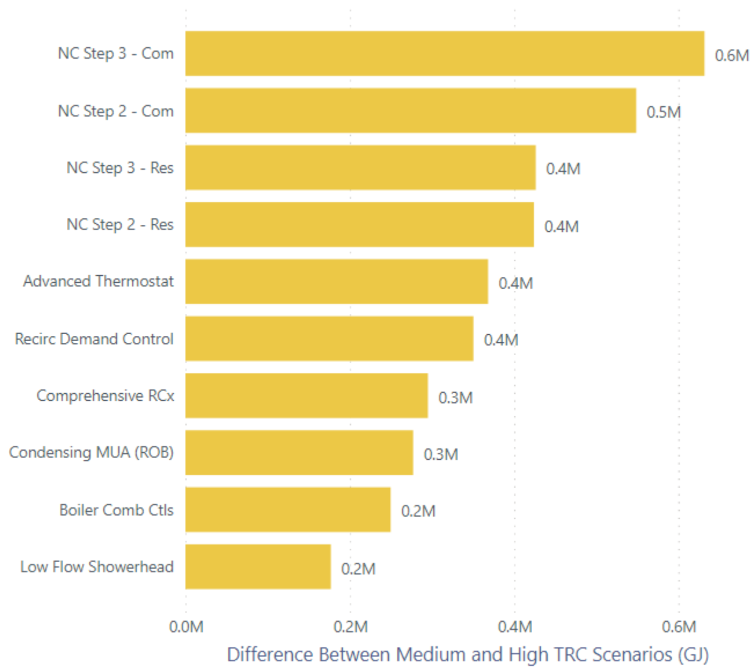

The forecasted gas consumption under the three market potential scenarios relative to reference case scenario for the commercial sector are shown in Exhibit 93 (TRC) and Exhibit 94 (MTRC). By 2040, the commercial low, medium, and high market TRC potential consumption levels are estimated to be 78 PJ, 77 PJ, and 72 PJ, respectively, while reference consumption is forecasted to reach 82 PJ. By 2040, the commercial low, medium, and high market MTRC potential consumption levels are estimated to be 78 PJ, 76 PJ, and 65 PJ, respectively, while reference consumption is forecasted to reach 82 PJ.

Exhibit 93 – Commercial Market Potential Consumption (GJ) Forecasts – Commercial, TRC

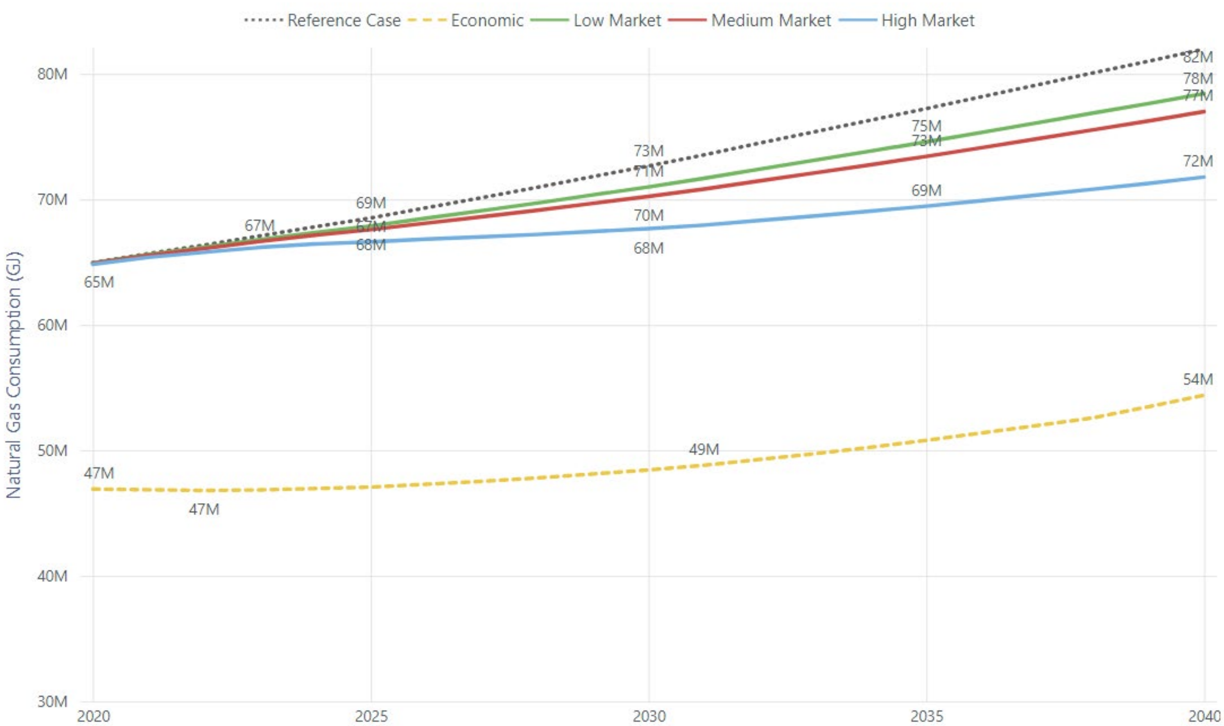

Exhibit 94 – Commercial Market Potential Consumption (GJ) Forecasts – Commercial, MTRC

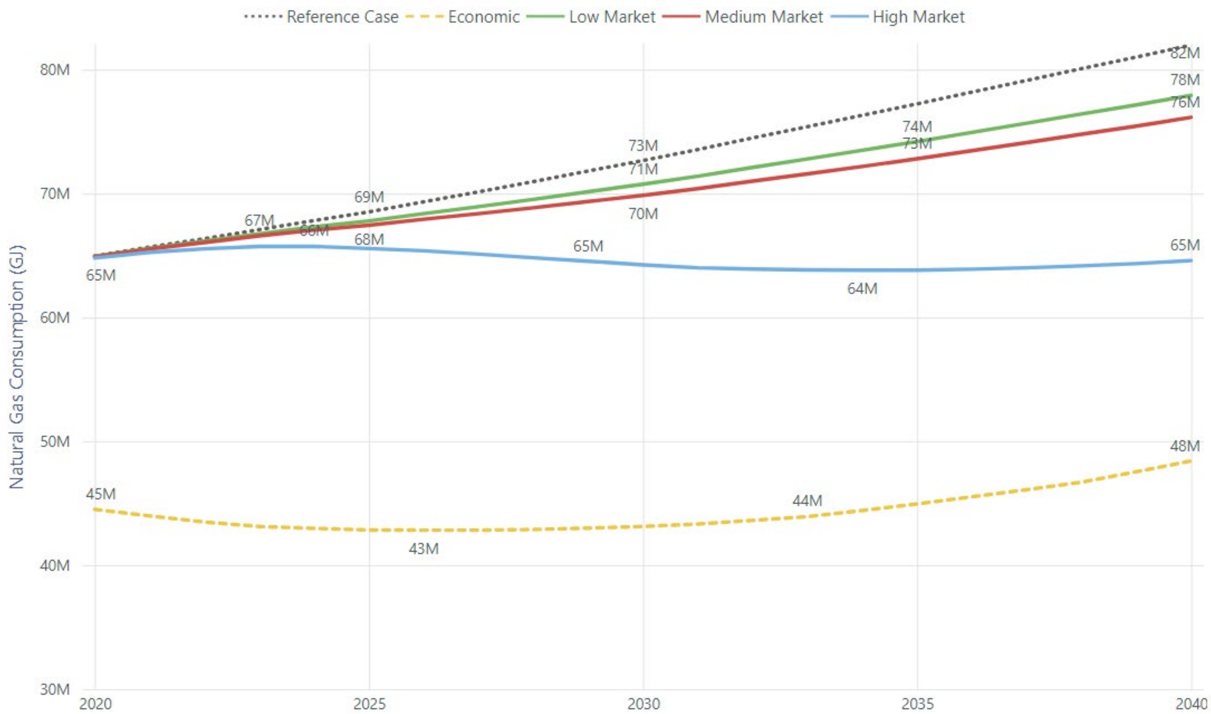

The remainder of this section presents detailed results of the medium market potential scenario only. Similarly detailed results of the low and high market potential scenarios can be found on the Power BI dashboard and the Excel workbooks.

Results by Region

The medium market potential savings for 2025 are presented by region in Exhibit 95 and Exhibit 96 using TRC and MTRC screen, respectively. Medium market potential savings for 2025 are estimated to be between 1% and 2% of reference case consumption in all regions in both medium market scenarios.

Exhibit 95 – Medium Market Potential Savings by Region in 2025 – Commercial, TRC

Region	Ref Case Consumption (GJ)	Medium Market Potential Savings (GJ)	% of Consumption
Lower Mainland x Van	33,493K	425K	1%
City of Vancouver	14,237K	184K	1%

Results by Segment

The medium market potential savings for 2025 are presented by segment in Exhibit 97 and Exhibit 98 using TRC and MTRC screen, respectively. The largest amounts of medium market potential savings are estimated to occur in apartments, other, and office segments.

Exhibit 97 – Medium Market Potential Savings by Segment in 2025 – Commercial, TRC

Segment	Ref Case Consumption (GJ)	Medium Market Potential Savings (GJ)	% of Consumption
Apartment	20,961K	222K	1%

Total	**68,513K**	**1,099K**	**2%**

Results by End Use

The medium market potential savings for 2025 are presented by segment in Exhibit 99 and Exhibit 100 using TRC and MTRC screen, respectively. More than two thirds of the savings come from the space heating end use.

Exhibit 99 – Medium Market Potential Savings by End Use in 2025 – Commercial, TRC

Parent End Use	Ref Case Consumption (GJ)	Medium Market Potential Savings (GJ)	% of Consumption
Space Heating	37,973K	652K	2%
Water heating	20,913K	257K	1%

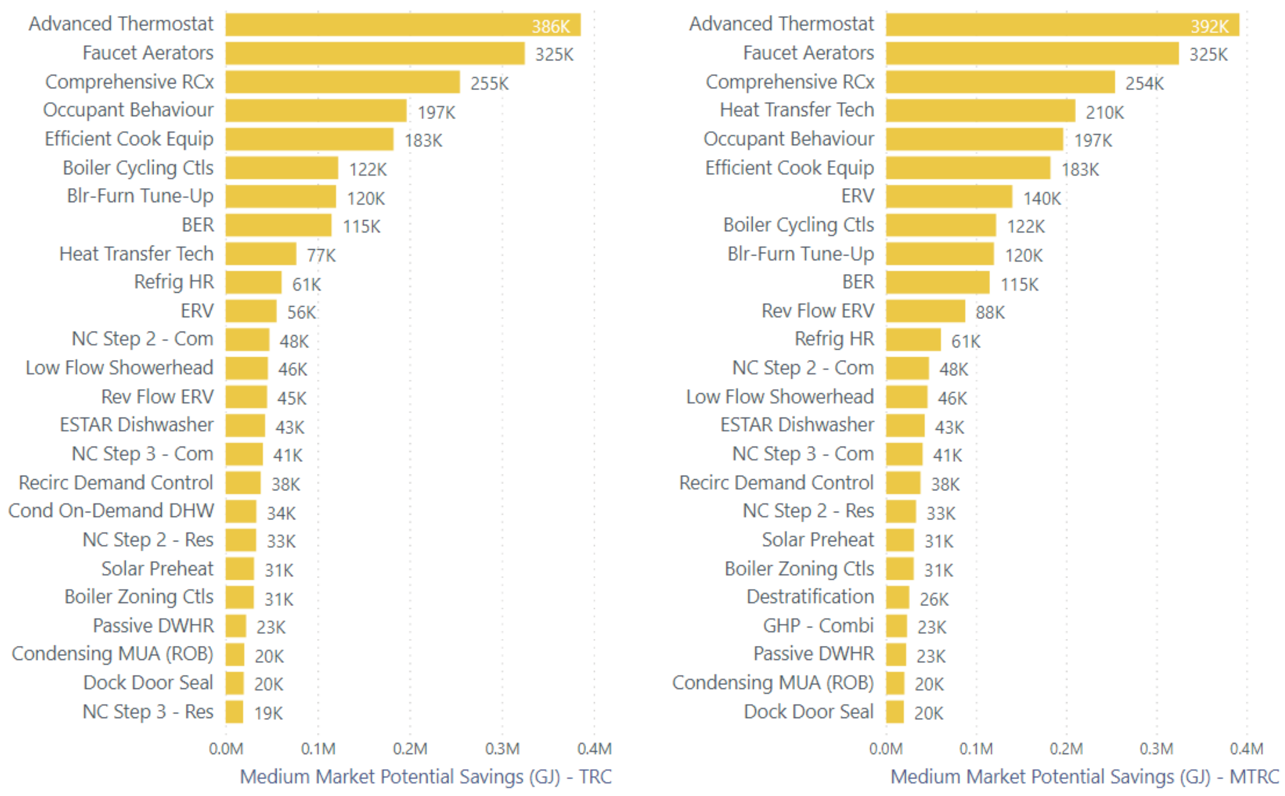
Total	**4,981K**	**5,833K**	**852K**

Results by Measure

The medium market potential savings by 2025 of the top 25 commercial measures are shown in Exhibit 102, sorted by decreasing potential. The top measures in the TRC medium market potential are shown on the left and the top measures in the MTRC scenario are shown on the right. Advanced thermostats, faucet aerators, and comprehensive recommissioning (RCx) top the list in both scenarios. Occupant behavior measures, efficient cooking equipment, and heat transfer technologies have large potential in both scenarios as well. A major change in this top-measures list when compared with the economic potential list is the relatively small contribution of energy recovery ventilators (ERV) and gas heat pumps (GHP Combi).

Exhibit 102 – Medium Market Potential (TRC on Left, MTRC on Right) - Gas Savings from Top 25 Commercial Measures in 2025 (GJ)



5.7.1 Incentive and Non-Incentive Spending

The incentive and non-incentive spending required to achieve the medium and high market potential are shown in Exhibit 103 (TRC) and Exhibit 104 (MTRC). Medium and high market incentives are assumed to be 50% and 100% of measures' incremental costs, respectively. In both medium and high scenarios, non-incentive costs are estimated to be 15% of incentive costs. The tables also show the total as well as incremental (that is, savings from new measures installed in a year) savings every year.

6 Industrial Sector Results

This section presents the industrial sector results and key findings, including:

- Base year (2019) natural gas use
- Reference case consumption forecast (2020 – 2040)
- Energy conservation measures evaluated in this CPR
- Technical potential savings
- Economic potential savings
- Market potential savings and scenarios

6.1 Industrial Segments and End Uses

In this CPR, the industrial sector is divided into 12 segments, 12 energy end uses, and two vintages.

	Segments	End Uses	Vintages
Industrial Sector	• Agriculture (includes greenhouses[40]) • Chemical • District energy providers • Fabricated Metal • Food & Beverage • Other Manufacturing (includes transportation[41] and other industrial) • Mining • Non-metallic Mineral (includes cement) • Pulp & Paper – Kraft • Pulp & Paper – TMP • Utilities • Wood Products	• Direct-fired heating • Direct Consumption of Gas in Process[42] • Heat Treating • Kilns • On-Site Power Generation[13] • Other[12] • Ovens • Petrochemical Refining and Process Heating • Process Boilers • Product Drying • Space Heating [includes HVAC air heating and HVAC boilers] • Water heaters	• Existing • New

40 Cannabis has been included in agriculture segment since there is not enough data at FEI to create a cannabis-specific forecast.
41 In the 2015 CPR, 'transportation' pertained to facilities that supported the transportation sector.
42 No CPR measures are applied to this end use; included for accounting purposes only.

6.2 Base Year Natural Gas Use

Base year (2019) industrial natural gas use is presented by segment in Exhibit 105, by end use in Exhibit 106, and by region in Exhibit 107.

Natural gas consumption in the industrial sector base year is highest:

- In the pulp and paper – kraft (31%), agriculture (13%), wood products (12%), and mining (12%) segments
- In the process boilers (36%), product drying (26%), and direct-fired heating (16%) end uses
- In the Lower Mainland excluding the Vancouver (33%), Northern BC (24%), and Southern Interior (26%) regions

Exhibit 105 – 2019 Industrial Natural Gas Consumption (GJ) by Segment[43]

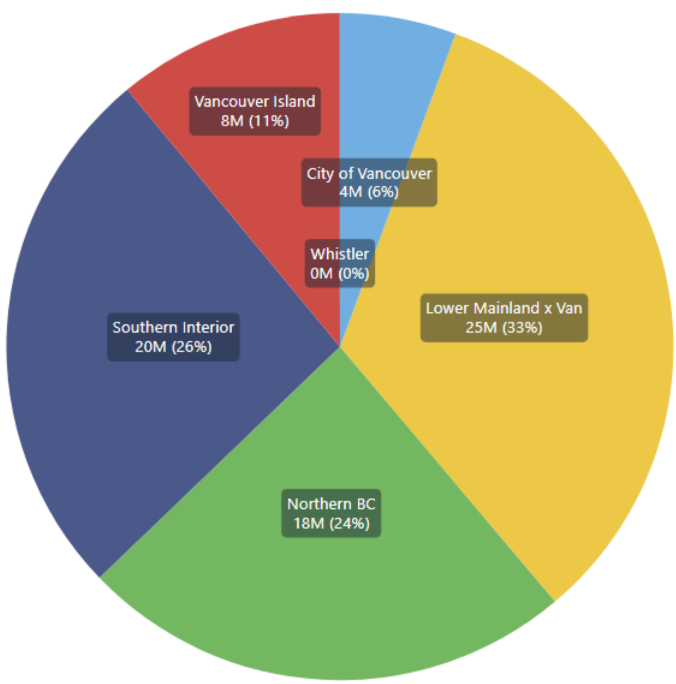
Segment	Natural Gas Consumption (GJ)	%
Pulp & Paper - Kraft	23,480K	31%
Agriculture	9,662K	13%
Wood Products	8,936K	12%
Mining	8,843K	12%
Non-metallic Mineral	4,657K	6%
Food & Beverage	4,548K	6%
Manufacturing	4,291K	6%
Chemical	4,014K	5%
Pulp & Paper - TMP	2,923K	4%
District Energy	2,555K	3%
Utilities	851K	1%
Fabricated Metal	526K	1%
Total	**75,286K**	**100%**

43 Please see Appendix B for how industrial sector NAICS codes were mapped into segments.

Exhibit 106 – 2019 Industrial Natural Gas Consumption (GJ) by End Use

Parent End Use	Natural Gas Consumption (GJ)	%
Process Boilers	27,045K	36%
Product Drying	19,465K	26%
Direct-fired Heating	11,817K	16%
Space Heating	5,737K	8%
Kilns	3,626K	5%
Direct Gas Use	1,553K	2%
Petrochem Refining	1,407K	2%
Other	1,209K	2%
Ovens	1,110K	1%
On-Site Generation	851K	1%
Water Heaters	823K	1%
Heat Treating	644K	1%
Total	**75,286K**	**100%**

Exhibit 107 – 2019 Industrial Natural Gas Consumption (GJ) by Region



6.2.1 Accounts

Base year industrial natural gas accounts are presented by segment in Exhibit 108 and by region in Exhibit 109. As shown in these exhibits, in 2019 the greatest number of industrial natural gas accounts were in:

- The manufacturing (37%), agriculture (21%), and food & beverage (13%) segments
- The Lower Mainland excluding Vancouver region (68%)

Exhibit 108 – 2019 Industrial Accounts by Segment

Segment	Accounts	%
Manufacturing	3,354	37%
Agriculture	1,930	21%
Food & Beverage	1,164	13%
Fabricated Metal	744	8%
Wood Products	701	8%
Chemical	437	5%
Non-metallic Mineral	247	3%
Utilities	201	2%
Mining	125	1%
Pulp & Paper - TMP	76	1%
Pulp & Paper - Kraft	26	0%
District Energy	18	0%
Total	**9,023**	**100%**

Exhibit 109 – 2019 Industrial Accounts by Region

Region	Accounts	%
Lower Mainland x Van	6,138	68%
Southern Interior	1,501	17%
City of Vancouver	680	8%
Northern BC	452	5%
Vancouver Island	247	3%
Whistler	5	0%
Total	**9,023**	**100%**

6.2.2 Tertiary Load

Tertiary load is the useful energy delivered to an end use. In the context of the CPR, tertiary load is the amount energy required to be delivered as an end use *service*: heat delivered by a furnace to a house, for example. This differs from consumption of natural gas which is impacted by the efficiency of the equipment: in the furnace example, consumption is equal to the tertiary load divided by seasonal efficiency of furnaces. Exhibit 110 provides 2019 tertiary load values.

6.2.3 Unit Energy Consumption

As explained in Exhibit 3, unit energy consumption (UEC) is the amount of energy used by each end use per unit. Defining "units" is challenging in the industrial sector. In the residential sector, consumption is typically analyzed per dwelling while in the commercial sector, consumption is analyzed per unit of floor area. In the industrial sector, consumption per unit of production capacity (kg of product, for example) would seem to be a useful approach. Unfortunately, the concept becomes inoperable when many different industries are included in the analysis. Nonetheless, it is desirable to have a way of representing growth in industries that is independent of changes in energy consumption caused by changes in fuel share or equipment efficiency. Therefore, 'units' in the industrial sector is used as a proxy of production capacity of different types of plants. The base year consumption is used as a proxy for the production capacity of different types of plants in each region and rate class.

Along with UEC values is *unit tertiary load*, which is the average tertiary load used by each end use in a dwelling, and *stock average efficiency*, which is the average efficiency of equipment serving the tertiary load for that end use. These values are included in the table because UEC by end use is calculated by dividing unit tertiary load with stock average efficiency.

Unlike the residential or commercial sectors, the end uses in the industrial sector are not common across the segments; rather, some end uses are specific to some segments. For example, the 'on-site generation' end use is only present in the 'utilities' segment. For the purposes of this report, UEC values are shown for one segment and region only, therefore UEC values are included only for the end uses that are present in that segment.

Unit tertiary load, stock average efficiency and UEC values for the pulp & paper – kraft segment in the Northern BC ("NBC") region are presented in Exhibit 110. This combination of segment and region was selected as the example because it A) is a significant consumer of gas, and B) has enough accounts to ensure consumption from one account cannot be determined through the information presented in this report, thereby protecting customer privacy.

Exhibit 110 – 2019 UEC Values by End Use, Pulp & Paper-Kraft Segment in Northern British Columbia

	Unit Tertiary Load (GJ/unit/yr)	Stock Average Efficiency (%)	UEC
Space Heating	0.02	0.62	0.03
Direct-fired Heating	0.38	1.00	0.38
Kilns	0.08	0.79	0.10
Product Drying	0.02	0.88	0.03
Process Boilers	0.34	0.67	0.51

6.2.4 Average Natural Gas Use per Account

Details on natural gas consumption per account by end use are provided in Exhibit 111 for an average Pulp & Paper – Kraft account in the Northern BC region. The following information is included in this exhibit:

- UEC: The amount of energy used by each end use per unit (a "unit" in the industrial sector is based on production capacity. Please see Section 6.2.3 for a discussion of a "unit" in the industrial sector.
- Fuel Share: The percentage of the energy end use that is supplied by each fuel (in this case, natural gas).
- Saturation: The extent to which an end use is present in a region, rate class and segment. In the industrial sector, saturation is either 100% or 0% because end uses are either used in a segment or are not.

Average annual gas consumption per unit would be calculated by multiplying these three variables. Similar to the UEC values presented in Section 6.2.3, only the end uses that are present in the segment and region are included.

Exhibit 111 – 2019 Average Annual Gas Use per Account by End Use, Pulp & Paper - Kraft Account in Northern British Columbia

	UEC	Fuel Share	Saturation	Average Annual Gas Use (GJ/Yr)
Space Heating	0.03	80%	100%	0.03
Direct-fired Heating	0.38	100%	100%	0.38
Kilns	0.10	93%	100%	0.10
Product Drying	0.03	93%	100%	0.02
Process Boilers	0.51	93%	100%	0.47
TOTAL				1.00[44]

44 Recall that "units" in the industrial sector is production capacity. In the base year, by definition, one industrial building unit uses 1 GJ, because base year consumption is the 'unit' for the base year.

6.3 Reference Case Natural Gas Use

This section profiles the reference case forecast (2020-2040) natural gas consumption for the industrial sector. The industrial production forecast, developed by FEI through survey of industrial customers, covers from 2020 to 2025. The first five-year period of the reference case forecast (2020 to 2025) incorporates how individual respondents expect their volume to change, and this five-year trend is extrapolated beyond 2025.

Reference case industrial natural gas consumption is presented by region in Exhibit 112, by segment in Exhibit 113, and by end use in Exhibit 114. These exhibits illustrate the following trends in consumption over the reference case:

- Overall gas consumption is forecasted to increase by approximately 7% between 2020 and 2040, but this increase is not evenly split between the regions, segments, or end uses. Some regions, segments, and end uses are forecasted to experience significant increases, while others are forecasted to remain stable or decrease.
- As shown in Exhibit 112, natural gas use in the Whistler region is forecasted to increase by 98%, while gas use in the Northern BC and Vancouver Island regions will remain relatively flat or decrease (1% decrease and 1% increase, respectively).
- As shown in Exhibit 113, natural gas use in the fabricated metal segment is forecasted increase by 39%, while gas use is forecasted to decrease in the non-metallic mineral and the pulp & paper – kraft segments (6% and 2% decrease, respectively).
- As shown in Exhibit 114, natural gas use in the heat-treating end use is forecasted increase by 28%, while gas use is forecasted to decrease by 4% in the kiln end use.
- Despite the differences in forecasted natural gas use, the same regions, segments and end uses as in the base year are expected to account for the largest shares of natural gas use in the industrial sector.

Exhibit 112 – 2020 vs 2040 Industrial Gas Consumption (GJ) by Region

Region	2020	2040	Change
Lower Mainland x Van	28,463K	31,860K	12%

6.4 Measure Assessment

6.4.1 List of Measures

The list of industrial measures is presented in Exhibit 115 by industrial end uses.

Please see the MS Excel file entitled "Ind_Measure Analysis Workbook" for a description of each measure and a full analysis.

Measures were classified in four measure type categories:

- Building Envelope
- Equipment
- Controls
- Energy Management (including behavioral measures)

Exhibit 115 – Industrial Sector Conservation and Energy Management Measures

Process Boiler	Space Heating

Other	**Greenhouse**
Combustion Testing Energy Management High-Efficiency Burners High-Efficiency Dryers High-Efficiency Furnaces High-Efficiency Kilns High-Efficiency Ovens Process Control Regenerative Catalytic Oxidizer Veneer Dryers Warm Mix Asphalt	Greenhouse Curtains Greenhouse Envelope Integrated Greenhouse Controls

6.4.2 Results

Exhibit 116 shows measure-level results for the industrial sector in order of decreasing cost effectiveness. Measures were assessed based on their replacement type: **retrofit** (immediate replacement at full cost) or **replace on burnout** (end of life replacement at incremental cost).

The TRC and MTRC are presented at the measure-level and exclude program costs and free ridership.

Some key findings of the measure assessment for the industrial sector include:

- Of the 39 measures included in the assessment, 34 pass the TRC screen and 38 pass the MTRC screen.
- The most attractive equipment replacement measure is boiler right-sizing, with a TRC of 167.7. This measure involves replacing an oversized boiler at equipment end of life, with a smaller, right-sized boiler. The measure TRC is exceptionally high because the incremental measure cost is either negligible or may even be negative in some cases.
- The most attractive energy management measure is process control, which has the potential for significant energy savings at a moderate capital cost.
- The most attractive building envelope measure is the greenhouse envelope measure (#7), which, as shown in Exhibit 115, only applies to the greenhouse end use. The most attractive building envelope measure that applies to the space heating end use is the air curtain measure (#14).
- Several measures that were included on the original list of measures were excluded from the analysis or modified. Please see the file called "Measure List Modifications.xlsx" for a list of changes.

Exhibit 116 – Industrial Sector Measures with Average TRC and MTRC Results

#	Measure	Measure Type	Replacement Type	TRC	MTRC
1	Boiler Right-Sizing[45]	Equipment	ROB	167.7	791.5
2	Process Control	Energy Management	RET	50.4	258.4
3	Furnace RET	Equipment	RET	11.7	56.6
4	Combustion Testing	Energy Management	RET	10.3	54.6
5	Energy Management	Energy Management	RET	10	54.3
6	Tank Insulation	Equipment	RET	10	50.9
7	Greenhouse Envelope	Building Envelope	RET	9.3	47.6
8	Regenerative Catalytic Oxidizer	Energy Management	RET	7.9	39.3

45 For the boiler right-sizing measure the incremental cost is negligible. A cost of $1,000 was used for this measure for the purposes of calculating the payback and TRC, to compare with other measures.

9	Integrated Greenhouse Environmental Controls	Energy Management	RET	6.8	34
10	Replace Steam Traps	Equipment	RET	5.3	28.1
11	Condensing Boiler	Equipment	ROB	5.7	26.9

39	Warm Mix Asphalt	Energy Management	ROB	0.1	0.5

6.5 Technical Potential

This section provides an overview of the technical potential savings results for the industrial sector. Overall results are presented below, followed by measure level results and supply curves for the TRC and MTRC results.

As shown in Exhibit 117, the majority of the industrial technical potential (15 PJ) would be available in 2021 and would increase slowly until reaching 19 PJ in 2040, indicating most of the available potential would be from retrofit measures as opposed to replace on burnout measures. The forecasted industrial natural gas consumption for the industrial sector is included for reference.

Exhibit 117 – Industrial Technical Potential Savings (GJ)

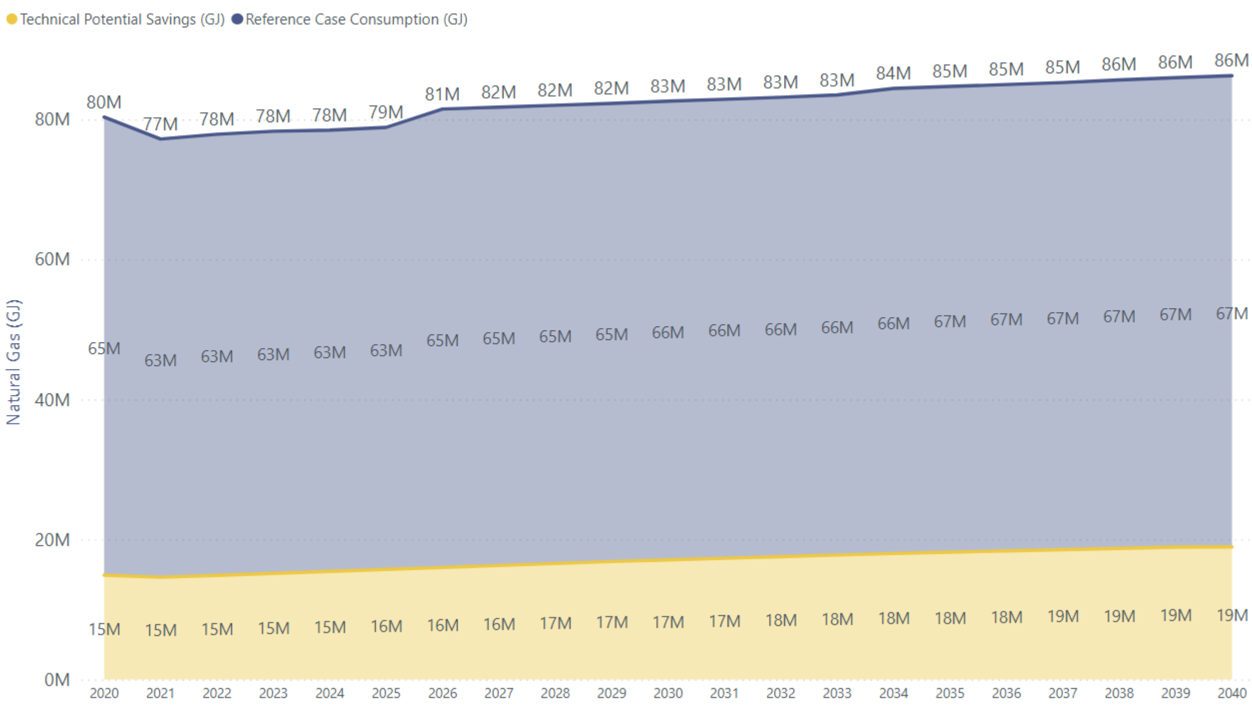

Exhibit 118 – Technical Potential Savings as a Percent of Industrial Reference Case Consumption (%)

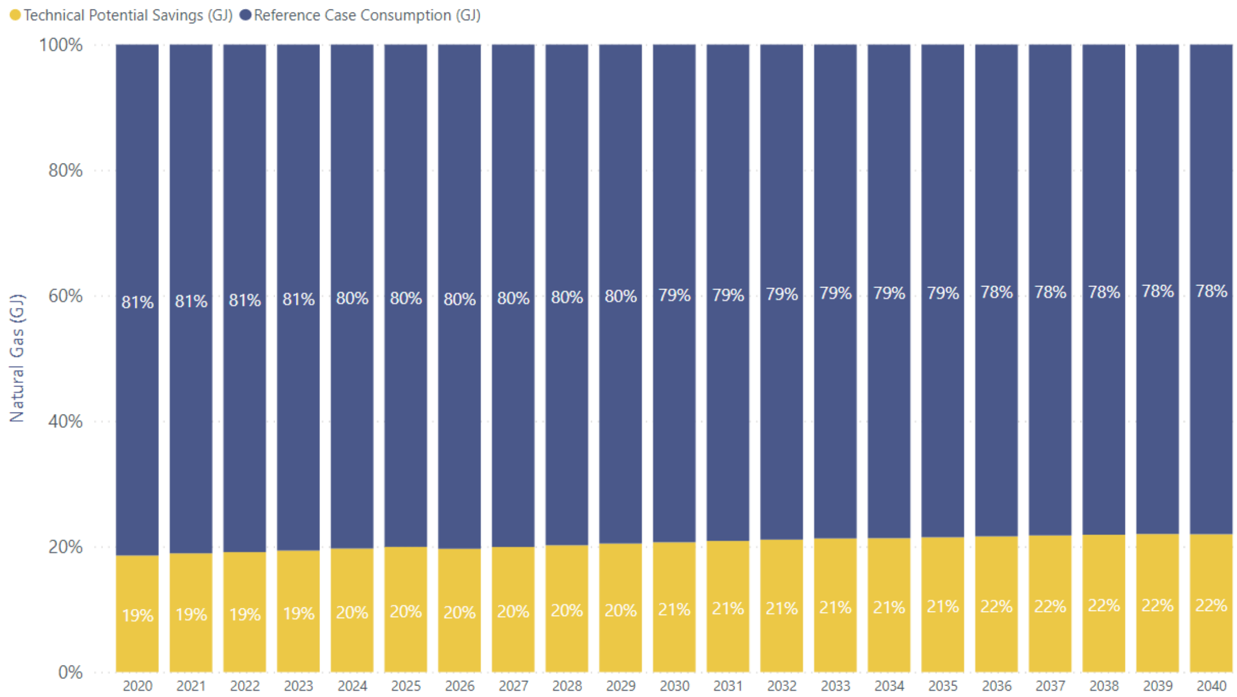
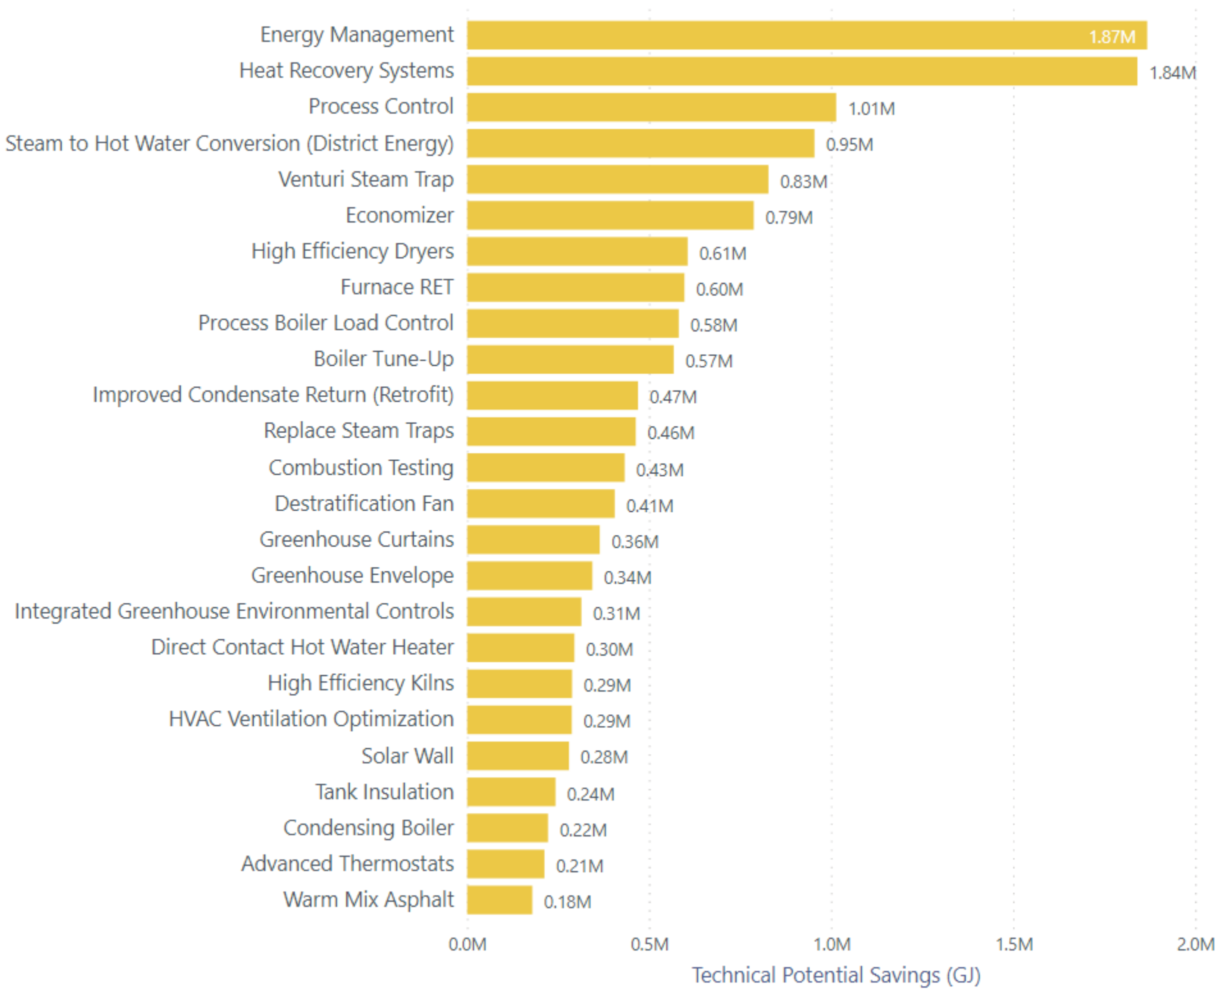


As shown in Exhibit 118, the technical potential savings is about 19% of industrial reference case consumption in 2021 and increases to 22% by 2040, further indicating that most of the available potential would be from retrofit measures as opposed to replace on burnout measures.

The technical potential savings in 2025 broken down by measure (only the top 25 measures are shown) are presented in Exhibit 119. The top three measures (energy management, heat recovery systems, and process control) are expected to contribute substantially to technical potential savings (approximately 1.9 PJ, 1.8 PJ, and 1 PJ by 2025). As was shown in Exhibit 116, all three measures pass the TRC test, so they will also be expected to contribute to economic potential savings, as described in the following section. From the five measures that pass the MTRC but fail the TRC, Steam to Hot Water Conversion is the only one that has a large technical potential (#4 on the list below).

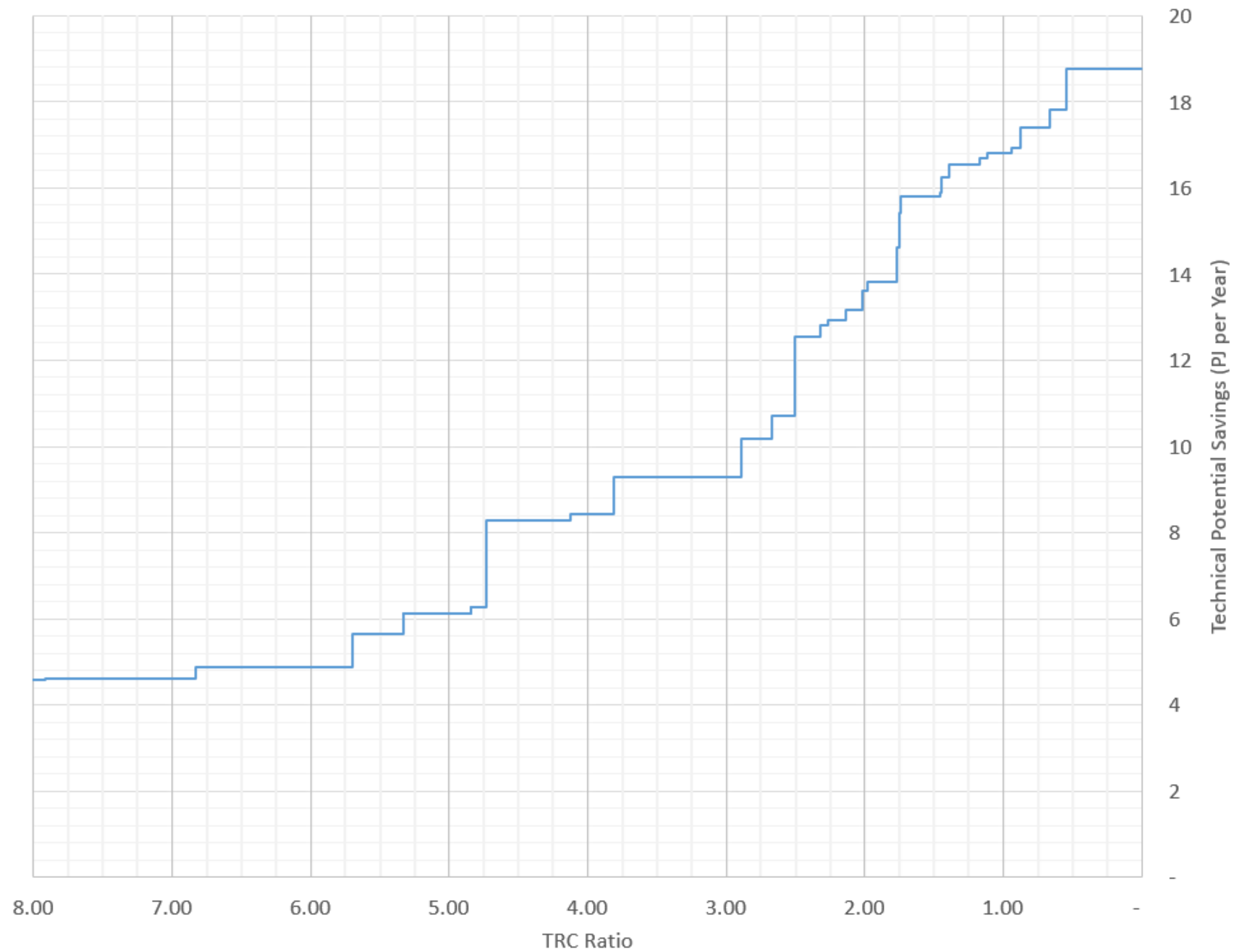
Exhibit 119 – Technical Potential – Top 25 Industrial Measures in 2025 (GJ)



The cumulative industrial sector technical potential savings in 2040 are presented in Exhibit 120 as a supply curve, with measures ordered by decreasing TRC ratio from left to right.

As shown, roughly 90% (17 out of 19 PJ) of the industrial sector technical potential savings by 2040 come from measures with a TRC of 1.0 or higher. Approximately 5 PJ of savings come from measures with a TRC ratio of greater than 8. These are shown in aggregate.

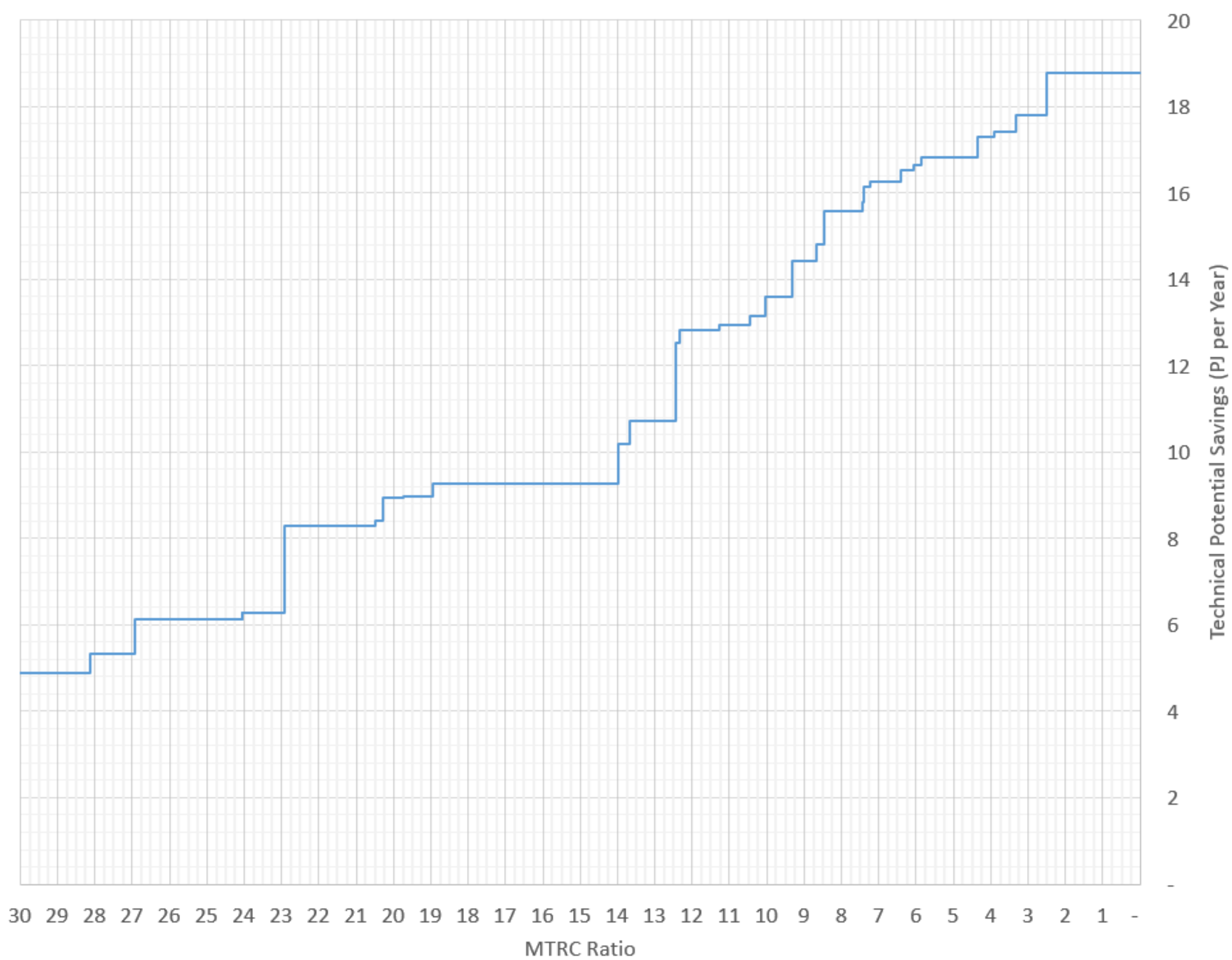
Exhibit 120 – Industrial Sector: Technical Potential Supply Curve, 2040 – TRC



Similar to Exhibit 120, the cumulative Industrial sector technical potential savings in 2040 are presented in Exhibit 121 as a supply curve, with measures ordered by decreasing MTRC ratio from left to right.

As shown, all of the industrial sector technical potential savings (approximately 19 PJ) by 2040, comes from measures with an MTRC of 1.0 or higher. Approximately 5 PJ of savings come from measures with an MTRC ratio of greater than 30. These are shown in aggregate.

Exhibit 121 – Industrial Sector: Technical Potential Supply Curve, 2040 – MTRC

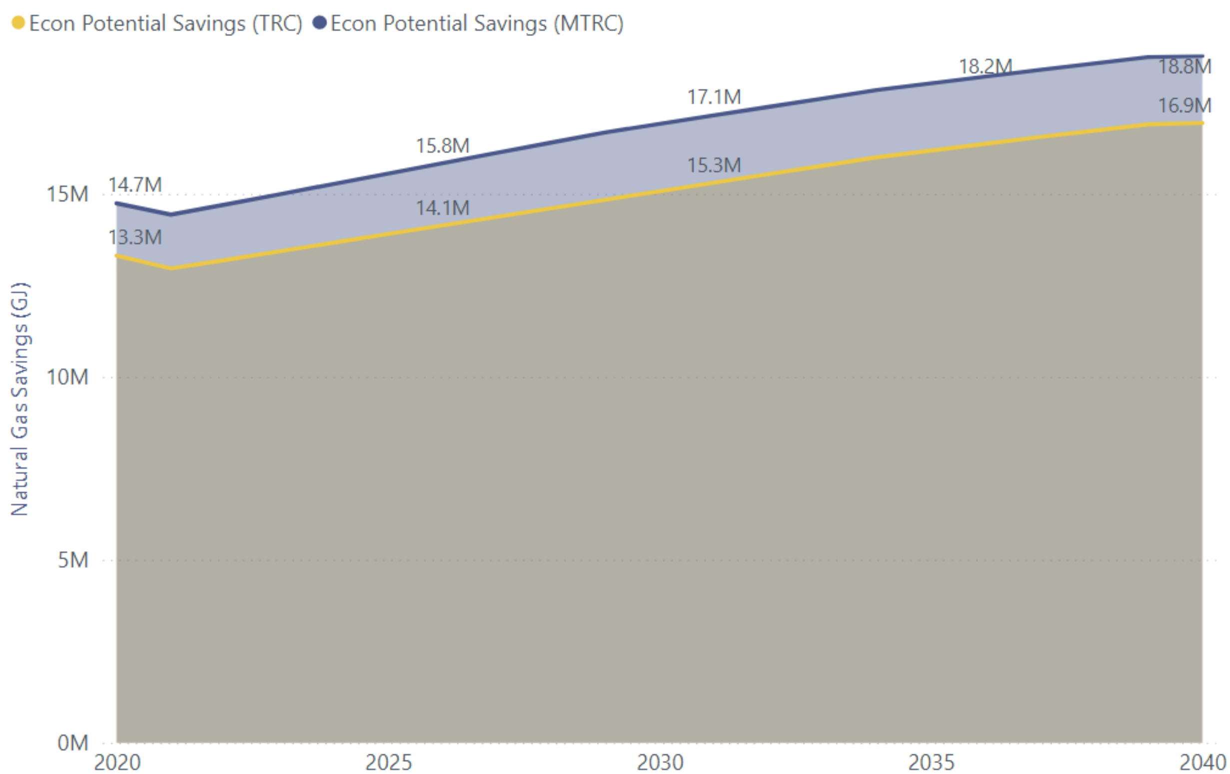


6.6 Economic Potential

This section provides an overview of the economic potential savings results. As was noted in section 6.3.2, 34 of the 39 measures examined have a TRC ratio over 1.0, so the difference between TRC and MTRC economic potential results for the Industrial sector is small.

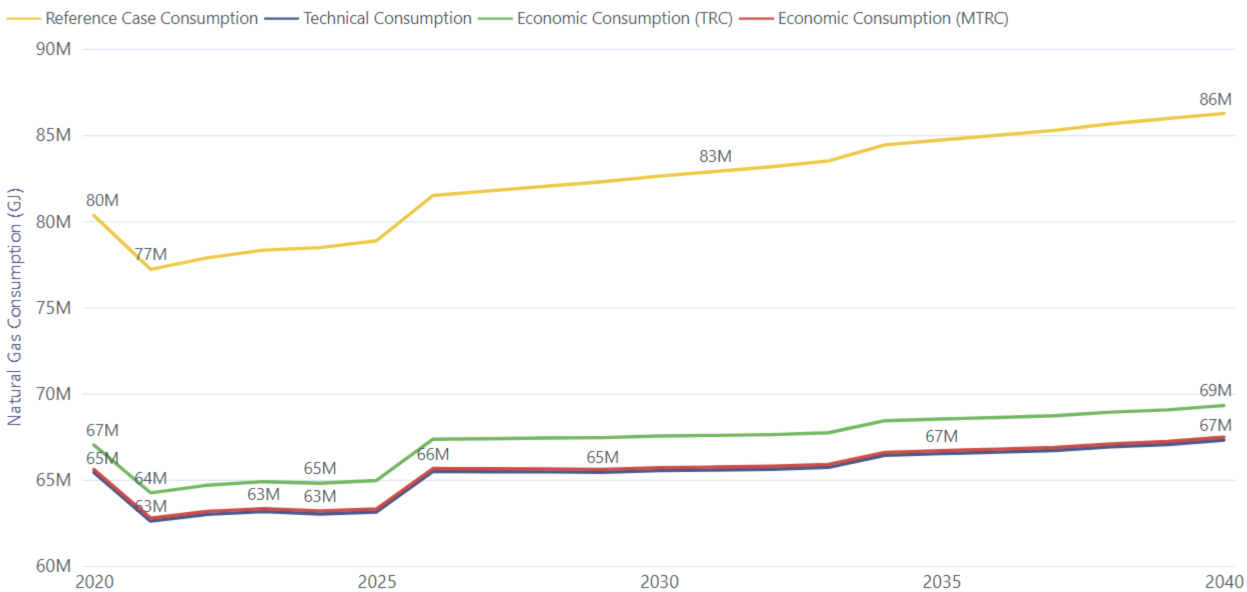
The industrial sector economic potential savings with a TRC screen and with an MTRC screen are shown in Exhibit 122. Although only four measures fail the TRC but pass the MTRC, the economic potential savings with an MTRC screen are roughly 1.7 PJ higher than with the TRC screen in 2025. This is mainly because one of those measures, steam to hot water conversion (district energy), represents the fifth largest technical potential (1 PJ) in 2025, as shown in Exhibit 119. Another way to look at it that the 92% of the MTRC economic potential comes from measures that pass the TRC as well.

Exhibit 122 – Economic Potential Savings (GJ) - Industrial, TRC and MTRC Screen



The forecasted gas consumption under the technical potential, economic potential with a TRC screen, economic potential with an MTRC screen, and reference case scenarios for the industrial sector are shown in Exhibit 123. The rapid decrease in technical and economic potential consumption in 2021 is a result of the implementation of the retrofit measures. The rest of the potential curve follows the shape of the reference case curve, as the replace on burnout measures are implemented at equipment end of life.

Exhibit 123 – Economic Potential Consumption (GJ) Forecasts – Industrial, TRC and MTRC



Results by Region

The economic potential savings in 2025 are presented by region in Exhibit 124 (TRC) and Exhibit 125 (MTRC). The highest level of economic potential savings (21% or 23% depending on the economic screen) is estimated to occur in the Lower Mainland outside of the City of Vancouver.

Exhibit 124 – Economic Potential Savings by Region in 2025 – Industrial, TRC

Region	Ref Case Consumption (GJ)	Economic Potential Savings (GJ)	% of Consumption
Lower Mainland x Van	28,893K	6,029K	21%
Southern Interior	19,995K	2,936K	15%
Northern BC	15,774K	2,793K	18%

Whistler	7K	2K	37%
Total	**78,864K**	**15,558K**	**20%**

Results by Segment

The economic potential savings in 2025 are presented by segment in Exhibit 126 (TRC) and Exhibit 127 (MTRC). The highest percentages of economic potential savings are estimated to occur in the agriculture, food & beverage, and fabricated metals segments. The largest absolute economic potential savings are estimated to occur in the pulp & paper – kraft segment.

Exhibit 126 – Economic Potential Savings by Segment in 2025 – Industrial, TRC

Segment	Ref Case Consumption (GJ)	Economic Potential Savings (GJ)	% of Consumption
Pulp & Paper - Kraft	20,542K	4,153K	20%
Agriculture	11,951K	3,503K	29%

Utilities	842K	0K	0%
Total	**78,864K**	**15,558K**	**20%**

Results by End Use

The economic potential savings in 2025 are presented by end use in Exhibit 128 (TRC) and Exhibit 129 (MTRC). The highest percentages of economic potential savings are estimated to occur in the process boilers, space heating, and heat treating end uses.

Approximately two-thirds of the savings are attributable to the largest end uses: process boilers (distributed across all segments except utilities).

Exhibit 128 – Economic Potential Savings by End Use in 2025 – Industrial, TRC

Parent End Use	Ref Case Consumption (GJ)	Economic Potential Savings (GJ)	% of Consumption
Process Boilers	29,383K	8,353K	28%

The TRC and MTRC economic potential savings for 2040 are presented by end use in Exhibit 130. As only four measures pass the MTRC but not the TRC screen, most savings totals are the same, except for the process boilers end use (954 TJ higher in MTRC), the kilns end use (467 TJ higher in MTRC), and the space heating end use (416 TJ higher in MTRC).

Exhibit 130 – Economic Potential Savings by End Use in 2040 – Industrial, TRC and MTRC

Parent End Use	Economic Savings (GJ) - TRC	Economic Savings (GJ) - MTRC	Difference (GJ)
Process Boilers	9,715K	10,669K	954K

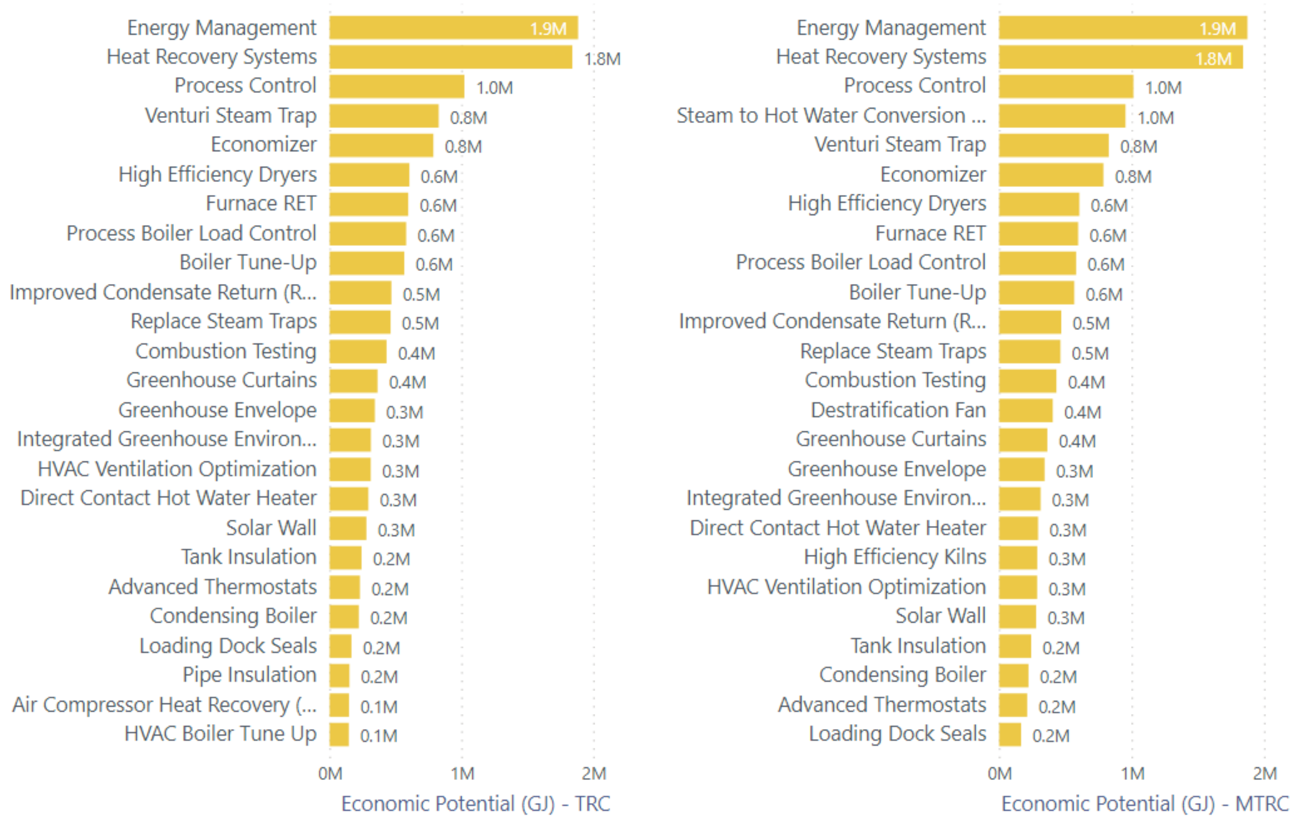
Total	**16,938K**	**18,775K**	**1,836K**

Results by Measure

The economic potential savings in 2025 broken down by measure (only the top 25 measures are shown) are shown in Exhibit 131. The top measures in the TRC economic potential are shown on the left and the top measures in the MTRC scenario are shown on the right. As in the technical potential scenario, the top three measures (energy management, heat recovery systems, and process control) are expected to contribute substantially to economic potential savings (approximately 1.9 PJ, 1.8 PJ, and 1 PJ by 2025).

The main difference between the two lists is the large contribution of steam to hot water conversion (district energy) measure in the MTRC economic potential. Destratification fans and high efficiency kilns are the other two MTRC-only measures that appear on the list on the right.

Exhibit 131 – Economic Potential (TRC on Left, MTRC on Right) - Top 25 Industrial Measures in 2025 (GJ)



6.7 Market Potential

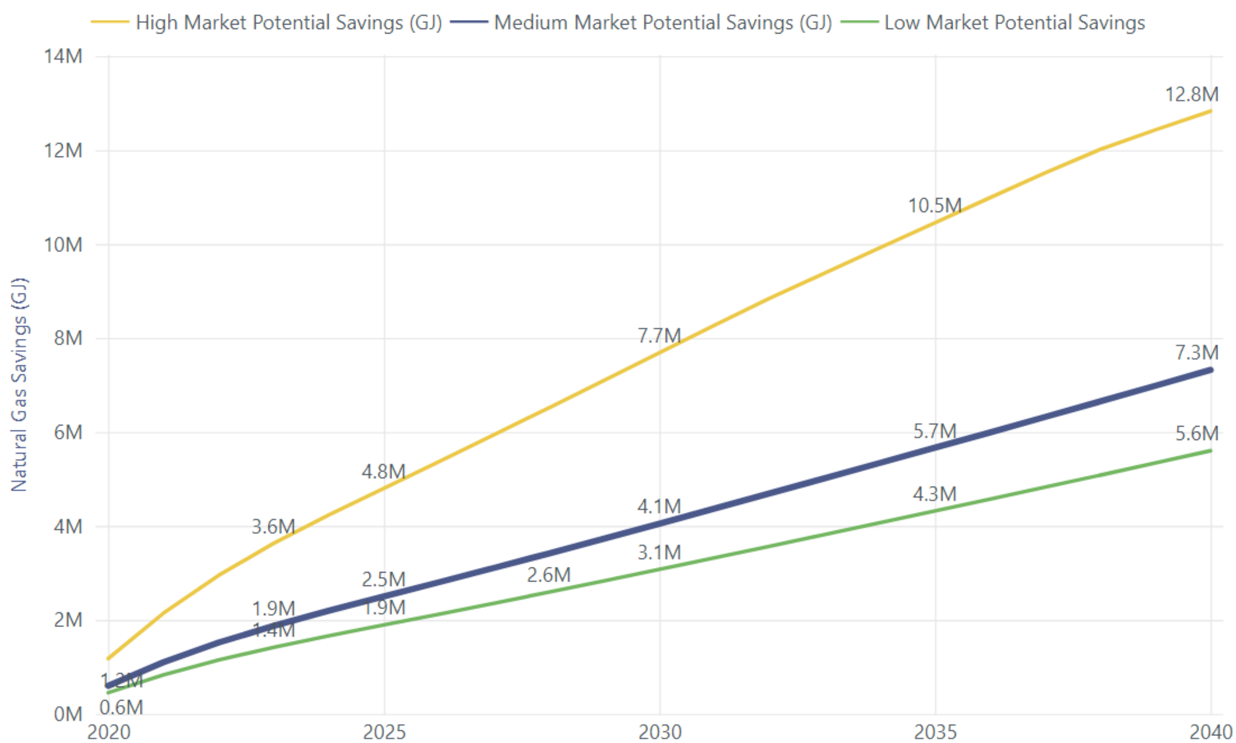
This section provides an overview of the low, medium, and high market potential results for the industrial sector.

Low, medium, and high scenarios assume that measure incentive levels will be 25%, 50% and 100% of incremental costs, respectively. For example, assume that a high-efficiency boiler may cost $10,000 more than a standard boiler, meaning the boiler would have an incremental cost of $10,000. In the medium scenario, this measure's hypothetical incentive from FortisBC would be $5,000. The other $5,000 would be paid by the end user. In all scenarios, the non-incentive program costs are assumed to be 15% of the incentive cost. In the example above, FortisBC's non-incentive spending would be $750. FortisBC's total cost for providing the measure to an end user would be $5,750.

The market potential savings results, with a TRC screen and with an MTRC screen, are shown in Exhibit 132 and Exhibit 133, respectively. These graphs are very similar because of the 39 measures included in the assessment, 34 pass the TRC screen and 38 pass the MTRC screen.

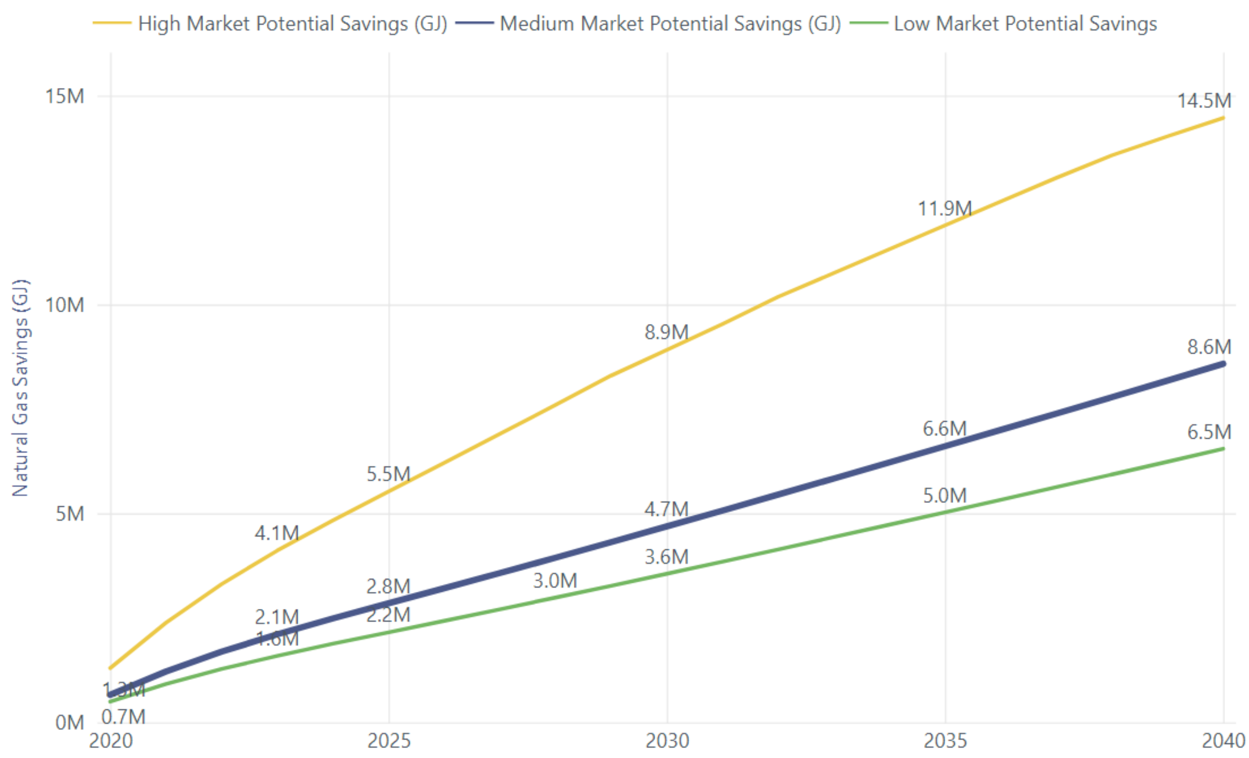
By 2040, the industrial low, medium, and high market TRC potential savings are estimated to be 5.6 PJ, 7.3 PJ, and 12.8 PJ, respectively.

Exhibit 132 – Market Potential Savings (GJ) – Industrial, TRC



By 2040, the industrial low, medium, and high market MTRC potential savings are estimated to be 6.5 PJ, 8.6 PJ, and 14.5 PJ, respectively.

Exhibit 133 – Market Potential Savings (GJ) – Industrial, MTRC



The market potential consumption results, with a TRC screen and with an MTRC screen, are shown in Exhibit 134 and Exhibit 135 respectively. These graphs are very similar because of the 39 measures included in the assessment, 34 pass the TRC screen and 38 pass the MTRC screen.

By 2040, the industrial low, medium, and high market TRC potential consumption levels are estimated to be 81 PJ, 79 PJ, and 73 PJ, respectively, while reference consumption is forecasted to reach 86 PJ.

By 2040, the industrial low, medium, and high market MTRC potential consumption levels are estimated to be 80 PJ, 78 PJ, and 72 PJ, respectively, while reference consumption is forecasted to reach 86 PJ.

Exhibit 134 – Market Potential Consumption (GJ) Forecasts – Industrial, TRC

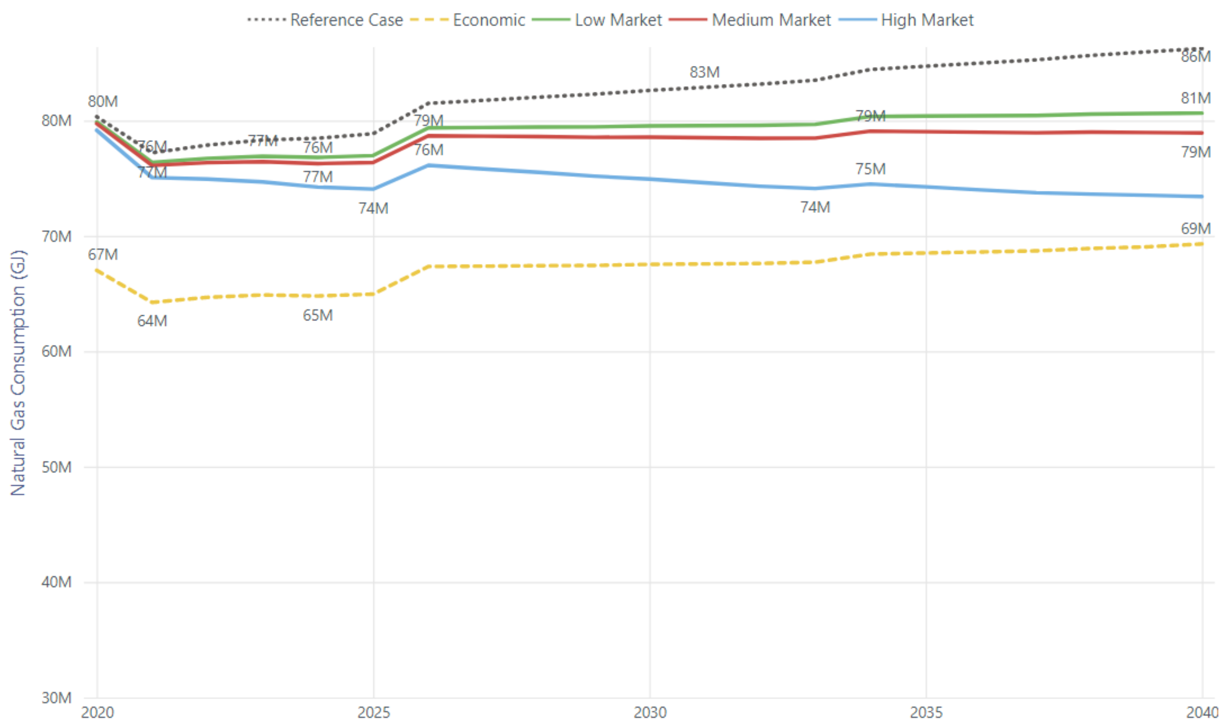


Exhibit 135 – Market Potential Consumption (GJ) Forecasts – Industrial, MTRC

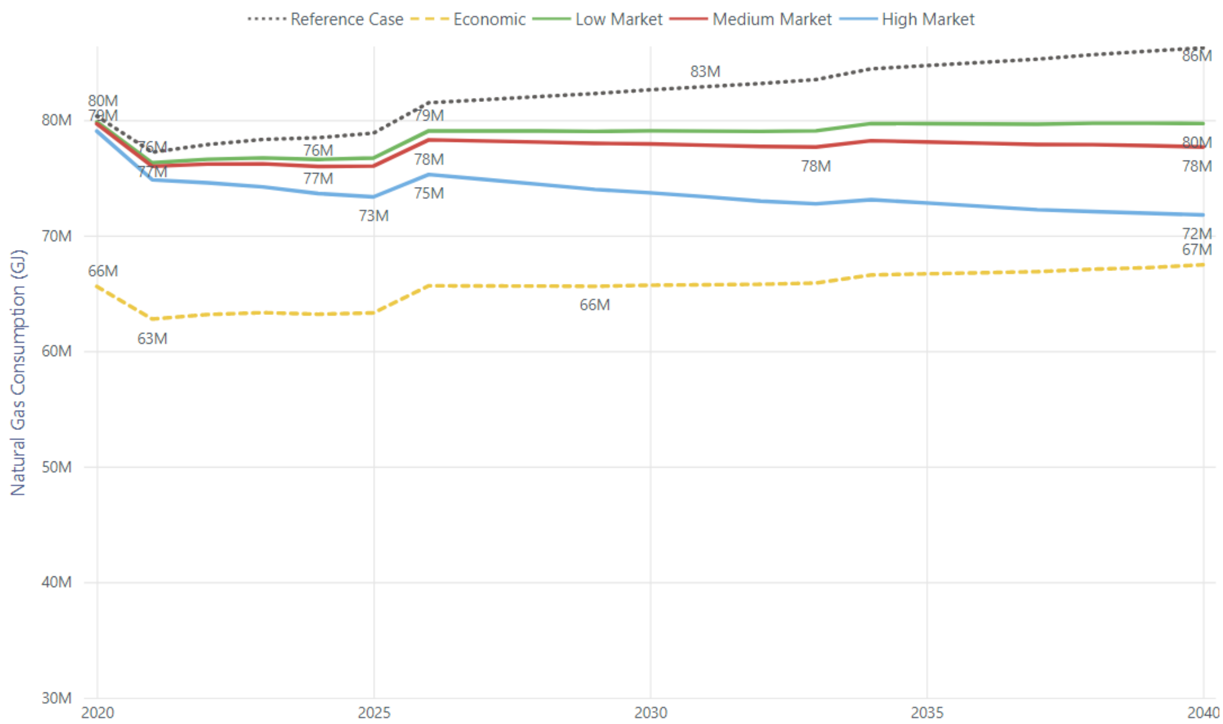

The remainder of this section presents detailed results of the medium market potential scenario only. Similarly detailed results of the low and high market potential scenarios can be found on the Power BI dashboard and the Excel workbooks.

Results by Region

The medium market potential savings for 2025 are presented by region in Exhibit 136 (TRC) and Exhibit 137 (MTRC). TRC medium market potential savings for 2025 are estimated to be between 3% and 4% of reference case consumption in all regions, other than Whistler, where they are estimated to be less than 1%. MTRC medium market potential percentages are similar except in City of Vancouver (5%) and Whistler (11%).

Exhibit 136 – Medium Market Potential Savings by Region in 2025 – Industrial, TRC

Results by Segment

The medium market potential savings for 2025 are presented by segment in Exhibit 138 (TRC) and Exhibit 139 (MTRC). In TRC medium market potential, the highest percentages savings are estimated to occur in the agriculture (5%) and fabricated metal segments (8%). The largest medium market potential savings (725 TJ) is estimated to occur in the pulp & paper – kraft segment. In MTRC medium market potential, the highest percentages savings are estimated to occur in the agriculture (5%), fabricated metal (8%) and district energy (7%) segments. The largest medium market potential savings (744 TJ) is still from the pulp & paper – kraft segment.

Exhibit 138 – Medium Market Potential Savings by Segment in 2025 – Industrial, TRC

Results by End Use

The medium market potential savings for 2025 are presented by end use in Exhibit 140 (TRC) and Exhibit 141 (MTRC). The highest percentages of economic potential savings are estimated to occur in the heat-treating end use (7% in both TRC and MTRC scenarios).

Under both economic screens, almost three quarters of savings are attributable to the Process Boilers end uses (1,500 TJ for TRC and 1,773 TJ for MTRC, distributed across all segments except utilities).

The TRC and MTRC medium market potential savings for 2040 are presented by end use in Exhibit 142. As only four measures pass the MTRC but not the TRC screen, most savings totals are the same, except for the process boilers end use (954 TJ higher in MTRC), kilns end use (188 TJ higher in MTRC), and the space heating end use (117 TJ higher in MTRC).

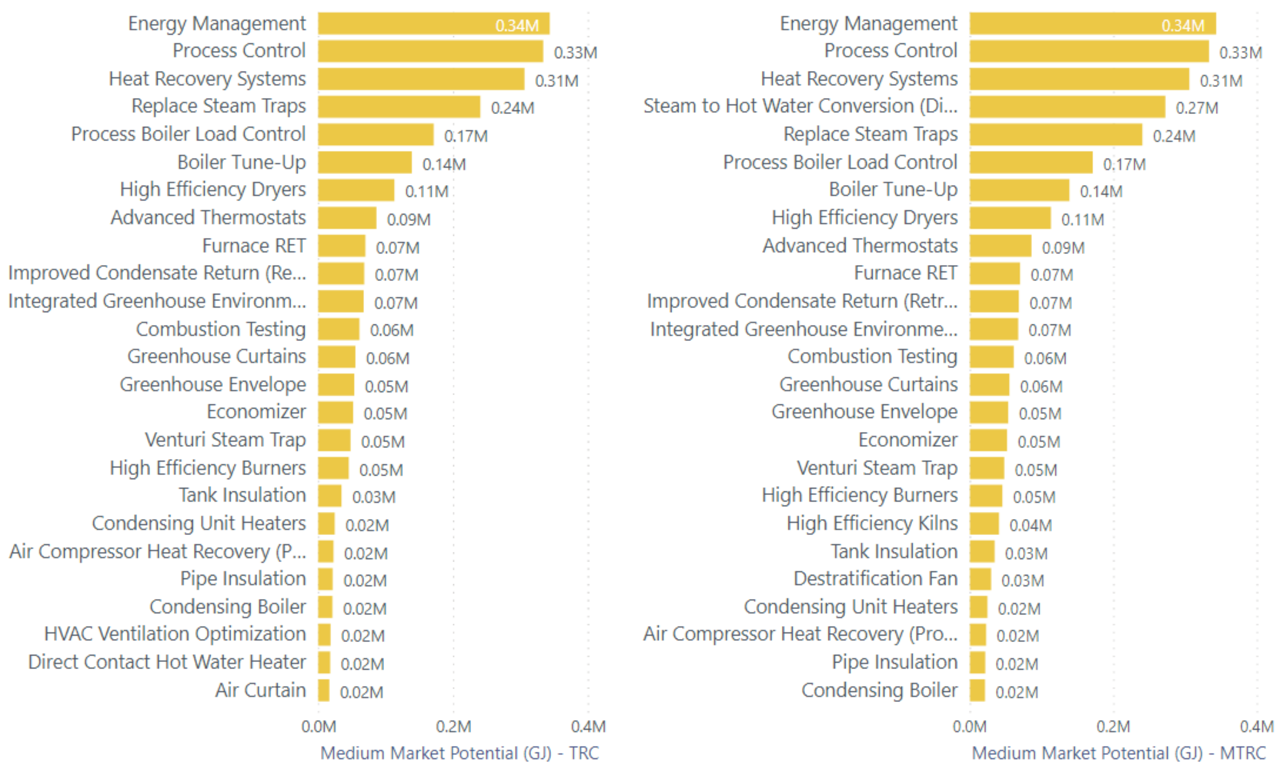
Results by Measure

The total medium market potential savings (GJ per year) in 2025 of each of the top 25 industrial measures are shown in Exhibit 143, sorted by decreasing potential. As in the technical and economic potential scenarios, the top three measures (energy management, process control, and heat recovery systems) are expected to contribute a large portion of the medium market potential savings (approximately 0.34 PJ, 0.33 PJ, and 0.31 PJ in 2025).

Exhibit 143 – Medium Market Potential (TRC on Left, MTRC on Right) - Gas Savings from Top 25 Industrial Measures in 2025 (GJ)



6.7.1 Incentive and Non-Incentive Spending

The incentive and non-incentive spending required to achieve the medium and high market potential are shown in Exhibit 144 (TRC) and Exhibit 145 (MTRC). Medium and high market incentives are assumed to be 50% and 100% of measures' incremental costs, respectively. In both medium and high scenarios, non-incentive costs are estimated to be 15% of incentive costs. The tables also show the total as well as incremental (that is, savings from new measures installed in a year) savings every year.

7 Portfolio Level Results

This section provides the results of the market potential savings on a portfolio (i.e. total of residential, commercial, and industrial sectors) level. It also presents estimated emissions reduction and job creation possibilities that can result from the energy savings in market potential scenarios.

7.1 Market Potential

Low, medium, and high scenarios assume that measure incentive levels will be 25%, 50%, and 100% of incremental costs, respectively. For example, assume that a high-efficiency furnace may cost $200 more than a standard furnace, meaning the furnace would have an incremental cost of $200. In the medium scenario, this measure's hypothetical incentive from FortisBC would be $100. The other $100 would be paid by the end user. In all scenarios, the non-incentive program costs are assumed to be 15% of the incentive cost. In the example above, FortisBC's non-incentive spending would be $15. FortisBC's total cost for providing the measure to an end user would be $115.

7.1.1 Results

The total market potential savings for all sectors, with a TRC screen and with an MTRC screen, are shown in Exhibit 146 and Exhibit 147, respectively. The medium market potential using the MTRC screen is 50% higher than the market potential using TRC screen.

By 2040, the total low, medium, and high market TRC potential savings are estimated to be 12 PJ, 16 PJ, and 27 PJ, respectively. By 2040, the low, medium, and high market MTRC potential savings are estimated to be 19 PJ, 24 PJ, and 46 PJ, respectively.

Exhibit 146 – Market Potential Savings (GJ) – All Sectors, TRC

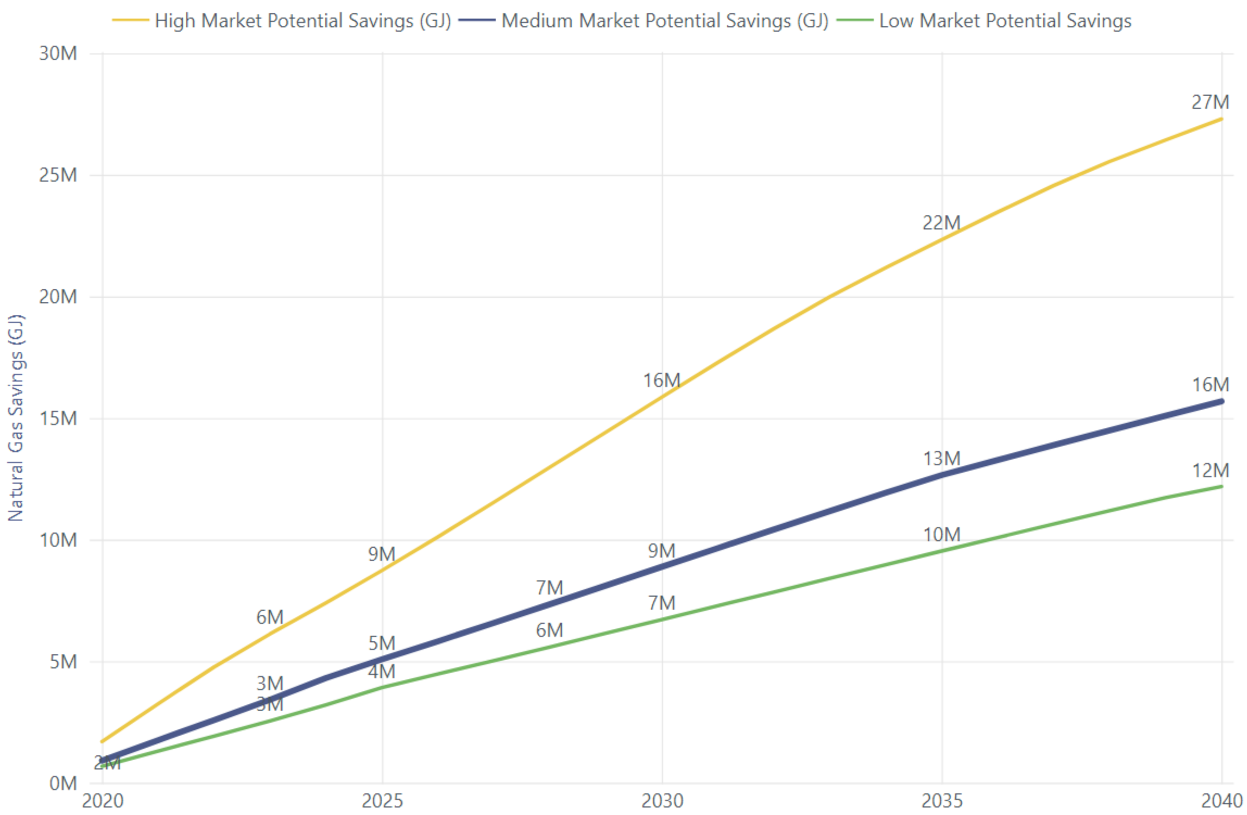

Exhibit 147 – Market Potential Savings (GJ) – All Sectors, MTRC

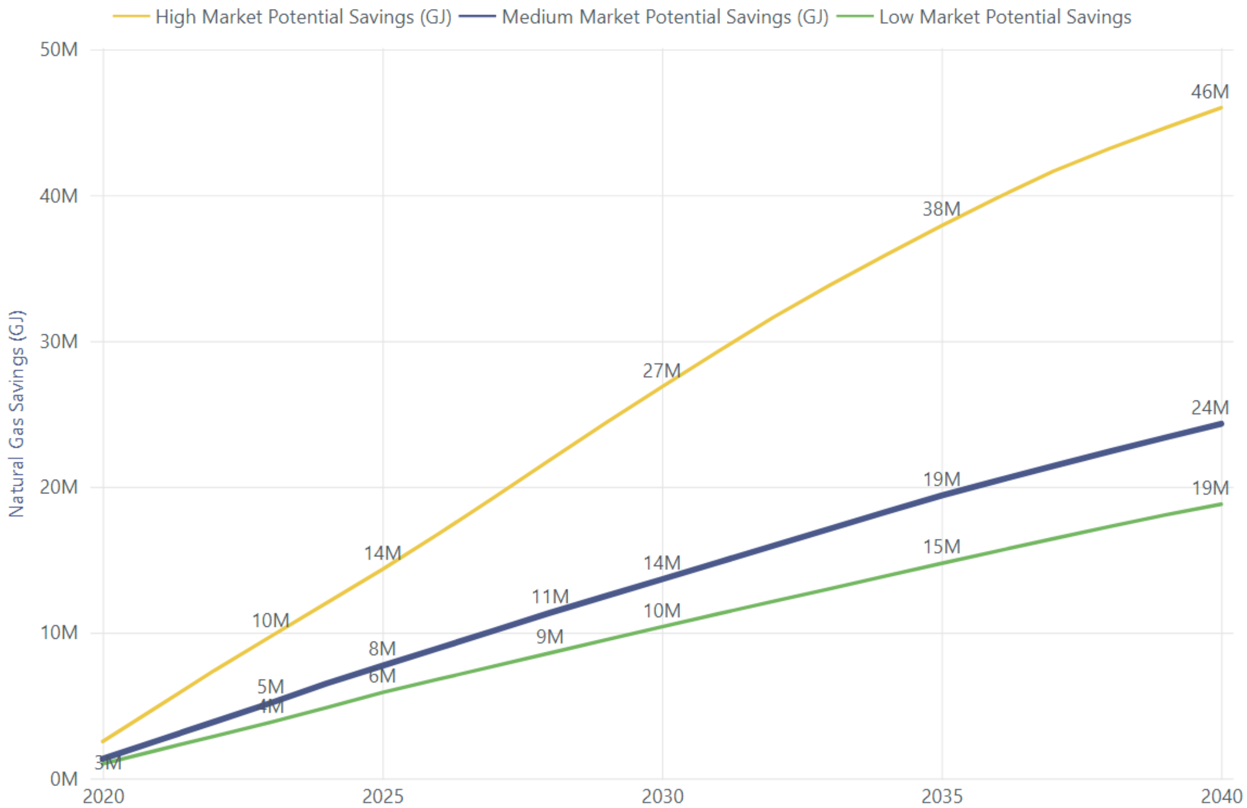

The forecasted total natural gas consumption under the three market potential scenarios relative to reference case forecast is shown in Exhibit 148 (TRC) and Exhibit 149 (MTRC). The reference consumption is forecasted to increase to 241 PJ – it is 222 PJ today. By 2040, the total low, medium, and high market TRC potential consumption levels are estimated to be 229 PJ, 226 PJ, and 214 PJ, respectively. By 2040, the low, medium, and high market MTRC potential consumption levels are estimated to be 222 PJ, 217 PJ, and 195 PJ, respectively.

Exhibit 148 – Market Potential Consumption (GJ) Forecasts – All Sectors, TRC

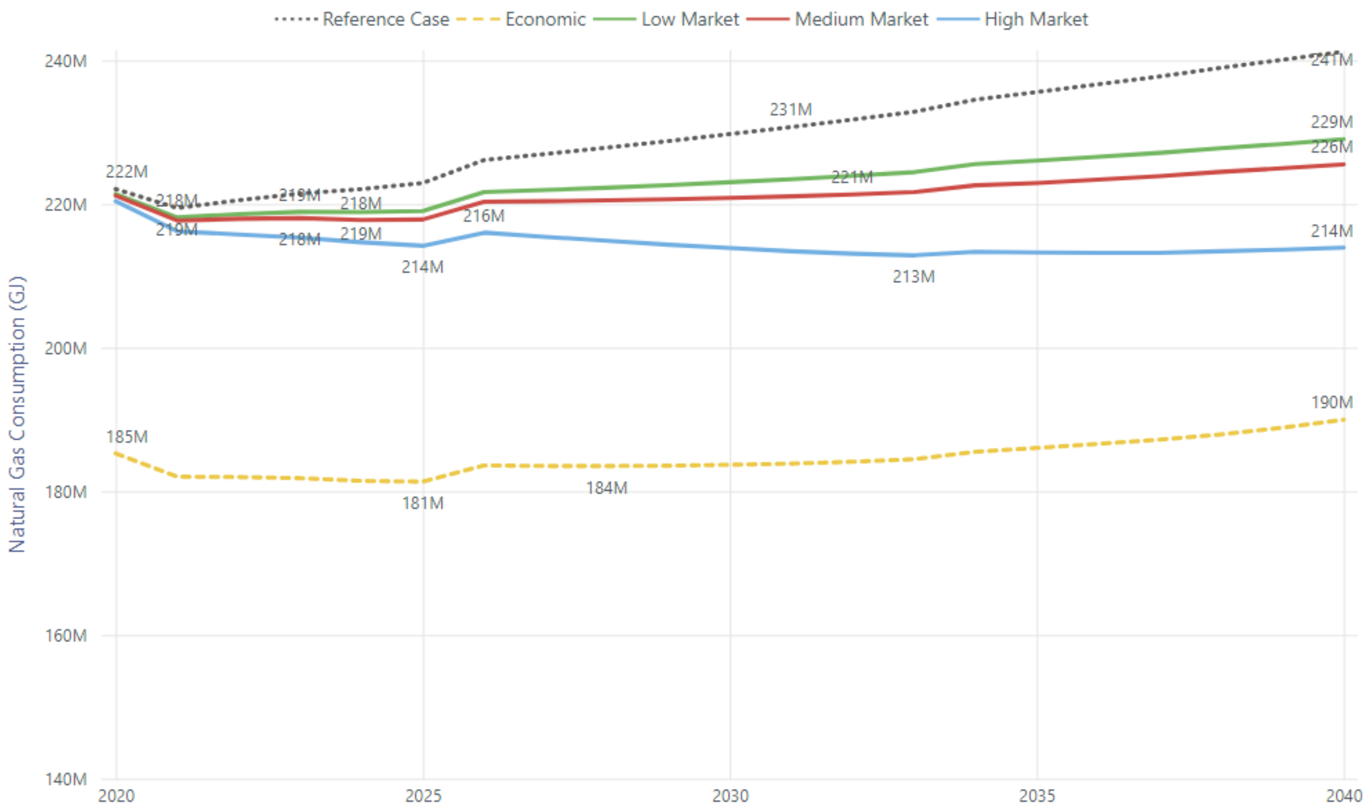

Exhibit 149 – Market Potential Consumption (GJ) Forecasts – All Sectors, MTRC

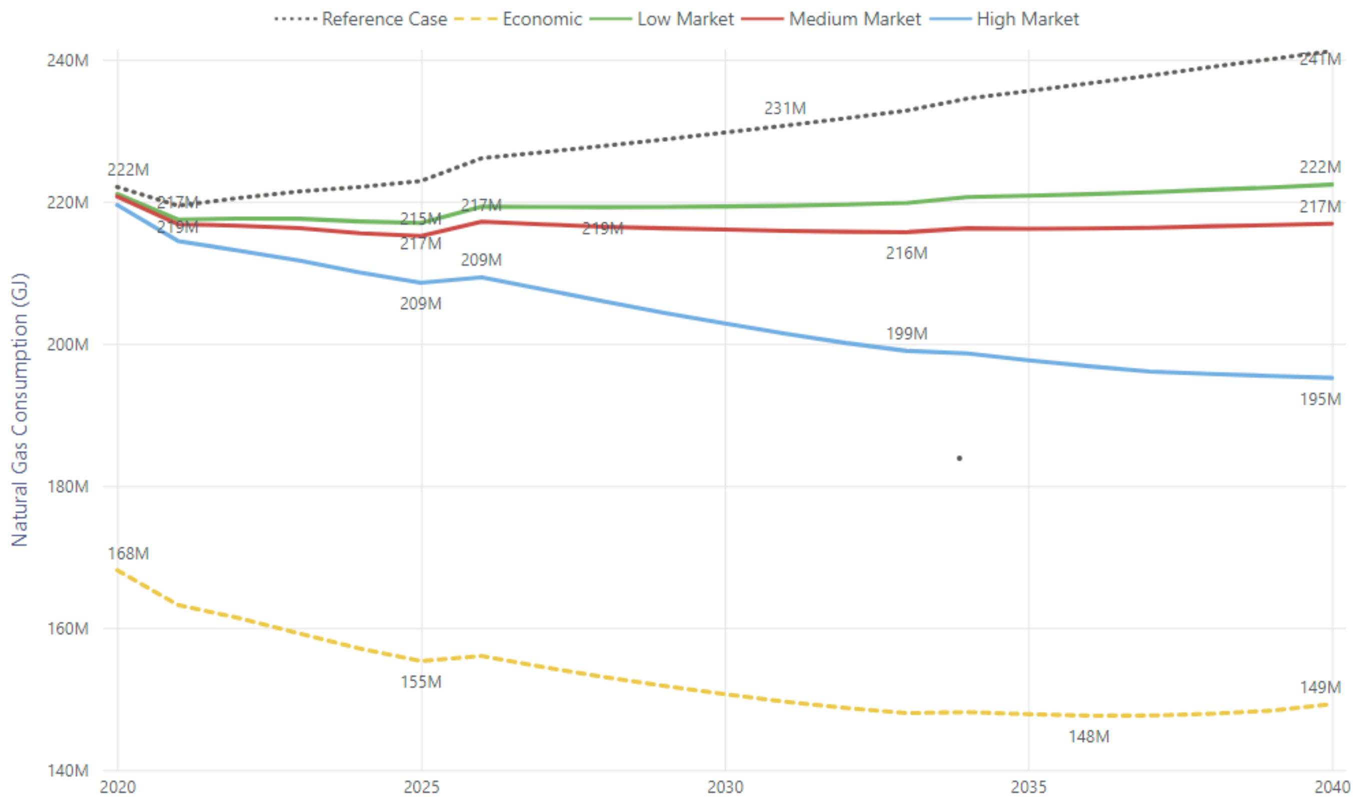

The medium market potential savings from the commercial, industrial, residential sectors are plotted together in Exhibit 150 (TRC) and Exhibit 151 (MTRC).

Under the TRC medium market scenario, by 2025, the industrial sector is estimated to have the most savings potential, followed by the residential and then commercial sectors. By 2030, the commercial sector overtakes residential. This is because there are only 14 residential measures that pass the TRC, and almost all of them are retrofit measures that can be implemented early in the study period. By 2040, potential savings from industrial, commercial, and residential sectors are estimated to be 7.3 PJ, 5.0 PJ, and 3.4 PJ, respectively.

Under the MTRC medium market scenario, the residential sector is estimated to have the most savings potential throughout the study period, followed by industrial and then commercial. By 2040, potential savings from residential, industrial, and commercial sectors are estimated to be 9.9 PJ, 8.6 PJ, and 5.8 PJ, respectively.

Exhibit 150 – Medium Market Potential Savings (GJ) – All Sectors, TRC

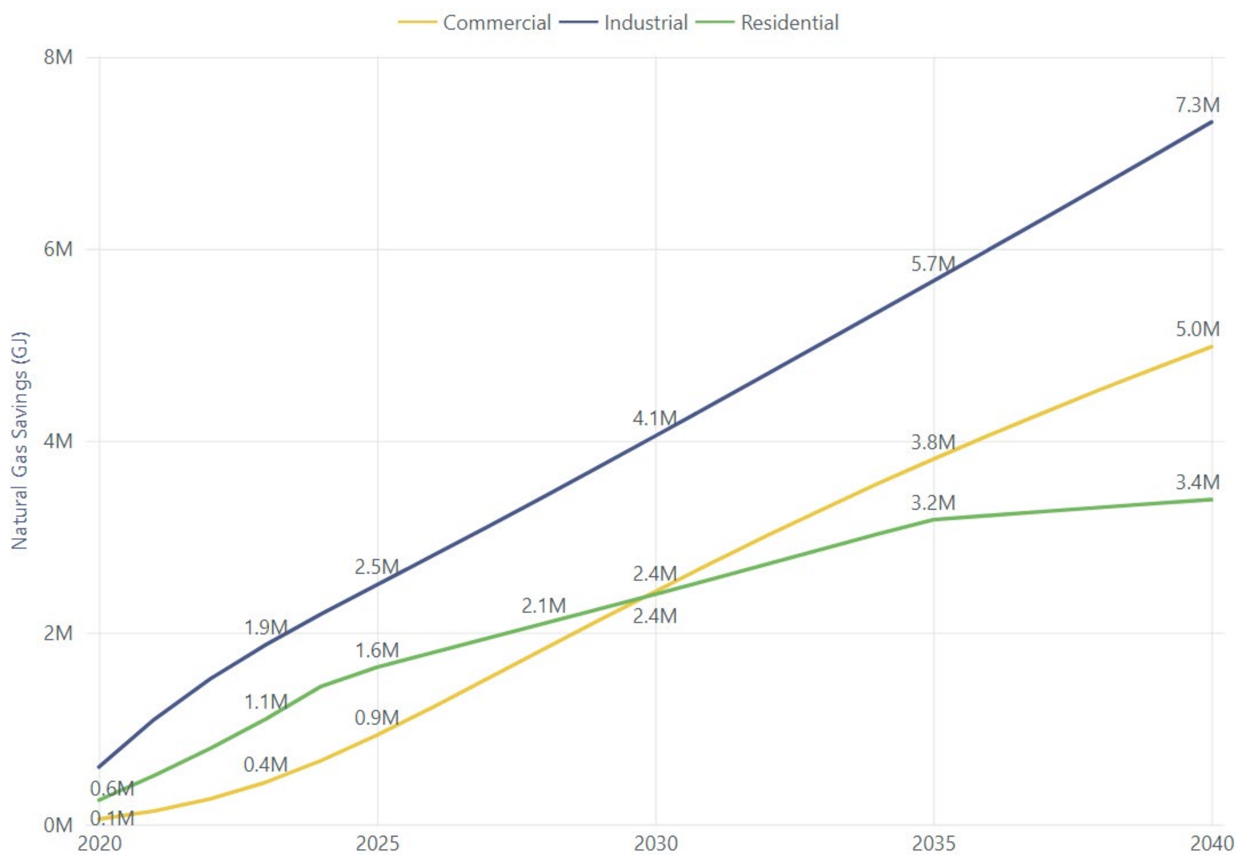

Exhibit 151 – Medium Market Potential Savings (GJ) – All Sectors, MTRC

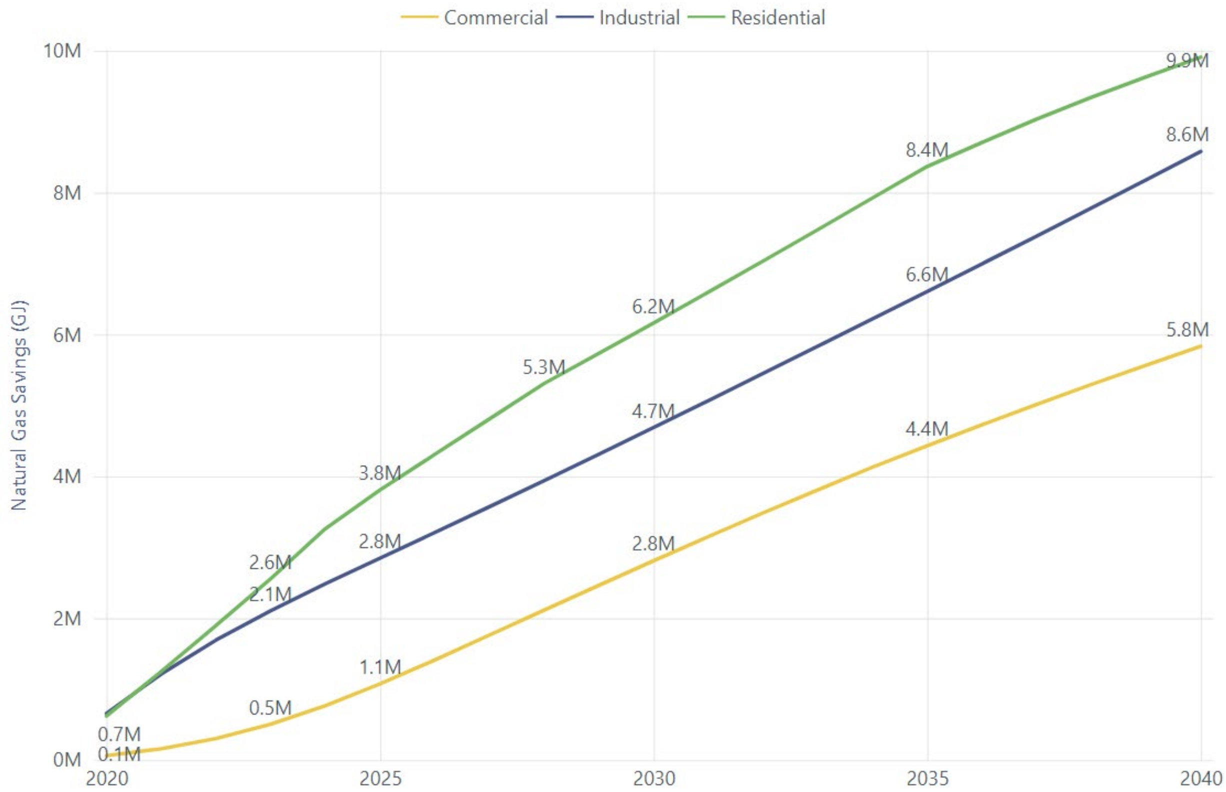

7.1.2 Incentive and Non-Incentive Spending

The incentive and non-incentive spending required to achieve the medium and high market potential are shown in Exhibit 152 (TRC) and Exhibit 153 (MTRC). Medium and high market incentives are assumed to be 50% and 100% of measures' incremental costs, respectively. In both medium and high scenarios, non-incentive costs are estimated to be 15% of incentive costs. For each year, the tables show the total as well as incremental savings from new measures installed in each year.

Note that these costs and savings are not directly comparable to the costs and savings of FortisBC's current DSM portfolio for several reasons, including:

- Market potential includes a mix of measures that does not align exactly with the current DSM portfolio.
- The current DSM portfolio includes a mixture of measures that pass the TRC test and measures that pass the MTRC test only. This report presents TRC and MTRC analysis separately.
- Program-level incentive and non-incentive costs are estimated, and do not align exactly with current DSM costs.
- DSM spending includes portfolio-level non-incentive costs, whereas CPR modelling does not.

7.2 Emissions

Reducing natural gas use results in lower greenhouse gas emissions. The estimated GHG emission reductions for the three sectors combined, in the medium and high market potential scenarios are shown in Exhibit 154 (TRC) and Exhibit 155 (MTRC).

These estimates use an emissions factor of 51.6 kg of CO_2e, or carbon dioxide equivalent, per GJ of natural gas saved.[46] The emissions reductions are shown in tCO_2e, or Tonnes of CO_2e.

Exhibit 154 – Estimated Greenhouse Gas Emissions Reduction (Tonnes of CO2e) – All Sectors, TRC

Year	Reference Case Emissions (tCO2e)	Medium Market Potential Emissions Reduction (tCO2e)	%	High Market Potential Emissions Reduction (tCO2e)	%
2025	11.5M	262k	2.3%	451k	3.9%
2030	11.8M	458k	3.9%	819k	6.9%
2035	12.1M	653k	5.4%	1.1M	9.5%
2040	12.5M	810k	6.5%	1.4M	11.3%

Exhibit 155 – Estimated Greenhouse Gas Emissions Reduction (Tonnes of CO_2e) – All Sectors, MTRC

Year	Reference Case Emissions (tCO2e)	Medium Market Potential Emissions Reduction (tCO2e)	%	High Market Potential Emissions Reduction (tCO2e)	%
2025	11.5M	399k	3.5%	740k	6.4%

46 Lifecycle emissions factor derived from *Environment Canada National Inventory Report on Greenhouse Gases and Sinks, 1990-2007*, consistent with FortisBC practice.

7.3 Employment Impacts

Employment impacts from spending on energy conservation measures in the market potential are presented in this section. Using multipliers, this analysis illustrates the economic effect investing in energy efficiency can have on the labour market.

The literature defines three types of impacts on employment: direct, indirect, and induced. Details of the analysis approach for each employment category are provided below.

7.3.1 Direct/Indirect Jobs

Direct and indirect jobs are created by spending, as capital and labour are required to create and ship products, and conduct the work associated with an efficiency project.

The CPR includes a variety of measure types, each of which would have different employment impacts.[47] For the purpose of this analysis, impacts were estimated in aggregate using the following approach:

1. Estimate DSM spending: The total annual medium market incentive cost for all sectors, multiplied by two (as the incentive represents 50% of the incremental cost of implementing the measure). This value represents the spending injected into the economy from implementing the CPR measures.
2. Estimate direct and indirect employment impacts:
    a. Apply the multiplier for direct jobs – to estimate direct jobs supported by spending.
    b. Apply the multiplier for indirect jobs – to estimate indirect jobs supported by spending.
3. Sum results for the study period to derive the total estimated number of jobs supported by spending on CPR measures.

7.3.2 Induced Jobs

Induced jobs are created when people or businesses spend more money because they have lower fixed costs, such as energy bills.

Lower energy costs result in higher disposable income for households and people often spend disposable income in their local economy (going out for dinner or to the movies, for example). Similarly, businesses can become more competitive when lower energy costs reduce their operating expenses, creating more

47 Multipliers for job impacts may vary by measure type, as different measures involve different industries, and levels of labour and capital. For a more detailed analysis of employment impacts by measure type and sector, please see "Analysis of Job Creation and Energy Cost Savings from Building Energy Rating and Disclosure Policy" by the Institute for Market Transformation and the Political Economy Research Institute (2012) and "The Economic Impact of Improved Energy Efficiency in Canada" by Efficiency Canada (2018).

working capital. The Institute for Market Transformation estimates that 60% of net jobs created through energy efficiency projects are associated with the energy cost savings.[48]

The following steps were taken for the TRC and MTRC scenario to estimate induced jobs:

- Estimate cost savings: Annual retail rates by sector were multiplied by the medium market potential savings to generate an annual cost savings figure.
- Estimate employment impacts: Apply the multiplier for induced jobs to estimate induced jobs.

7.3.3 Summary of Employment Impacts

The analysis uses the following multipliers:[49]

- Direct jobs: 5 job-years[50] per $1 million CAD spent on energy efficiency measures.
- Indirect jobs: 4 jobs-years per $1 million CAD spent on energy efficiency measures.
- Induced jobs: 4 jobs-years per $1 million CAD saved, used to estimate induced jobs from bill savings resulting in energy efficiency measures.

Multipliers for direct and indirect jobs are net numbers, meaning they account for job losses in other sectors that may result from spending on energy efficiency.

Using the method described in the sections above, the following exhibits provide the cumulative incentive spending, total spending (double the incentive spending), direct and indirect jobs-years resulting from this spending, customer bill savings, induced jobs resulting from bill savings, and total employment impacts for the study period. Exhibit 156 and Exhibit 157 present results using spending and bill savings levels for the TRC and MTRC screens, respectively.

48 Institute for Market Transformation and Political Economy Research Institute. "Analysis of Job Creation and Energy Cost Savings." (2012).
49 Multipliers derived from Pembina Institute. "Deep emissions reductions in the existing building stock." April 11, 2017. (Online) Available at: http://www.pembina.org/pub/building-retrofits. Per dollar value multipliers were not converted from the source year to 2020 dollars.
50 A "Job-year" is defined as the resources to employ 1 person for 12 months.

Exhibit 156 – Annual and Cumulative Employment Impacts from CPR Measures, 2020-2040 - TRC Scenario

Year	Incentive Spending ($ Millions)	Total Spending ($ Millions)	Direct Job-years	Indirect Job-years	Bill Savings ($ Millions)	Induced Job-years	Total Job-years

7.4 Findings and Conclusions

Readers are encouraged to use the CPR Data Visualization Tool to explore output data and draw their own insights for the purposes of DSM planning, program research and program design.

This section summarizes findings of this study at a high level:

- This study has found significant cost-effective and market achievable natural gas savings throughout the study period 2020-2040, and in all sectors and segments.

  Across all sectors, and using the MTRC screen, medium market potential savings are estimated at approximately 8 PJ, or 4% of reference consumption in 2025, rising to 24 PJ, or 10% of reference consumption in 2040.

  This estimated 24 PJ savings by 2040 includes potential savings from Residential, Industrial, and Commercial sectors of 9.9 PJ, 8.6 PJ, and 5.8 PJ respectively.

- In the ***residential sector***, only a small number of measures are cost-effective based on the TRC test, most being low-cost retrofit measures. Measures that pass the MTRC screen only become more important in the residential sector as the study period progresses.
  - The opportunities for equipment replacement measures, especially space heating measures, are much smaller relative to previous studies. This is primarily due to increasingly higher federal and provincial minimum energy performance standards (MEPS) for furnaces, which have caused DSM opportunities to become increasingly scarce.
  - In terms of percentage of reference case consumption forecast, more residential opportunities are available in the domestic hot water end use than the space heating end use throughout the study period. In absolute terms, savings potential for DHW measures (4 PJ by 2040 in the medium market potential scenario, MTRC screen) approaches that of space heating measures (5 PJ by 2040 in the medium market potential scenario, MTRC screen).

- ***Commercial sector*** savings show the most variance between the high and medium market potential scenarios. Using the MTRC screen, by 2040 the difference in potential between the medium and high market scenarios is 11.6 PJ.

  Gas heat pumps (GHPs) and efficient new construction are major contributing factors to this difference. These measures have high technical and economic potential, but future uptake is uncertain. For example, in the medium scenario, GHPs are modeled as an innovative technology with low forecasted growth. In the high scenario, they are modeled as an innovative technology with high forecasted growth, especially in the second half of the study period (2030-2040).

- The ***industrial sector*** is estimated to have the largest cost-effective savings potential on the TRC economic screen relative to other sectors. However, industrial customers require shorter payback periods relative to commercial and residential customers. Achieving savings from industrial measures that are cost-effective but have longer customer payback periods may be challenging and/or more expensive due to higher incentives and program costs.

- This CPR is the first to use a model that is fully compatible with the end use model developed for FortisBC's Long-Term Gas Resource Plan (LTGRP). The LTGRP provided the CPR's reference case, at a level of granularity not available to previous CPRs.

  Questions about the trends or assumptions in the reference case were easily answered by delving into the LTGRP model and the data upon which it was based. Furthermore, the results of the CPR will be provided to the LTGRP project for further analysis. Because the models are compatible, the LTGRP can easily explore variations in the CPR's potential estimates with different assumptions about economic conditions in the province or different budget envelopes for DSM programs.
- This CPR does not consider announcements related to the federal carbon tax made in 2021, which were made after modelling was complete for this project. Increases in the federal carbon tax are expected to positively impact the savings potential presented in this CPR: as natural gas costs rise, more measures will become cost-effective and pass the benefit/cost tests, and all measures will become more attractive financially to end users.

Appendix C-2

SUPPLEMENTAL INFORMATION FOR DEMAND SIDE RESOURCES – DSM ANALYSIS

APPENDIX C-2: SUPPLEMENTAL INFORMATION FOR DEMAND SIDE RESOURCES - DSM ANALYSIS

This appendix provides supplemental information to the DSM analysis results presented in Section 5 Demand Side Resources. Two separate analyses are provided. The first analysis provides the forecast long-term demand after DSM savings are applied for all sectors combined for the alternate future scenarios described in Section 5. The second analysis provides an overview of cost effectiveness test results for the residential, commercial and industrial sectors for (1) the Diversified Energy (Planning) Scenario with High DSM Budget Settings (DEP High Scenario), (2) the Reference Case, and (3) the Upper Bound Scenario.

For each of the residential, commercial and industrial sectors, a table is presented with an aggregate value for the sector over the planning horizon and the results for each year. FEI then presents four figures that compare DEP High to the Reference Case for each sector, illustrating the Total Resource Cost Test (TRC), Modified Total Resource Cost Test (MTRC), Utility Cost Test (UCT) and Cost of Conserved Energy (CCE) over the planning horizon. While the figures still show the Upper Bound scenario, there are no DSM settings considered in this scenario so the results for this scenario are nil.

1.1 Total Annual Demand After DSM Savings for Alternative Scenarios–Excluding LCT

Figure C2-1 and C2-2 below illustrates annual energy demand, excluding LCT[1], before and after estimated DSM energy savings for all sectors combined.

Figure C2-1 below, which is the same as Figure 5.5 discussed in Section 5.4.2, illustrates the following annual energy demand forecasts:

- Diversified Energy (Planning) – Pre-DSM
- Diversified Energy (Planning) – Post-DSM Medium (DEP Medium)
- Diversified Energy (Planning) – Post-DSM High (DEP High)
- Reference Case – Pre-DSM
- Reference Case – Post-DSM

[1] LCT in this case refers to LCT, Global LNG and the New Large Industrial Loads as they are all excluded from the DSM analysis.

Figure C2-1: Annual Demand Before and After Estimated DSM Savings (Excluding LCT) - All Sectors Combined

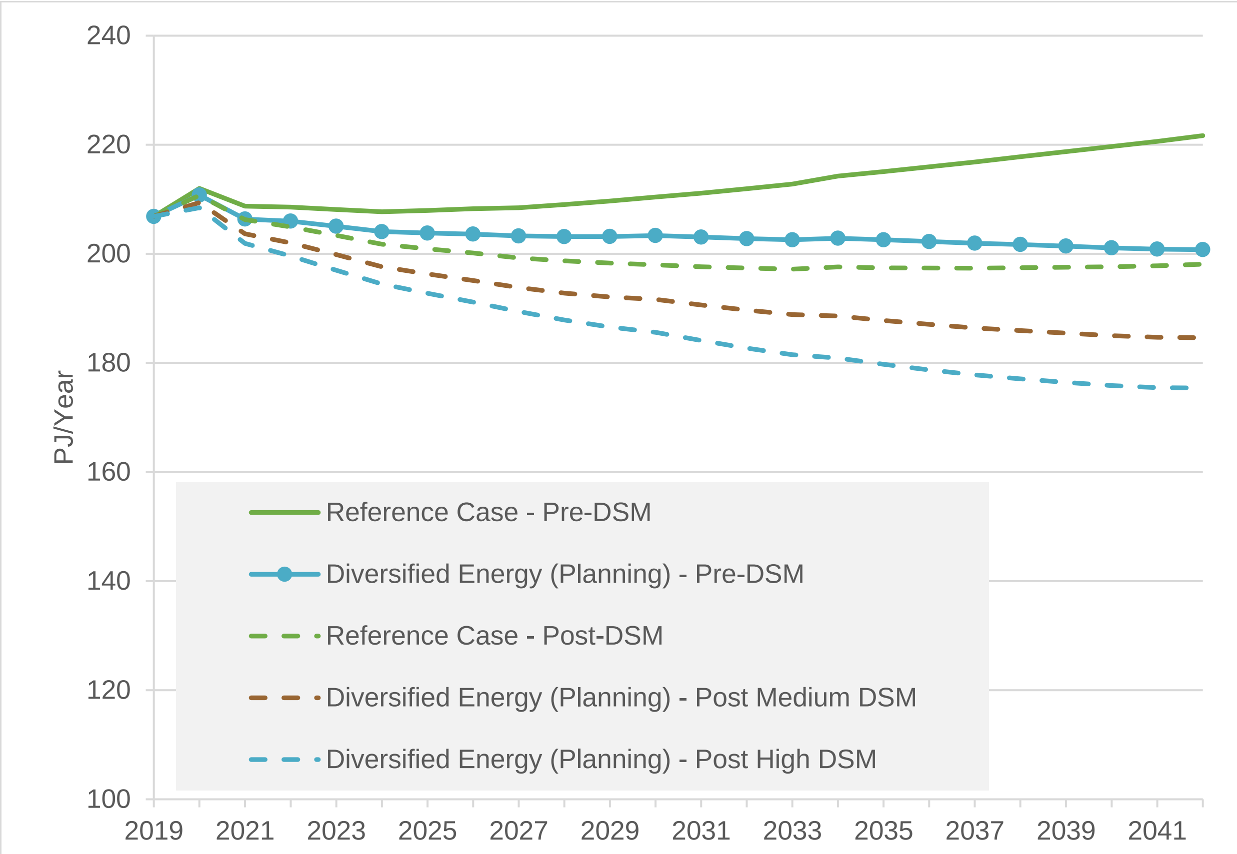

Figure C2-2 below compares the following annual energy demand forecasts:

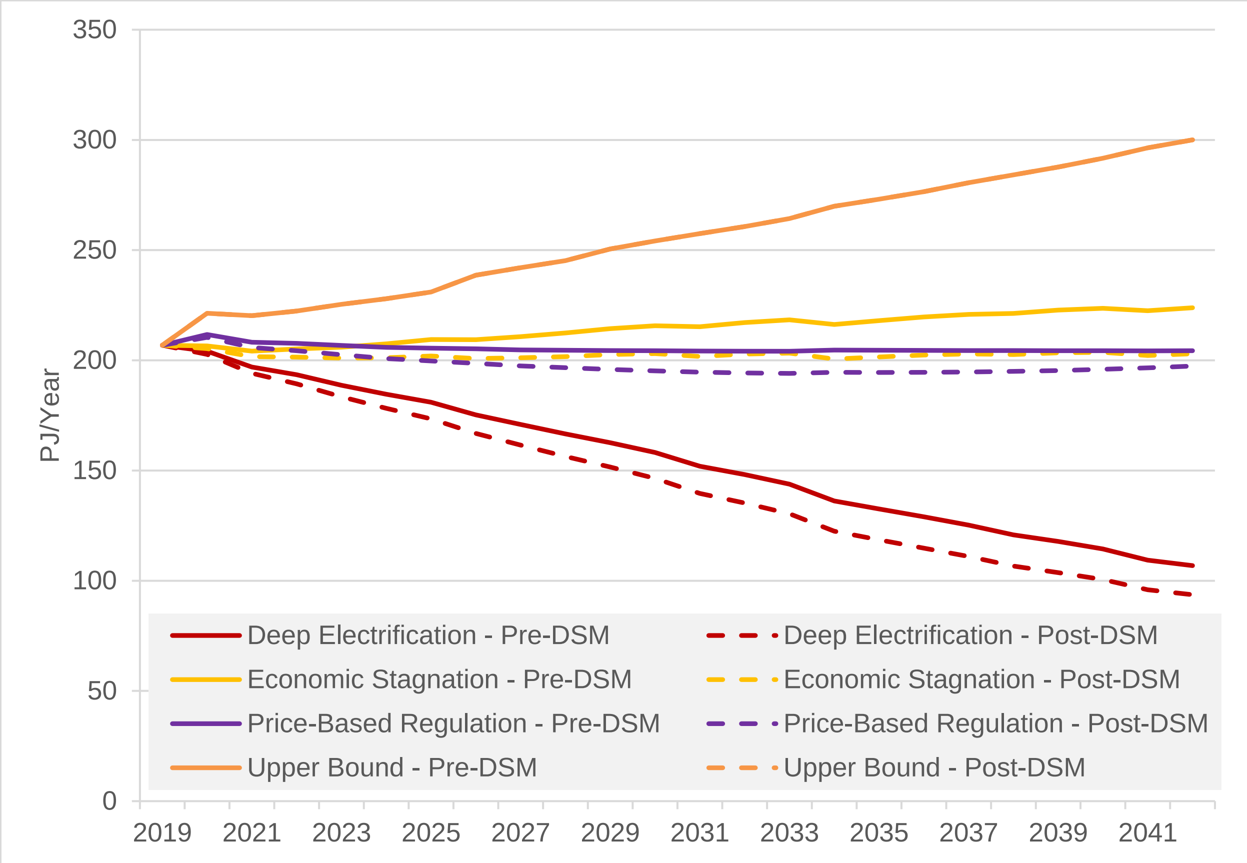
- Deep Electrification-Pre-DSM
- Deep Electrification-Post-DSM
- Economic Stagnation-Pre-DSM
- Economic Stagnation-Post-DSM
- Price Based Regulation-Pre-DSM
- Price Based Regulation-Post DSM
- Upper Bound – Pre-DSM, which is equivalent to Upper Bound - Post-DSM

Figure C2-2: Annual Demand Before and After Estimated DSM Savings (Excluding LCT) - All Sectors Combined



In summary, annual energy savings for each of the six scenarios are as follows:

- DEP High annual energy savings are forecast to account for a 13 percent reduction in demand in 2042 while DEP Medium savings are forecast to account for an 8 percent reduction;
- Reference Case annual energy savings are forecast to account for a 11 percent reduction in Reference Case projected demand in 2042;
- Deep Electrification annual energy savings are forecast to account for a 12 percent reduction in Deep Electrification projected demand in 2042;
- Economic Stagnation annual energy savings are forecast to account for a 9 percent reduction in Economic Stagnation projected demand in 2042; and
- Price-Based Regulation annual energy savings are forecast to account for a 3 percent reduction in Price Based Regulation projected demand in 2042.

1.2 Cost Effectiveness Test Results for the Residential Sector

Table C2-1 below summarizes the DEP High cost effectiveness test results for the residential sector while Figures C2-3 to C2-6 illustrate how cost effectiveness test results vary across scenarios. The aggregate residential sector TRC ratio (1.5) and the aggregate UCT (1.4) are lower than the corresponding portfolio level results of 4.1 and 4.0, respectively. Aggregate residential CCE results are higher than the corresponding portfolio level CCE results, as is typical of the residential sector, and the results do decline over time. The Reference Case demonstrates higher cost-effectiveness test results, and this may partially be explained by the higher proportion of conventional natural gas in the fuel mix for the Reference Case.

Table C2-1: Estimated Diversified Energy (Planning) – High DSM Cost Effectiveness Test Results – Residential Sector

Year	TRC	MTRC	UCT	CCE ($/GJ)
Portfolio Aggregate	**4.1**	**14.2**	**4.0**	**11.3**
Residential Aggregate	**1.5**	**4.8**	**1.4**	**17.2**
2022	1.3	4.0	1.1	18.3
2023	1.3	4.1	1.1	18.4
2024	1.3	4.2	1.2	18.3
2025	1.4	4.3	1.2	18.2
2026	1.4	4.5	1.3	18.1
2027	1.4	4.6	1.3	17.9
2028	1.4	4.7	1.3	17.8
2029	1.5	4.8	1.4	17.7
2030	1.5	4.9	1.4	17.5
2031	1.5	5.0	1.4	17.4
2032	1.5	5.0	1.5	17.3
2033	1.5	5.0	1.5	17.2
2034	1.5	5.0	1.5	17.1
2035	1.6	5.1	1.5	16.9

2039	1.5	5.0	1.5	16.5
2040	1.5	4.9	1.5	16.6
2041	1.5	4.8	1.5	16.5
2042	1.5	4.8	1.5	16.4

Figure C2-3: Estimated TRC Results by Scenario – Residential Sector

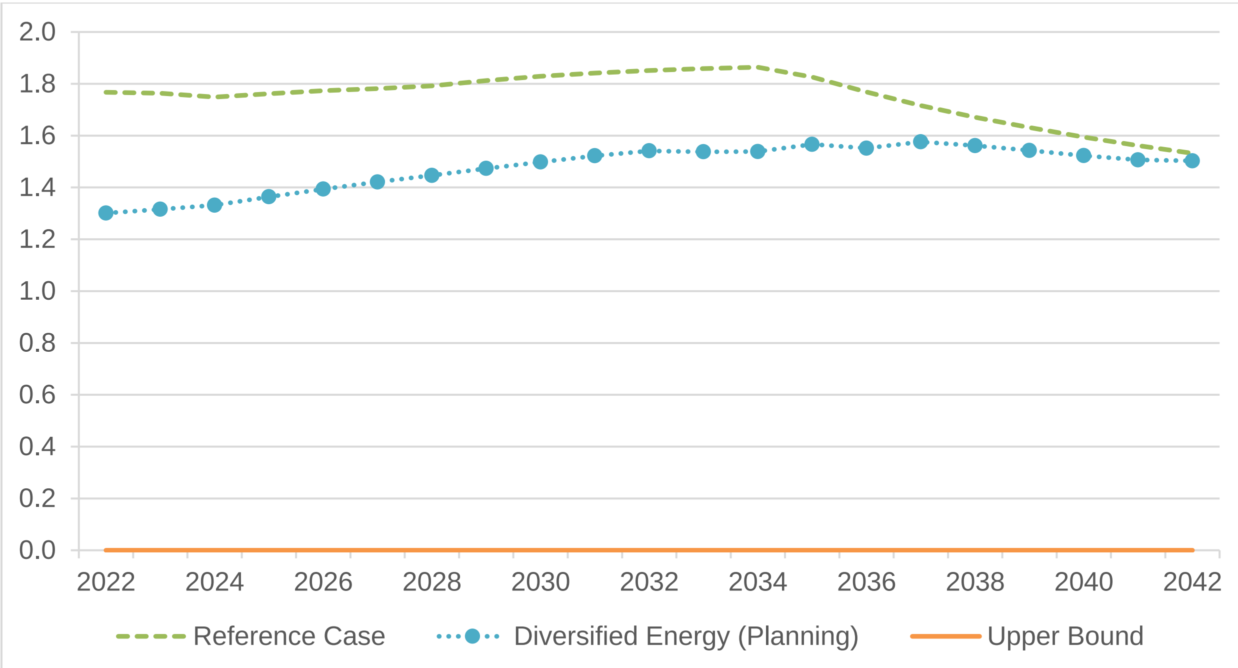

Figure C2-4: Estimated MTRC Results by Scenario – Residential Sector

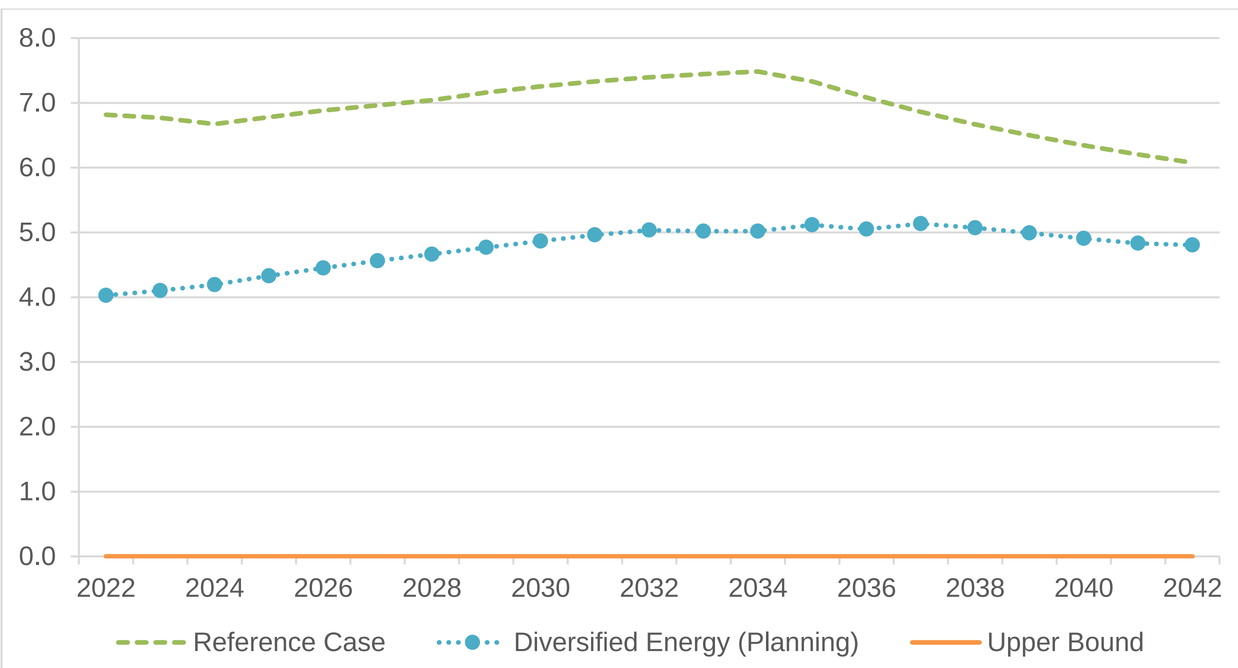

Figure C2-5: Estimated UCT Results by Scenario – Residential Sector

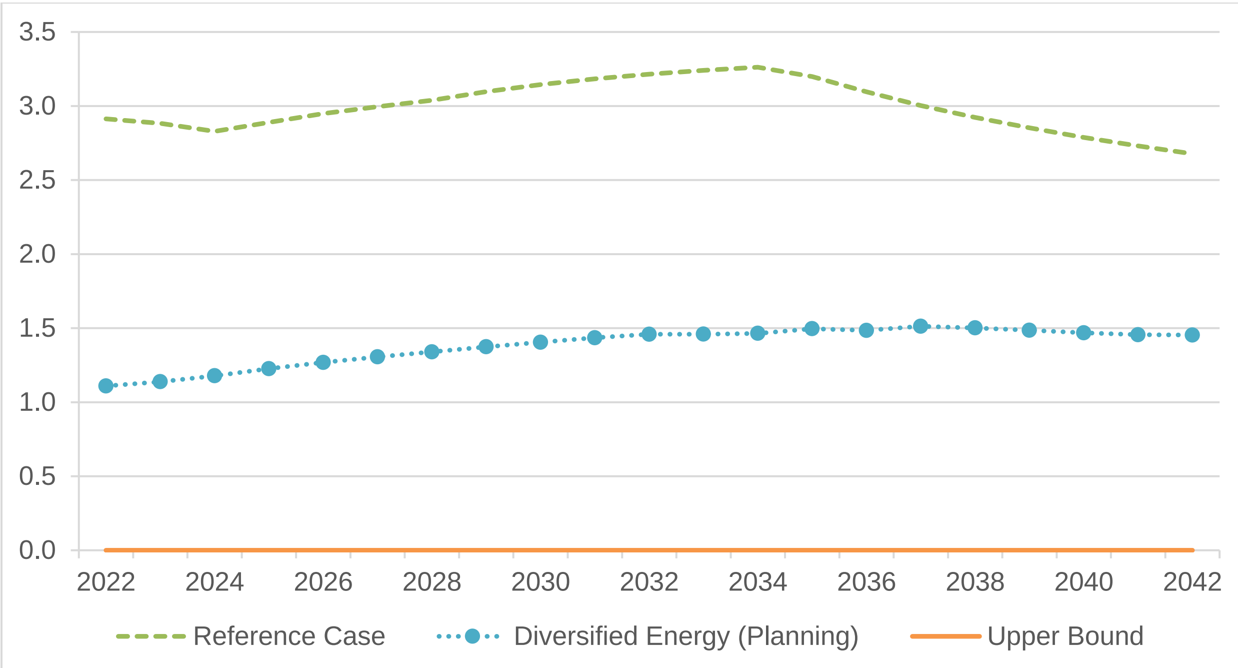

Figure C2-6: Estimated CCE Results by Scenario ($/GJ) – Residential Sector

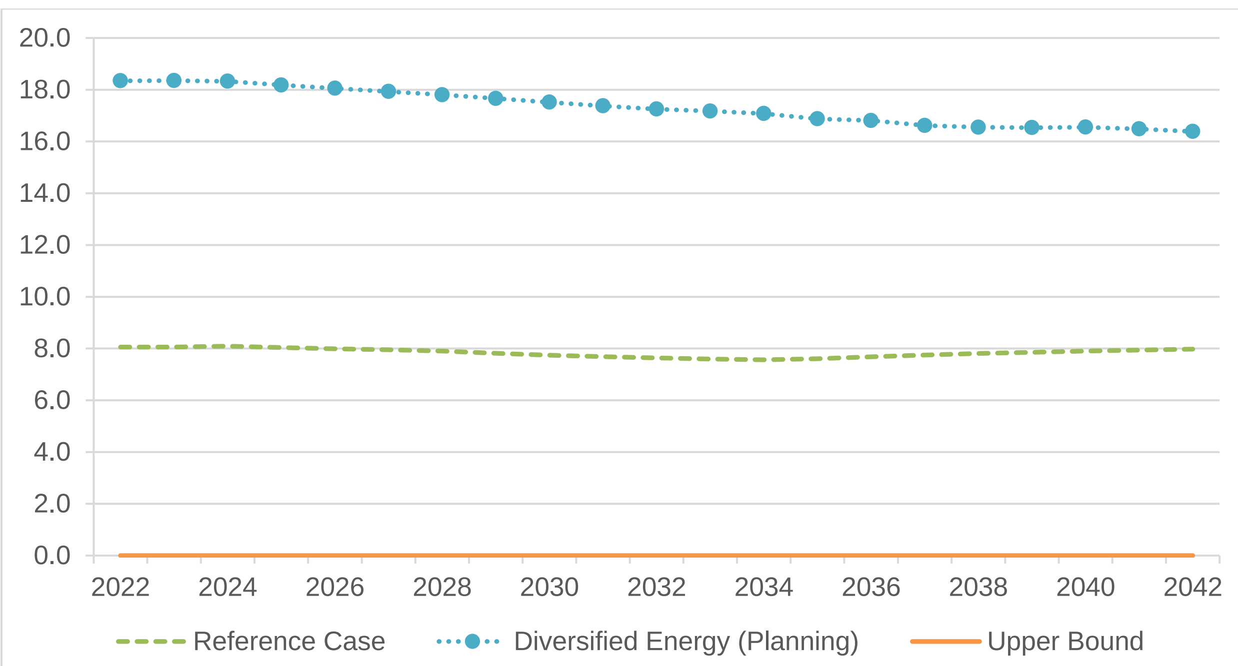

1.3 Cost Effectiveness Results for the Commercial Sector

Table C2-2 below summarizes the DEP High cost-effectiveness test results for the commercial sector while Figures C2-7 to C2-10 illustrate how cost-effectiveness test results vary across scenarios. The aggregate commercial sector TRC ratio is lower and the aggregate UCT is lower than the corresponding portfolio level results. Aggregate commercial CCE results are somewhat lower than the corresponding portfolio level results and annual results increase slightly over time. The Reference Case demonstrates higher cost-effectiveness test results, and this may partially be explained by the higher proportion of conventional natural gas in the fuel mix for the Reference Case.

Table C2-2: Estimated Diversified Energy (Planning) – High DSM Cost Effectiveness Test Results – Commercial Sector

1.4 Cost Effectiveness Test Results for the Industrial Sector

Table C2-3 below summarizes the DEP High cost-effectiveness test results for the industrial sector while Figures C2-11 to C2-14 illustrate how cost-effectiveness test results vary across scenarios. The aggregate industrial sector TRC ratio and the aggregate UCT is higher than the corresponding portfolio-level results. Aggregate industrial CCE results are lower than the corresponding portfolio-level results. The results vary over the years but remain relatively flat over time. For the industrial program area, the Reference Case and DEP High scenarios are more closely aligned for the TRC and MTRC, but reflect larger differences for the UCT. This may be partially explained by the higher proportion of conventional natural gas in the fuel mix for the Reference Case as described in Section 5.

Table C2-3: Estimated Diversified Energy (Planning) – High DSM Cost Effectiveness Test Results – Industrial Sector

Year	TRC	MTRC	UCT	CCE ($/GJ)

Acronyms

AMI	advanced metering infrastructure
ASHP	air-source heat pump
Btu	British thermal unit
C&I	commercial and industrial
CNG	compressed natural gas
DR	demand response
DSM	demand-side management
EE	energy efficiency
ETEE	enhanced targeted energy efficiency
ETO	Energy Trust of Oregon
FEI	FortisBC Energy Inc.
G2E	gas to electricity
GJ	gigajoule
GHG	greenhouse gases
GSHP	ground-source heat pump
IRP	integrated resource planning
IRPA	integrated resource planning alternative (Ontario equivalent for NPS)
LNG	liquefied natural gas
NESE	Northeast Supply Enhancement
NGDR	natural gas demand response
NPS	non-pipe solutions (also referred to as non-pipe alternatives (NPA))
NYSERDA	New York State Energy Research and Development Authority
OEB	Ontario Energy Board
PSC	New York Public Service Commission
PCT	participant cost test
REV	Reforming the Energy Vision
RIM	rate impact measure
RNG	renewable natural gas
SCADA	supervisory control and data acquisition
SCT	societal cost test
SPM	Standard Practice Manual (i.e. the California SPM, the National SPM)
TMA	Transportation Mode Alternative
TRC	total resource cost test
UCT	utility cost test

Executive Summary

FortisBC Energy Inc. (FEI) retained ICF Consulting Canada, Inc. (ICF) to research and report on the status of Non-Pipe Solutions (NPS) for natural gas distribution companies in North America. NPS are non-traditional and/or demand-side solutions that substitute for traditional capital investment in the gas distribution system infrastructure, including expansion of the gas network to new communities, reinforcement projects, or replacing older leak-prone pipes. Examples include energy efficiency, natural gas demand response, and electrification (i.e. gas to electricity) among others.

The potential for NPS to contribute to gas distribution system planning is largely based on the following:

- In some cases, NPS may be less expensive than traditional infrastructure investments, allowing natural gas customers to benefit from a downward pressure on transport and distribution rates
- Some NPS options may be more “modular” than traditional infrastructure investments, thus allowing for more “right-sized” solutions whose deployment is paced depending on need
- NPS may also reduce the risk of stranding gas distribution assets before the end of their book life, perhaps as a result of future carbon policies

In this report, ICF presents a review of NPS practices in a number of jurisdictions, with a particular focus on regions with relevant NPS activity. This report will be filed as part of FEI’s upcoming LTGRP submission to the BCUC and will partially fulfill the requirement “to provide an update of its analysis of opportunities for energy efficiency to be used to cost-effectively replace or defer infrastructure investments in its next LTGRP”, as per Decision and Order G-39-19.[1]

I. Definition of NPS

NPS can be used to address a range of different types of issues, based on the types and locations of the constraints and infrastructure investments faced by the utility. These issues include upstream constraints on pipeline capacity to the utility service territory, as well as existing and potential future infrastructure capacity constraints and investment requirements downstream of the city gate. This report focuses on distribution-level (demand side) NPS, which are located downstream of city gates.

[1] BCUC, ‘FortisBC Energy Inc. 2017 Long Term Gas Resource Plan: Decision and Order G-39-19’, 2019, p. Section 2.2.2, pp. 14–17 <https://www.bcuc.com/Documents/Proceedings/2019/DOC_53485_Decision-and-G-39-19-FEI-2017LTGRP.pdf> [accessed 12 November 2021].

Exhibit 1 summarizes the broad range of NPS options in two high-level categories:

Exhibit 1 Categorization of NPS Options

Distributed Infrastructure (Supply Side) Options

Liquefied Natural Gas (LNG)	Compressed Natural Gas (CNG)	Renewable Natural Gas (RNG) and Power to Gas (P2G)
Facility on land, on a barge or offshore with natural gas stored in cooled down liquid. The LNG must be delivered to the facility, and must then be gasified before being injected into the pipe network.	Facility on land with natural gas stored under high pressure in gaseous form. The CNG must be delivered, and is often trucked in. The CNG is decompressed before being injected into the pipe network.	Biomethanization facility that converts organic matter (often bio waste) into biogas. The biogas mainly contains methane but also other gases, some of them undesirable. The biogas is cleaned before injection into the pipe network. The RNG plant and the connection point to the network can be connected in an area of high constraint.

No-Infrastructure (Demand Side) Options

Enhanced Targeted Energy Efficiency (ETEE)	Natural Gas Demand Response (NGDR), and ***Enhanced Interruptible Rates***	Electrification (Gas to Electricity, G2E)
Gas consumption reduction in multiple buildings through a variety of technology upgrades and/or behavioural changes. Typically delivered in the form of an incentive, or a "kicker" adding to an existing franchise-wide program aimed at convincing multiple customers to implement the upgrades.	Curtailment of gas demand over a specific set of hours during peak demand periods through an automated system or a planned schedule. Gas DR can be used to alleviate day-long constraints at city gates or hourly constraints on the distribution system. Interruptible Rates are traditional gas utility resource akin to DR.	Conversion of space, water heating or even food service gas end-use to electrotechnologies on a geo-targeted basis to reduce peak day demand on parts of the natural gas distribution system. The electrotechnologies of choice to alleviate gas winter peak demand constraints are air-source and ground-source heat pumps. Although these technologies can help reduce natural gas peak demand, they generally contribute to electric peak demand.

Distributed infrastructure NPS options have a different risk profile than traditional distribution infrastructure because they can be generally be added in smaller and shorter-term capacity increments, reducing their risk of becoming stranded assets if the demand growth does not materialize as forecasted. However, distributed infrastructure NPS options are also typically more expensive than regular distribution infrastructure on a per unit capacity basis.

Nonetheless, CNG injection (CNG delivered by trucks) has been used to provide incremental natural gas capacity to the densely urbanized areas of New York City. Satellite LNG stations and propane-air stations have also been used for decades on nodes of the transmission pipeline network.

II. Jurisdictional Review

To date, there is limited experience with implementing NPS projects to address peak demand constraints. However, there have been significant developments with regards to NPS in the last few years. When ICF completed the 2018 IRP study for Enbridge Gas, it did not identify any natural gas utilities that were actively factoring in the impact of DSM programs on peak hour or peak day demand forecasts on their facilities planning. A few gas utilities had begun to consider these impacts, but their efforts were still in the early stages. ICF followed up twice with several of these utilities to document their progress since the 2018 IRP study to gain a better appreciation of the evolution of NPS. First, we consulted the utilities in 2020 as part of a study commissioned by Enbridge.[2] We then reached out to many of the same utilities in late 2021 as part of the present study. ICF consulted with Central Hudson (Upstate New York), Columbia Gas (Massachusetts), ConEdison (Downstate New York), NYSEG (Upstate New York), and NW Natural (Oregon).

In 2020, ICF identified several natural gas utilities that were considering the impact of their energy efficiency programs on the peak hour or peak day demand forecasts they use for their facilities planning. However, pilot projects related to NPS have been modest to date. As part of our current research and consultations, ICF identified several additional recent developments, not only in terms of new pilot programs but also with regards to NPS policy framework development.

NPS are being increasingly considered by gas utilities that are contemplating the modernization of long-term planning of their natural gas distribution systems in the context of decarbonization policies that include electrification.[3] For instance, New York, Colorado, Oregon, and California have started pursuing active electrification of their building sectors, leading to concerns over the adequacy of traditional utility infrastructure planning.

III. Long-Term Gas Capacity Planning and NPS Framework

In jurisdictions that have adopted a building electrification policy through legislation and rulemaking, gas utilities and utility commissions have started to pay greater attention to or even reform the approach to long-term gas capacity planning. Intervenors and stakeholders request better alignment of energy resources with climate policy direction in anticipation of reduced growth or even a potential decline in future natural gas demand, increasing the relevance of NPS options.

NPS can help address near-term natural gas demand growth that may be counter to the longer-term demand trajectory. Furthermore, NPS can help avoid issues with underutilized or abandoned pipes where demand is not guaranteed during the entire book life of the new pipe. NPS are only one instrument of a reformed long-term gas capacity planning approach in the context of a building electrification policy.

In anticipation of increased NPS activities, gas utilities seek the adoption of an NPS framework that can guide consideration and potential investments in NPS based on clear guidance from the utility commission. New York State and Ontario have both made progress towards adopting NPS frameworks. A NPS framework can, for instance, include:

- **A NPS process**, that is embedded in the natural gas infrastructure planning process. Steps of the NPS process can include steps such as: a characterization of the gas network needs or constraints requiring remedial action, a first-pass screening of these needs to remove traditional infrastructure projects that cannot be substituted by an NPS (e.g. a facility investment required to address a safety risk) and an evaluation process that includes but is not limited to technical feasibility within the timeline, and an economic assessment of NPS options.
- **Guidance on cost recovery, accounting treatment, and performance incentive for the utility,** which provides guidelines regarding how expenses related with NPS will be funded

[2] ICF, 'IRP Jurisdictional Review Report', *Completed on Behalf of Enbridge Gas Inc.*, 2020 <https://www.rds.oeb.ca/CMWebDrawer/Record/706445/File/document> [accessed 12 November 2021].
[3] With the notable exception of Ontario, jurisdictions that are working on implementing NPS pilots and developing an NPS framework have a decarbonization policy that includes building electrification.

through natural gas retail rates, and regarding how the natural gas utilities is to be rewarded for pursuing NPS.

- **Guidance on impact evaluation as well as reporting on progress.** The approach to impact evaluation and reporting should: (1) be flexible enough to adapt to the multiple types of NPS, and (2) strike the right balance between cost and rigour, thereby avoiding excessive reporting requirements. In the near-term, impact evaluation of NPS will generally not be able to leverage data from advanced metering infrastructure (AMI) meters for natural gas. Although this is not necessarily a barrier to implementing NPS, the absence of AMI data can impact the design of NPS projects[4] and the accuracy of impact evaluation results.
- **Guidance on how to perform economic assessment of the NPS solutions.** The economic assessment, or cost-benefit analysis, of the NPS solutions is largely grounded in a comparison between the cost of deploying NPS projects, and the avoided cost of the avoided traditional infrastructure project. These avoided costs include not only avoided cost of downstream capacity, reliability benefits, and/or avoided cost of obsolete pipe replacements, but also the avoided cost of upstream capacity, avoided cost of the natural gas commodity, and the valuation of net GHG abatement among other benefit streams. Developing a NPS cost-effectiveness testing approach based on the California Standard Practice Manual (SPM)[5] and/or on the National Standard Practice Manual[6] for Distributed Energy Resources is most appropriate.
- **Guidance on the approach to stakeholder engagement.** The recommended approach should strike the right balance between the overall flexibility of the process and the ability for stakeholders to add value by suggesting innovative solutions.
- **Guidance on the approach to implementation of the NPS projects and programs.** The framework should include recommendations on how, when, and from whom to source NPS. The recommendations should be commensurate with the size of the capital project to be substituted by an NPS.

Sufficient flexibility is a critical success factor for NPS frameworks. NPS projects can often be ramped up to address capacity needs, allowing gas utilities to react to observed impacts and evolving peak demand requirements.[7]

IV. NPS Pilot Projects and Programs

While ICF identified several NPS pilot projects, they remain relatively uncommon and constrained to a small number of jurisdictions.

---

[4] The lack of AMI data can make it more challenging to "right-size" NPS projects. It can also impact the NPS options that are being considered.
[5] CPUC, *California Standard Practice Manual Economic Analysis of Demand-Side Programs and Projects*, *California Public Utilities Commission* (California, United States of America, 2001) <https://doi.org/10.1016/B978-1-85617-804-4.00018-5>.
[6] National Energy Screening Project, *National Standard Practice Manual for Benefit-Cost Analysis of Distributed Energy Resources*, 2020 <https://www.nationalenergyscreeningproject.org/wp-content/uploads/2020/08/NSPM-DERs_08-24-2020.pdf>.
[7] Unlike traditional infrastructure upgrades which typically result in the acquisition of one large "block" of capacity, NPS projects can often be modulated to address capacity needs.

The majority of the relevant pilots that ICF identified have been implemented by utilities in NY State. Exceptions include a NGDR pilot project in Southern California, an ETEE pilot project in Oregon, and a NGDR project in Colorado. Ontario has yet to implement any NPS pilot projects but Enbridge is in the early stages of identifying two pilot projects based on recent direction from the OEB to develop and implement two NPS pilot projects in sufficient time to collect measurement and verification results by winter 2022-2023.

ICF's research suggests that the majority of NPS pilots have tested NGDR technologies. This has included direct load control of smart thermostats to reduce space heating loads during peak demand periods. Some utilities have also piloted behavioural NGDR programs in large commercial and industrial buildings.

Three utilities in New York State have piloted or are in the process of piloting gas to electricity (G2E) conversion programs. There has only been limited additional activity with regards to ETEE pilot programs that are seeking to assess the magnitude of peak demand impacts related to the implementation of natural gas energy efficiency measures. Only one of these programs, which was focused on low-income weatherization, has yielded results to date.

ICF identified only one utility that used distributed infrastructure – a satellite CNG insertion station – for its NPS attributes, although this was not considered to be an NPS project by its respective regulator. RNG production facilities are becoming increasingly common infrastructure but reliability under peak demand conditions continues to be a challenge for these facilities and we have not found any that were deployed primarily for their NPS attributes. In addition, LNG facilities and propane-air facilities have been used for decades to alleviate transmission-level constraints.

V. Conclusions

The primary conclusions from this review include:

1) ICF identified some recent progress with regards to NPS both in New York State and in other jurisdictions, mostly as NPS are increasingly being considered as a novel component of reformed long-term natural gas infrastructure planning in the context of long-term decarbonization strategies. Jurisdictions that are planning for franchise-wide G2E in the medium or long term are considering NPS to solve local peak demand constraints or avoid obsolete pipe replacements without traditional gas infrastructure projects, which are typically amortized over 40+ years. The implications for electricity infrastructure needs as part of such wide-spread G2E are not assessed as part of this report.
2) Utilities in a small number of jurisdictions, such as New York State and Oregon, have made relevant progress in the development of NPS in terms of long-term capacity planning and analysis (e.g. National Grid Long-Term Capacity Planning reports) and pilot projects (ConEdison's NGDR pilot projects). In Colorado, NPS are being considered in the context of legislation encouraging widespread electrification of the building stock.
3) Recent and anticipated near-term developments with regards to NPS in New York State and Ontario are likely to provide useful examples and broader guidance on how to tackle many of the challenges associated with the broader implementation of NPS, such as:
    a. Treatment of issues related to utility remuneration and return on investment for different types of NPS
    b. Approaches to performance measurement and verification of NPS projects
    c. Transparency in the planning of NPS
    d. Minimizing the timeline for implementing and evaluating the impact of NPS

   e. Challenges associated with the sourcing of NPS

4) The lack of natural gas AMI meters is a challenge but not a barrier to NPS. Gas utilities have found workarounds to address the lack of AMI meters by using the interval data feeds from smart thermostats and water heater controllers, leveraging data from SCADA pipe pressure meters, and employing data feeds from electric AMI meters (e.g. using post G2E conversion electricity consumption to infer the baseline space heating gas demand). The resulting impact assessment may be less accurate, but there is also a reasonable amount of uncertainty with regards to long-term load growth forecasts, particularly for certain portions of the distribution network with fewer customers and less diverse energy use.

5) The timeline for NPS implementation is less of a hurdle if NPS decision and implementation is embedded in the capital project planning and decision process. If the NPS process was to overlap with the leave to construct application process, a three to five years lead time prior to forecasted capacity shortfall may be appropriate. It may be possible to implement smaller-scale NPS projects in a shorter timeline. Shorter timelines can generally be achieved by streamlining the approval and implementation process for NPS projects.

6) While GHG emission reductions are not the primary benefit utilities are seeking through NPS opportunities, decarbonization goals and policies are a key driver for adopting NPS. Not all NPS options lead to GHG emissions reductions, and the emissions abated by specific NPS projects are only ancillary to the policy goal of NPS. NPS are relevant to gas system decarbonization pathways since they can be used to avoid deploying new natural gas infrastructure whose medium- and long-term utilization may be significantly impacted by future decarbonization policies. This helps avoid potential issues with amortizing the cost of infrastructure over 40+ year timelines, during which it may become underutilized or obsolete.

1 Introduction

FortisBC Energy Inc. (FEI) retained ICF Consulting Canada, Inc. (ICF) to research and report on the status of Non-Pipe Solutions (NPS) for natural gas distribution companies in North America. NPS are non-traditional and/or demand-side solutions that substitute for traditional capital investment in the gas distribution system infrastructure, including expansion of the gas network to new communities, reinforcement projects, or replacing older leak-prone pipes. Examples include energy efficiency, natural gas demand response, and electrification (i.e. gas to electricity) among others.

Ongoing gas utility energy efficiency programs and interruptible rates have impacted the need for gas infrastructure investments for a number of years. However, this is different from the geo-targeted approach employed by NPS, where alternative options to replace or defer particular distribution infrastructure projects are considered.

The potential for NPS to contribute to gas distribution system planning is largely based on the following:

- In some cases, NPS may be less expensive than traditional infrastructure investments, allowing natural gas customers to benefit from a downward pressure on transport and distribution rates
- Some NPS options may be more “modular” than traditional infrastructure investments, thus allowing for more “right-sized” solutions whose deployment is paced depending on need
- NPS may also reduce the risk of stranding gas distribution assets before the end of their book life, perhaps as a result of future carbon policies

This report will be filed as part of FEI’s upcoming Long Term Gas Resource Plan submission to the BCUC and will partially fulfill the requirement “to provide an update of its analysis of opportunities for energy efficiency to be used to cost-effectively replace or defer infrastructure investments in its next LTGRP”, as per Decision and Order G-39-19.[8]

This study draws on a range of similar studies on NPS. For instance, FEI has been completing research and tracking developments with regards to NPS to determine if it could potentially use DSM to defer future natural gas infrastructure projects. As part of the regulatory process surrounding FEI’s 2017 Long Term Gas Resource Plan, FEI requested that ICF complete a report to respond to evidence from Energy Futures Group about the state of the industry regarding the use of NPS and the use of energy efficiency to defer or reduce the need for incremental infrastructure investments. This report was completed in 2018 and was submitted as expert witness testimony.

ICF’s report draws on research completed by ICF on behalf of Enbridge in 2018. ICF’s 2018 IRP study assessed the viability of employing targeted energy efficiency as an alternative to natural gas distribution system reinforcement infrastructure projects.[9] In addition to completing a jurisdictional review of NPS developments in other jurisdictions across North America and an assessment of distribution system planning and policy changes needed to facilitate NPS, the study included a detailed measure-level analysis of peak demand impacts and an assessment of a number of case studies.

[8] BCUC, p. Section 2.2.2, pp. 14–17.
[9] ICF, *Natural Gas Integrated Resource Planning: Initial Assessment of the Potential to Employ Targeted DSM to Influence Future Natural Gas Infrastructure Investment – Final Report*, 2018. Completed on behalf of Enbridge Gas Distribution and Union Gas Limited

In 2020, ICF updated the jurisdictional review portion of the IRP Study for Enbridge[10] as part of the OEB case EB-2020-0091, in which Enbridge requested that the OEB establish a framework to govern NPS activities in Ontario. ICF staff also testified as expert witnesses as part of this proceeding, which was completed in 2021.

[10] ICF, 'IRP Jurisdictional Review Report'.

2 Applicable Measures/Technologies

NPS are a set of non-traditional and/or demand-side solutions that can be used as substitutes to traditional capital investment in the gas distribution infrastructure. NPS are expected to generate additional benefit streams compared to traditional energy efficiency programs, including Avoided Cost of Downstream Capacity, Reliability Benefits, and Avoided Cost of Replacement of Obsolete Pipes (Often *Leak-Prone* Pipes).[11]

2.1 Purpose of NPS

NPS can be used to address a range of different types of issues, based on the types and locations of the constraints and infrastructure investments faced by the utility. These issues include upstream constraints on pipeline capacity to the utility service territory, as well as existing and potential future infrastructure capacity constraints and investment requirements downstream of the city gate.

This report focuses on distribution-level NPS, which are located downstream of city gates. Downstream (distribution-level) capacity constraints differ from upstream (transmission-level) constraints in that the investment needed to relieve the constraint is generally the responsibility of the distribution utility rather than an upstream pipeline. As a result, distribution-level NPS allow the distribution utility to both address capacity constraints and potentially reduce investments in long-lived infrastructure. In addition, the upstream capacity constraints that can be addressed by NPS tend to be based on peak day requirements for upstream pipeline capacity and peak day and seasonal requirements for upstream storage capacity.

At the distribution level, the constraints that can be addressed through NPS include daily requirements on parts of the system including transmission capacity, but are also driven by shorter term capacity requirements, down to the hourly or sub-hourly level as the distribution system gets closer to the end-user and as the distribution system piping becomes smaller in diameter. As a result, NPS at the distribution level can include measures and technologies that can reduce demand or shift demand away from peak periods for shorter periods of time relative to the upstream constraints. However, addressing distribution-level constraints requires a more thorough understanding of load growth and system capacity and customer characteristics, even in the low-diversity branches of the distribution system.[12]

NPS options can also be deployed to enhance distribution system reliability, potentially at a lower cost than traditional gas infrastructure options. Reliability benefits are focused on reducing the likelihood of low gas pressure in the distribution system during cold snaps and enhancing a natural gas utility's ability to react to unlikely yet impactful events such as extreme weather, accidents, fires, and terrorist incidents that cause supply and/or pressure disruption. For instance, over the past few years, extreme weather events, wildfires, and a pipeline explosion in FEI's service territory caused supply issues, prompting the utility to ask its customers to reduce their natural gas consumption. NPS options, such as gas DR or compressed natural gas

[11] The traditional benefit stream of energy efficiency programs includes avoided natural gas commodity costs, avoided upstream pipeline capacity (short-term contracting or building new pipelines), net greenhouse gas (GHG) abatement, and non-energy impacts.

[12] The level of diversity is defined and measured by the variety of end-uses and gas-using equipment, and the number of customers needing gas. A large population of heterogeneous customers has a high diversity level. A small population of homogeneous customers has a low diversity level. Low diversity level means more variability of the load and more challenging predictability of the load, both of which makes distribution infrastructure more challenging to plan for – especially in the long term.

(CNG), could have been used to either lower natural gas demand during these events or provide targeted supply to help alleviate demand constraints.

While GHG emission reductions are not the primary benefit utilities are seeking through NPS opportunities, decarbonization goals and policies can be a key driver for adopting NPS. However, not all NPS options lead to GHG emissions reductions. Nonetheless, NPS are relevant to gas system decarbonization pathways since they can be used to avoid deploying new natural gas infrastructure whose medium- and long-term utilization may be significantly impacted by future decarbonization policies. This helps avoid potential issues with amortizing the cost of infrastructure over 40+ year timelines, during which it may become underutilized or abandoned. However, some NPS options may impact electric peak demand, requiring additional electricity generation and investments to electric transmission and distribution infrastructure.

To date, there is limited experience with implementing NPS projects. However, as they become more common, NPS may sometimes be preferred over large gas infrastructure projects due to their modularity. NPS projects can often be ramped up to address capacity needs and their cost can generally be amortized over much shorter timelines. This enhances NPS' ability to avoid the potential for stranded gas infrastructure assets.

2.2 Categorization of NPS Options

The resources included in the definition of NPS vary depending on the utility and jurisdiction and have been evolving. For instance, in some parts of the United States, compressed natural gas (CNG) and liquefied natural gas (LNG) are considered important NPS options. In Ontario, where most of the NPS activity in Canada has been focused thus far,[13] NPS were first viewed as geo-targeted energy efficiency programs to reduce hourly gas peak demand. However, in its recent decision,[14] the Ontario Energy Board (OEB) has set a broader definition for NPS.

Exhibit 2 summarizes the broad range of NPS options in two high-level categories:

- **Distributed infrastructure:** Distributed infrastructure, as first formulated by National Grid,[15] represent natural gas infrastructure that are typically associated with the transportation or supply network. In the context of NPS, they are sited in areas of high constraint on the natural gas distribution network. In its recent decision, the OEB referred to this category of NPS as supply-side alternatives.
- **No-Infrastructure Options:** No-infrastructure options represent resources that are deployed behind the meter in the customers' premises. The OEB refers to this category as demand-side alternatives.

---

[13] In Ontario, NPS have been referred to as Integrated Resource Planning Alternatives (IRPA). The IRPA terminology can be used interchangeably with NPS since both terms emphasize the local or geo-targeted nature of resource deployment to obtain maximum value. Ontario has also been using "Integrated Resource Planning" (IRP) to describe the integration of NPS in local distribution and transmission infrastructure planning, as opposed to franchise-wide gas planning as is the common usage of IRP terminology in British Columbia.

[14] Ontario Energy Board, *Decision and Order EB-2020-0091 Integrated Resource Planning Proposal* (Toronto, Ontario, Canada, 2021).

[15] National Grid, *Natural Gas Long-Term Capacity Report for Brooklyn, Queens, Staten Island and Long Island ("Downstate NY")* (New York City, NY, USA, 2020) <https://millawesome.s3.amazonaws.com/Downstate_NY_Long-Term_Natural_Gas_Capacity_Report_February_24_2020.pdf>.

Most of resources listed in Exhibit 2 can be deployed to seek benefits on a franchise-wise basis; however, they are considered as NPS when they are geo-targeted and considered as alternatives to distribution system infrastructure.

Exhibit 2 Categorization of NPS Options

Distributed Infrastructure (Supply-Side) Options

Liquefied Natural Gas (LNG)	Compressed Natural Gas (CNG)	Renewable Natural Gas (RNG) and Power to Gas (P2G)
Facility on land, on a barge or offshore with natural gas stored in cooled down liquid. The LNG must be delivered to the facility, and must then be gasified before being injected into the pipe network.	Facility on land with natural gas stored under high pressure in gaseous form. The CNG must be delivered, and is often trucked in. The CNG is decompressed before being injected into the pipe network.	Biomethanization facility that converts organic matter (often bio waste) into biogas. The biogas mainly contains methane but also other gases, some of them undesirable. The biogas is cleaned before injection into the pipe network. The RNG plant and the connection point to the network can be connected in an area of high constraint.

No-Infrastructure (Demand-Side) Options

Enhanced Targeted Energy Efficiency (ETEE)	Natural Gas Demand Response (NGDR), and ***Enhanced Interruptible Rates***	Electrification (Gas to Electricity, G2E)
Gas consumption reduction in multiple buildings through a variety of technology upgrades and/or behavioural changes. Typically delivered in the form of an incentive, or a "kicker" adding to an existing franchise-wide program aimed at convincing multiple customers to implement the upgrades.	Curtailment of gas demand over a specific set of hours during peak demand periods through an automated system or a planned schedule. Gas DR can be used to alleviate day-long constraints at city gates or hourly constraints on the distribution system. Interruptible Rates are traditional gas utility resource akin to DR.	Conversion of space, water heating or even food service gas end-use to electrotechnologies on a geo-targeted basis to reduce peak day demand on parts of the natural gas distribution system. The electrotechnologies of choice to alleviate gas winter peak demand constraints are air-source and ground-source heat pumps. Although these technologies can help reduce natural gas peak demand, they generally contribute to electric peak demand.

Distributed infrastructure NPS options have a different risk profile than traditional distribution infrastructure because they can be generally be added in smaller and shorter-term capacity increments, reducing their risk of becoming stranded assets if the demand growth does not materialize as forecasted. However, distributed infrastructure NPS options are also typically more expensive than regular distribution infrastructure on a per unit capacity basis.

A few jurisdictions are also exploring renewable natural gas (RNG) and power-to-gas as NPS. The role of these supply sources is currently relatively limited for practical reasons. The longer-term potential for these types of resources to serve constrained areas of a natural gas distribution system is limited by land occupation, population density, and the availability of locally-sourced feedstock. They would also only be considered as infrastructure alternatives in cases where the supply was highly reliable.

This study is focused on the demand-side resources: ETEE, NGDR and G2E. However, additional details on each of the NPS categories mentioned above, including distributed infrastructure are provide below.

2.2.1 Distributed Infrastructure

Distributed Infrastructure NPS options include geotargeted CNG, LNG, and RNG facilities, as well as commercial or market-based alternatives such as peaking supply, third-party assignments, or exchanges.

The utility regulator in Downstate New York established a precedent in 2019 by refusing CNG, LNG, and RNG as eligible NPS in a high-profile proposal made by ConEdison, the Smart Solutions Program.[16] The regulator took the view that using a performance incentive[17] to reward ConEdison for pursuing CNG, LNG, and RNG is inappropriate because these solutions must be considered as basic and urgent requirements to meet reliability requirements in ConEdison distribution license, and should not be rewarded in a similar fashion to other NPS options. Conversely, the OEB ruled that CNG, LNG and RNG are eligible to be considered as NPS options in Ontario.

Despite the ruling regarding distributing infrastructure in New York, CNG injection (CNG delivered by trucks) are increasingly being used to provide incremental natural gas capacity to the densely urbanized areas of New York City. Satellite LNG stations and propane-air stations have also been used for decades on nodes of the transmission pipeline network.

2.2.2 Natural Gas Demand Response (NGDR)

Demand response (DR) is widely applied in electricity markets. NGDR programs are starting to receive more attention as an NPS option. Exhibit 3 presents a typology of DR inspired by electricity DR.

Dispatchable NGDR solutions and programs attempt to lower demand by controlling the individual end-uses (e.g. space heating and water heating). In a dispatchable program, consumers agree to have their gas demand reduced when supply levels for the constrained area are in jeopardy (e.g., during a cold week in the winter). There are many methods to encourage participants to have their end-uses controlled remotely. For example, utilities can offer free devices, credits on gas bills, or lower gas rates, or they can leverage behavioural program approaches.

The gas industry has been implementing an approach to DR, using interruptible rates, for quite some time. Interruptible rates were originally designed to improve load factors, by "filling valleys" or increasing demand during off-peak periods. This allows gas utilities to amortize infrastructure costs over larger volumes of natural gas sales. It also reduces the need for high cost capacity during peak demand periods. Interruptible rates encourage customers to subscribe by offering lower rates in exchange for the ability for the gas utility to interrupt service during peak demand periods. Subscribers are typically required to shift to alternate fuels during interruptions – most often petroleum products.[18] The backup fuel equipment and storage capacity is an eligibility requirement for participation in many of these programs. Subscribers to interruptible rate programs may have to react to up to two dozen service interruptions per year.

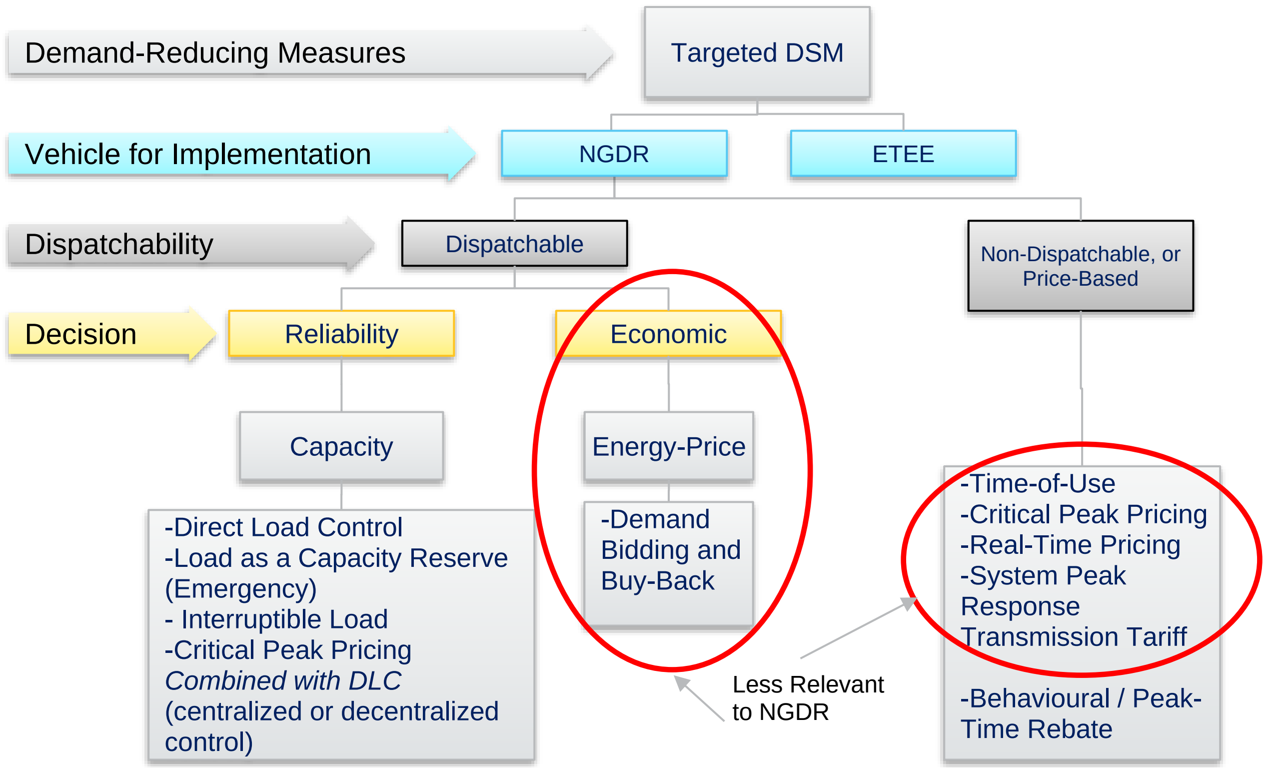
---

[16] NY Public Service Commission, *Case 17-G-0606 Order Approving with Modification the Non-Pipeline Solutions Portfolio*, 2019 <http://documents.dps.ny.gov/public/Common/ViewDoc.aspx?DocRefId=%7B64CE307C-4FD6-4043-8BE2-A5F04C5080E8%7D> [accessed 31 July 2020].

[17] ConEdison also requested a true-up to actual costs that would split overruns or underruns 50/50. A similar approach is used for electric non-wire solutions projects.

[18] The benefit of relying on a back-up fuel is that the gas service interruption can last for a large amount of time – i.e. a full day, or several days – with the only constraints being the size of the on-site fuel tank and delivery time for more fuel.

Exhibit 3 Suggested Typology for NGDR



Source: ICF expansion of a NERC industry-standard typology of electricity DR [19]

In addition to interruptible rates, utilities are starting to deploy novel NGDR options, such as those noted in Exhibit 3. They are starting to rely on a broader variety of technologies and/or price-based solutions such as advanced thermostats, behavioural programs, and direct load control (i.e. remotely-controlled curtailment). These approaches can help shift natural gas demand that has traditionally been served with firm service away from natural gas during peak periods. NGDR may prove to be more reliable at reducing peak demand since gas utilities can remotely dispatch during peak events.

A small number of gas utilities are also starting to deploy novel approaches to interruptible rates as they seek to expand the pool of customers that participate in these initiatives. For example National Grid's NGDR program in New York is offering its commercial and industrial building sector a "firm-service rate" with voluntary curtailment as opposed to mandatory interruption. Participants in this program have the right to firm service but are rewarded for curtailing their peak demand upon request. Conversely, a participant in a traditional interruptible rate does not have the right to a firm service and gets penalized for not participating in an event.

National Grid also required participants in its NGDR program to implement "clean DR". "Clean DR" is any NGDR approach that avoids the use of a fossil fuel-based back-ups during curtailment periods.[20] While the majority of traditional interruptible rates require a reliable fossil

[19] NERC, *Demand Response Availability Report* (Atlanta, GA, USA, 2011).

[20] "Clean DR" was introduced by the regulator of New York State at the start of a recent proceeding on gas planning that we will discuss in the remainder of this report. The regulator did not define it, however, except for mentioning that it would avoid the combustion of a petroleum product as a back-up energy source.

fuel-based back-up, a clean DR approach may see customers making use of biofuels, switching to resistive electric heating,[21] and/or relying on a thermal storage system.[22]

As we discuss in more detail in subsequent sections of this memo, some NGDR options have been pilot-tested by different utilities across North America. Although utilities are still assessing NGDR's potential to respond to their immediate needs, it may have growing relevance in NPS considerations given its ability to specifically curtail peak demand. However, the value of a DR program is dependent on the value of the peak demand reduction, which varies widely by jurisdiction.

2.2.3 Gas to Electricity (G2E) Conversion

G2E conversion (electrification from natural gas) is a relatively new concept in NPS. Electrification of gas-fired equipment be used to offset growth in natural gas requirements and investments in infrastructure. G2E programs have mainly focused on deploying air-source heat pumps (ASHPs), ground-source heat pumps (GSHPs), and heat pump water heaters (HPWHs). Any GHG emissions reductions from these technologies are dependent on the use of relatively "green" electricity. In addition, although these technologies can help reduce natural gas peak demand, they generally increase electric demand during peak winter periods, potentially increasing electric system capacity requirements.[23, 24] As a result, the assessment of G2E NPS needs to address the potential cost impacts on the electric grid, and on the customer, increasing the complexity of the NPS assessment.

Downstate New York has investigated G2E as a possible NPS; especially given the critical gas shortages in the area that have led to moratorium on new firm gas connections. However, the state regulator has not yet ruled on whether G2E programs can be employed as NPS in the state. Enbridge in Ontario also proposed that G2E conversion (e.g. electric ASHPs, geothermal systems, and district energy systems) be included as an option within its proposed NPS Framework. The utility acknowledged that these would be new activities that go beyond gas distribution and submitted that they should be considered a rate-regulated activity. However, the OEB ruled that "as part of this first-generation IRP Framework, it is not appropriate to provide funding to Enbridge Gas for electricity IRP alternatives" (i.e. G2E conversions).[25]

2.2.4 Enhanced Targeted Energy Efficiency (ETEE)

Energy efficiency (EE) includes a wide array of energy conservation measures that reduce natural gas consumption associated with space heating, water heating, food services, and industrial processes in residential, commercial, and industrial facilities. EE programs are mainly

---

[21] Because interruption callups would likely happen during short periods of time, during cold snaps, electric resistance is probably the most technically and economically feasible solution from a customer standpoint. Heat pumps are more expensive than resistive heat, making economic viability challenging for so few hours of use. Heat pumps' performance and capacity is hampered during cold snaps while resistive heating equipment is not. However, it should be noted that using resistive electric heating during peak demand periods will contribute to electric system peak demand. Depending on the electric generation mix at this time, this may not result in net GHG emissions reductions.
[22] A gas-fired thermal storage solution would be a novel technology to be developed. To ICF's knowledge, mature thermal storage technologies are only electric.
[23] The impact of G2E NPS will depend on the nature of the local electric grid. A system that is currently summer peaking could absorb a certain amount of G2E without impacting overall system peak.
[24] End use facilities may also need to implement costly upgrades to their electric panels to accommodate the increase in electric load. In addition, mass adoption of electrification will require significant electric distribution and transmission infrastructure investments.
[25] Ontario Energy Board, *Decision and Order EB-2020-0091 Integrated Resource Planning Proposal*.

focused on reducing annual (or sometimes seasonal) volumes of natural gas consumption and they don't typically track or even estimate peak demand impacts of the EE measures.

ETEE has the following two characteristics that differentiate it from generic franchise-wide energy efficiency:

- **ETEE are "geo-targeted" in that they focus on specific areas of the distribution network:** Program administrators of ETEE programs can use a subset of the same conservation measures used franchise-wide to alleviate peak demand constraints downstream of city gates. In other words, ETEE is typically focused on specific branches of the distribution system. Geo-targeting generally requires additional promotion of some of the same EE technologies that are eligible to all customers in the distribution license. This can include additional marketing or increased incentives (sometimes called "incentive kickers"[26]). ETEE can also include incremental measures that are not eligible for rebates in the utility's broader EE programs.
- **ETEE focuses on reducing demand during specific hours:** Downstream constraints are often driven by hourly rather than daily peak demands and tend to be for a few hours at a time. The use of ETEE require a thorough understanding of the "load shape" of the gas savings, hour by hour. This is a critical aspect of ETEE because ICF's research suggests that relatively little data collection and analytical work has been completed to date to quantify the hourly demand profile from natural gas conservation measures.[27] Based on our current review of relevant pilot programs, this continues to be the case.

EETE programs can also be focused on alleviating peak demand constraints at the transmission level (i.e. upstream constraints), and they would then be focused on measures that reduce peak day demand rather than peak hour demand.

2.3 Peak Coincidence and Appropriateness of ETEE Measures

The ideal ETEE measure is one that scores well on the standard DSM benefit-costs tests (TRC, PCT, RIM, UCT), while also having a gas savings profile that coincides with peak demand. As such, cost-effective space heating measures (both HVAC equipment and thermal envelope improvements) tend to have the greatest potential as ETEE measures. However, any energy efficiency measure that reduces natural gas demand during the period of interest (e.g., peak day or peak hour) could provide potential benefits as an ETEE measure.

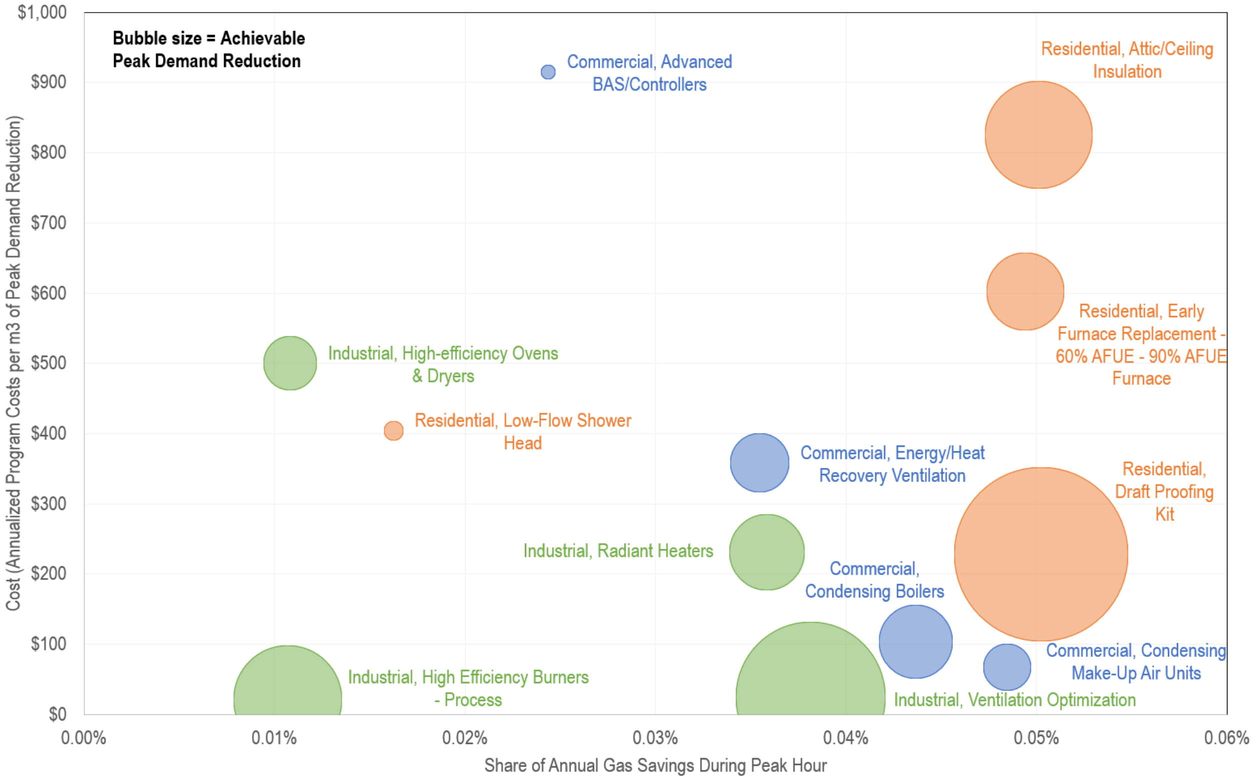
This phenomenon is demonstrated in Exhibit 4, which is based on the analysis ICF completed as part of its 2018 IRP Study for Enbridge.[28] Although these costs are not necessarily relevant to the FortisBC context, it is useful to discuss the relative differences between the measures included in this exhibit. The exhibit shows the costs and peak hour demand savings potential of an assortment of residential, commercial, and industrial EE measures. Here, it is evident that although space heating measures such as insulation, draft proofing, and high efficiency HVAC equipment are among the measures

---

[26] "Incentive Kickers" are add-on to the franchise-wide EE incentive to induce more participation from a subset of customers.
[27] ICF, *Natural Gas Integrated Resource Planning: Initial Assessment of the Potential to Employ Targeted DSM to Influence Future Natural Gas Infrastructure Investment – Final Report*.
[28] As noted previously there is very limited data collection on the peak demand impacts of targeted energy efficiency measures. As such, ICF is not aware of any data to help validate the results of this analysis.

with the highest concentration of gas savings during the peak demand hour (furthest right along the x-axis), they are not necessarily the most cost-efficient measures in terms of reducing peak hour demand. For example, commercial condensing makeup air (MUA) units and residential attic/ceiling insulation both have gas savings that are highly coincident with the peak demand hour but the cost per unit peak demand savings is much lower for commercial condensing MUA units.

Exhibit 4 Relative Peak Hour Savings and Costs of Select Residential, Commercial, and Industrial DSM Measures

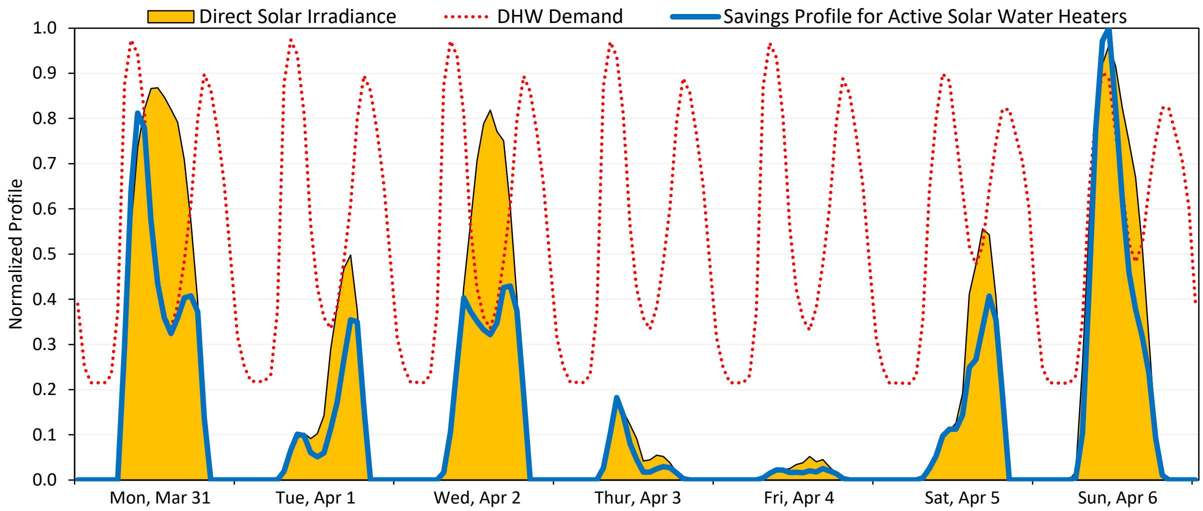


As part of our 2018 IRP Study for Enbridge, ICF developed hourly load profiles of the demand savings for a variety of energy efficiency measures. The approach for deriving measure-level load profiles fell broadly into the following categories:

- **Uniform savings profile:** For many measures, it was assumed that the savings profile matches the end-use profile to which it applies. For example, the distribution of energy savings resulting from a building envelope measure (e.g., attic insulation) was assumed to follow the space heating load profile.
- **Non-uniform savings profile:** For some measures, such as controls measures, the measure savings are not uniformly distributed and it is necessary to develop estimates of how the measure savings are distributed. This can be accomplished by developing custom load profiles for these measures. Although these measures may have non-uniform savings profiles, their savings may still be partially dependent on end-use load profiles coupled with variations in other parameters, such as building occupancy, control strategy, or solar irradiation. For such measures, customized approaches are necessary to generate hourly gas savings profiles. For example, Exhibit 5 shows how normalized DHW and solar irradiance profiles can be used to generate an hourly gas savings profile for residential active solar water heaters.

- **No impact on peak demand:** Certain measures do not coincide with peak (i.e., none of the savings occur during the peak). At the extreme, this includes measures such as high-efficiency pool heaters for the residential sector. For ETEE programs that are focused on winter peak demand, it may not be necessary to estimate peak demand savings from these measures.

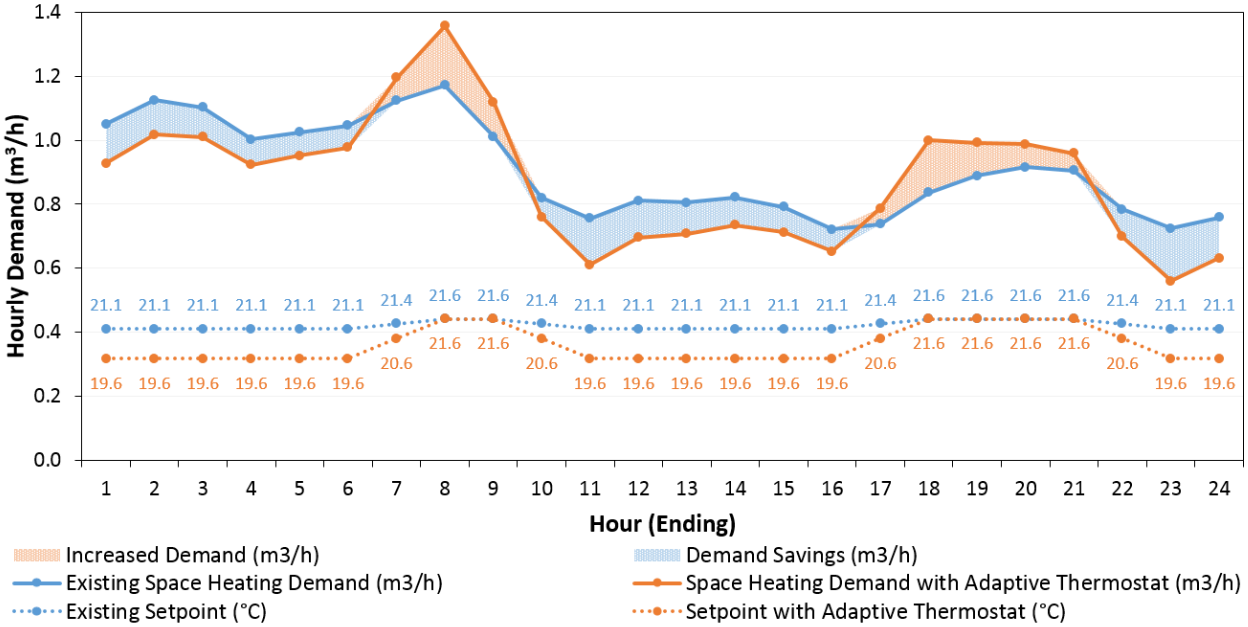
Exhibit 5 Savings Profile for Residential Active Solar Water Heaters



Among this group of DSM measures having more complex hourly gas savings profiles are two high-profile DSM measures: adaptive thermostats and tankless water heaters. Due to the prominence of these measures in current DSM portfolios across North America, ICF investigated their peak demand impacts in greater detail.

For adaptive thermostats, building performance simulations were conducted in EnergyPlus for two different temperature schedules. These schedules represent the reference and measure cases, the latter of which consists of more aggressive nighttime and daytime temperature setbacks, as would be expected with the implementation of an adaptive thermostat. The resulting gas demand profiles are also illustrated in Exhibit 6, where it can be observed that the early morning temperature recovery period induced by nighttime temperature setbacks is likely to lead to an increase in the winter peak hour demand that typically occurs between 7-9 am.

Exhibit 6 Residential Sector Hourly Demand Comparison for Adaptive Thermostats



ICF's analysis of tankless water heaters accounted for the fact that tankless water heaters typically achieve a uniform energy factor in the range of 0.9, while the uniform energy factor for storage water heaters typically falls in the range of 0.6. These higher efficiencies, which make tankless water heaters a cornerstone of many utility DSM programs, are made possible by the fact that hot water is only produced as it is needed. As such, tankless water heaters do not lose heat to the environment during periods of inactivity, as is the case for storage water heaters. Tankless water heaters do, however, require significantly higher heating capacities in order to produce hot water on demand (e.g., 180 kBtu/h compared to 40 kBtu/h for an equivalent storage water heater). This fact brings into question the impacts of tankless water heaters on peak hourly demand. These impacts are not obvious, as they depend greatly on the temporal diversity of hot water consumption among a larger population of consumers.

To further investigate these impacts, ICF used EnergyPlus to model and compare gas demand for both tankless and storage water heaters. This analysis leveraged publicly available residential hot water draw profiles with high temporal resolution (5 minutes).[29] In order to assess population level impacts, the draw profiles of profligate water consumers with different usage patterns (morning, evening, distributed) were superimposed upon one another to simulate the hot water demand of a community consisting of 129 households.

The modeled daily load profiles for tankless and storage water heaters are illustrated in Exhibit 7, where it can be seen that, even at a 5-minute resolution, gas demand from tankless water heaters rarely exceeds that of storage water heaters. ICF's analysis suggests that it is highly unlikely that widespread adoption of tankless water heaters will increase peak hourly demand (assuming storage water heaters as a baseline). However, this theoretical analysis does not necessarily confirm that tankless water heaters will lead

to significant peak demand reductions.

3 NPS Developments Across North America

To date, there is limited experience with implementing NPS projects to address peak demand constraints. However, there have been significant developments with regards to NPS in the last few years. When ICF completed the 2018 IRP study for Enbridge Gas, it did not identify any natural gas utilities that were actively factoring in the impact of DSM programs on peak hour or peak day demand forecasts on their facilities planning. A few gas utilities had begun to consider these impacts, but their efforts were still in the early stages. ICF followed up twice with several of these utilities to document their progress since the 2018 IRP study to gain a better appreciation of the evolution of NPS. First, we consulted the utilities in 2020 as part of a study commissioned by Enbridge.[30] We then reached out to many of the same utilities in late 2021 as part of the present study. ICF consulted with Central Hudson (Upstate New York), Columbia Gas (Massachusetts), ConEd (Downstate New York), NYSEG (Upstate New York), and NW Natural (Oregon).

In 2020, ICF identified several natural gas utilities that were considering the impact of their energy efficiency programs on the peak hour or peak day demand forecasts they use for their facilities planning. However, progress on pilot projects related to NPS had been modest to date. As part of our current research and consultations, ICF identified several additional recent developments, not only in terms of new pilot programs (as described in Section 5) but also with regards to NPS policy framework development.

NPS are being increasingly considered by gas utilities that are contemplating the modernization of long-term planning of their natural gas distribution systems in the context of decarbonization policies that include electrification.[31] For instance, New York, Colorado, Oregon, and California have started pursuing active electrification of their building sectors, leading to concerns over the adequacy of traditional utility infrastructure planning.

3.1 FEI NPS Experience

FEI owns and operates approximately 50,000 km of natural gas transmission and distribution pipelines across BC, providing natural gas to over 1 million customers in the province. FEI has traditionally built regional peak demand forecasts based on a customer-by-customer analysis of the relationship between peak demand and weather based on historically observed trends, with current peak hour use per customer being held constant over the planning horizon. However, the utility has been exploring how peak hour demand per customer may vary at the end-use level based on load profile analysis.[32] This approach also translates consumption savings into peak demand impacts, allowing the utility to explore the potential impacts of broad based DSM programs upon peak hour demand.

Although FEI has investigated how end-use forecast modelling might be able to help inform peak demand forecasting, the utility has not assessed DSM or other non-pipe solutions as an alternative to infrastructure at a detailed level due to concerns related to the magnitude and reliability of peak demand impacts as well as the timelines associated with these projects. In addition, the results from their traditional peak demand forecast method remains FEI's base forecast for planning purposes since the exploratory end-use method is not based on metered FEI customer data. However, FEI is continuing to monitor potential metering solutions that may allow FEI to validate the results of the exploratory end-use forecasting method.

---

[30] ICF, 'IRP Jurisdictional Review Report'.
[31] With the notable exception of Ontario, jurisdictions that are working on implementing NPS pilots and developing an NPS framework have a decarbonization policy that includes building electrification.
[32] FortisBC, 2017 Long Term Gas Resource Plan, Dec. 14, 2017, p.149.

FEI has been monitoring a small number of potential system constraints and studying a range of supply-side reinforcement options. However, FortisBC staff have indicated that there are no specific major gas infrastructure projects where DSM could be used as an alternative in FEI's service territory in the next several years. In addition, we understand that FEI continues to examine expanding its forecasting approach and the capacity impacts of franchise-wide energy efficiency. FEI has also indicated that it is starting to assess metering solutions that may enable further study into whether DSM can be used as a cost effective alternative to infrastructure spending.

3.2 NPS Framework

Ontario and the New York State are the two jurisdictions that have taken the lead with regards to developing formal frameworks for NPS.

In New York State, the driver behind the development of the framework was supply problems that were so acute that they forced the gas utilities to declare moratoriums on new customer connections. The pipelines serving the region are at capacity and their number has not increased despite significant growth in natural gas demand over the past decade due to a shift away from heating oil. The issue is so pronounced that parts of ConEd in Downstate New York imposed a moratorium on new customers connections. Moratoriums have also been declared in National Grid New York, National Grid Long Island, and Niagara Mohawk (Capital Region) service territories. NYSEG had to impose a moratorium as well.

In Ontario, Enbridge sought to be responsive to direction by the OEB to consider NPS as part of a leave to construct applications and sought to demonstrate that NPS could not be a replacement for the Dawn-Parkway System Expansion project.[33]

Both Ontario and the State of New York have thereby worked on policy frameworks to ensure that NPS are formally being considered as part of the long-term planning of the natural gas transmission and distribution networks. An NPS framework codifies how natural gas utility planners ought to consider NPS both in a systematic fashion when capital upgrades are being considered, and in comparison with each other based on a set of fair, pre-determined criteria.

The Ontario framework[34] was developed based on an application from Enbridge and an oral hearing with the Ontario Energy Board. The OEB ruled on Enbridge's application in an appendix to Decision and Order EB-2020-0091. The New York State NPS framework[35] was proposed by ConEd in 2020 as part of a rate case and is still being deliberated in front of the Public Services Commission (PSC).

The Ontario (OEB) framework and the New York framework (i.e. ConEd's proposed framework) have the following points in common:

- **A NPS process**, which entails a characterization of the gas network needs or constraints requiring remedial action, a first-pass screening of these needs to remove traditional infrastructure projects that cannot be substituted by an NPS (e.g. a facility investment required to address a safety risk) and an evaluation process that includes but is not limited to technical feasibility within the timeline, and an economic assessment of NPS options. In New York, there are three types of upgrades that trigger the consideration of NPS an

[33] The project has been withdrawn since then.
[34] Ontario Energy Board, *Decision and Order EB-2020-0091 Integrated Resource Planning Proposal*.
[35] ConEdison, *Proposal For Use Of A Framework To Pursue Non-Pipeline Alternatives to Defer Or Eliminate Capital Investment in Certain Traditional Natural Gas Distribution Infrastructure. Case 19-G-0066*, 2020 <http://documents.dps.ny.gov/public/Common/ViewDoc.aspx?DocRefId=%7B2CCB0D2A-183A-483B-9F56-87878E0471FA%7D>.

alternative: load relief upgrades (i.e. installing a large main to support growth in peak demand), regulator station upgrades (i.e. upgrading the pressure regulator for continued reliability), and main pipe replacements (i.e. replacement of obsolete pipes, such as wrought irons pipes or unprotected steel pipes).

- **Guidance on cost recovery, accounting treatment and performance incentives for the utility,** which provides guidelines regarding how expenses related with NPS will be funded through natural gas retail rates, and regarding how the natural gas utilities is to be rewarded for pursuing NPS.
- **Guidance on impact evaluation as well as reporting on progress.** The New York framework provides guidance on how to assess avoided peak natural gas load rather than annual savings. Ontario provides guidance on frequency of reporting and nature of reporting about its NPS activities and portfolio to keep the OEB and stakeholder appraised of progress.
- **Guidance on how to perform economic assessment of the NPS solutions.** The economic assessment, or cost-benefit analysis, of the NPS solutions is largely grounded in a comparison between the cost of deploying NPS projects, and the avoided cost of the avoided traditional infrastructure project. These avoided costs include not only avoided cost of downstream capacity, reliability benefits, and/or avoided cost of obsolete pipe replacements, but also the avoided cost of upstream capacity, avoided cost of the natural gas commodity, and the valuation of net GHG abatement among other benefit streams. The proposed methods have many similarities.
  - The New York framework proposes a benefit-cost analysis handbook in appendix of the framework which aligns with the main principles that were set by the California Standard Practice Manual (SPM) for Demand-Side Energy Resources. The main decision test is the societal cost test (SCT), but New York Gas Utilities are also required to compute the utility cost test (UCT) and the rate impact measure test (RIM), which are three traditional economic tests that were originally described in the California SPM.
  - The Ontario framework proposes the use of the Discounted Cash Flow-Plus Test (DCF+). The DCF+ test has been the traditional test employed in Ontario to assess both transmission pipeline applications and to assess regular franchise-wide energy efficiency programs. In appearance, the DCF+ test seems to differ from New York's California SPM-inspired approach. In the details, however, it is similar because the final DCF+ test result, used to make decision, is akin to the SCT[36], which such tests as the RIM, the participant cost test (PCT) and the total resource cost test (TRC) also being computed as part of the interim steps prior to obtaining the final DCF+ cumulative result.

The New York framework differs from Ontario framework in that it has added details and guidance on how, when and from whom to source NPS. For instance, for large NPS, ConEd would be required to launch a public solicitation for solutions from third party suppliers. For smaller NPS projects, however, gas utilities benefit from more latitude on the implementation

[36] Just like cost-benefit analysis under the California SPM framework, the DCF+ test compared net present value of cost and net present value of benefits. The DCF+ test has three phases that are used separately and in combination. Each phase has a different set of benefits and cost being considered. The decision factor is the combination of all benefits and costs from the three phases. Phase 1 is akin to the RIM. Phase 2 is akin to the PCT with GHG emissions (abated or added) being valued and incorporated in the test. The cumulative of Phase 1 and 2 is akin to the TRC. The cumulative combination of Phase 1, 2 and 3 of the DCF+ is akin to the SCT.

approach. Gas utilities can, for instance, augment existing franchise-wide energy efficiency programs or heat pump programs by geo-targeting the marketing effort in the areas of high constraint, and/or top-off the franchise-wide incentive with an “incentive kicker.”

In the proposed framework, ConEd stressed the importance of flexibility of the framework in light of its experience with *non-wire* alternative projects; i.e. the equivalent of NPS but in the electricity sector. For instance, the demand growth for natural gas may not materialize as per the load forecast, canceling or reducing the need for NPS. Or else, the natural gas demand may increase unexpectedly, requiring quickness of intervention that can only be achieved by a traditional infrastructure upgrade. NPS projects can often be ramped up to address capacity needs, allowing gas utilities to react to observed impacts and evolving peak demand requirements.[37]

The Ontario framework is characterized by added details on approach to ensure the gas utilities plan NPS in a transparent manner, including the requirement to perform annual stakeholder engagement and NPS project-specific (targeted) stakeholder engagement events, the creation of a Technical Working Group to advise the OEB on the adjudication of future NPS projects, and requirements to make efforts to accommodate participation of Indigenous groups.

The Ontario framework requires Enbridge Gas to develop and implement two NPS pilot projects in 2022. Enbridge has not deployed NPS pilot projects to date. As presented in the next pages, New York gas utilities, including but not limited to ConEd, have implemented many pilot NPS projects and are in the process of implementing many more.

3.3 Jurisdictional Scan

As some jurisdictions such as New York State, Oregon, and California have implemented decarbonization policies and are starting to consider how they can electrify their building stock, NPS are being considered as options that gas utilities can deploy to replace or defer some future gas infrastructure investments.[38] NPS are increasingly being considered as an approach to meet isolated and temporary peak demand constraints in specific areas of the distribution network, and to avoid to the replacement of obsolete pipes.

The following sections provide an overview of relevant NPS developments in several jurisdictions.

3.3.1 New York

New York State (particularly Downstate New York) has seen a broad range of proposed NPS projects, including distributed CNG and LNG projects, as well as local RNG projects. ConEd, one of the large investor-owned natural gas utilities in the State, has proposed a framework for NPS to the PSC.[39] In addition, a few innovative NPS pilot projects based on EE, gas DR, and electrification programs have been implemented or proposed. More pilot programs and projects are underway. NPS are expected to become part of the routine long-term capacity planning

---

[37] Unlike traditional infrastructure upgrades which typically result in the acquisition of one large “block” of capacity, it may be possible to modulate some NPS projects to address capacity needs.

[38] Regulatory Assistance Program (RAP), ‘Under Pressure: Gas Utility Regulation for a Time of Transition’, 2021 <https://www.raponline.org/wp-content/uploads/2021/05/rap-anderson-lebel-dupuy-under-pressure-gas-utility-regulation-time-transition-2021-may.pdf> [accessed 17 January 2022].

[39] ConEdison, *Proposal For Use Of A Framework To Pursue Non-Pipeline Alternatives to Defer Or Eliminate Capital Investment in Certain Traditional Natural Gas Distribution Infrastructure. Case 19-G-0066*.

process for the NY utilities, and the State has been active in developing a set of best practices surrounding NPS, including ConEd's proposed NPS framework.

There are several drivers that have led to New York State being the pioneer and North American leader in NPS:

- **Precedent with Non-Wire Alternative in the Electricity Sector:** The State of New York is considered by many as one of the two states, along with California, that has pioneered and is leading the way in operationalizing Non-Wire Alternatives (i.e. using energy efficiency, and distributed energy resources to substitute for traditional electricity grid infrastructure.)
- **Strong Natural Gas Demand Growth Forecast (Prior to 2020):** When New York State started exploring NPS, they had been experiencing and were forecasting a long-term growth trend in natural gas demand, including both customer growth and consumption growth in certain areas of the State. This growth was driven by conversions from heating oil to gas, as well as new construction, primarily in the Downstate regions of the State. However, gas growth forecasts have been modest since then, at least partially due to the new Climate Leadership and Community Protection Act (CLCPA) legislation, the plan laid out in the New Efficiency: New York (NENY) report[40] by the NYSERDA, and, more importantly, as a result of the corresponding Accelerated Energy Efficiency Order.[41] State policies are encouraging a redoubling of efforts on energy efficiency and promotion of electric heat pumps. They are also contemplating widespread electrification of the building stock.
- **Constraints on the Development of Long Term Infrastructure:** The cancellation of several of the recent natural gas pipeline projects designed to bring new pipeline capacity into Downstate New York, including the Northeast Supply Enhancement (NESE) and Constitution Pipelines, is causing a perception that new interstate pipeline projects will become increasingly challenging to develop.
- **Public Concerns and Focus due to the Proliferation of Moratoria and the NESE Project Consultations:** The moratoriums on new connections in New York have created a challenging landscape that the gas utilities have had to navigate. These circumstances have resulted in the utilities launching innovative pilots and projects in order to demonstrate best efforts to solve their capacity constraints.
- **Strong Decarbonization Policies from the State Government:** NPS are in alignment with the formal state policies. Now that long-term natural gas growth forecast are more modest, NPS is being seen as an instrument to ensure reliability of the gas supply in isolated areas of the gas distribution network that are experiencing drops in gas pressure, and as alternatives to the replacement of leak-prone pipes.

In short, the significant supply shortage in the state, coupled with the experience with non-wire alternatives on the electric side, have led New York State gas distribution companies to consider NPS to alleviate constraints on pipeline capacity to the city gates (i.e. calling for intensifying EE, gas DR, and electrification over their entire service territories).

[40] NYSERDA, *New Efficiency: New York*, 2018 <https://www.nyserda.ny.gov/-/media/Files/Publications/New-Efficiency-New-York.pdf> [accessed 20 August 2020].
[41] State of New York Public Service Commission, *Case 18-M-0084 ORDER ADOPTING ACCELERATED ENERGY EFFICIENCY TARGETS*, 2018.

However, over the course of the past two years, the focus in New York has shifted away from supply shortages at city gates towards New York State decarbonization policy and its impact on the future natural gas outlook. With lower overall growth on peak demand, New York gas utilities have started focusing on peak demand constraints on the distribution network (e.g. where customers are experiencing low gas pressure during cold snaps) and areas replacing obsolete pipes.

ConEd

ConEd delivers natural gas to approximately 1.1m customers in Manhattan and several boroughs of New York City. ConEd has been directly impacted by the cancelation of NESE, and has been first in launching NPS pilot projects. Furthermore, over the years, ConEd had become over-reliant on Delivered Services, short-term gas delivery contracts through existing pipelines.

In 2017, to address the growing concern of over-reliance on short-term contracts and the moratorium, ConEdison developed non-pipeline solution pilot projects with the long-term goal of reducing the need for new pipeline capacity. This effort is included as part of the Smart Solutions for Natural Gas Customers Program, including NGDR programs, a gas innovation program or renewable alternatives to natural gas heating, and a market solicitation for additional NPS.[42]

The 2017 public tender for NPS resulted in a portfolio of NPS projects that met cost-effectiveness requirements. However, the tendering process did not lead to sufficient cost-effective options to avoid or defer the need for NESE. Nevertheless, the effort resulted in a $412m ($305m USD) portfolio of projects, including a mix of EE and electrification as well as supply-side measures such as CNG and RNG. The portfolio was submitted to PSC for approval on September 28, 2018.[43] Only three solutions were accepted, only on a pilot basis and only for one year worth of funding. The delivered CNG solution was accepted, but deemed unacceptable as an NPS. The three pilot projects approved by the PSC included a targeted single-family residential G2E program (GSHPs), a low-income residential weatherization ETEE program, and a targeted multi-unit residential building G2E program (ASHPs).

Both with in its portfolio submission and with its proposed NPS framework, ConEd proposed a shareholder incentive approach to obtain a reward from pursuing NPS options based on a shared savings approach and the SCT (70% of net benefits under the SCT would go to ratepayers and 30% of the net benefits would go to the Company).

In order to complement its existing portfolio of NPS, ConEd issued a request for information in January 2020 with a submission deadline of April 2020.[44] ConEd's goal was to explore new options not previously examined as part of the earlier solicitation. The utility hoped to see proposals for DR enablement (i.e. installation of related equipment and/or controls) to allow greater participation in existing gas DR programs or new programs for smaller customers. The 2020 RFI also solicited hydrogen pipeline-injection proposals (i.e. Power-to-Gas).

National Grid

National Grid provides natural gas to 1.9 million customers in Brooklyn, Queens, Staten Island, and Long Island. The utility has seen sustained growth in demand throughout its service territory.

National Grid was in a similar situation than ConEd was after the cancellation of the NESE pipeline and had to announce a moratorium on new gas hookups in 2019 in both its Long Island and New York service territories, which has since been lifted until September 2021. In 2020, National Grid published a Long-Term Capacity Report,[45] followed in May 2020 with a Supplemental Report[46] to present a comprehensive analysis of its capacity constraints and all available options for meeting its long-term demand. At that time, National Grid was contemplating a shortfall to meet demand growth over the course of 10 years.

National Grid's economic analysis, in the two reports, provides a useful illustration of the infrastructure investment challenges faced by utilities in jurisdictions with ambitious decarbonization targets like New York State. Natural gas is currently preferred by many customers for space and water heating, and new pipeline capacity may be needed to meet expected demand growth, but gas demand may plateau and begin to decline before these new assets are fully depreciated due to the pressure of decarbonization policies.

The approach used by National Grid assumes that EE, gas DR, and G2E can be deployed incrementally and almost on a just-in-time basis allowing the utility to throttle the amount of capacity and adapt quicker and more accurately to changes in the demand.[47] NESE was the least costly scenario in a "high demand growth future" (the upper bound of National Grid's demand forecast). However, NESE was also the costliest scenario under a low demand growth future (the lower bound) because the infrastructure would be underutilized while needing to be amortized in full. However, the "No-Infrastructure" scenario did not perform much better, even in a low-demand growth scenario. The least cost scenarios in the low demand future were mixes of distributed infrastructure solutions (CNG, LNG and smaller infrastructure upgrades), and no-infrastructure solutions (ETEE, NGDR and G2E).

Since 2020, National Grid has moved ahead with numerous NPS pilot projects including NGDR and improved interruptible rate programs.

Central Hudson

Central Hudson is a gas and electric utility that delivers gas to approximately 84,000 customers in New York State's Mid-Hudson River Valley. The utility has attempted to use beneficial electrification to avoid costly replacement of leak-prone pipes on its distribution system. They refer to the approach as a "transportation mode alternative". The initiative offers technical assistance and incentives to convince customers to fully electrify their space heating via ground-source heat pumps or air-source heat pumps and cut their gas connections. The initiative targets pipes that are scheduled for replacement due to obsolescence, particularly when the pipes connect to only a handful of customers.

---

[45] National Grid, *Natural Gas Long-Term Capacity Report for Brooklyn, Queens, Staten Island and Long Island ("Downstate NY")*.

[46] National Grid, *Natural Gas Long-Term Capacity Supplemental Report for Brooklyn, Queens, Staten Island and Long Island* (New York City, NY, USA, 2020) <https://millawesome.s3.amazonaws.com/Downstate_NY_Long-Term_Natural_Gas_Capacity_Supplemental_Report_May_8_2020.pdf>.

[47] To be fair, EE, gas DR and G2E also have lead time as well as forecasting and performance uncertainties. So, the assumption that EE, gas DR and G2E can be throttled and reach target with accuracy is debatable.

To be successful in avoiding the replacement of a pipe, Central Hudson needs to be able to convince all the customers connecting to a particular pipe to switch off of natural gas. However, this has been challenging since in New York State the utilities have an obligation to provide gas service and customers have the right to retain their gas services. As noted in Section 5, this program has had some success but has also encountered situations where customers have been unwilling to electrify their equipment to allow for pipe retirements.

In a 2018 Order from the PSC establishing electric and gas rate plans, the PSC required Central Hudson to submit an implementation plan to identify NPS.[48] Central Hudson explored the opportunity of offering geo-targeted EE programs to high constraint areas of its distribution system due to intra-day drops in pressure on certain laterals of its system.

Central Hudson commissioned a study on the avoided cost of its distribution system.[49] The study was based on a novel approach based on probabilistic (as opposed to deterministic) load forecasting. The focus of the analysis was to value the avoidable distribution cost due to peak-coincident load growth. The analysis estimated location-specific patterns for individual gas systems (i.e. subsections of the gas distribution network). Because increases and decreases in load compound over time, the trajectory of the load can deviate substantially from a simpler deterministic load growth model. The analysis generated indexes measuring the likelihood of pressure drops – due to spikes in intra-day coincident demand – that would trigger the requirement for an upgrade.

Based on this study, Central Hudson identified three systems with a likelihood of triggering an upgrade over a 10-year time horizon. Two of them were unsuitable for NPS due to timeline issues. The third system (the Vassar Road (PN) System) was identified as relevant for an NPS project since analysis suggested that there was a 20% chance that an upgrade would be required in the next 10 years. Central Hudson followed through with an ETEE pilot that offered incremental incentives for smart thermostats.

NYSEG

There has been an active moratorium on new natural gas connections in the Lansing, New York area since 2017. In June 2021, NYSEG gained approval to implement the majority of its proposal to implement an NPS project in the Town of Lansing to improve its low-pressure situation during peak hours. The approved projects include G2E (residential ASHP, commercial GSHP, community GSHP), ETEE at two public authority buildings, ETEE (heat recovery) at industrial facilities, C&I building NGDR (using electric boilers as backup) and education & outreach program. None of these projects had started as of late 2021. Projects that were not approved included smart thermostat gas DR in the zone of highest impact (not cost-effective), LNG , CNG delivery and injection, and hydrogen generation and injection.[50,51]

3.3.2 Ontario

In Ontario, the Ontario Energy Board (OEB) recently established an NPS framework that provides a basis for the consideration, design, planning, implementation, and monitoring of NPS pilots and projects in a transparent manner.[52] The framework also lays out requirements for annual stakeholder consultations, annual reporting on NPS progress, and project-specific stakeholder consultations to ensure that NPS options are considered where they are relevant. While Enbridge Gas has yet to implement NPS pilot projects, the OEB has established a Technical Working Group to advise on NPS pilots and Enbridge is required to select and deploy two NPS pilot projects by the end of 2022.

The process that led to the development of an NPS framework in Ontario is different from the process that led to a similar outcome in New York State. Enbridge was encouraged by the OEB in 2014 to examine whether Integrated Resource Planning (IRP) for natural gas infrastructure was warranted as part of three Leave to Construct applications by Enbridge Gas Distribution Inc. and Union Gas Limited in the Greater Toronto Area.[53] The applications were bound and adjudicated together by the OEB, as “GTA-Parkway” projects. In 2016, as part of mid-term review of the energy efficiency framework by the OEB, the OEB directed the utilities to work jointly on a transition plan to integrate energy efficiency into their infrastructure planning activities.[54]

In 2018, Enbridge Gas Distribution filed an IRP transition plan and a study from ICF Canada that was mainly focused on ETEE.[55] In 2019, as part of a Leave to Construct Application, the OEB found that Enbridge’s process for considering ETEE as an alternative to the Bathurst Reinforcement project had not been appropriate. Later that year, Enbridge proposed an NPS framework to:[56] (1) be responsive to the OEB’s encouragements and findings; (2) create the policy guidance to be successful in pursing NPS; and (3) demonstrate that NPS was not a viable alternative to the Dawn-Parkway Expansion pipeline project. This led to an oral hearing process with the OEB that culminated in the establishment of a formal NPS framework in the province.

3.3.3 Oregon

Headquartered in Portland, Oregon, NW Natural serves 750,000 natural gas customers in 140 communities in Oregon and Southwest Washington. NW Natural collaborates with the Energy Trust of Oregon (ETO) for the delivery of its broad-based DSM programs in Oregon. The utility contributes ratepayer-funding for DSM and provides assumptions that feed into the ETO’s planning. Programs, DSM forecasts, and targets are all set by the ETO, along with program delivery.

[56] Enbridge Gas, ‘Integrated Resource Planning Proposal, EB-2019-0159’, 2019 <https://www.rds.oeb.ca/CMWebDrawer/Record/675587/File/document> [accessed 17 January 2022].

The NW Natural Gas IRP typically includes DSM as a key resource to meet forecasted load. Both latest IRP studies in 2018[57] and 2021[58] considered traditional storage, ETEE, NGDR, LNG, RNG, and blue hydrogen (hydrogen produced from natural gas with carbon capture, utilization and storage), and Power-to-Gas as options for meeting forecasted load. In 2021, in particular, the NPS solutions have been compared against the North Coast Feeder System Reinforcement Project. NPS solutions that were looked at included a new LNG plant, and an improved interruptible rate for C&I customers. The supply-side solutions was determined to be superior to LNG from a cost standpoint (net present value), and superior to the C&I interruptible rate due to the insufficiency of the capacity that could be freed up using the new program.

Over the years, NW Natural has been able to enhance its collaboration with the ETO and has streamlined the processes to develop more accurate DSM forecasts. For instance, during the 2019-2020 period, ETO achieved 97% of its target for the Oregon service territory and 101% for the Washington service territory. Avoided cost have significantly changed in 2021 compared with 2018 in alignment with state policy. NW Natural have updated its GHG compliance costs to align with societal cost of carbon, thereby increasing upstream avoided cost by approximately 40% for space heating end use (the increase varies depending on the end-use). The base case use, the EPA social cost of carbon, was $75 USD in 2021.

NW Natural continues to use an iterative method the utility developed as part of the 2018 IRP to determine the avoided cost of distribution infrastructure. In 2017, NW Natural indicated plans to collaborate with the ETO to include projections on the impact of peak savings. For the 2018 IRP, the ETO had projected the impact of peak savings both for a design day and for a peak hour over a time horizon of 20 years. The ETO estimated that 1.40% of annual gas consumption savings would overlap with peak day demand, and that 0.09% of the savings would overlap with peak hour demand. As such, annual savings of 100 GJ would results in a 1.4 GJ reduction in peak day demand and a 0.09 GJ reduction in peak hour demand.

NW Natural has expressed the need to address gaps related to the magnitude and ongoing reliability of targeted energy efficiency peak hour savings, the cost and timing at which the savings accrue, and the methodology for measurement of the savings.

NW Natural is currently an advanced stage of implementing its Geo-Targeted Energy Efficiency (GeoTEE) pilot project, in close collaboration with the ETO. The project is designed to obtain data on the peak demand impacts of geo-targeted energy efficiency measures. This will allow for the consideration of geo-targeted energy efficiency as a viable option for deferral and avoidance of future distribution system investments.

The GeoTEE pilot project includes three phases:

- **Phase 1:** Targeted marketing and customer engagement for a certain segment of NW Natural's distribution system to promote EE through existing broad-based EE programs.
- **Phase 2:** Targeted incentive kickers (i.e. adders) to top off incentives available through existing broad-based EE programs, within cost-effectiveness (UCT) bounds.
- **Phase 3:** Larger incentive kickers to top off incentives available through existing broad-based EE programs, beyond cost-effectiveness threshold.

---

[57] NW Natural, *2018 Integrated Resource Plan*, 2018 <https://www.nwnatural.com/uploadedFiles/NW Natural 2018 IRP.pdf> [accessed 18 August 2020].
[58] NW Natural, '2018 Integrated Resource Plan Update 3, Docket No. LC 71/UG-170911', 2021 <https://webfrontend-sc-pd.azureedge.net/-/media/nwnatural/pdfs/nwnatural_2018_irp_update.pdf?la=en&rev=1f83206ac10d4312b92c171c3264fd8b&hash=370D028AA3F29C2805F590D0BC884B07> [accessed 17 January 2022].

It was critical to the experimental design of the project to select a loop of the distribution system that can be more easily isolated for the pilot. NW Natural installed a SCADA meter to monitor the hourly flow of gas at the entrance of the target area and they will compare daily and monthly data against the aggregated data from the SCADA meter.

Results from 2018/19 were delayed due to issues relating to a faulty meter. NW Natural is in the process of analyzing data from 2019/20, 2020/21, and 2021/22. They expressed concerns about the potential impact of COVID-19 on the dataset, but they have not yet confirmed whether this was indeed an issue of real concern. To date, no results have been made available from this pilot project.

NW Natural has also committed to file a study on NGDR options for residential and C&I customers in 2022.

3.3.4 Colorado

As part of a suite of state climate legislation passed in 2021, Colorado SB21-264[59] requires that gas distribution utilities file and obtain commission approval of a “clean heat” plan that shows how they intend to reduce GHG emissions associated with carbon dioxide and methane by at least 4% relative to 2015 levels by 2025, and 22% relative to 2015 levels by 2030. Possible "clean heat resources" allowed to be part of a clean heat plan include:

- Gas energy efficiency programs
- Recovered methane (such as biomethane; methane derived from solid waste, pyrolysis of municipal solid waste or biomass, or wastewater treatment; coal mine methane; or methane that would have been leaked without repairs of the gas distribution and service pipelines form the city gate to customer end use)
- Green hydrogen
- Beneficial electrification
- Pyrolysis of tires if the pyrolysis meets a recovered methane protocol
- Any technology that the Commission finds is cost-effective and that the division finds results in a reduction in carbon emissions from the combustion of gas in customer end uses or meets a recovered methane protocol approved by the air quality control commission

Utilities must also consider methane leakage from the transportation and delivery of gas from the gas distribution and service pipelines from the city gate to the customer end use, and from delivery of gas to other local distribution companies. The legislation allows the Colorado Public Utilities Commission to require that utilities evaluate NPS, noting that:

> *“To count toward a gas distribution utility’s compliance with the clean heat targets, the utility must quantify the actual methane reductions achieved by any leak repairs and the commission must find that the leak reductions are cost-effective. The commission may require the utility to evaluate non-pipeline alternatives.”*

Outside of legislation, Xcel Energy (the largest gas utility in the state) is currently running a pilot intended to better understand the roles that more frequent energy data and NGDR can play in supporting the gas system through its Heat Savers Mode Study.

[59] State of Colorado, ‘Adopt Programs Reduce Greenhouse Gas Emissions Utilities, SB21-264’, 2021 <https://leg.colorado.gov/bills/sb21-264> [accessed 17 January 2022].

The NGDR pilot is being implemented in Summit County, Colorado, a mountainous region with multiple ski resorts where pipeline expansion is particularly difficult and costly. Xcel is hoping the pilot results will help the utility better manage demand and avoid building out additional gas infrastructure going forward. In particular, the pilot involves the installation of wireless energy monitors that allow it to better understand localized load shapes and daily peaks in the overall gas consumption of individual homes to help improve system planning, and a NGDR component leveraging smart thermostats in conjunction with behavioral prompts through a customer-focused mobile app to reduce gas demand during peak periods.

3.3.5 California

California has been taking steps towards decarbonizing its economy for several years. In 2016, State Executive Order B-30-15[60] established an interim target of a 40% reduction in GHG emissions below 1990 levels by 2030. In 2017, the California Air Resources Board (CARB) issued a Scoping Plan[61] to identify measures to achieve this target. The least costly identified pathway calls for efficient electrification of up to 30% of space heating and water heating by 2030. In 2019, Executive Order N-19-19[62] mandated State government agencies to pursue California's climate targets in government buildings and government-funded infrastructure. In 2018, Senate Bill 100[63] stipulated that California's electricity grid must be decarbonized by 2045 and Executive Order B-55-18[64] adopted a target of carbon neutrality by 2045.

Key Californian agencies, including the California Energy Commission (CEC), the California Public Utilities Commission (CPUC), and CARB, are increasingly adopting initiatives towards electrification and decarbonization, both in transportation and buildings. For instance, in 2021, CEC adopted a new building standard[65] that will come into effect in 2023 and will encourage electric heat pump technology and establish electric-ready requirements for new buildings.

Californian electric utilities are following suit, launching their own electrification programs and other initiatives. For instance, in 2021, Southern California Edison filed an electrification plan[66] targeting 250,000 heat pump installations and 65,000 electrical upgrades for households by 2030. Southern California Edison is calling for large-scale building electrification through the

[65] California Energy Commission, 'Energy Commission Adopts Updated Building Standards to Improve Efficiency, Reduce Emissions From Homes and Businesses', 2021 <https://www.energy.ca.gov/news/2021-08/energy-commission-adopts-updated-building-standards-improve-efficiency-reduce-0> [accessed 25 March 2022].
[66] Southern California Edison, 'Testimony of Southern California Edison Company (U 338-E) in Support of Its Application for Approval of the Results of Its 2018 Local Capacity Requirements Request for Proposals (LCR RFP)', 2019 <https://docs.cpuc.ca.gov/PublishedDocs/SupDoc/A1904016/2040/283296439.pdf> [accessed 25 March 2022].

replacement of natural gas appliances with electric heat pumps, heat pump water heaters, and electric cooktops.

In this policy context, natural gas utilities have to plan for a slower growth if not a reduction in demand. This will require a different approach to natural gas infrastructure planning. While natural gas demand may start declining overall, the natural gas utilities may still need to address peak demand growth in certain portions of their distribution networks. Some of their infrastructure investments may face increasing uncertainty in terms of their long-term volumes.

Starting in 2020, CPUC initiated a proceeding to address reliability standards[67] that reflects the challenges faced by natural gas utilities in the State. The utility commission is seeking to modernize the approach to natural gas infrastructure planning. The proceeding will assess the possible future role of NPS, an approach to balance the cost of replacement and repair against natural gas service reliability benefits, and an approach to determine which pipelines may be proactively decommissioned.

ICF identified an NPS pilot in California: the SoCalGas Smart Control Thermostat Program. SoCalGas' pilot program started in advance of the 2017/18 heating season. It is a NGDR program, utilizing thousands of residential smart thermostats to temporarily alleviate peak demand constraints. While the pilot program was not labeled as an "NPS project" at the time, it was deployed to test the ability to use demand-side resources to avoid the need for natural gas facility investments. More information on the pilot can be found in Appendix A.

The California experience provides valuable insight in to the potential for NPS to address gas capacity and environmental concerns. However, care needs to be taken when applying the California experience in other jurisdictions. The California climate in general is more conducive to the use of electric heat pumps than most other jurisdictions. There is significant incremental power capacity available during the winter to meet incremental load without requiring a major expansion of the electric system. In addition, the winter contribution from solar power in California is also more reliable than the jurisdictions further north.

3.3.6 New England

Considering that natural gas market conditions and other energy market conditions in New England States (i.e. Maine, Vermont, New Hampshire, Massachusetts, Rhode Island, and Connecticut) are similar to New York, as well as the prevalence of natural gas DSM programs in the region and the well documented lack of pipeline capacity into the region, ICF reviewed the information on NPS activities in the region, and reached out to several utilities in the region to discuss their experience with NPS.

The region has extensive experience with distributed sources of natural gas supply, including distributed CNG and LNG, both to provide natural gas to large consumers without access to the natural gas grid and to provide additional natural gas capacity in locations experiencing capacity constraints. However, ICF's research suggests that there is limited interest in NPS in the region, with no active NPS programs other than the existing broad-based DSM programs and the aforementioned distributed supply options.

ICF reached out to several gas utilities in the New England region, but was only able to consult with one. ICF spoke with Columbia Gas of Massachusetts in late 2020 to discuss the utility's experience with NPS. Columbia Gas staff indicated that the utility does not pursue any NPS or

[67] California Public Utilities Commission, 'Assigned Commissioner's Amended Scoping Memo and Ruling, Rulemaking 20-01-007', 2021 <https://docs.cpuc.ca.gov/PublishedDocs/Efile/G000/M415/K275/415275138.PDF> [accessed 25 March 2022].

geo-targeted EE or DR, despite supply constraints that have led to moratoria in adding new gas customers in Northampton and Easthampton. Columbia Gas also indicated that they view NPS as cost-prohibitive, and that the impacts of geo-targeted EE or DR would be insufficient to avoid new pipes in highly constrained areas of its distribution system.

Although ICF's research suggests that there is limited progress with regards to NPS in the New England States, we noted that Eversource was approved for cost recovery for three GeoMicroDistrict (networked geothermal) pilot programs in the greater Boston area. With construction scheduled to begin in mid-to-late 2022 and a three year pilot timeframe, this district energy system concept will employ "networked geothermal boreholes, connected by a shared loop in the current gas right-of-way that provides thermal energy to customer buildings".[68] This approach could represent an alternative role for gas utilities.

Electrification of space heating is being extensively discussed across the six New England States. For instance, Liberty Utilities in New Hampshire is planning a pilot project seeking to deploy ASHPs to substitute fossil fuel-fired heating appliances in a dual-fuel configuration and with integrated controls during the 2021-2023 period[69]. Another example includes Massachusetts' 2050 Decarbonization Roadmap, which was published in December 2020[70] by the state government. The roadmap suggests that the state will be pursuing state-wide electrification of buildings through ASHPs, GSHPs, and variable refrigerant flow heat pump systems. If these plans materialize, they may help address future natural gas peak demand constraints.

4 NPS Pilot Projects and Programs

ICF compiled an inventory of NPS Pilot Projects and Programs across North America. The results of our work is summarized below. The complete list of NPS pilot projects along with details that ICF collected about these pilot projects can be found in Appendix A.

Based on our research, ICF identified two leading jurisdictions on the topic of codifying and establishing a formal framework around NPS; New York State and Ontario. Both jurisdictions have a framework. The framework is only proposed in New York State and is waiting for a final decision, but many utilities in New York State have already implemented NPS pilots. Enbridge, the largest utility in Ontario, has received a mandate from its regulator to pursue NPS. In both cases, the frameworks establish procedures and guidelines for a routine examination of NPS options. This process is embedded into the core infrastructure planning function of the relevant gas distribution companies in these jurisdictions, so that NPS can be considered early, systematically, and on an equal footing with traditional gas network infrastructure investments.

The majority of the relevant pilots that ICF identified have been implemented by utilities in NY State. Exceptions include a Natural Gas Demand Response (NGDR) pilot project in Southern California, an enhanced targeted energy efficiency pilot project in Oregon, and a NGDR project in Colorado. Ontario has yet to implement any NPS pilot projects. Rather, Enbridge is in the early stages of identifying two pilot projects, based on recent direction from the OEB to develop and implement two NPS pilot projects in sufficient time to collect measurement and verification results by winter 2022-2023.

4.1 NGDR Pilots

ICF's research suggests that the majority of NPS pilots have tested NGDR technologies. This has included direct load control of smart thermostats to reduce space heating loads during peak demand periods. These pilots have employed both a direct install approach and a bring-your-own thermostat model.[71] ConEd, National Grid, and SoCalGas have all deployed NGDR pilots focused on smart thermostats. Central Hudson is also utilizing smart thermostats, but has focused mostly on their energy efficiency attributes. When we spoke with them in 2021, they told us they are considering augmenting their program with NGDR events in the near future.

Some utilities have also piloted behavioural NGDR programs. For instance, ConEd, National Grid, and Niagara Mohawk ran behavioural pilot programs focused on large C&I customers, while National Grid is testing a behavioural program focused on its residential and small commercial customers. In behavioural NGDR programs focused on C&I facilities, customers are notified of a DR event and they must decide how to curb their natural gas consumption. For instance, they can decide to lower temperature setpoints for their space heating or water heating. Behavioural NGDR programs focused on residential and small commercial customers may instead rely on marketing via emails or other communication channels during cold weather events. Behavioural programs are better suited to commercial and industrial facilities since it is typically more challenging for gas utilities to automate responses to DR events, unlike the control signals that can be sent to smart thermostats in residential and small commercial applications.

In addition to behavioural programs, National Grid and Niagara Mohawk are piloting enhanced interruptible rates for C&I customers. Furthermore, ConEd tested direct load control, a form of NGDR, with advanced water heater controllers.

[71] In a "bring your own thermostat" model, customers purchase the smart thermostat, install the device themselves, enroll the device themselves, and sign up into the program through the platform.

There are several reasons for the popularity of NGDR NPS programs. For instance, direct load control of smart thermostats is of interest since they are a natural extension of existing electricity demand response thermostat programs (mostly focused on curbing the air conditioning load in the summer). In addition, the penetration of smart thermostats is high and they are relatively inexpensive compared to many other gas energy efficiency measures (e.g. high efficiency furnaces, water heaters, gas heat pumps, etc.). The devices and associated hardware and software also come with telemetric capabilities that facilitate the measurement and verification of peak demand impacts (e.g. temperature setpoint, indoor temperature, and duty cycle.)

Behavioural programs focused on larger buildings have also been of interest since the larger gas consumption for these facilities makes it easier to more accurately meter and justify the costs of the telemetric instruments to monitor peak demand impacts. Enhanced interruptible rates are a natural extension of existing interruptible rates, which gas utilities have used for decades to increase the utilization factors of their distribution networks. Furthermore, interruptible rates are dependable and do not have duration constraints due to the availability of backup heating systems. The availability of backup systems also means that there is typically no interruption of space or water heating service from a customer perspective. However, similar to traditional interruptible rate programs, customers have to assess the cost required to maintain back-up heating equipment and the required fuel compared to any monetary benefits associated with their participation in the program.

4.2 G2E Pilots

ConEd tested full electrification of suburban homes with ground-source heat pumps (GSHP) in an area of high constraint on a pilot basis. The fact that ConEd serves both electric and gas customers helped facilitate the implementation of this pilot. However, ICF did not assess the impact of the pilot on energy bills or rates. ConEd was also planning to test full electrification of multifamily buildings with ASHP but the pilot implementer failed to recruit a participating building.

Another relevant program that is being implemented by Central Hudson, its Transportation Mode Alternative (TMA) program, is focusing on avoiding the replacement of leak-prone pipes by converting all customers serviced by specific pipe segments to electrotechnologies (i.e. electrification). The program has been targeting pipe segments with very small numbers of customers (i.e. generally 1-3 customers but as many as 18 customers). Based on the latest update that they have filed with their regulator, Central Hudson has demonstrated success in converting customers to electrotechnologies and retiring certain pipe segments. However, there are several cases, with as few as two customers, where they have not been able to convince the customers to replace their gas-fired equipment.

While utilities in NY are promoting heat pumps of all kinds through a suite of generous incentive programs, these programs are not necessarily aimed at promoting G2E. Customers that use fuels such as heating oil, propane, and electric resistive heat are also eligible, and there is a stronger business case for these customers to implement heat pumps compared to customers with gas-fired space heating equipment. Furthermore, the incentives are available to customers across the entire state, as opposed to being geotargeted. National Grid has considered offering incentive kickers (incremental incentive on top of the licence-wide incentive) to customers in areas of high constraint but, to date, the utility has not followed with a pilot program.

4.3 ETEE Pilots

There has only been limited activity with regards to ETEE pilot programs that are seeking to assess the magnitude of peak demand impacts related to the implementation of natural gas energy efficiency measures. ICF identified four pilots focused on Enhanced Targeted Energy Efficiency (ETEE), including the following:

- **ConEd's low-income weatherization program:** ConEd's program used a direct install approach to implement weatherization measures in low-income households and it is the only ETEE program that has yielded results to date.
- **Central Hudson's non-DR smart thermostat pilot program:** Central Hudson's program is offering incremental (i.e. top-up) incentives on measures that are already incented through their broader programs to drive additional participation in a targeted area. However, Central Hudson also intends to leverage the smart thermostats' DR capabilities in the future.
- **NW Natural's multi conservation measure program:** NW Natural, in collaboration of Energy Trust of Oregon, is using enhanced marketing and direct outreach to boost participation in existing gas energy efficiency programs in a targeted area and is not offering any incremental incentives.
- **NYSEG's portfolio of non-pipe alternative projects:** NYSEG's program includes the installation of gas energy efficiency measures such as industrial heat recovery, G2E measures (ASHPs and a community loop GSHP project), and public education and outreach.

The complete list of NPS pilot projects along with details that ICF collected about these pilot projects can be found in Appendix A.

4.4 Distributed Infrastructure Options

While CNG and LNG are being discussed extensively as an NPS option by gas utilities in the United States, CNG has only been deployed as an NPS in New York City, and LNG was only one of many suggested options. Furthermore, CNG and LNG are considered as supply side options rather than NPS in New York State based on direction from the state regulator.

NY and Ontario are accepting RNG and P2G (hydrogen injection) as an NPS option. However, the role of RNG is relatively limited at the moment for a variety of practical reasons. For instance, the potential for RNG to serve constrained sections of a natural gas distribution system is limited by land space needs, population density, and the availability of locally-sourced feedstock. To be effective at curtailing peak demand, RNG and P2G would need to be coupled with a form of storage.

As for P2G, analysis and experimentation on hydrogen injection are occurring in some jurisdictions, such as Ontario. However, the technology is still in the process of development and is generally lagging behind other options in terms of its maturity.

5 Tracking Impacts

Gas utilities have much less experience than electric utilities with assessing the hourly profile of the impact of demand-side resources. This is challenge for NPS programs because the suitability of NPS to defer or avoid traditional gas infrastructure depends on the ability of NPS to influence gas demand during peak periods. Natural gas utilities have much less experience with assessing the hourly profiles of the impact of demand-side resources for the following main reasons:

- **Natural gas is easier to store:** In addition to some inherent storage capacity in the natural gas transmission and distribution infrastructure, gas utilities sometimes employ underground storage facilities or LNG storage. Gas utilities can also sometimes store additional natural gas within their pipeline network by pre-emptively boosting the pressure in the system in advance of an expected increase in demand.
- **Larger safety margins in natural gas systems:** Natural gas distribution systems are designed with a larger safety margin than electric distribution systems because the consequences of an interruption of the natural gas service in the middle of the winter are larger[72] and costlier[73] than that for an electricity outage. Moreover, the cost of over-sizing gas pipes is modest compared to the cost of replacing the pipes if supply capacity was to become prematurely insufficient.
- **Lower penetration of gas AMI meters:** The penetration of gas advanced metering infrastructure (AMI) is much lower than the penetration of electric AMI meters. This can be at least partially attributed to the aforementioned points, which have meant that it has historically been less critical to track natural gas demand on an ongoing basis. The cost of installing natural gas AMI meters is also higher compared with the monetary value of the commodity. The commodity cost of natural gas (the marginal cost) is lower than that of electricity, and does not vary as much on a temporal basis. AMI meters are more expensive to deploy because they require a source of electricity – whether it is a battery or a connection with an electric circuit. This either increases the cost of the devices or the cost of installation. As a result, the business case for natural gas AMI meters is not as attractive.

As part of ICF's previous related research for Enbridge in 2018 and 2020, the gas utilities that we consulted generally expressed concerns with the accuracy of the peak demand impacts in the absence of more and better data on hourly natural gas demand profiles that would come from natural gas AMI meters. Our current research suggests that this is still a concern for gas utilities. However, it has not prevented gas utilities from pursuing NPS pilots when policy, market circumstances, and/or public perception have created the necessary drivers to pursue NPS. As a result, NPS pilots have been selected and designed such that they account for the lack of gas AMI meters. The accuracy of the results from these pilots is still being assessed.

---

[72] An outage may activate emergency actions, for instance, like distributing and installing portable electric heater, and/or moving people into warming centres. A large scale relight could take weeks rather than days or hours to resolve.

[73] Safely relighting a section of the distribution system requires a series of time-consuming steps, including: (a) Turning off service valves at every customer meter in the affected area; (b) Correcting the underlying issue that created the loss of system pressure; (c) Reintroducing gas into the affected mains and services; (d) Purging the affected mains and services to ensure that the pipes are filled with 100% natural gas; and (e) Unlocking customer meters and relighting customer appliance pilot lights on a customer by customer basis.

The granular data gathered during NPS pilots can and should be utilized to increase the accuracy of forward-looking NPS impact assessments. Piloting demand-side energy solutions is a preferred approach of utilities, electric or gas, prior to full scale deployment of most forms of programs, even for programs promoting energy efficiency measures that have been tried and tested in neighbouring service territories.

To ICF's knowledge, none of the NPS pilots or programs that have been implemented to date have employed AMI for measurement and verification (M&V) purposes. Gas utilities such as Enbridge have advocated for AMI to be recognized as an enabler of more wide-spread NPS, based on the fact that jurisdictions without AMI may have to overdesign their programs due to higher uncertainty regarding the peak demand impacts. As part of its recent Order and Decision, the OEB concluded that there was insufficient information to determine if AMI is an enabler of cost-effective NPS projects.[74]

ICF noted that NGDR pilots have been the most ubiquitous form of NPS pilot projects. This is at least partially due to the fact that NGDR pilot projects do not necessarily require AMI meters to evaluate their impacts. NGDR pilots can provide granular data that can be used to plan future NPS projects including but not limited to ETEE programs.

In the residential sector, NGDR programs have generally taken the form of a smart thermostat program or a smart domestic hot water controller program. The data feed coming from the devices at intervals (5, 10 or 15 minute intervals) through wireless communication solutions (i.e. duty cycle of the appliances, temperature setpoints, and current temperature) are used to assess the impact of the NGDR pilot projects. The same data feed can also be utilized to gain greater accuracy in the hourly load profiling of the residential space and water heating load profiles for "baseline" buildings.

NGDR programs in C&I buildings are not generally able to leverage this type of data. However, many C&I building meters are read more frequently than residential building meters – often daily compared with monthly for residential buildings. Alternatively, dedicated telemetric pulse-counting devices can be installed on the gas meters of larger facilities to track the impacts of NPS projects on a smaller interval. While telemetric instruments may not be a cost-effective solution for full-scale deployment of an ETEE or NGDR programs, the expense can be justified for pilot projects.

Assessing impacts from G2E pilots can rely on the data stream of electricity AMI meters (when they exist). Electric utilities can provide insights about the space heating and domestic water heating load profile from AMI data disaggregation analytics, particularly if isolating all-electric homes with resistive heat. There is an excellent correlation between the disaggregated electricity load and the space heating load for these buildings. The space heating load profile thereby obtained can then be utilized to forecast the baseline hourly gas load profile prior to the G2E conversion. Furthermore, the study of the data feed from an electric AMI meter on a given building prior and after G2E conversion can inform the determination of what the baseline space heating gas hourly load profile was prior to G2E conversion.

The greatest challenges remain with assessing impacts from ETEE programs. For the foreseeable future, ETEE will be more challenging than NGDR and G2E because existing metering infrastructure does not have the granularity to track impacts in smaller facilities, such as individual homes. Two strategies can help with tackling the M&V challenge with ETEE:

- Collaborating with electric utilities to refine the space heating and domestic hot water load profiles. More electric utilities have AMI meters than gas utilities. The data feed from electric AMI meters can be used to inform space heating and DHW load profiles by isolating homes

[74] Ontario Energy Board, *Decision and Order EB-2020-0091 Integrated Resource Planning Proposal*.

heated with resistive heating appliances and using AMI data disaggregation analytics to isolate the space heating and water heating load profiles.[75]

- Starting with NGDR pilot projects to get access to the data feed of smart thermostats and water heater controllers.

ICF also noted that two natural gas utilities, NW Natural and NYSEG, are using the natural gas pressure data feed from a Supervisory Control and Data Acquisition (SCADA) meter to track the impacts of NPS measures.

In conclusion, ICF's research suggests that the lack of natural gas AMI meters has not been a significant barrier to the deployment of G2E, NGDR, and ETEE pilot programs. However, it does require utilities to be more creative with how they track the impacts of their programs. While it does also increase the uncertainty band around the impact forecast, there are strategies to improve the overall accuracy. While an uncertainty band will remain in the absence of AMI meters, there is also a reasonable amount of uncertainty with regards to long-term load growth forecasts, particularly for certain portions of the distribution network with fewer customers and less diverse energy use.

[75] Electric AMI meter data disaggregation analytics provide excellent accuracy for space heating and domestic hot water load because these constitute the largest electricity end-uses in all-electric buildings. A challenge is that the building stock of resistive-heated buildings is different than that for natural gas-heated building, but calibrated building energy modeling can provide analytical solutions to make the necessary corrections to the load profile.

6 Timing Requirements

Large infrastructure projects have long implementation timelines, and regulated natural gas infrastructure projects are not exempt from this general rule. There is a risk that deployment of NPS may not be able to offset natural gas peak demand quickly enough to avoid a capacity shortfall, at which point it will be too late to build the regular pipe solution on time. This is particularly true for ETEE, NGDR, and G2E, which come in small increments and are dependent of the willingness of customers to subscribe to a program. It also highlights the importance of monitoring the impacts of NPS projects on an ongoing basis.

ICF's 2018 IRP Study and 2020 Study, which were both completed on behalf of Enbridge, suggest a utility would require up to 5 years to properly implement ETEE as an alternative to infrastructure investments. In other words, if a shortage is forecasted in less than five years, the pipe solution may be more dependable to avoid capacity shortfalls. Research completed as part of this study supports maintaining a meaningful lead time when determining whether a traditional infrastructure project can potentially be replaced by an NPS.

The lead time to implement NPS projects varies depending on the type of NPS, and depending on regulatory approval process. Traditional broad-based (i.e. franchise-wide) natural gas energy efficiency program filings are typically independent from leave to construct applications for new pipelines or compressor stations and also run on a different calendar. Gas utilities also often have some flexibility with regards to the scope and timing of their energy efficiency programs; especially if they are operating under multi-year DSM frameworks, similar to the approach used in BC. If the process to obtain regulatory approval for NPS projects is drawn out, this may lead to additional challenges with regards to timing.

Over the past two years, gas utilities in New York and California have been able to plan, implement, and obtain ex-post impact estimates from NGDR pilot projects and an ETEE pilot project (i.e. Central Hudson's "incentive kickers" for smart thermostats) in a relatively short timeframe. This included one year to launch and implement the pilot projects and a one-winter long measurement period.[76]

The amount of lead time to assess whether infrastructure projects can potentially be substituted by an NPS should thereby be dependent on whether the processes to obtain regulatory approval for the NPS is interlaced with the process to gain approval for traditional capital investments. If the NPS process is independent from the leave to construct application, a comfortable length of time of five years seems most appropriate for a large capital project. If the two are interlaced, perhaps starting immediately upon identifying the need for the new large capital project, it is conceivable to shorten the lead time down to 3 years with the first of the three years used to launch an NPS, monitor and report on impacts.

The timeline is also dependent on the size of the project. Less lead time is generally needed to implement smaller-scale NPS projects, which are generally focused on replacing or deferring lower capacity distribution infrastructure. Exhibit 8 is an example of capital project categorization based on ConEd's suggested NPS framework. ConEd has suggested that large projects require a three to five years of lead time, while smaller may require as little as 18 months of lead time.

[76] Although it is possible to assess the effectiveness of a program in this constrained timeframe, it is often challenging to do so and the results may be less reliable; especially if the weather is unusually warm or cold.

Exhibit 8 Suitability Criteria for NPA Consideration and Sourcing Approach as per ConEd Proposed NPS Framework[77]

Categorization	Timeline	Cost ($USD)
Large Project	>36-60 months	>$2 millions
Small Project	>18 months	≤$2 millions

The framework proposed by ConEd has two main attributes that enable the proposed timelines:

- It is presumed that NPS options are being considered and implemented as part of the routine, short- and long-term capital expenditure planning and capital project implementation. NPS are imbricated within the process, and are on the same calendar.
- The framework provides high-level guidelines on how the gas utility is procure NPS projects. For instance, large NPS projects must go through a public solicitation process to help ensure that the best technology solutions are brought forward by third-party developers at a competitive price. However, small NPS projects can leverage broad-based programs. For instance, ConEd may choose to provide incremental incentives and targeted marketing to boost program participation in a given area. This is an important option since it would be very challenging to implement NPS projects in a constrained timeline otherwise. If an NPS project is unable to generate sufficient peak demand impact, the utility needs enough time to proceed with the original capital infrastructure project.

Pursuing a variety of NPS projects may also help to mitigate timeline and performance risks associated with NPS. NGDR and residential G2E using ASHP have proven to be relatively fast to deploy, while some ETEE and G2E measures have longer lead times due to their costs and impact on building operations. For instance, building envelope retrofits, early replacements of furnaces and water heaters, GSHP deployment, and district heating systems may require longer lead times on average. All of these measures also have different risk profiles. Implementing a variety of measures with different lead times and risk profiles may increase an NPS program's chance of succeeding.

An example of large project employing a variety of NPS is NYSEG's NPS portfolio in its Lansing area near Ithaca. NYSEG pursued a public solicitation and received many C&I ETEE and G2E projects from a variety of project developers. The variety of NPS in the portfolio of projects pursued by NYSEG helped reduce the overall risk with regards to performance and timeline.

Two examples of small capital projects requiring a more nimble approach are the two NPS projects deployed by Central Hudson. Central Hudson's smart thermostat program used incentive toppers to bolster adoption of smart thermostat in a particular area. Central Hudson Transportation Mode Alternative also targets small portions of its distribution grid, thereby requiring an expedited process in each suitable area. The Transportation Mode Alternative program seeks to retire obsolete pipes servicing a very small number of customers. Time is of the essence because obsolete (leaky) pipe replacements are coordinated with road pavement replacement work. As such, the decision to either replace the pipe or retire it in place needs to be made quickly, so as not delay road pavement work.

More details on both NYSEG and Central Hudson's pilot projects are provided in Appendix A.

[77] ConEdison, *Proposal For Use Of A Framework To Pursue Non-Pipeline Alternatives to Defer Or Eliminate Capital Investment in Certain Traditional Natural Gas Distribution Infrastructure. Case 19-G-0066*.

7 Conclusions

In this report, ICF presents a review of NPS practices in a number of jurisdictions, with a particular focus on regions with relevant NPS activity. ICF's research represents a targeted effort to update the jurisdictional review completed as part our 2018 IRP Study and 2020 NPS Jurisdictional Review Study, both completed behalf of Enbridge. ICF's research suggests that New York State and Ontario are currently at the forefront of innovation with regards to NPS, with a number of interesting developments in other jurisdictions such as California, Colorado, and Oregon.

The primary conclusions from this review include:

1) ICF identified some recent progress with regards to NPS both in New York State and in other jurisdictions, mostly as NPS are increasingly being considered as a novel component of reformed long-term natural gas infrastructure planning in the context of long-term decarbonization strategies. Jurisdictions that are planning for franchise-wide G2E in the medium or long term are considering NPS to solve local peak demand constraints or avoid obsolete pipe replacements without traditional gas infrastructure projects, which are typically amortized over 40+ years. The implications for electricity infrastructure needs as part of such wide-spread G2E are not assessed as part of this report.
2) Utilities in a small number of jurisdictions, such as New York State and Oregon, have made relevant progress in the development of NPS in terms of long-term capacity planning and analysis (e.g. National Grid Long-Term Capacity Planning reports) and pilot projects (ConEdison's NGDR pilot projects). In Colorado, NPS are being considered in the context of legislation encouraging widespread electrification of the building stock.
3) Recent and anticipated near-term developments with regards to NPS in New York State and Ontario are likely to provide useful examples and broader guidance on how to tackle many of the challenges associated with the broader implementation of NPS, such as:
    a. Treatment of issues related to utility remuneration and return on investment for different types of NPS
    b. Approaches to performance measurement and verification of NPS projects
    c. Transparency in the planning of NPS
    d. Minimizing the timeline for implementing and evaluating the impact of NPS
    e. Challenges associated with the sourcing of NPS
4) The lack of natural gas AMI meters is a challenge but not a barrier to NPS. Gas utilities have found workarounds to address the lack of AMI meters by using the interval data feeds from smart thermostats and water heater controllers, leveraging data from SCADA pipe pressure meters, and employing data feeds from electric AMI meters (e.g. using post G2E conversion electricity consumption to infer the baseline space heating gas demand). The resulting impact assessment may be less accurate, but there is also a reasonable amount of uncertainty with regards to long-term load growth forecasts, particularly for certain portions of the distribution network with fewer customers and less diverse energy use.
5) The timeline for NPS implementation is less of a hurdle if NPS decision and implementation is embedded in the capital project planning and decision process. If the NPS process was to overlap with the leave to construct application process, a three to five years lead time prior to forecasted capacity shortfall may be appropriate. It may be possible to implement smaller-scale NPS projects in a shorter timeline. Shorter timelines

can generally be achieved by streamlining the approval and implementation process for NPS projects.

6) While GHG emission reductions are not the primary benefit utilities are seeking through NPS opportunities, decarbonization goals and policies are a key driver for adopting NPS. Not all NPS options lead to GHG emissions reductions, and the emissions abated by specific NPS projects are only ancillary to the policy goal of NPS. NPS are relevant to gas system decarbonization pathways since they can be used to avoid deploying new natural gas infrastructure whose medium- and long-term utilization may be significantly impacted by future decarbonization policies. This helps avoid potential issues with amortizing the cost of infrastructure over 40+ year timelines, during which it may become underutilized or obsolete.

While ICF identified a significant number of relevant NPS pilot projects, few have yielded published results. Nonetheless, these pilot projects provide useful insights. ICF is recommending the following potential options as next steps for NPS pilots and/or research for FEI:

- **Enhanced smart thermostat NGDR pilot program:** NGDR using smart thermostats are relatively easy and fast to deploy, which explains why a relatively large portion of the pilot projects we identified focused on this technology. ICF noted that existing smart thermostat DR programs are focused only on curtailing the natural gas peak demand. FortisBC may want to consider a residential and small business smart thermostat DR program in coordination with BC Hydro and FortisBC's Electric Utility that focused on both summer peak load curtailment (AC) and winter gas peak demand curtailment.. A joint program will be more cost-effective since it can yield additional benefits. A smart thermostat NGDR pilot program would have the added benefit of yielding a wealth of data about the baseline load profile of space heating in British Columbia through analyzing the data feed from the smart thermostats (e.g. duty cycle, indoor temperature).
- **C&I ETEE pilot:** ICF's research suggests that there has been much less focus on ETEE as an NPS, including any M&V of the associated peak demand impacts of gas EE measures. FEI may want to consider an ETEE pilot focused on larger facilities, where it is simpler and more cost-effective to deploy the necessary telemetric equipment to measure peak demand impacts. FEI could employ a combination of incentive kickers and enhanced customer marketing and direct outreach.
- **G2E with ground-source heat pumps (GSHP):** GSHPs are significantly more efficient than air-source heat pumps. As an added benefit, GSHPs have a lower winter peak impact because they maintain their performance even during the worst cold snaps. ConEd has been testing the deployment of GSHPs as an NPS, and NYSEG is interested in pursuing community/ district heating-style geo-exchange loops. GSHPs and/or geo-exchange loops may be interesting for FEI to consider as well, since utilities are well-positioned to fund capital intensive projects that can be funded over an extended period.

While many of the challenges that were highlighted in the Enbridge 2018 IRP Study and the Enbridge 2020 study are being addressed, the industry is still a long way from a mature practice of NPS. New York State has a head start compared to other jurisdictions due to its unique circumstances, but there is limited relevant activity in other jurisdictions.

To help advance the consideration of NPS in BC, FEI may be interested in submitting an application to BCUC to formalize a framework for the consideration and deployment of NPS projects. Following the model of frameworks that have been developed in New York State and

Ontario, this would provide guidance and direction regarding important aspects such as the assessment process for NPS projects, the approach for cost-effectiveness analysis, the allocation of risk, monitoring and reporting requirements, timeline, sourcing, and cost recovery.

Appendix A: Inventory of NPS Projects

The following section provides details on the NPS pilot projects that ICF identified as part of our jurisdictional scan of North American natural gas utilities. ICF identified only one “full scale” NPS program: Central Hudson’s Transportation Mode Alternative (TMA) program. All other pilot projects have self-imposed limitations on their applicability and were generally designed to test a variety of NPS options, using different strategies to assess the impacts.

Utility and NPS Pilot	Typology and Technologies	Research Questions	Status & Key Takeaways	Approach to M&V
ConEd – Smart Solutions (partially approved)	G2E with ground-source heat pumps in low-rise residential buildings; ETEE via residential low-income weatherization; G2E with air-source heat pumps in multi-unit residential buildings (accepted by commission but implementation was aborted); CNG/LNG (proposed but rejected as an NPS)	ConEd is investing in pilot projects and evaluation studies to ground future analysis and projections.	RFP for Whole Building Electrification Services was issued in July 2021 requesting proposals from experienced vendors with the capability to deliver innovative solutions	For large C&I customers, ConEd is in the process of installing AMI meters including encoder receiver transmitter (ERT) gas modules that get attached to the gas meters for provision of hourly interval readings on a once per day basis.
ConEd – Performance-Based Gas DR	NGDR Behavioural DR program in C&I building (Targets and call ups)	ConEd is investigating their customers' acceptance of NGDR programs and their value for gas utilities.	One event in 2019/2020 PY, achieved a demand reduction of 37,349 m^3 of gas from 156 participants, which was 54% of the pledged demand reduction.	Compared actual metered load on the event day to either an average day or weather-adjusted customer baseline load (CBL). ConEd used four different metering options for collecting of actual interval data – (1) AMI meters, (2) customer submitted consumption data from BMS, EMS, or other recording devices capable of recording hourly data, (3) annual meter reads from meters equipped with a volume corrector, and (4) Interface Management Unit data by upgrading the customer meter with an AMI Interface Management Unit.
ConEd – Thermostat DLC	NGDR, Advanced Thermostat DLC	ConEd is investigating their customers' acceptance of NGDR programs, their impact, and their value for gas utilities.	Two test events during the winter of 2019/2020 achieved a net average reduction of 1,529 m^3 per test event including the snapback effect, with about 19% of customers opting out.	The M&V approach focused on smart thermostats and was based on furnace runtime data from the thermostats. ConEd noted that it was challenging to establish the baseline for this program and that ERT meters would provide limited additional benefits in this regard.
ConEd – Water Heater Control	NGDR, Water Heater Controller	The energy efficiency and demand response potential of Aquanta's smart gas water heater controllers	Installed more than 200 Aquanta controllers in single family homes under this program. Impact evaluation for 2019 & 2020 PY are under process.	The M&V approach focused on comparing actual metered load on the event day to either an average day or weather-adjusted customer baseline load.
Central Hudson – Smart Thermostat Pilot	ETEE with Smart Thermostat incentive adders (2x the franchise-wide incentive)	Evaluating the impact of incentive adders on the adoption of smart thermostats	A total of 21 thermostats were purchased under this promotional program. Looking ahead, Central Hudson will set incentive adders from 2 to 4 time the franchise-wide incentive.	Central Hudson used a deemed savings approach (No measurement).

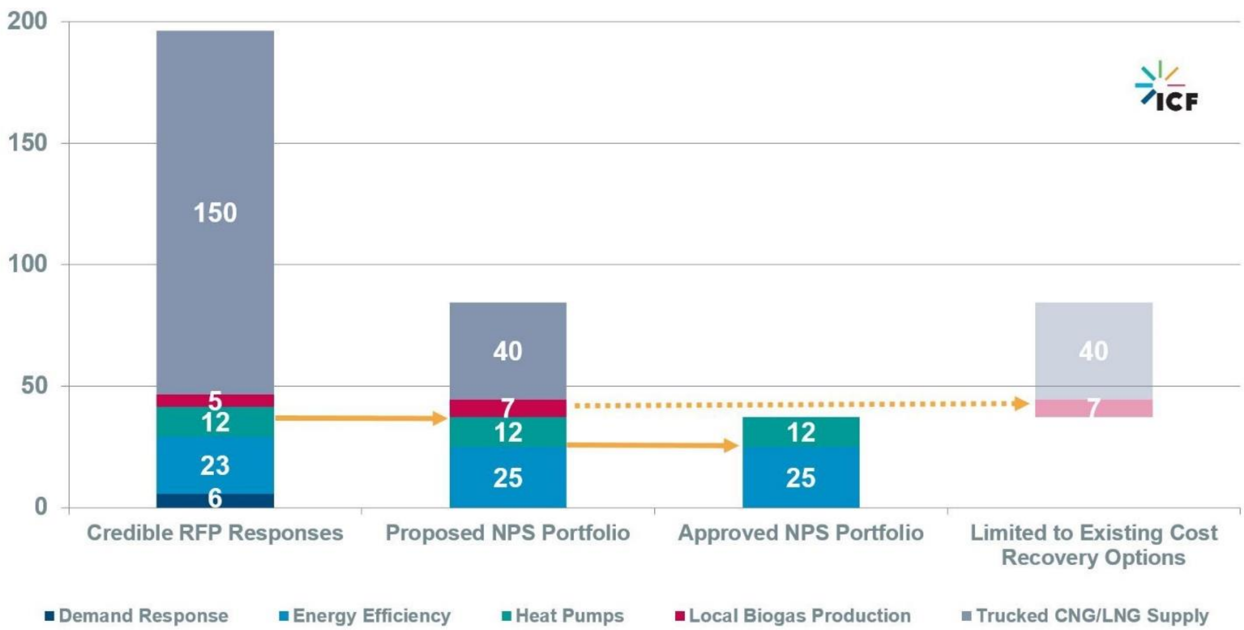
Utility and NPS Pilot	Typology and Technologies	Research Questions	Status & Key Takeaways	Approach to M&V
Central Hudson – Transportation Mode Alternatives	G2E – Full building electrification including space heating (heat pumps), electric or heat pump water heaters, and food service measures.	N/A (full-scale program)	Designed for radial mains with low customer saturation to facilitate strategic abandonment of leak-prone pipes. Currently underway in 11 identified locations.	Not applicable. By definition, no more natural gas is used in areas where this program is successful.
National Grid – Gas DR REV Demo Project	NGDR C&I Behavioural Program based on self-imposed targets; NGDR, C&I Enhanced Interruptible Rate approach with Non-Gas backup	Test the concept of NGDR and investigate the optimal ways to implement DR to generate value for both the utility and customers.	A total of 17 participants enrolled in the project, contributed 6,691 m^3/hr of peak demand reduction, which is indicative of a daily reduction of 133,820 m^3.	National Grid uses a device that reads pulses from their C&I customer meters to verify impacts from the C&I NGDR program. The utility is also accounting for the lack of AMI gas metering in the experimental design of its future pilots.
Niagara Mohawk – Commercial Gas DR	NGDR C&I Behavioural Program, based on self-imposed targets.	Test the concept of NGDR and investigate the optimal ways to implement DR to generate value for both the utility and customers.	A total of 5 participants enrolled in the project with a targeted reduction in demand of 3,610 m^3. Only one event called, achieved 110% of the target.	Niagara Mohawk uses a device that reads pulses from their C&I customer meters to verify impacts from the C&I NGDR program. The utility is also accounting for the lack of AMI gas metering in the experimental design of its future pilots.
National Grid – C&I Expanded DR	NGDR, Enhanced Interruptible Rate approach. Customers are required to have an alternate non-gas fuel source. Customers are rewarded for agreeing to interruption call-ups (a “reservation-based incentive”), rather than being penalized for not executing on interruption call-ups.	Expansion of Gas DR REV Demo	A total of 156 customers were enrolled, committed to a total of 493,890 m^3 of daily peak load reduction. Two 3-hour test events were called, with the portfolio performing at 83% of the weather-adjusted baseline.	Compared actual metered load on the event day to weather-adjusted customer baseline load (CBL).
National Grid – Non-Firm DR Rate	Legacy “Interruptible Rate” that has been re-named to differentiate it from the C&I Expanded DR, and slightly modified. Unlike the “C&I Expanded DR”, customers must switch over to a back-up system at a pre-determined temperature threshold, on an automatic basis in certain cases.	Test the effectiveness of voluntary peak reductions in terms of reducing intra-day demand and whether market-based credits will drive customer behavior to reduce consumption.	Two tiers: Tier 1 (fully automatic switchover of equipment at 16°F) service will have volumetric delivery rates set at 50% below the tail block volumetric rate, and Tier 2 (an automatic, semi-automatic, or manual switchover of equipment at 20°F) service will have volumetric delivery rates set at 60% below the tail block volumetric rate. No results are available to date.	National Grid installs a KYZ-pulse reader on the facility gas meter of participants to measure impacts, and an automatic, remote switching device as applicable.

Utility and NPS Pilot	Typology and Technologies	Research Questions	Status & Key Takeaways	Approach to M&V
National Grid – Bring Your Own Thermostat DR	NGDR, Smart Thermostat	Test case for estimating program potential and capability.	A total of 2,251 thermostats were enrolled for 2020-2021 PY. Four 4-hours long events were called, with average per event net savings (including snapback effect) per customer from 0.53 – 0.94 m^3.	National Grid used the data feed from the smart thermostats (15-minute interval runtime data). They developed a 'treatment and control' design for the 2020-21 BYOT program. Customer devices were randomly assigned to three different treatment groups, of which 1-2 groups could be dispatched during an event (treatment), with the non-dispatched group(s) serving as the control.
National Grid – Behavioural DR	NGDR, Residential and Small Commercial Behavioural	Investigate how customers react to messages notifying them of impending cold weather and suggesting ways to lower their gas consumption during peak hours.	Email alerts were sent to a total of 489,969 customers, out of which 2,894 customers (0.6%) committed to reducing their load.	
NYSEG – NPA Pilot (Proposal filed with NYPSC in Oct 2020)	ETEE including Industrial heat recovery and public education, G2E in buildings (ASHP and Community-Loop GSHP),	N/A	The projects are the results of two requests for proposals from developers.	M&V approach is being laid out on a project-by-project basis in collaboration with the project developer. Since the project is mostly focusing on large C&I buildings, daily reads are not out of the questions, and load profiles could be deemed and adjusted based on the heating degree days for a specific day. No M&V associated with the education component.
NW Natural – GeoTEE Pilot	EE, Geo-targeted energy efficiency. Three phases: geotargeted marketing, low incentive adder, high incentive adder.	Analysis of geo-targeted energy efficiency as an option for deferral and avoidance of future distribution system investments.	No results are available to date.	Selected a loop of the distribution system that can be easily isolated for the pilot and installed an AMI meter on the loop for measurements.
SoCalGas – Smart Thermostat Control Program	NGDR, Smart Thermostat	N/A	During the 2018-2019 PY, 43,103 customers were called for DR morning and evening events. Average event energy savings per participant were 0.311 m^3 for the morning event, leading to an aggregated event savings of 10,534 m^3 (15.1%), and 0.235 m^3 per participant for the evening event, leading to aggregated event savings of 2,152 m^3 (15.5%).	Gas load impacts (usage reductions) on event days were estimated by applying the best practices that have been developed for electric DR program measurement and evaluation in California. The M&V approach used the data feed received from the smart thermostat: duty cycle, indoor temperature, and setpoint.

ConEd – Smart Solutions (Partially Approved)

In December 2017, ConEd issued an RFP for market participants to provide NPS targeting peak-day relief in key areas. Based on the results of the solicitation, ConEd developed a portfolio of cost-effective NPS projects. However, the NPS suggested by the market participants did not lead to sufficient cost-effective options to avoid or defer the need for new pipeline capacity. Nevertheless, the effort resulted in a $412m ($305m USD) portfolio of projects, including a mix of ETEE and electrification as well as supply-side measures such as CNG and LNG. As shown in Exhibit 9, the portfolio was targeted at offsetting peak-day gas demand by 84,500 Dth. The portfolio was submitted to the New York Public Service Commission (herein PSC) for approval on September 28, 2018.[78]

Exhibit 9 Peak Day relief (1,000's of Dth/day) by Stage if NPS Process[79]



On February 7, 2019, the PSC ruled on the proposed NPS Portfolio, approving $300.5m ($222.6m USD) for the demand-side measures (energy efficiency & G2E) of the proposed portfolio with some conditions, while rejecting the rest $111.5m ($82.6m USD) portion of the proposal for the supply-side measures (CNG/LNG). PSC noted that these projects should instead be included within ConEd's existing capital program and/or the utility's upcoming rate filing.

While some of the intervenors were comfortable with the proposed LNG and CNG projects, arguing that these solutions would be preferable to a new pipeline due to their modularity and the reduced risk of stranded infrastructure assets, PSC ruled that the shared savings suggested by ConEd were inappropriate.[80] They argued that the proposed portfolio of NPS would fail to avoid the need for additional supply capacity to city gates and that the Petition lacked evidence that the proposed alternatives were an appropriate match to additional supply in terms of

[78] ConEdison, *Case 17-G-0606 – Petition of Consolidated Edison Company of New York, Inc. for Approval of the Smart Solutions for Natural Gas Customers Program*.
[79] ICF, 'What Can We Learn from New York's Non-Pipeline Solutions Ruling?', 2019 <https://www.icf.com/insights/energy/non-pipeline-solutions> [accessed 31 July 2020].
[80] ConEdison also requested a true-up to actual costs that would split overruns or underruns 50/50. A similar approach is used for electric non-wire solutions projects.

reliability (i.e. number of hours or days needed versus number of hours or days delivered by the NPS).

Though the PSC agreed to a $300.5m ($222.6m USD) budget for the specified demand-side measures, it directed that this funding should come from an expanded energy efficiency budget that had been announced previously. In April 2018, NYSERDA and the PSC published expanded energy efficiency targets for the state[81] and in December 2018 the PSC passed an order formally adopting expanded energy efficiency budgets and targets for utilities.[82] The PSC also instructed ConEd to include the ‘approved’ $300.5m ($222.6m USD) budget for NPS within the budget and plan it was scheduled to file in March 2019, as part of the separate proceeding for expanded energy efficiency budgets. Though PSC did not allow any new money, the NPS measures were approved since they aligned with the state’s existing plans to significantly increase funding to both improve energy efficiency and drive heat pump adoption.

Although most of the funding was tied up in additional cases, the PSC NPS order did allow ConEd to get started on some pilot projects, through the approval of $40.1m ($29.7m USD) for the first year of the demand-side initiatives. ConEd used the initial funding tranche to implement three one-year pilot programs:

- **Electrification program:** This pilot targeted residential customers in Westchester County for gas to ground-source heat pump conversions. ConEd reported results that exceeded targets, largely due to the higher than anticipated count of participating homes (i.e. 60 participants).
- **Residential sector weatherization program:** ConEd reported results that were lower than the targets for this program.
- **Electrification project:** This project was focused on a conversion to air-source heat pumps in a multi-unit residential building in the Bronx. The project was unsuccessful due to lack of suitable participants.

ConEd – Performance-Based Gas DR Pilot

ConEd’s Performance-Based Gas DR Pilot was launched in the winter of 2018/19. It is a behavioural NGDR Pilot targeting C&I customers and multi-unit residential buildings with centralized heating systems. This pilot is testing the effectiveness of incentivizing customers to provide net reductions in their natural gas demand during peak demand days (i.e. for a 24-hours period) on the coldest winter days. As part of the Performance-Based Gas DR pilot, building operators are asked to pledge daily savings on peak days and they are given advance notice of the need to curtail their demand on peak days. Participant incentives are based on their performance.[83] It is a behavioural program because it depends on actions taken by customers on the basis of utility notifications.

ConEd set participation limits of 500 customers in the first program year (2018/19), 750 customers in 2019/20, and 1,000 customers in 2020/21.[84] ConEd’s second status report for

[84] ConEdison, ‘Gas Demand Response Pilot Implementation Plan, 2021-2022, Case 17-G-0606’, 2021 <https://www.coned.com/-/media/files/coned/documents/save-energy-money/rebates-incentives-tax-credits/smart-usage-rewards/gas-demand-response-implementation-plan.pdf> [accessed 17 January 2022].

2019/2020 indicates that a total of 309 customers enrolled in the program and pledged 81,654 m^3 (2,886 Dth) of gas reductions. ConEd called one test during the 2019/2020 program year. The status report noted that the resulting impacts of 156 of the customers were measured and that they achieved demand reductions of 37,349 m^3 of gas (1,291 Dth) against a pledged quantity of 60,638 m^3 of gas (2,096 Dth) reduction. This translates to 54% of the pledged impact.[85]

During the 2020/21 program year, 590 customers enrolled in the program and pledged 107,330 m^3 (3,765 dth) of gas reductions. During the single test event, ConEd estimated a load reduction of 19,470 m^3 (683 dth) for customers who utilized curtailment of their gas-fired CHP equipment. However, they calculated an increase in net load of 18,670 m^3 (655 dth) for customers who curtailed gas-fired space heating and/or water heating equipment. ConEd is investigating these results further to determine if their approach to estimating demand impacts underpredicted customer consumption during the event day or if the methodology wasn't sensitive enough to capture customers' attempts to reduce load.

ConEd also noted that the temperatures experienced on the coldest days of the 2019/20 and 2020/21 program years were mild compared to gas system design temperatures. As such, the pilot provided limited insights into the ability to curtail peak demand at colder temperatures. This applies to both the performance-based pilot and the residential thermostat pilot that is discussed below.

ConEd – Residential Thermostat DLC

ConEdison's residential DLC Pilot was also launched in the winter of 2018/19. This program is deploying both ConEd's fleet of advanced thermostats that are also used for summer electricity peak curtailment and additional thermostats that were enrolled through a bring-your-own thermostat component. The advanced thermostats are used to control HVAC equipment and reduce natural gas demand during peak periods.

Over 2,800 thermostats were enrolled in the program in the 2019/20 program year. The program had two test events with an overall average reduction of 1,529 m^3 of natural gas (56.1 dth) per event including the snapback effect (i.e. incremental gas required to recover from temperature setbacks).[86] The average peak demand impact on a per-thermostat basis for the 4-6 hour events was 0.57 m^3 (0.020 dth), with higher average savings for longer setback periods and the morning test period. Snapback reduced the calculated load reduction by an average of 52%.[83] ConEd also found that around 19% of enrolled customers opted out during that program year.

ConEd carried out two additional events during the 2020/21 program year, with 5,014 participating customers and 4-6 hour temperature setbacks per event. They observed an average of 0.68 m^3 (0.024 dth) of gas load reduction per device including snapback and a higher out-out rate of 37%. This higher opt-out rate can be at least partially attributed to the testing of larger temperature setbacks (i.e. 3-4°F (1.7-2.2°C)). Based on its testing of different

[85] Con Edison, 'Performance-Based Gas Demand Response Pilot Guidelines, 2021/2022 Capability Period', 2021 <https://www.coned.com/-/media/files/coned/documents/save-energy-money/rebates-incentives-tax-credits/smart-usage-rewards/gas-demand-response-pilot-guidelines.pdf> [accessed 12 November 2021].

[86] The snapback effect is an increase in energy demand that happens due to the synchronization of a fleet of asset because of a DR event. In other words, the entire fleet of heating equipment that was curtailed start at the same time and operate at full capacity simultaneously to bring back the space temperature at its original setpoint. There are many DR strategies to minimize and soften the snapback.

temperature setbacks, ConEd's pilot has indicated that larger setbacks can result in higher average load reductions, even after accounting for opt-outs and snapback.

ConEd – Smart Gas Water Heater Controllers Pilot

ConEdison's Aquanta Smart Gas Water Heater Controllers Pilot was implemented from December 2018 to September 2020. This pilot program was designed to test the energy efficiency and demand response potential of Aquanta's smart gas water heater controllers. The pilot targeted residential customers in single family homes to install 300 Aquanta controls. The Aquanta controllers are Wi-Fi enabled, which allows customers to access them from any Wi-Fi enabled device. It also provided ConEd with a fleet portal for data gathering and DR event management. As part of this program, over 200 controllers were installed in single family homes in Westchester.[87]

Documentation suggests that ConEd and its EM&V contractor were performing the impact evaluation of the Aquanta Pilot for the 2019 and 2020 program years, with a report due to be released in Q2 2021. However, ICF was unable to verify that this work has been completed or gain access to the report to assess the results.

Central Hudson – Smart Thermostat Pilot program

In March 2018, NY's PSC ordered Central Hudson to assess natural gas demand-side solutions. Central Hudson's avoided gas distribution study didn't identify any constraints on its gas distribution system other than a portion of its system referred to as the PN Line, which serves in the southern portion of the Town of Poughkeepsie.

Central Hudson evaluated its six existing portfolios of energy efficiency and electrification technologies in conjunction with incentive kickers (i.e. adders) in a peak load management application focusing on the PN Line. To assess the use of kickers, Central Hudson performed a simplified analysis to compare the incremental costs of higher incentives and benefits associated with more concentrated load reductions.[88] Exhibit 10 summarizes the results for the locational benefits of the measures, indicating smart thermostats as the most cost-effective measure.

[88] Central Hudson Gas & Electric Corporation, 'Assessment of Natural Gas Demand-Side Load Management Solutions', 2020 <http://documents.dps.ny.gov/public/Common/ViewDoc.aspx?DocRefId=%7B1CB068E6-2DE6-490E-B5F1-1816192281F9%7D> [accessed 12 November 2021].

Exhibit 10 Simplified Benefit Cost Analysis of Kickers on Top of Broad-Based DSM Incentive for Central Hudson[89]

Measure	Locational Benefits	Locational Costs	Locational Net Benefits	Locational BC ratio	Avoided pipline capacity (CCFh-yr)
Smart thermostat	$ 371,344	$ 313,817	$ 57,527	1.18	74
Heat Pump Water Heater	$ 351,958	$ 1,589,387	$ (1,237,429)	0.22	75
ASHP - All-Electric Whole Home	$ 361,190	$ 1,067,952	$ (706,761)	0.34	60
ASHP - Dual-Fuel	$ 83,869	$ 270,449	$ (186,581)	0.31	14
Efficient Combi Boiler	$ 452,707	$ 2,323,269	$ (1,870,562)	0.19	73
Efficient Furnace	$ 539,779	$ 603,607	$ (63,828)	0.89	75

As a result of this analysis, Central Hudson implemented a “kicker incentive” to promote ENERGY STAR certified smart thermostats to customers served by the Vassar Road portion its PN Line. In November 2020, Central Hudson initiated its “Double the Rebates” marketing campaign to approximately 750 residential and commercial customers, with increased incentives available up until May 1, 2021. A total of 21 thermostats were purchased under this promotional program, representing approximately 3% buy-in from the targeted group. Central Hudson will implement this initiative on an as-needed basis and will set the incentive levels (i.e. anywhere from 2 to 4 times the regular incentive) based on consideration of existing portfolio budgets.[90]

Central Hudson – Transportation Mode Alternatives (TMA)

Central Hudson’s Transportation Mode Alternatives (TMA) program is designed to facilitate strategic abandonment of leak-prone pipes that are not otherwise integral to the distribution system. This opportunity is best suited for radial mains with low customer saturation. Under this program, each customer served by the targeted section must convert all of their current natural gas end uses to electricity. Central Hudson is using a direct install approach for this program, which includes efficient electric heat pumps and water heating systems, as well as ranges, dryers, and other appliances as needed.[91]

Based on the latest available results, 40 separate TMA project locations have been identified where it is potentially feasible and cost-effective to permanently retire sections of leak-prone pipe. These 40 project locations include approximately 100 customers. Out of the 40 projects, a total of 21 projects were included in the NPA Implementation Plans (2019, 2020 and 2021 Plan). Thus far, three projects involving a total of six customers have been completed and three more projects involving 24 customers are in progress. In addition, five projects have been found to be unsuitable upon further investigation and ten projects have been postponed due to lack of sufficient customer interest to proceed with an G2E solution.[92]

[91] Central Hudson Gas & Electric Corporation, ‘Central Hudson’s Demand Reducing Measures Status Report and Proposals. Case 20-G-0131’, 2020 <http://documents.dps.ny.gov/public/Common/ViewDoc.aspx?DocRefId=%7B6F5B0C7C-2D0F-48F9-8E65-0B8DBDDCFE90%7D> [accessed 12 November 2021].
[92] Central Hudson Gas & Electric Corporation, ‘Non-Pipeline Alternatives Annual Report, Case 17-G-0460’.

Central Hudson has partnered with ICF to deliver these projects. A direct install approach favouring ASHPs over GSHPs has been adopted considering the small number of customers, the requirement for 100% participation within each area, the cheaper and faster installation of ASHPs.

National Grid – Gas DR REV Demo Project

In 2017, National Grid launched a DR pilot for its large commercial firm customers with the goal of alleviating peak hour demand on its distribution system. This DR pilot program focused on expanding NGDR beyond interruptible or temperature-controlled customers who can perform fuel switching. The program has two options: Daily DR and Hourly DR. In the case of the Daily DR program option, participants must have the ability to reduce their gas consumption by shutting off non-heating gas equipment or switching to a non-gas heating backup. The Hourly DR program option is focused on customers who can only shift their gas loads to a different time period within the same day. In the case of the Hourly DR program option, customers are restricted from using a fossil-fuel backup during the DR events.[93]

This pilot project was designed and developed to test the concept of NGDR and to start exploring the optimal ways to implement DR to generate value for both the utility and its customers. A total of 17 large commercial facilities participated in the project over the course of three winter program period but the participation fluctuated, with a maximum of 16 participants. This project contributed 6,691 m^3/hr (241 Dth/hr) of peak demand reduction and this hourly reduction would be indicative of a daily reduction of 133,820 m^3 (4,820 Dth), which is equivalent to 2.5% of the reduction produced by National Grid's non-firm customers.[94]

National Grid – C&I Expanded DR

The C&I Expanded DR initiative is a program for large C&I customers capable of reducing peak day gas loads over a 6 or 8-hour period. The program depends on customers to completely curtail their gas loads over a 6-hour period by switching to an alternate, non-gas fuel source or completely shutting down their natural gas equipment. Participating customers were offered a reservation-based incentive at the beginning of the season. To receive 100% of the stated incentive, customers need to comply with all DR events. If they don't meet this condition, customers receive either 50% or none of the stated incentive, depending on the number of events called in the season.[95]

A total of 156 customers were enrolled for the 2020/21 expanded DR program that committed 493,890 m^3 (17,790 Dth) of daily peak load reduction. Over 90% of the participants in the 2019/20 program season returned for the 2020/21 program. Due to a mild winter, no DR events were called during the season. However, two 3-hour test events were called in December 2020 and almost all customers participated in one of the events. In aggregate, the participants

[93] National Grid, 'Reduce Your Natural Gas Usage and Earn Incentives, Natural Gas Demand Response Program for Firm Customers', 2021 <https://www.nationalgridus.com/media/pdfs/bus-ways-to-save/demand_response_program.pdf> [accessed 12 November 2021].

[95] National Grid, '2020-2021 Expanded Gas Demand Response Implementation Plan', 2020 <https://documents.dps.ny.gov/public/Common/ViewDoc.aspx?DocRefId=%7B1043D93F-B2CD-4E27-86EF-FCCA68F2635D%7D> [accessed 12 November 2021].

reduced their daily load by 71,293 m^3 (2,568 Dths) for the sum total of both the events and the entirety of the 3-hours, with the portfolio performing at 83% of the weather-adjusted baseline.[96]

National Grid – Bring Your Own Thermostat DR

This is a residential and small commercial customer-focused program, which uses communicating thermostats to remotely lower temperature set points and shift peak hour gas loads. A total of 2,251 thermostats were enrolled at the end of 2020/21 heating season. To accurately measure the impact of the DR events, National Grid used a treatment and control approach, randomly dividing the enrolled participants into three groups for the DR events. They dispatched one or two groups and the other(s) served as the control group(s).[96]

A total of four separate 4-hour long events were called during the 2020/21 PY, including three morning events and one evening event. The average per event usage savings per customer ranged from 1.69-1.83 m^3 (0.061-0.066 Dth), while the net event savings (including snapback effect) ranged from 0.53-0.94 m^3 (0.019-0.034 Dth). These estimates are statistically significant at a 95% confidence level.[96]

Without access to interval metered data, National Grid utilized the 15-minute runtime data recorded from the participating thermostats. This runtime data was then transformed into Dths utilizing an estimated 80,000 BTU/Hour input assumption for the average customer heating equipment. National Grid is currently working to verify this input assumption using actual hourly data sampled from participating customers.

National Grid – Non-Firm DR Rate

In addition to the DR program for firm customers described above, National Grid has two non-firm rates as well, which are called "non-firm DR" in recognition of the reduction they provide during event hours. The non-firm DR rates are the former interruptible and temperature-controlled rates that were offered by National Grid. The non-firm DR program has two tiers: Tier 1 includes a fully automatic switchover of equipment at -8.9°C (16°F), and Tier 2 can have an automatic, semi-automatic, or manual switchover equipment at -6.7°C (20°F). National Grid installs KYZ-pulse readers on facility gas meters of participants to measure impacts, and an automatic, remote switching device as applicable.[97]

National Grid – Behavioral DR

This is a non-incentivized program that uses e-mails or mobile messaging to notify customers of impending cold weather and to suggest ways to lower their gas consumption during peak hours.[96] Two behavioral DR events were called during the 2020/2021 heating season, including a large event and a separate much smaller event that was focused on trying to measure impacts. The first event was conducted on the coldest day of the winter season and sent cold weather email alerts to 489,969 residential and small commercial customers. A total of 2,894

[97] National Grid, *Case 19-G-0309 - Proceeding on Motion of the Commission as to the Rates, Charges, Rules and Regulations of The Brooklyn Union Gas Company d/b/a National Grid NY for Gas Service and KeySpan Gas East Corp. d/b/a National Grid for Gas Service*, 2019 <http://documents.dps.ny.gov/public/Common/ViewDoc.aspx?DocRefId=%7BE11E743B-6CAF-4905-AA13-4807CE7A56B4%7D>.

customers committed to reduce their load but impacts could only be estimated due to the lack of hourly metering.

More recently, National Grid installed devices that are capable of reading hourly gas consumption from traditional drive-by meters on 900 select customers. Due to delays in the implementation of the metering and a small sample size, National Grid was not been able to more accurately assess impacts of its second behavioural NGDR program during the 2020/21 heating season. However, the utility is hoping to use these meters to measure impacts of behavioural NGDR events during the 2021/22 heating season.[96]

Niagara Mohawk (aka National Grid Upstate) – Commercial Gas Demand Response Project

This is a customer-centric, voluntary NGDR program targeting large commercial, firm gas customers in the Eastgate gas territory. The program launched in September 2019 and was scheduled to run over two winters. For Season 1, the project enrolled a total of five (5) participants, with a reduction target of 3,610 m^3 (130 Dth). Due to the mild winter, only one event was called on February 28, 2020. Out of the five participants, only one failed to meet their reduction target. The other four participants overperformed during the event, resulting in a 10% increase in total achievement (i.e. a total of 3,970 m^3 or 143 Dth).[98]

NYSEG – Approved Portfolio of NPS Projects

In October 2020, NYSEG filed a proposal with the NYPSC to implement an NPS project in the Town of Lansing, New York to improve its low-pressure situation during peak hours. The solution includes residential and non-residential heat pump installations, a community loop ground source heat pump project, the installation of gas energy efficiency solutions, industrial heat recovery, and a coordinated public education and outreach effort.[99]

In June 2021, the PSC approved procurement of seven NPS projects for a total estimated cost of $9.7 million with some modifications. Together, the projects do not pass the SCT test (although there was some debate regarding the valuation of GHG reductions). However, they do pass the UCT tests, which is why NYSEG is pursuing them and the PSC granted permission. These projects are expected to reduce the natural gas demand by approximately 56 MCF per hour. The approved projects include G2E (residential ASHP, commercial GSHP, community GSHP), ETEE at two public authority buildings, ETEE (heat recovery) at industrial facilities, NGDR at C&I buildings (i.e. using electric boilers as backup), and an education and outreach program. None of these projects had started as of late 2021.

The increase in electricity bills after G2E conversions will be higher than the reductions in their gas bills. The operators of participating buildings have agreed and are willing to pay higher energy bills. While NYSEG has agreed to an incentive amount to offset the cost of the G2E conversions, the amount is insufficient to make up for the incremental cost of ownership of all-electric HVAC.

[98] National Grid, *Case 17-E-0238 & Case 17-G-0239 Report of Niagara Mohawk Power Corporation d/b/a National Grid on the Proposed Implementation of Advanced Metering Infrastructure*, 2018 <http://documents.dps.ny.gov/public/Common/ViewDoc.aspx?DocRefId=%7B5A9009BC-356F-4B0F-B3C7-F255EA8AA5A8%7D>.

[99] NYSEG News, 'NYSEG Files Plans for Industry Leading Non-Pipe Alternatives to Serve Natural Gas Customers, Among First of Its Kind', 2020 <https://electricenergyonline.com/article/energy/category/oil-gas/89/862079/nyseg-files-plans-for-industry-leading-non-pipe-alternatives-to-serve-natural-gas-customers-among-first-of-its-kind-.html> [accessed 12 November 2021].

Projects that were not approved include smart thermostat gas DR in the zone of highest impact (i.e. component not cost-effective), LNG and CNG delivery and injection, and hydrogen generation and injection.[100,101]

NW Natural – GeoTEE

NW Natural's Geo-Targeted Energy Efficiency (GeoTEE) pilot project is being implemented in close collaboration with Energy Trust Oregon (ETO). The project is designed to obtain measured data needed to more accurately consider geo-targeted energy efficiency as a viable option for deferral and avoidance of future distribution system investments.

The GeoTEE pilot project includes three phases:

- **Phase 1:** Targeted marketing and customer engagement for a certain segment of NW Natural's distribution system to promote EE through existing broad-based EE programs.
- **Phase 2:** Targeted incentive kickers (i.e. adders) to top off incentives available through existing broad-based EE programs, within cost-effectiveness (UCT) bounds.
- **Phase 3:** Larger incentive kickers to top off incentives available through existing broad-based EE programs, beyond cost-effectiveness threshold.

It was critical to the experimental design of the project to select a loop of the distribution system that can be more easily isolated for the pilot. NW Natural installed a SCADA meter to monitor the hourly flow of gas at the entrance of the target area and they will compare daily and monthly data against the aggregated data from the SCADA meter.

Results from 2018/2019 were delayed due to issues relating to a faulty meter. NW Natural is in the process of analyzing data from 2019/20, 2020/21, and 2021/22. They expressed concerns about the potential impact of COVID-19 on the dataset, but they have not yet confirmed whether this was indeed an issue of real concern. To date, no results have been made available from this pilot project.

Colorado Xcel Energy – Heat Savers Mode Study

The Heat Savers Mode Study is a NGDR pilot[102] that is being implemented in Summit County, Colorado, a mountainous region with multiple ski resorts where pipeline expansion is particularly difficult and costly. Xcel is hoping the pilot results will help the utility better manage demand and avoid building out additional gas infrastructure going forward. In particular, the pilot involves the installation of wireless energy monitors that will allow the utility to better understand localized load shapes and daily peaks over time to help improve system planning, and a NGDR component leveraging smart thermostats in conjunction with behavioral prompts through a customer-focused mobile app to reduce gas demand during peak periods.

SoCalGas Smart Control Thermostat Program

In the SoCalGas Smart Control Thermostat program, participants were granted access and control of the temperature settings over specific 4-hour events during the winter season in

exchange for an economic incentive. The program started during the 2017/18 heating season showed impressive growth, reaching approximately 50,000 customers during 2018/19 program year. Customers signed up to receive smart thermostats and take advantage of existing advanced metering infrastructure (AMI). [103,104] The program is event-based and the load reductions are attained on event days from temporary temperature setbacks. The events are generally take place between the hours of 5-9 am or 6-10 pm.

During the 2018/19 program year, 33,895 customers were called for morning events (5-9 am) and 9,208 customers for evening events (6-10 pm). The average load reduction per participant during the morning event was 0.765 m^3/hr (0.027 CCF/hr or 15.1% average reduction), while evening event participants reduced their load by an average of 0.665 m^3/hr (0.020 CCF/hr or 15.5% average reduction). Average event energy savings per participant was 0.311 m^3 (0.110 CCF) during the morning event 0.235 m^3 (0.083 CCF) during the evening event.[105]

About ICF

ICF (NASDAQ:ICFI) is a global consulting and digital services company with over 7,000 full- and part-time employees, but we are not your typical consultants. At ICF, business analysts and policy specialists work together with digital strategists, data scientists and creatives. We combine unmatched industry expertise with cutting-edge engagement capabilities to help organizations solve their most complex challenges. Since 1969, public and private sector clients have worked with ICF to navigate change and shape the future. Learn more at icf.com.

Appendix D

ENERGY SUPPLY PORTFOLIO

Appendix D-1

NATURAL GAS MARKET OVERVIEW

APPENDIX D-1: NATURAL GAS MARKET OVERVIEW

1.1 INTRODUCTION

This appendix provides a high level overview of the North American and regional natural gas marketplace which informs the LTGRP regarding the outlook on natural gas pricing, supply, and demand, however does not significantly impact the strategies implemented within the LTGRP. Some information in this appendix is provided by global energy market providers who prepare their own proprietary analysis (i.e. IHS Markit), while other information comes from some reports that are publicly available on Federal or Provincial websites.

The policy developments discussed in Section 2.2 that seek to address climate change and reduce GHG emissions will have an impact on the energy market, specifically the oil, natural gas, and electricity sectors. The natural gas and electricity markets have already seen impacts from such policies, as demonstrated through legislation in the early 2010's that resulted in coal plant retirements. Despite the urgency driving much of the recent policy initiatives, the nature of any impact they may cause on regional natural gas supply, demand, and infrastructure remains uncertain. The policies, targets and initiatives discussed in Section 2.2 illustrate that the conversation around the role of the gas system in decarbonizing Canada's GHG emissions is undefined.

The most recent supply and demand projections incorporate all known policies in the outlooks; however, an "evolving policies" or "fast transition" to net-zero scenario[1] is also provided to illustrate a pathway to achieving carbon net neutrality.

This section is organized as follows:

- **Section 1.2 – Natural Gas Prices –** This section provides an overview of North American and regional market prices (i.e., AECO/NIT);
- **Section 1.3 – Natural Gas Supply –** This section provides an overview of North American and regional supply (i.e., Western Canadian Sedimentary Basin);
- **Section 1.4 – Natural Gas Demand –** This section discusses North American demand, as well as regional LNG export and natural gas fired power demand.

1.2 NATURAL GAS PRICES

Henry Hub is the official pricing point for natural gas futures on the New York Mercantile Exchange (NYMEX) and is used as the benchmark for the North American natural gas market. The notable growth of shale gas supply since 2008 has resulted in a significant drop in natural gas prices. As illustrated below in Figure D1-1, prior to the shale gas revolution, Henry Hub prices in the "Pre-

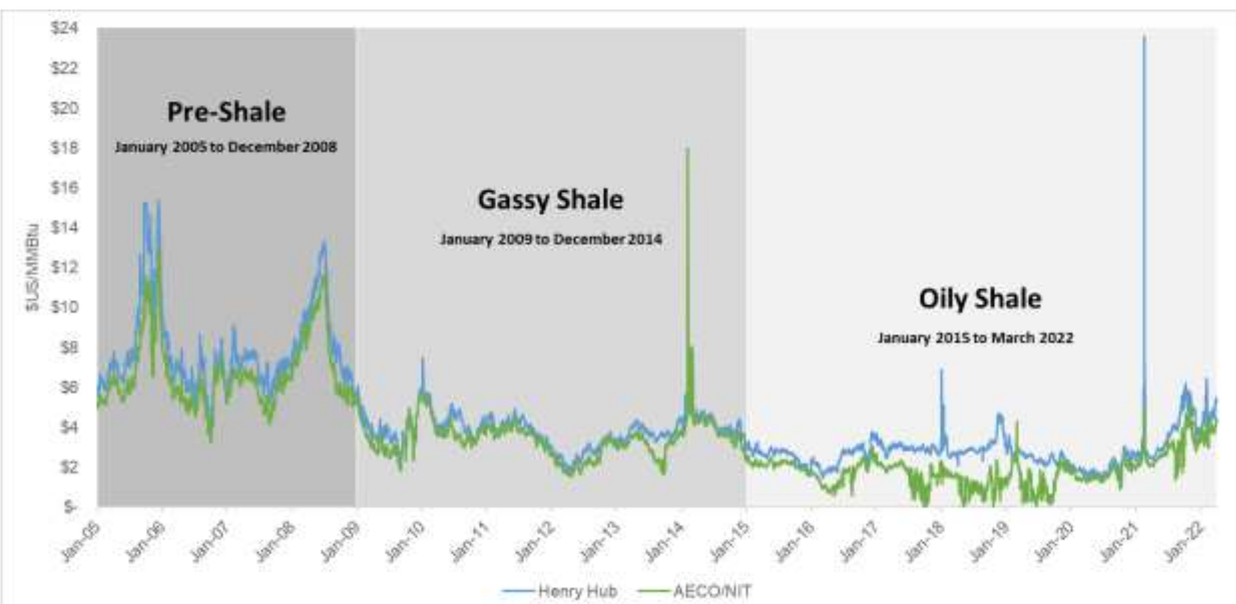
[1] The Canada Energy Regulator (CER) provides net-zero modelling for the first time in its "Evolving Policies" scenario, as part of its Canada's Energy Future 2021, released in December 2021. Additionally, IHS Markit provided a "Fast Transition" scenario as a pathway to net-zero carbon emissions in North America in May 2021.

Shale" era from January 2005 to December 2008 averaged $7.85 US/MMBtu[2] with market prices spiking over $12.00 US/MMBtu several times. During the "Gassy Shale" gas era from January 2009 to December 2014, Henry Hub had an average price of $3.84 US/MMBtu.

Currently, in the "Oily Shale" era from January 2015 to March 2022, Henry Hub prices have averaged $2.85 US/MMBtu. However, price volatility exists with price spikes above $23.00 US/MMBtu but also price dips below $2.00 US/MMBtu. The daily Henry Hub prices spiked to $23.45 US/MMBtu in February 2021 due to the Winter Storm Uri that affected much of the central part of the United States and disrupted energy systems, particularly in and around Texas. The daily Henry Hub prices dipped below $2.00 US/MMBtu for extended periods during the 2015/16 and 2019/20 winters, as well as the 2020 summer, this was due to an oversupply of gas and the global economic shutdown from the COVID-19 pandemic, respectively.

Recently, Henry Hub prices have become more interconnected with global markets, which has led to higher prices as well as increased pricing volatility; this is due to LNG exports helping to meet increased demand in tight global market conditions. Henry Hub prices have experienced greater connection to global markets beginning in 2021, as the insularity that once shielded North American prices from oversea turmoil disintegrates[3] due to LNG exports comprising a much larger portion of US demand. Natural gas demand also experienced a significant rebound in 2021, as the US and Canada began to recover from the economic downturn in 2020, and Henry Hub prices averaged $4.52 US/MMBtu for the 2021/22 winter (November 1 to March 31).

Figure D1-1: Henry Hub and AECO/NIT Historical Natural Gas Spot Prices[4]

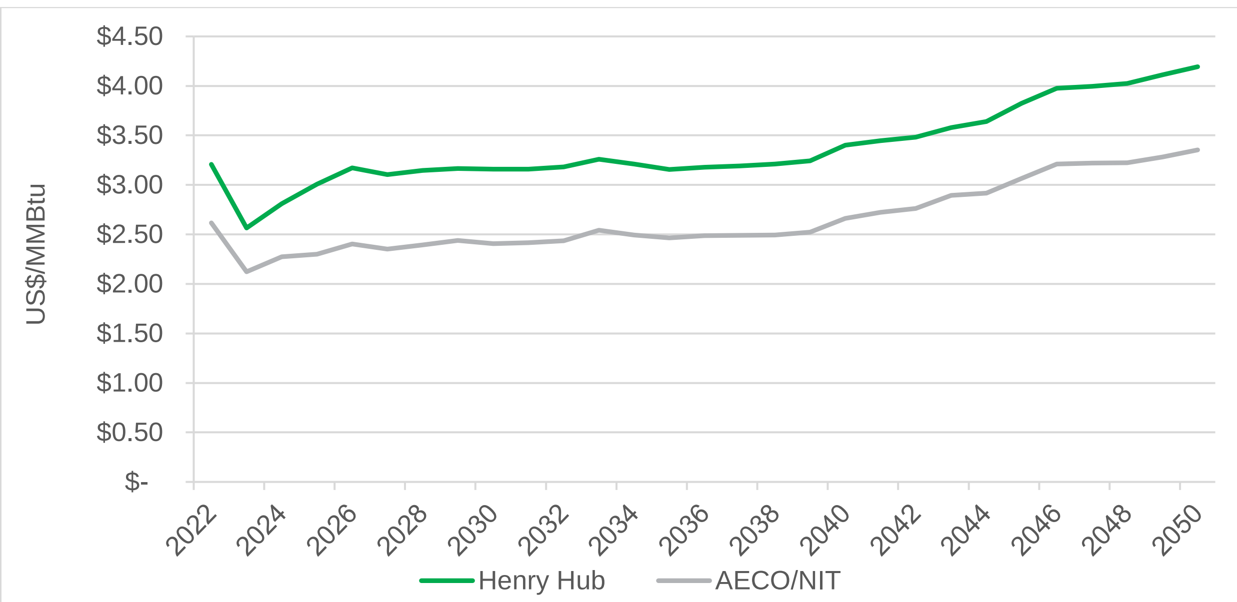


[2] MMBtu is defined as one million British Thermal Units.
[3] Bloomberg (January 2022). "U.S. Natural Gas Faces Wild 2022 as Foreign Crises Exert Pull."
[4] Platts. "Platts Gas Daily Market Fundamentals". https://www.platts.com/products/gas-daily.

As illustrated in Figure D1-1, AECO/NIT[5] prices trade at a discount to the Henry Hub price. This discount is driven primarily by the development of shale gas basins located much closer to key consuming markets in the US Northeast, such as the Marcellus and Utica shale gas plays. These basins do not face the costly transportation tolls that need to be paid by the more distant WCSB producers.

Figure D1-2 below shows IHS Markit's (S&P Global) long term natural gas price forecast, released in February 2022, for the Henry Hub and AECO/NIT markets in real 2021 dollars. In 2023, forecasted Henry Hub natural gas prices are expected to decrease due to increased production, however prices rebound the following year and remain flat over the long term, with prices above $3.00 US/MMBtu and steadily increasing from 2040 to 2050 to above $4.00 US/MMBtu. However, the forecasts do not include temporary price spikes or dips that can occur due to extreme weather events or other supply/demand imbalance events, as was shown in Figure D1-1. Additionally, this forecast was completed prior to the Russian invasion of Ukraine and thus does not include the impact of the current geopolitical climate and does not illustrate the current futures price market. IHS Markit has since noted[6] that they will be revising their outlooks to reflect "these new realities that we believe will endure over the next few years" which should be adjusted in their August 2022 long-term forecast.

Figure D1-2: Natural Gas Price Forecast (2021 Real Dollars)[7]



5 FEI procures most of its supply from the Station 2 and AECO/NIT supply hubs. After the TC Energy North Montney Mainline was placed into service in January 2020, Station 2 prices have strengthened relative to AECO/NIT and now typically trade at parity to AECO/NIT, and therefore only AECO/NIT is shown.

1.2.1 Natural Gas Price Competitiveness to Other Fuel Sources

After the shale gas revolution, North American natural gas became more economically attractive relative to other fuel sources as it was significantly disconnected from other competing fuels. Figure D1-3 sets out prices (historical prompt month and futures, on a $US/MMBtu equivalent basis)[8] for West Texas Intermediate (WTI) crude oil, Japanese Korean Marker (JKM) LNG, and National Balancing Point (NBP) UK gas that compete with North American natural gas. As the figure below shows, prices for JKM and NBP are over $20 US/MMBtu higher than the Henry Hub price, as prices began to rise after the beginning of the COVID-19 pandemic due to the re-balancing of global supply and demand and a global energy shortage. More recently, natural gas prices in Europe and LNG prices continue to surge due to the Russian invasion of Ukraine.

Figure D1-3: Competing Fuel Prices[9]

---

[8] Commodities futures are agreements to buy or sell a raw material at a specific date in the future at a particular price. Prompt-month prices refer to prices of the futures contract that is closest to expiration and is usually for delivery in the next calendar month; historical prompt-month data thus records the actual historical prices of these prompt-month contracts.

[9] US EIA & CME Group. (March 4, 2022).

1.3 NATURAL GAS SUPPLY

The North American natural gas market continues to be influenced by the abundance[10] of shale gas supply, which is a result of the rapid development of unconventional natural gas reserves. The rapid increase in domestic supply was enabled by efficient drilling technologies and associated gas from oil and natural gas liquid plays. Significant improvements have been made to two essential technologies, horizontal drilling and hydraulic fracturing, that are used to unlock natural gas trapped in shale formations. The use of horizontal drilling and hydraulic fracturing is critical for accessing the natural gas potential of North America's shale basins and to maintain production growth in the next decade.

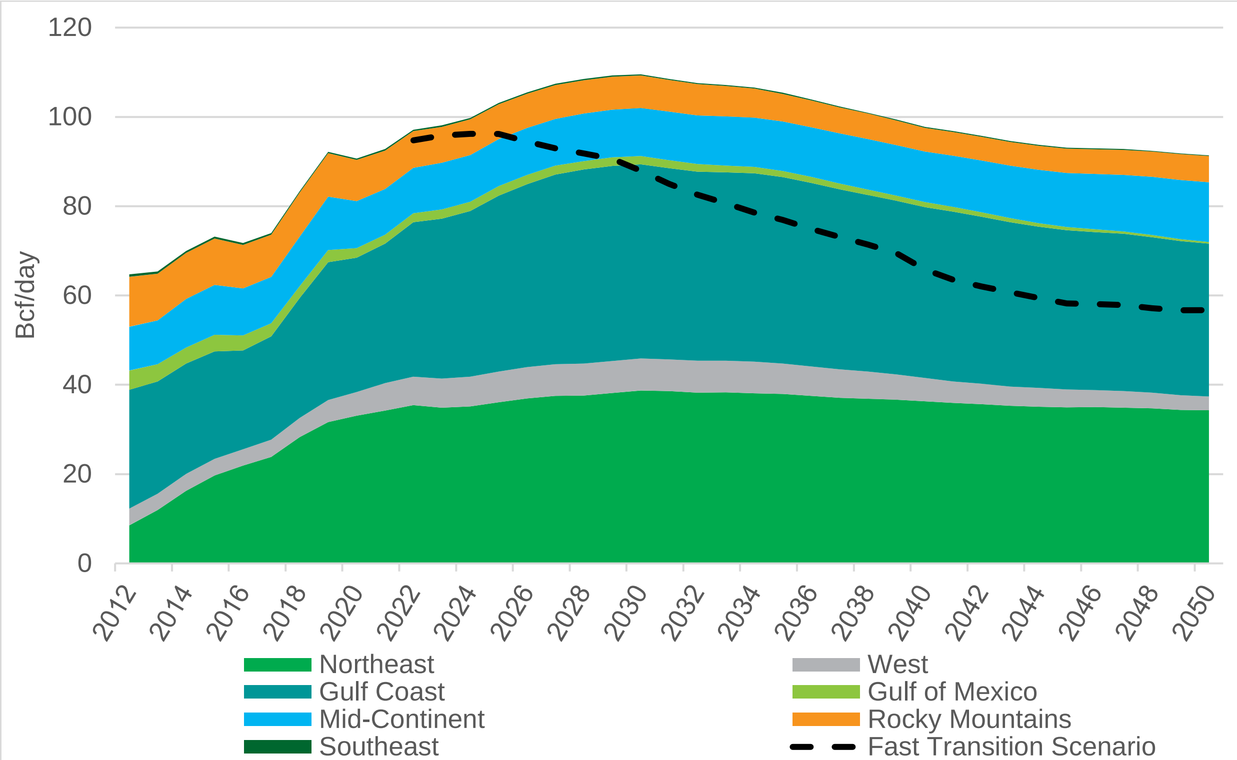
1.3.1 US Supply Forecast

In the US, supply growth will be driven by the low cost shale formations in the US Northeast, specifically the Marcellus and Utica basins, and the Gulf Coast, which includes the Permian basin. Figure D1-4 provides IHS Markit's latest long term supply forecast from February 2022, based on current or known policies, and shows production growing through 2030 then beginning to lower due to declining demand and increased solar and wind resources. In 2021, gas production within the US was 93 Bcf/day, which is 19 Bcf/day or 25 percent higher than production in 2017.

The figure below also provides what natural gas supply could be in a "fast transition" scenario with additional policies restricting production growth in a pathway to achieve economy wide carbon net neutrality by 2050 in the US.

[10] Gas market analysts currently predict that North America holds around 100 years of recoverable supply, based on current consumption levels. The total amount of supply is estimated at 2,926 trillion cubic feet (Tcf), compared to US dry gas production of 30 Tcf in 2020. https://www.eia.gov/tools/faqs/faq.php?id=58&t=8

Figure D1-4: US Natural Gas Production[11]



1.3.2 Regional Supply Forecast

The majority of Canada's natural gas supply originates within the Montney formation, located in the northwest of the Western Canadian Sedimentary Basin. The natural gas potential in the Montney shale formation is one of the largest and lowest cost upstream resources in North America, and is forecast to continue to be the significant driver of growth in Canadian natural gas production. This is illustrated through Figure D1-5 below, which is based on the CER's projected production growth in Canada based on current policies.

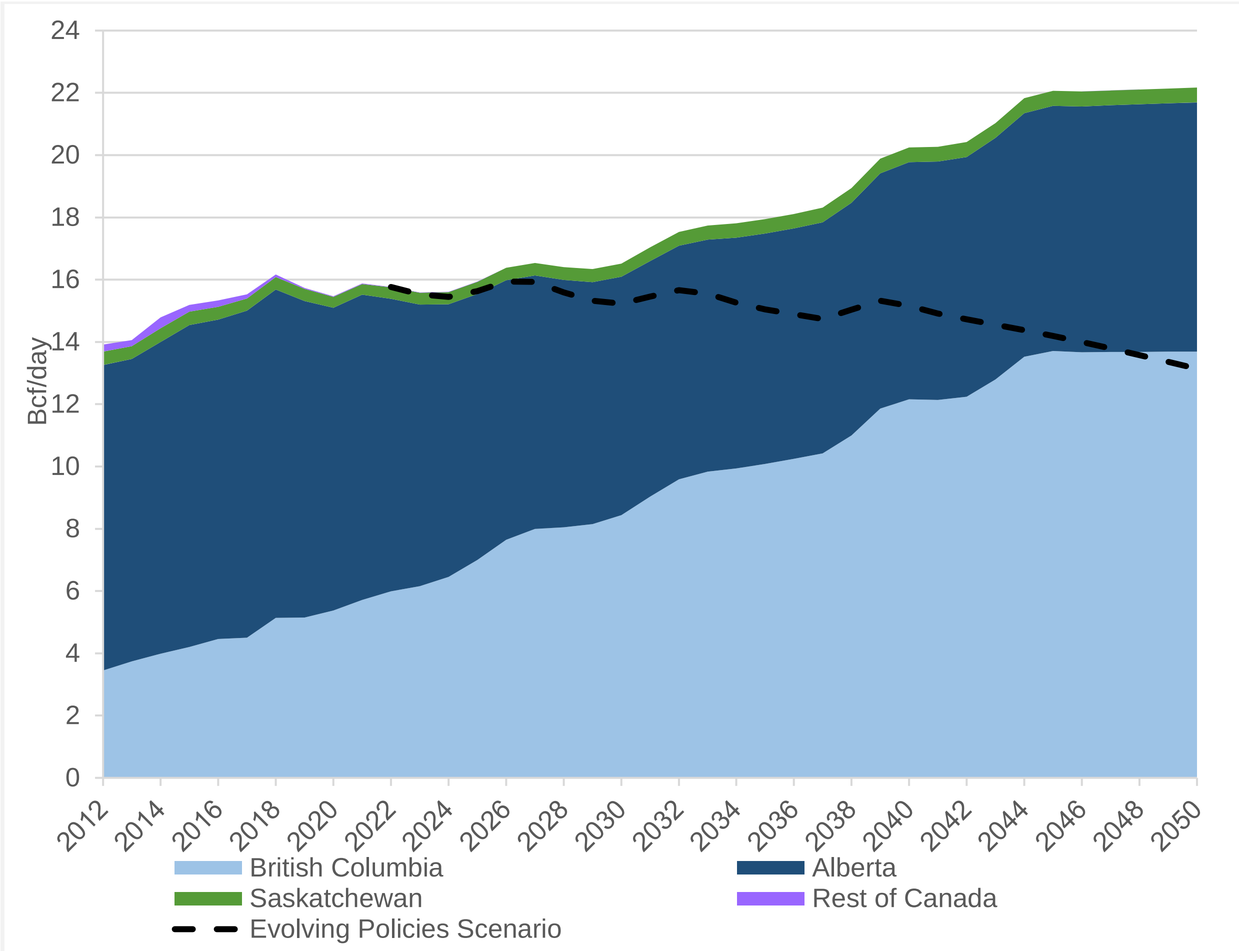
In 2021, gas production within BC was approximately 5.7 Bcf/day, which is 27 percent higher than the production in 2017. The CER expects this trend to continue, as illustrated in the figure above, as BC, and specifically the Montney basin, is expected to grow through 2040. Additionally, the CER expects that BC will surpass Alberta as Canada's biggest natural gas producing province, which is driven largely by LNG exports.

The below figure also provides what natural gas supply could be in the CER's "evolving policies" scenario, which is based on strengthening or expanding existing global and domestic policies to reduce GHG emissions. Notably, even under the "evolving policies" scenario, natural gas

[11] Source: © 2022 S&P Global. All rights reserved. The use of this content was authorized in advance. Any further use or redistribution of this content is strictly prohibited without prior written permission by S&P Global.

production remains near current levels for the next two decades, largely due to LNG export growth in BC.

Figure D1-5: Marketable Natural Gas Production by Province[12]



1.4 GAS DEMAND

The majority of demand growth in recent years has been from LNG exports, exports to Mexico, power demand, as well as industrial demand, specifically from the petrochemical sector. The market is also seeing increased natural gas demand from the power sector due to more switching from coal to natural gas electricity production, as well as from the retirement of coal plants. Furthermore, new incremental demand from US LNG being exported overseas will continue to drive the majority of the long-term demand growth. Lastly, the below subsections provide IHS Markit's gas demand forecast, this demand could be met in the future through a combination of natural gas and renewable gas, which includes RNG, biomethane, and other low carbon gas such

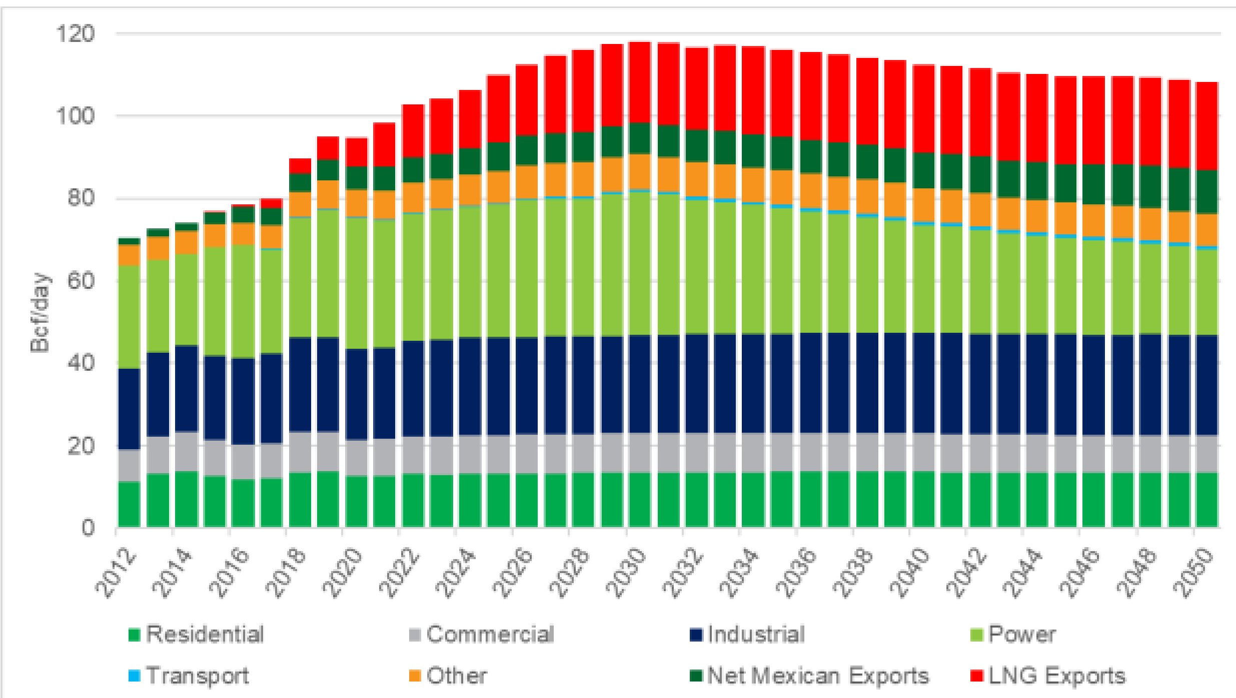
[12] CER (December 2021). "Canada's Energy Future 2021."

as hydrogen; however, demand will be also challenged with carbon policy initiatives and electrification across North America.

1.4.1 US Gas Demand

In the US, IHS Markit's latest long term outlook from February 2022 forecasts gas demand to peak in 2030 and decline thereafter to 2050, however, demand would still be higher compared to current levels with gas demand for LNG exports being the largest contributor to US demand. Figure D1-6 shows slight growth in power demand until 2030, and then a decline due to increasing renewables and battery storage. The development of the LNG export sector is expected to increase by 13 Bcf/day above current levels by 2040. In total, IHS Markit currently forecasts the US gas market will grow by 7 percent or about 6 Bcf/day above current levels by 2050.

Figure D1-6: US Gas Demand[13]

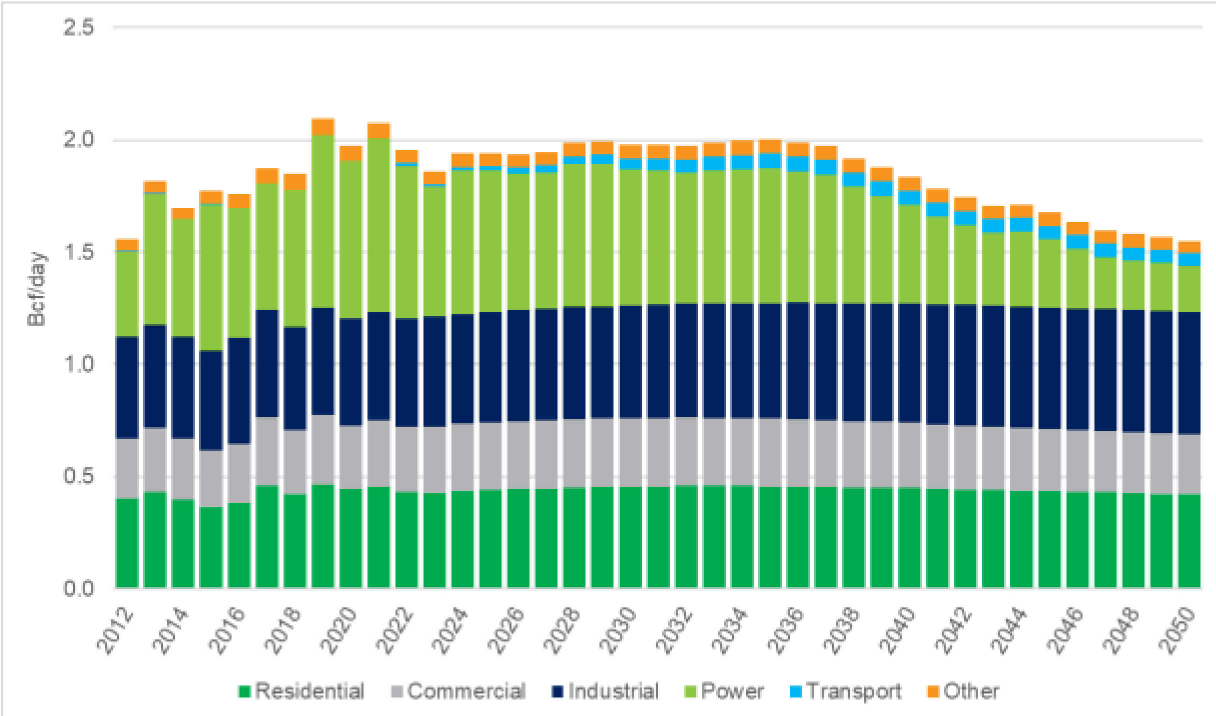


1.4.1.1 US Pacific Northwest (US PNW) Demand

In the US PNW, which is comprised of Washington, Oregon, and Idaho, IHS Markit expects regional demand to remain around approximately 2 Bcf/day until the late 2030's, as shown in Figure D1-7 below. In 2021, demand was 2.1 Bcf/day, which is 11 percent higher than in 2017 due to the power sector increasing its use of natural-gas fired generation, specifically through gas-fired plants along the I-5 corridor.

[13] Source: © 2022 S&P Global. All rights reserved. The use of this content was authorized in advance. Any further use or redistribution of this content is strictly prohibited without prior written permission by S&P Global.

Figure D1-7: US Pacific Northwest Gas Demand[14]



The natural gas and power sectors are becoming increasingly interconnected in the PNW and California, especially as more coal-fired power generation plants retire. This development has resulted in increased demand for natural gas-fired power generation, in a region that is already constrained during the winter, which can cause pricing volatility at Sumas/Huntingdon depending on certain market conditions. The historical price volatility at the Sumas market hub, and forward prices for the next three years, was illustrated in Section 6 (Figure 6-4 and Figure 6-5), of the 2022 LTGRP.

In the region, government policies and renewable portfolio standards to reduce GHG emissions to meet state environmental objectives and targets have replaced the loss of coal-fired power generation with natural gas-fired generation and renewable resources. However, in peak periods when the renewable resource supply in the US PNW cannot meet demand, natural gas-fired power plants are relied upon as the marginal resource to balance the region's electricity supply. Further, even when the renewable resources are available, these plants may still consume natural gas, and export electricity to other states, specifically California.

This dynamic is expected to continue for at least the next five to ten years,[15] until the PNW region can build out adequate amounts of renewable resources and battery storage to relieve the increased annual dependence on natural gas as the balancing resource for the power utilities.

[14] Source: © 2022 S&P Global. All rights reserved. The use of this content was authorized in advance. Any further use or redistribution of this content is strictly prohibited without prior written permission by S&P Global.

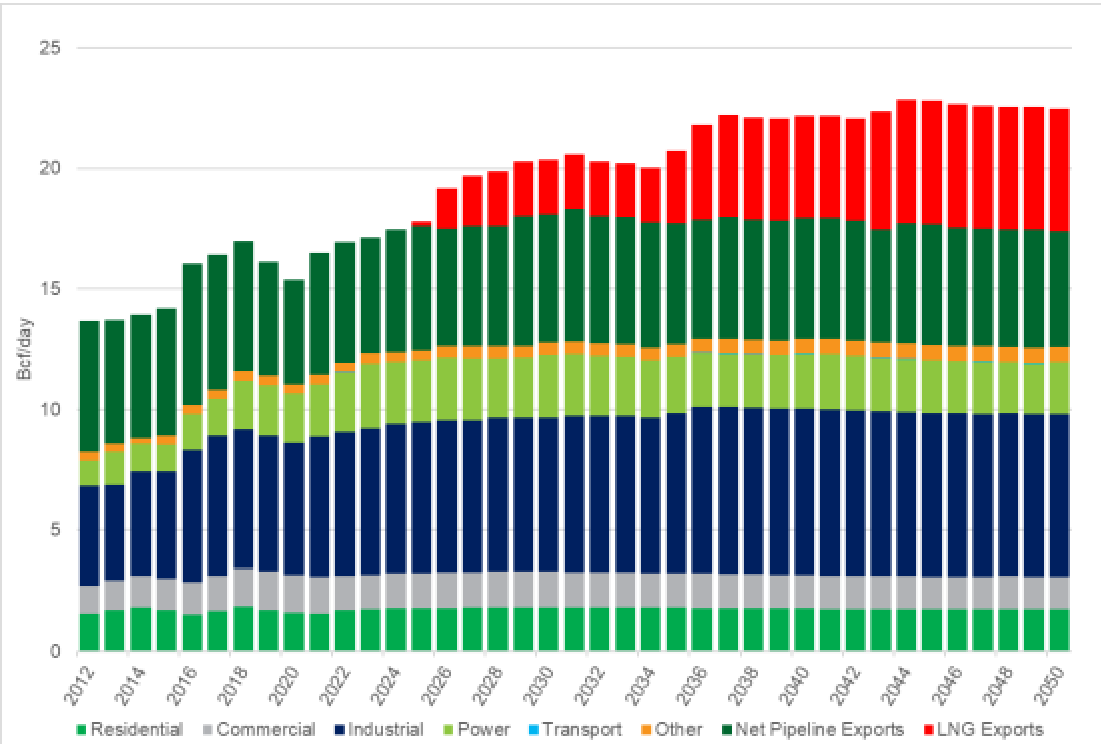
[15] This risk could continue even further than ten years, as electric utilities continue to need firm peaking reliable resources for ramping demand conditions.

However, reliance on natural gas as the marginal resource is expected to continue[16] as it is reliable and provides flexible generation during extreme weather events. This will continue to put a strain on peaking resources and peak winter demand, enhancing price volatility and the connection to power markets.

1.4.2 Canada Demand

Overall in Canada, demand in 2021 was approximately 16.5 Bcf/day, which is identical to the demand in 2017, as shown in Figure D1-8 below. Demand is expected to grow through 2050, largely driven by LNG exports increasing to 5.1 Bcf/day.

Figure D1-8: Canada Gas Demand[17]



A number of LNG export liquefaction terminals had been proposed on the west coast of BC, as well as large diameter pipelines to transport natural gas from new production basins in northeast BC to these terminals. The main driver of these projects had been the desire to take advantage of the historically lower North American natural gas prices compared to Asian natural gas prices. Moreover, Asian markets are seeking to diversify their sources of supply and are attracted by the political stability and mature market structure for accessing natural gas that Canada offers.

16 North American Electric Reliability Corporation (December 2021). "2021 Long-Term Reliability Assessment." https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2021.pdf

17 Source: © 2022 S&P Global. All rights reserved. The use of this content was authorized in advance. Any further use or redistribution of this content is strictly prohibited without prior written permission by S&P Global.

While the vast majority of these projects were able to receive their export licences from the NEB (now the CER), further development stalled soon after due to market conditions that included the substantial fall in oil prices in 2016, and the glut of LNG supply in 2017 that lead to a significant decline in global LNG prices. Not only did the projects have to deal with these challenging market conditions, they also faced ongoing considerable environmental and regulatory hurdles in BC. These factors caused many developers to cancel their LNG projects in BC; however, FEI continues to monitor the development of LNG export projects in BC, including two that remain active on the west coast of BC, LNG Canada and Woodfibre LNG, which are included in IHS Markit's forecast in Figure D1-8.

LNG Canada is a joint venture company comprised of five global energy companies (Shell, PetroChina, KOGAS, Mitsubishi Corporation, and PETRONAS). Construction on Phase One of LNG Canada (6.5 million tonnes per annum, or 1.8 Bcf/day) began in 2019, and is expected in service no earlier than 2025. LNG Canada is also considering the development of two additional trains that would double the output of LNG. FEI believes that the LNG Canada project may not have a significant impact on security of supply in the region, given that LNG Canada has contracted for the construction of a dedicated supply pipeline and that the majority of supply required by the project will come from proprietary production[18] by the project partners. FEI will continue to monitor the development of this project to ensure FEI retains access to gas supply at fair market prices.

Pacific Oil and Gas Limited, a Singapore based company, has formed a company called Woodfibre LNG Ltd. It is proposing to construct and operate a LNG export terminal, with a capacity of 2.1 million tonnes per annum (MTPA) (around 0.3 Bcf/day) located near Squamish. Development of the project has been ongoing, and Woodfibre LNG provided a Notice to Proceed and announced that pre-installation work is planned for 2022 with major construction beginning in 2023, and the facility in service in 2027. FEI will provide natural gas transportation service for the supply required by the facility, and will need to expand its existing system, which includes pipeline looping and adding compression[19].

Woodfibre LNG has already secured firm transportation capacity on Westcoast's T-South system for a significant portion of their demand requirements. Currently, that capacity is being used to serve existing market demand, and as discussed in Section 6.2.4.2, the regional gas supply infrastructure is already constrained during the critical winter heating season. Should Woodfibre LNG become operational, the supply available for customers in the Lower Mainland and along the I-5 Corridor would be reduced, which could cause more pricing volatility at the Huntingdon marketplace.

[18] The CER assumes in Canada's Energy Future 2020 that "75 percent of LNG feedstock will come from natural gas production dedicated to supplying LNG facilities".
[19] FortisBC: "Talking Energy." https://talkingenergy.ca/project/eagle-mountain-woodfibre-gas-pipeline-project

1.5 CONCLUSION

This Appendix first provided an overview of North American natural gas market prices, supply, and then discussed demand in the PNW region. The “evolving policies” and “fast transition” scenarios illustrate the uncertainty in conventional natural gas supply and demand in North America, and provides scenarios as additional policies are implemented over time.

Demand in BC is expected to increase through LNG export projects, including those that could be developed in the Lower Mainland, such Woodfibre LNG. Meeting the needs of such projects that require daily baseload gas volume can only be fulfilled by adding new pipeline capacity rather than other resources, such as storage. The development of new pipeline systems will only proceed if other parties are prepared to financially underpin any expansion.

All parties will need to work collaboratively in order to develop solutions that serve the interest of everyone concerned at large, ranging from project developers, pipeline companies, gas producers, Indigenous groups and local stakeholders, in order to ensure the successful advancement of large scale projects in the BC and PNW natural gas marketplace.

EXECUTIVE SUMMARY

Report Overview and Objectives

B.C. is a major producer and supplier of natural gas and the Government of B.C. is trying to decarbonize natural gas use and usher in the clean energy transition. Renewable and low-carbon gases can be used to decarbonise many sectors that are difficult to electrify, create new economic opportunities, and serve as tools to enable the transition towards a resilient, affordable, and low-emission energy system. BC Bioenergy Network (BCBN), the Government of B.C. and FortisBC commissioned this report to estimate the technical supply potential and production costs of renewable and low-carbon gases in B.C., Canada and the United States. This study uses the best information available to inform the supply outlook for renewable and low-carbon gases in B.C. The analysis, conclusions and recommendations in this report are those of the report authors, and do not necessary reflect the views of the report's sponsors.

Background and Objective

The Province of British Columbia (B.C.) has set ambitious greenhouse gas emission reduction targets, including becoming a net-zero jurisdiction by 2050. The CleanBC *Roadmap to 2030* (the Roadmap) includes plans to establish a greenhouse gas (GHG) emissions cap for natural gas utilities.[1] It would require natural gas utilities to reduce the carbon emissions related to their gas sales to approximately 6 Mt of CO_2e per year by 2030. It is anticipated that this cap will, in part, drive the production and acquisition of renewable gases as a key measure to displace fossil natural gas. The Roadmap also expands on an earlier commitment to a minimum of 15% (energy-based) renewable content retailed annually through the natural gas distribution system by 2030. The GHG Reduction Standard proposed in the CleanBC *Roadmap* will likely require an even higher percentage of renewable gas by 2030.

Additional regulatory action has been taken to kick-start the production and use of clean and renewable gases in B.C.'s natural gas distribution system. In 2021, the Province of B.C. amended the Greenhouse Gas Reduction Regulation (GGRR) in part to widen the scope of fuels gas utilities may use to reduce GHG emissions. The GGRR incentivises the production and utility purchase of low-carbon natural gas substitutes, including hydrogen, renewable natural gas (RNG), synthesis gas (syngas), and lignin. The cost of these clean resources will be recovered from the utilities' ratepayers.

The purpose of the report was to quantify the supply potential of renewable and low-carbon gases that could be used to lower overall GHG emissions from B.C. gas use. The study did not consider alternative options, such as switching natural gas heating to wood pellets, heat pumps, or increased energy efficiency.

This report examines four pathways to transition from fossil natural gas:

1. The production of hydrogen or methane from either renewable electricity or wood (pipeline injection).
2. The production of hydrogen from natural gas combined with carbon capture and sequestration or as a by-product of carbon black production, or the use of waste hydrogen (pipeline injection).
3. The production of syngas from wood to displace natural gas used in lime kilns at pulp mills.
4. The production of lignin from black liquor to displace natural gas used in lime kilns at pulp mills.

Technologies/Pathways

The report describes various technologies and resources used to produce the above types of low-carbon gas. Each technology relies on a supply chain, e.g., feedstock production or collection, pre-treatment, and

[1] The report was written based on the 2018 renewable gas commitment rather than the emission cap announced in the Roadmap.

gas processing. Gases injected into the pipeline system also require gas conditioning and compression. The resulting combination of processes is called a 'pathway'. Pathways can be grouped by the energy resource they rely on. Three main resources have been considered for a total of twelve pathways:

- **Organic waste:** Production of methane by fermenting of organics. These include agricultural waste, municipal organics, human waste collected at wastewater treatment plants, and gas generated in landfills.
- **Woody biomass:** Production of wood gas, also called syngas, through thermochemical means, such as gasification. Syngas may then be used as a gas at the point of production or upgraded to pure hydrogen or methane for pipeline injection.
- **Non-biomass resources:** Production of hydrogen via electrolysis or using fossil natural gas, including blue and turquoise hydrogen produced from fossil natural gas and green hydrogen produced from (green) electricity. The latter is commonly termed 'green hydrogen' as it can be produced from 'green' (renewable) electricity.

For each of these three groups, four specific pathways are described in Table 6. Lignin extracted from black liquor in kraft pulp mills is another wood-based resource. It can be used as a fuel in lime kilns but is technically more challenging and more expensive than using syngas from wood gasification. The value of lignin as a feedstock for non-energy application can also be expected to rise above the value as an energy source.

Table 1 Pathways for low carbon gas considered in this report

Organic Residue* (Anaerobic treatment)	Woody Biomass (Thermochemical pathways)	Non-Biomass Resources (Electrolysis and SMR)
Agricultural RNG: Digestion and gas conditioning using agricultural waste.	Syngas: Wood gasification to produce a gas used in lime kilns of kraft pulp mills.	Green hydrogen: Electrolytic production of hydrogen from water and clean electricity.
Municipal RNG: Digestion of source-separated organics (green bin) and industrial food waste.	Hydrogen from syngas: Syngas processed with water-shift reaction.	Blue hydrogen: Steam methane reforming of fossil methane with CO_2 capture and storage.
RNG from wastewater treatment plants: Digestion of water treatment sludge to produce RNG.	Methane from syngas: Syngas processed with water-shift and methanation step.	Turquoise hydrogen: 'Pyrolysis' of fossil methane, producing carbon black and hydrogen.
Landfill gas: Gas captured at landfills and conditioned to produce RNG.	Lignin as a replacement for natural gas in the pulp industry: Lignin extracted from black liquor to produce a dry lignin fuel.	Waste hydrogen: Hydrogen produced as a by-product in industrial processes.

* In reality, some of these feedstock types can be combined at any given plant; a strict separation is not possible but is used in the report to derive estimates for the potential of each waste type

Scenarios and Cost Curves

Potential by 2030 and 2050

The potential for producing renewable and low-carbon gases differs between the pathways, mainly due to the underlying resources available in B.C. The report compares and combines existing analyses to develop a comprehensive overview of resources available by 2030 and 2050.

The resource potential represents the theoretical availability of various biomass feedstock types, electricity, and fossil natural gas to produce renewable and low-carbon gases. The technical potential constrains the resource potential as it estimates the capacity for each pathway after accounting for geographic limitations, transport constraints, conversion efficiency and various system assumptions. This also includes technological readiness and realistically achievable implementation rates. The resulting potentials in the Maximum and Minimum scenarios for each pathway are further lowered as they consider timelines, harvesting practices and different outcomes with respect to resource availability and the speed of deployment. They represent the upper and lower bounds of renewable and low-carbon gas supply potential that can likely be achieved in B.C. by 2030 and by 2050, as shown in Figure 4. Some economic constraints, such as competing uses, price, or market developments, have not been considered in the estimation of these bounds.

The 2030 scenarios assume lower gas production levels than for 2050 as there are development cycles, learning curves and build-out rates for new or emerging technologies. More mature and lower-cost projects will likely be developed first. Most renewable and low-carbon gas production by 2030 lies with anaerobically produced RNG pathways (around 6 petajoules) and blue and turquoise hydrogen. The scenarios suggest that the 2018 CleanBC target of 15% renewable content in the natural gas system by 2030 cannot be met using provincial renewable resources alone. By 2050, blue and turquoise hydrogen make up most of the potential but wood-based pathways also represent a large share of the technical potential.

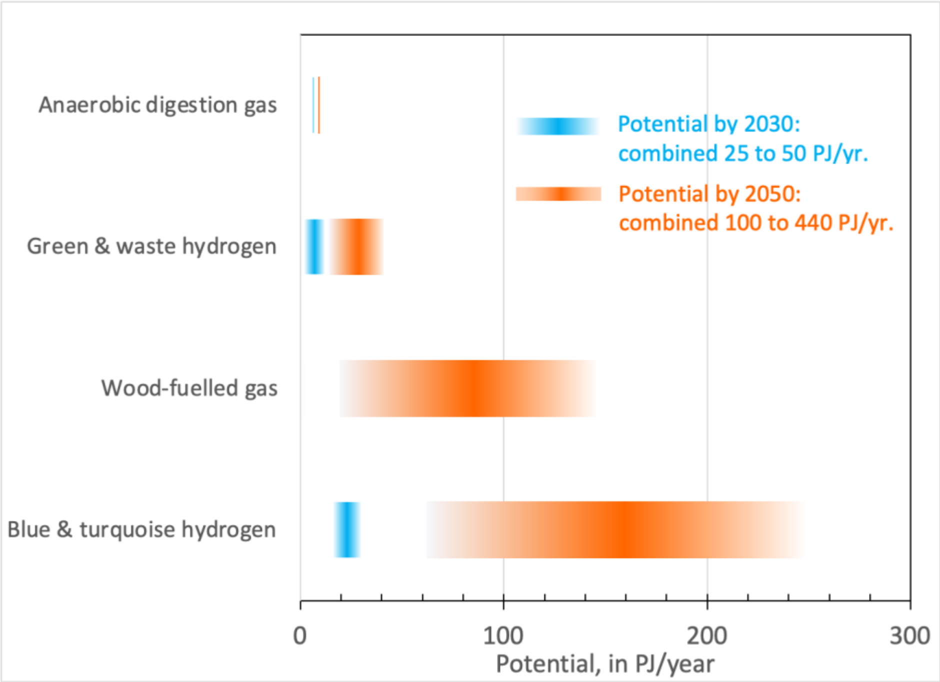

Figure 1 Minimum and Maximum Renewable and Low-Carbon Gas Production Scenarios for B.C. for 2030 and for 2050

Figure 4 shows:

1. By 2050, between 104 (Minimum) and 444 (Maximum) petajoules of renewable and low-carbon can be produced with in-province resources, i.e. between half and twice B.C.'s current natural gas use. Renewable gases alone could amount to produce between 42 and 195 petajoules annually, roughly a quarter to all of the natural gas currently retailed in B.C.
2. By 2030, between 25 (Minimum) and 50 (Maximum) petajoules can be produced with in-province resources; of the Maximum, only about 19 petajoules would be renewable gases.
3. Between 2030 and 2050, supply expands significantly in the Maximum scenario because the industry is built up quickly, and additional resources become available, such as new on-grid wind power, wood residue currently used for producing power or pellets, and the establishment of large-scale blue and turquoise hydrogen production.
4. Blue and turquoise hydrogen offer the highest technical potential. Renewable gases account for almost half of the gases produced by 2050. B.C. could replace almost all its current fossil natural gas use with renewable gas, mainly from woody feedstock.
5. Among renewable sources (as defined under the GGRR), wood-based pathways have the highest potential for renewable gas production under optimistic assumptions with respect to resource availability.
6. Traditional RNG from anaerobic digestion or biogas has lower potential (~10 petajoules by 2050). Other pathways will be crucial to achieve substantial decarbonization of the natural gas system.
7. Even with Site C being developed and the addition of 1,300 MW of new on-grid wind power, the availability of surplus electricity constrains the potential for producing green hydrogen in B.C. to about 27 petajoules by 2050 (40 petajoules when including off-grid production with wind power).

Cost curves

Each low-carbon gas has costs associated that are specific to the resource, technology, production process and various other parameters. The relation between potential and cost is illustrated in a cost curve (**Figure 3** below). The (horizontal) x-axis indicates the potential in petajoules of gas produced per year and the (vertical) y-axis indicates the production cost for each pathway, in 2021 Canadian dollars. The lowest-cost pathway is shown on the left, with the cost of respective pathways increasing to the right. Costs are determined by assumptions of initial capital expenditure, operational costs, including electricity and gas costs, and the cost of woody feedstock, where applicable.

The cumulative production potential increases as options with higher production costs are considered, resulting in a stepped graph. Eventually, costs surpass the $31 per gigajoule price limit[2] for natural gas utility acquisitions under the GGRR. The economic potential under the current regulatory framework is limited to the area outlined by a dashed black line.

Figure 2 and **Figure 3** shows that green hydrogen is expected to remain more costly than the $31 threshold (in 2021). By 2050, gases from (waste) woody biomass is projected to be available at a cost comparable to that of blue hydrogen. Production costs are estimated as sector averages; the body of the report provides more detailed cost curves for each pathway. The Maximum scenario represents an upper bound that would require very strong policies to achieve. It is unlikely that this scenario will come to pass but rather, that renewable and low-carbon gas production in B.C. will fall in-between the Minimum (104 petajoules) and Maximum (444 petajoules) scenarios by 2050. The scenarios are further elaborated in the body of the report.

[2] The threshold is indexed with inflation, so increases over time in nominal, but remains constant in 2021 dollars.

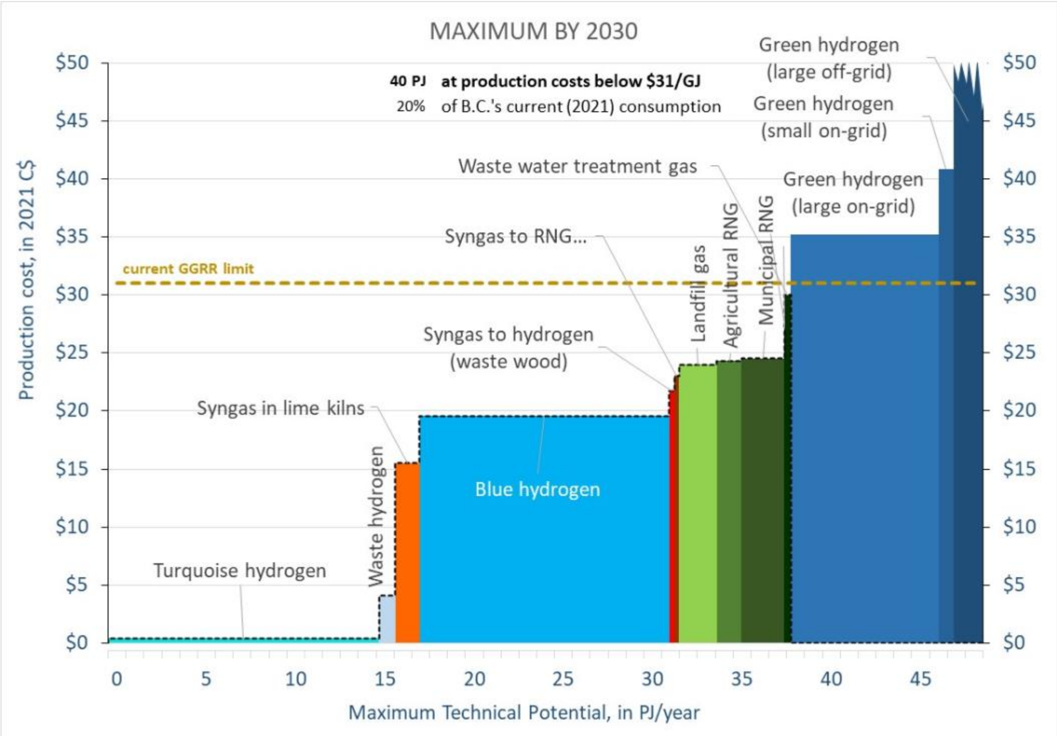

Figure 2 Production Cost and Technical Potential in the Maximum Scenario by 2030. Market prices may be higher than costs.

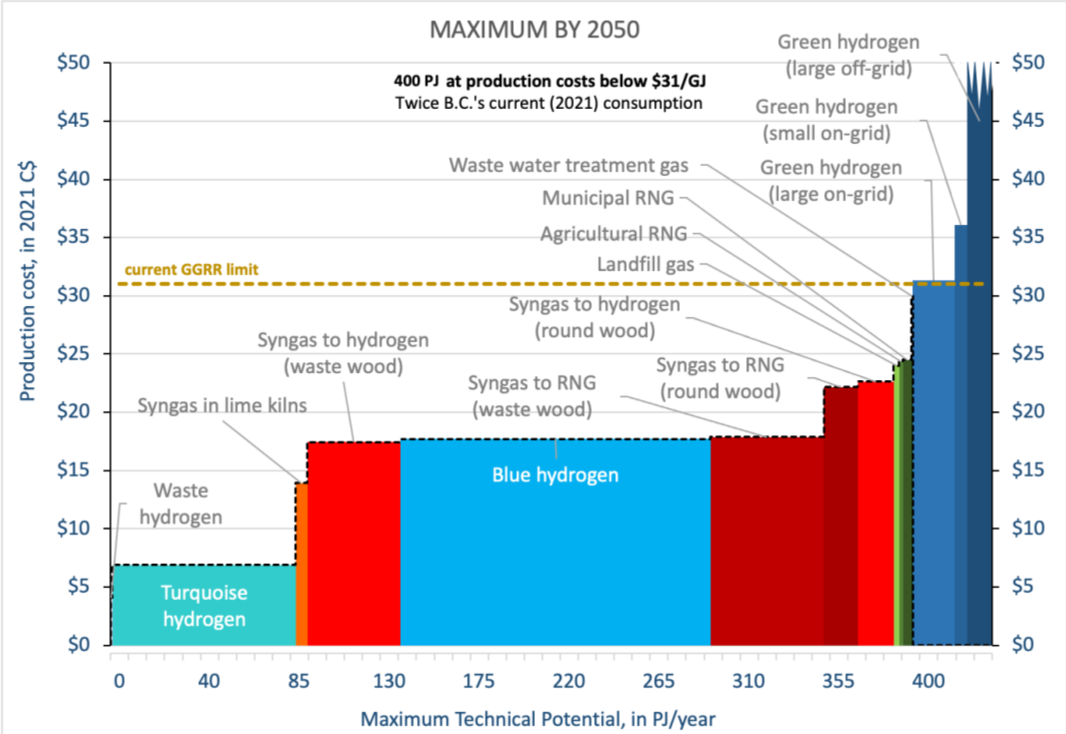

***Note*: For better readability, the scale of the x-axis (potential in PJ/year) is different for each graph**

Figure 3 Production Cost and Technical Potential in the Maximum Scenario by 2050. Market prices may be higher than costs.

Key Considerations

Cost Limits

In 2017, the Government of B.C. established the GGRR to require all natural gas utilities to purchase renewable natural gas up to a limit of 5% of their 2015 natural gas sales volumes, at a maximum price of $30 per gigajoule. In 2021, the regulation was further amended to:

- expand the volume limit to 15% of the utility's 2019 fossil natural gas sales;
- expand the range of resources that qualify under the initiative (i.e., to add green hydrogen, lignin, and syngas) and
- enable the maximum price to escalate each year with inflation (e.g., to $31 in 2021).

For a natural gas public utility to exceed these limits, and still recover the costs from their ratepayers, prior BC Utilities Commission approval would have to be obtained. The achievable economic potential would increase if natural gas utilities were enabled to pay higher prices for low-carbon gas. This would likely occur if the current renewable gas target were replaced with a carbon intensity target. Alternatively, the price limit could be defined as an average price, allowing for a mix of low and high-cost gas production.

Imports

Existing regulations allow gas utilities to acquire RNG from outside of B.C. Technically, there is enough potential in the rest of Canada to meet the 2030 target and when including the U.S., to replace all of B.C.'s retailed fossil natural gas by 2050. There is a trade-off between potentially lower costs for ratepayers when using out-of-province resources and socio-economic benefits when developing projects inside B.C.

Purchasing low-carbon and renewable gases outside of B.C. at low costs can hedge against higher gas costs while offering the option to sell any surplus gas later if sufficient gas can be sourced inside B.C. This could lower the cost for B.C. ratepayers but may at the same time reduce the impetus to develop projects inside B.C.

On the other hand, B.C. public natural gas utilities are unlikely to secure as much of this gas as they wish to due to competition. In the U.S., several jurisdictions have implemented renewable gas policies and have created lucrative markets for RNG certificates. Quebec has also enacted a RNG mandate. To take advantage of low-cost renewable gas supply from outside of the province, utilities will need to move quickly as competition for low-cost and low-carbon and renewable gas is likely to intensify.

GHG Reduction and Emissions

The technical potential established in this report is based on petajoules of renewable and low-carbon gas rather than tonnes of CO_2e displaced. A policy based on carbon abatement or carbon intensity of pipeline gas would have to look at a different metric to measure compliance.

Natural gas has a reported burner tip carbon intensity of 50 grams CO_2e per megajoule.[3] Another 6-12 grams need to be added for upstream emissions in B.C., according to current knowledge. The carbon intensities of renewable and low-carbon gases discussed in this report range from about 3 grams (wind-powered green hydrogen) to around 22 grams (blue hydrogen). Agricultural RNG can have negative carbon intensities due to avoided methane emissions.

The carbon intensity can vary significantly from one pathway to another, or even between projects within the same pathways. Some scientific sources claim that the additional energy needed to produce blue and turquoise hydrogen and the sequestration or conversion of carbon dioxide may result in higher carbon

[3] B.C. Best Practices Methodology for Quantifying Greenhouse Gas Emissions, 2020. B.C. Ministry of Environment and Climate Change Strategy, Victoria, B.C., April 2021

intensity than fossil natural gas itself, especially when taking into account fugitive emissions related to hydraulic fracturing. The CleanBC *Roadmap to 2030* includes measures to regulate and reduce upstream emissions from natural gas production.

Building the Renewable and Low-Carbon Gas Industry in B.C.

The cost of building a renewable and low-carbon gas production sector to replace fossil gas use in B.C. could range between $5 billion and $20 billion for the 2050 Minimum and Maximum scenario, respectively. This is the same order of magnitude as recent foreign investments in the Kitimat liquified natural gas terminal and will take place over more than two decades. The critical next step is for governments, indigenous communities, utilities, and other industry participants to work collectively on policies and investments that will unlock and enable this potential. The report discusses several policy instruments to attract the required investment. These include R&D and demonstration support, policies favouring gas production inside B.C., the monetisation of social and environmental co-benefits, and low-interest financing and joint ventures between gas utilities and industry.

Conclusions

The Province of B.C. is rich in natural resources, including a resilient electrical system built almost exclusively on hydropower, vast lands covered by forest, and a prosperous agricultural sector. This suggests that renewable and low-carbon gases can play the prominent role that CleanBC has assigned them.

1. The potential supply of renewable and low-carbon gases combined is sufficient to reach CleanBC’s 15% target by 2030. The anticipated build-out rate of renewable gas production by 2030 will likely require either renewable gas imports from neighbouring jurisdictions and/or the use of low-carbon gas, such as blue or turquoise hydrogen, to reach the 15% target.
2. Provincially sourced renewable gases can displace 195 of the 200 PJ of natural gas by 2050 assuming, among other things, that the available agricultural, solid waste and forest residual feedstocks are used for this purpose.
3. Blue and turquoise hydrogen offer the highest technical potential, pending advancements in innovation and scaling-up.
4. Among renewable sources, i.e. excluding blue and turquoise hydrogen, wood-based pathways have the highest potential for renewable gas production under optimistic assumptions with respect to resource availability. These pathways still require research and demonstration to achieve the technical readiness required for a large roll-out.
5. Mature technologies such as anaerobic digestion can contribute most in the early stages of converting B.C.’s gas sector to renewable gas. Other pathways will be crucial to achieve substantial decarbonization of the natural gas system.
6. Based on the foreseeable cost of green electricity the production cost of green hydrogen is anticipated to be greater than $31 per gigajoule in the 2030 and 2050 scenarios. Green hydrogen production requires the installation of significant infrastructure such as wind turbines and related electrical transmission. The maximum potential to produce green hydrogen at a cost below $31 per gigajoule is 27 petajoules per year by 2050, even with the development of Site C hydroelectric dam and new wind-power generation.
7. Investment of up to $20 billion may be required to facilitate the transition from natural gas to renewable and low-carbon gases by 2050. This investment is comparable to other investments in

energy in B.C., such as LNG Canada, a $40 billion terminal for the liquefaction, storage, and loading of LNG in the port of Kitimat, B.C.

8. The price limit of $31 per gigajoule set by the GGRR will likely capture most of the technical potential in B.C. Yet, offering this gas price may not be sufficient to build this industry. B.C. will need a stronger regulatory framework conducive to significant investment in renewable and low-carbon gas production. Like in the renewable electricity sector, efforts will need to focus on providing stable investment climates, moderating risks, and providing adequate returns.
9. Importing RNG from outside B.C. can hedge against future high costs to keep BC's industry competitive and protect ratepayers but may diminish the overall investment in the renewable and low-carbon gas sector within B.C.
10. National and international competition for RNG will increase further with time. California's Low-Carbon Fuel Standard (LCFS) market provides higher financial gains than B.C.'s. While B.C. could import RNG there is also a risk that some renewable and low-carbon production will be exported from the province.

TABLE OF CONTENTS

Glossary

$ or C$	Canadian dollars; all costs in this report are given in CAD
AAC	Annual allowable cut, the maximum volume of timber available for harvesting each year from a specified area of land, usually expressed as cubic metres of wood per year
AD	Anaerobic digester, a plant for producing biogas
Adt	Air dry tonne (seasoned wood, counted as having 20% moisture)
ATR	Auto-Thermal Reforming - A method of converting natural gas into hydrogen or syngas where the heat needed to reform the hydrogen is generated internally.
BCBN	BC Bioenergy Network
BCTMP	Bleached Chemi Thermo Mechanical Pulp
BCUC	BC Utilities Commission
Biogas	A methane-rich gas created by the anerobic digestion process that is not compatible with the existing natural gas system without upgrading due to its high CO_2 content and/or other contaminants.
BPA	Biomethane Purchasing Agreement
BTU	British Thermal Unit, 1 BTU = 1.055 kJ
CAPEX	Capital costs (of a project)
CCU, CCS	Carbon capture, utilization or storage are processes used to prevent the CO_2 from reaching the atmosphere by either storing it in a geological formation or mineral or by using it in a product.
CFB	Circulating fluidized bed, a reactor type used for gasification
CH_4	Methane
CHP	Combined heat and power
CI	Carbon intensity of a fuel usually measured on a life-cycle rather than consumption (tailpipe) basis
CLD	Construction, land clearing and demolition waste
CO	Carbon monoxide
CO_2	Carbon dioxide
CO_2e	Carbon dioxide equivalent, a measure for GHG warming potential of a gas
EU	European Union
FICFB	Fast Internally Circulating Gasifier
FN	First Nation
FPI	FPInnovations, the research arm of the Canadian forest industry
FT or F-T	Fischer-Tropsch, a gas-to-liquid technology

g	Gram
GHG	Greenhouse Gas
GGRR	Greenhouse Gas Reduction Regulation
GIS	Geographic Information System
GJ	Gigajoule 1 GJ = 0.278 megawatt-hours (MWh) or 0.95 MMBtu 1 GJ is equal to the energy content of 28 litres of gasoline (at 20°C)
H_2	Hydrogen
H_2O	Water
H_2S	Hydrogen sulfide
ha	Hectare, an area of 100 x 100 m; 1 ha = 2.4 acre
HHV	Higher Heating Value - The heat set free from the complete combustion of a material, including condensation heat released by any water in the flue gas.
HTG	Hydrothermal gasification, a technology which uses water at supercritical or similar temperatures and pressures to form a syngas.
HTL	Hydrothermal liquefaction, a technology which produces a biocrude, and in some cases, some by-product syngas
IEA	International Energy Agency
IFS	Industrial Forestry Service Ltd, a forestry consulting firm
IPP	Independent Power Producer, a non-utility generator that is not a public utility but owns facilities to generate electric power for sale to utilities and/or end users.
kg	Kilogram, 1 kg = 2.2 lb
km	Kilometer
kW	Kilowatt
kWh	Kilowatt-hour
l	Litre
LCFS	Low-carbon fuel standard
LFG	Landfill gas captured from the natural breakdown of biodegradable materials in a landfill.
LHV	Lower heating value, same as net calorific value
MC	Moisture content or the percentage of the water in the biomass fuel. The moisture content can be measured on the dry basis which is the percentage of moisture relative to the dry mass or wet basis which considers the total mass including moisture and the dry matter. The wet basis is used unless otherwise stated.
MECCS	B.C. Ministry of Environment and Climate Change Strategy

MJ	Megajoule or 1/1000th of a gigajoule
MSW	Municipal solid waste
MW	Megawatt
MWe	Megawatt of electrical output
MWh	Megawatt-hour
NGV	Natural gas vehicle (a vehicle running on natural gas)
NRCan	Natural Resources Canada
O & M	Operation and maintenance
O_2	Oxygen
odt	Oven-dry tonne, same as bone dry tonne, the solid matter content of biomass. Referred to simply as “dry tonne” in the text of this report.
OPEX	Operational cost (of a project)
OSB	Oriented strand board, an engineered panel product made from stands of wood used as a plywood alternative
PJ	Petajoule; 1 PJ = 1 million GJ
PPA	Power purchase agreement
PSA	Pressure swing adsorption - a gas upgrading system that uses the differential capacity of CO_2 to be absorbed by a media to separate methane from CO2. It has the advantage of separating oxygen and nitrogen from a gas biogas source.
psi	Pounds per square inch; 1 psi = 6.9 kPa
PV	Photovoltaic
R&D	Research and development
RFS	Renewable Fuel Standard
RIN	Renewable Identification Number, a U.S. system for subsidizing renewable fuels.
RNG	Renewable natural gas (upgraded to pipeline quality from biogas, landfill gas or syngas)
ROI	Return on Investment: the amount of net revenue provided by a capital investment, usually on an annualized basis.
SMR	Steam Methane Reforming is a method of hydrogen or syngas production where natural gas or other fuel is reacted with steam to form a mixture of hydrogen and carbon oxides.
SPF	Spruce Pine Fir, standard coniferous lumber produced primarily in the interior.
SSO	Source-Separated Organics - Organic material such as food waste, garden waste, leaves and other organic material collected separately from other municipal solid waste, often using green bins placed on the curbside.
t	Metric tonne; 1 tonne = 1,000 kg = 2,204 lb

TFL	Tree farm licence, a license (area-based tenure) to harvest timber and manage a forest, recreation and cultural heritage values. TFLs exist within TSA boundaries.
TRL	Technology Readiness Level, a method to estimate technical maturity for commercial application
TSA	Timber supply area, a geographic area defined by the government for the purpose of organization and management; tenures of various types are auctioned off from within each TSA to allocate harvesting rights.
TSL	Timber sale licence
TWh	Terawatt-hour, 1 TWh = 1 million MWh
UBC	University of British Columbia
US	United States
WWTP	Wastewater treatment plant
Yr.	Year

1.0 BACKGROUND AND OBJECTIVE

In 2018 the Government of the Province of British Columbia (B.C.) released the CleanBC Plan, demonstrating leadership in climate change mitigation through ambitious greenhouse gas emission abatement targets.[4] This Plan set a target for 2030 of displacing a minimum of 15% natural gas with renewable gas. This was reiterated in the 2021 Clean BC Roadmap to 2030, which also refers to the intent of government to set an overall emissions cap on natural gas use in B.C. Currently (2021), about 200 petajoules of natural gas are retailed each year. It is the objective of this study to update previous estimates of the renewable and low-carbon gas supply potential and develop a growth strategy for increasing production in B.C. to 2030 and 2050. Other questions addressed in this report are the cost and carbon intensity of each gas and in what B.C. regions are resources most prevalent.

1.1 Previous Work and Political Context

The CleanBC Plan and Roadmap are a continuation and consolidation of various clean energy incentives, legislation and regulations that date back more than a decade. The provincial renewable gas target aims to decarbonize the natural gas grid and builds on FortisBC's voluntary renewable natural gas program that has been operating for over ten years.

The *Greenhouse Gas Reduction Regulation*[5] (GGRR) allows regulated utilities to acquire and/or produce renewable gases up to 15% total gas supply throughput and up to a cost of $31 per GJ. To better gauge how the target is likely to be met, the report quantifies locally available resources and the relative costs of gases and lignin displacing natural gas, and determines whether additional measures are necessary to enable a transition towards low-carbon gas. This study looks at the four possible energy types eligible under the GGRR (see Section 1.5) and integrates the results.

Previous reports and studies have dealt with the provincial bioeconomy and form the basis of the current work:

1. In 2010, the B.C. government commissioned a report on the provincial bioeconomy. This report suggested that the market potential for new bioproducts could reach $200 billion, exceeding the market for bioenergy ($170 billion).[6] The report strongly suggested that a comprehensive vision for B.C.'s bioeconomy be developed, followed by an effort to resolve issues around access to forest biomass, which currently prevents new industry entrants from easily accessing feedstock. Other recommendations involved technology, infrastructure and marketing roadmaps.
2. In 2016, the B.C. Government produced a report on the future of the forestry industry, which suggested that the sector maximize its value through the development of new bioproducts, biochemicals, and bioenergy – a biorefining approach that could lead to new employment and improved performance across the sector.[7] A similar report examining the B.C. pulp and paper

industry recommended an alliance between all B.C. pulp and paper companies to examine new bioproduct opportunities.[8]

3. In 2015, Industrial Forestry Services prepared a report for BC Hydro's Long-Term Planning Process on the potential for bio-based electricity in B.C. This report found that fibre supply would decline until 2026 due to the mountain pine beetle epidemic, after which it would stabilize. The report suggested that while 21 million m^3 of biomass was surplus to the industry shortly after the peak of the epidemic in 2015, this surplus would decline to 7.9 million m^3 in 2025 and remain at that level for the foreseeable future. The report also found that most of this wood is in the form of standing timber, and that harvesting this wood would be uneconomic, costing over $150 per dry tonne delivered.[9] Finally, this report highlighted the fact that while mill closures have left surplus wood behind, these closures have reduced the amount of easily accessed processing residues that have supported pellet production in the past.
4. The Resource Supply Potential for Renewable Natural Gas in B.C. (Hallbar Consulting, 2017).
5. The B.C. Hydrogen Study (Zen Clean Energy, 2019).
6. A pre-feasibility study for syngas and biomethane production at B.C. pulp mills (Tom Browne, 2019).
7. The confidential study, Revitalization of the B.C. Bioenergy Sector: Assessment of biomass feedstocks in B.C. (ENVINT, 2019).
8. Renewable Natural Gas (Biomethane) Feedstock Potential in Canada (Torchlight Bioresources, 2020).
9. An analysis conducted by Guidehouse Consulting and FortisBC demonstrated that using the existing gas system to distribute renewable and low carbon gases can achieve an 80% GHG reduction by 2050 and be a more affordable and resilient pathway for B.C. to reduce emissions.

1.2 Purpose of this Study

The purpose of this study is to evaluate and quantify the supply potential of renewable gases that could be used for decarbonization in B.C. The province possesses a provincial energy system supported by gas and electrical delivery infrastructure. The electrical system relies almost exclusively on hydropower. The gas system is supplied by B.C.'s abundant natural gas basins. Vast lands are covered by forest, and the Province has a prosperous agricultural sector. All of this suggests that renewable and low-carbon gases can meet or even exceed the limits that CleanBC has assigned to it. This report identifies diverse sources of supply within and out of B.C., their potential volumes and production costs. The data is based on previous work inside and outside of Canada and on calculations conducted by the authors of this study. Key objectives that this report addresses include:

- Establishing B.C.-wide supply potential and carbon intensity for all renewable and low carbon gas types

[8] B.C. Ministry of Forests, Lands, Natural Resource Operations and Rural Development, *British Columbia Pulp and Paper Sector Sustainability: Sector Challenges and Future Opportunities*, September, 2016. https://www2.gov.bc.ca/assets/gov/farming-natural-resources-and-industry/forestry/competitive-forest-industry/pulp_and_paper_sept_2016.pdf

[9] Industrial Forestry Service Ltd, *Wood-based biomass in British Columbia and its potential for new electricity generation*, July, 2015. https://www.bchydro.com/content/dam/BCHydro/customer-portal/documents/corporate/regulatory-planning-documents/integrated-resource-plans/current-plan/wood-based-biomass-report-201803-industrial-forestry-service.pdf

- Developing cost curves for provincially produced gases and cost analysis for imported renewable natural gas (RNG),
- Updating information from previous reports with new assumptions reflecting the changing resource availability,
- Identifying unique use-cases and end-uses such as evaluating the potential for required infrastructure in B.C. and using industrial consumers as host-sites for renewable and low-carbon gas production.
- Informing strategies to increase production capacity and deployment to achieve the province's GHG reduction targets.

This study's focus is the displacement of natural gas consumption delivered through the B.C. pipeline system with renewable and low-carbon gases. The use of these gases for transportation is not specifically considered, although the latter can be achieved using gas from pipelines. The goals and metrics used, however, refer to the approximately 200 petajoules of natural gas currently being delivered throughout B.C. for a variety of purposes, mainly for industrial use and space and water heating. Leaving aside strategies such as fuel switching (with the exception of using lignin and syngas in the forest products industry) and energy efficiency, the focus is on decarbonizing the gas coming to energy users through the natural gas grid.

1.3 Structure of this Study

This report has three main sections:

1. An analysis of pathways for renewable and low-carbon gas production or fossil gas displacement (Chapters 2, 3, and 4);
2. Supply portfolios or scenarios for the development of these pathways (Chapter 5);
3. A high-level deployment strategy (Chapter 6).

The pathways themselves are grouped by product (e.g., hydrogen versus syngas), by resource (e.g., forestry versus agricultural feedstock), and by technology (e.g., biochemical versus thermochemical):

- RNG from anaerobic digestion of agricultural and municipal waste streams (Chapter 2)
- Renewable gases from forest resources (Chapter 3);
- Hydrogen from non-biomass resources (Chapter 4);

Each of these chapters provides the technical supply potential and production costs for the pathways discussed. Apart from hydrogen derived from natural gas, all pathways are resource constrained and pathways based on woody biomass compete for the same resource. Market prices and the impact of competition for the resource, the final product, or the market value of renewable and low-carbon gas for sale to the U.S. are not taken into consideration to determine the technical potential. The technical potential should be taken as an upper bound of what would theoretically be possible if each resource were fully used. This is unlikely to occur, however, and a lower minimum resource potential has also been defined, based on less optimistic assumptions. Within these scenarios, the commercial potential is defined as the amount of gas that can be produced at no more than $31 per gigajoule.

1.4 Key Metrics Used

The cost analyses always refer to Canadian dollars, unless stated otherwise in the text or tables. Cost projections are made in 2021 dollars, i.e., inflation is assumed to occur but is not reflected in these numbers as the cost projections reflect a change with respect to today's costs, net of inflation. All gas potentials are based on the higher heating value (HHV) of the gases, given gas billing and transactions are generally based on HHV in B.C.

The cost of renewable and low-carbon gases purchased by B.C. utilities for the purposes of the GGRR is currently (in 2021) limited to $31 per gigajoule, indexed with inflation. As this report uses 2021 dollars, any future increases of the carbon purchasing price limit do not affect the results and estimates. This price is an upper limit for gas costs utilities may offer while still recovering their costs from the ratepayer base. It is possible, however, to contract for gas deliveries at higher prices if the BCUC approves of such contracts. The BCUC may do so if these purchases are deemed to be in the public interest. The price limit is nevertheless used as the current limit in this report as it reflects the desire of the regulator to limit overall costs to ratepayers, and the authors' interpretation is therefore that only limited amounts of renewable and low-carbon gases (e.g., from demonstration projects) would be offered higher pricing under the current regulatory regime.

1.5 Definitions

In this report, renewable gas refers to, in line with the GGRR, hydrogen, renewable natural gas (RNG), synthesis gas made from biomass (syngas), and lignin (used to displace natural gas). The report uses the term 'Renewable Natural Gas' (RNG) as an umbrella term for all gases made from renewable resources, including through anaerobic digestion, landfill gas, or syngas conversion to RNG. Gas produced from natural gas, such as blue and turquoise hydrogen, is referred to as 'low-carbon gas'.

Biogas is gas produced from organics generated at farms, from municipal organics (green bin and industrial or commercial organic waste), and by processing sludge from wastewater treatment plants. Gases emitted and collected in landfills is called landfill gas. RNG refers to methane produced from renewable resources. This include both anaerobic processes using organic waste and thermochemical processes that gasify solid biomass to produce RNG.

The report uses colour coding for hydrogen. Colours are attributed only to signify the pathway that the gas is created by. Hydrogen itself is a colourless gas: hydrogen produced from fossil fuels through steam methane reforming (SMR) is called blue if the associated carbon is not emitted to the atmosphere but sequestered in geological formations or otherwise used. 'Turquoise hydrogen' means that carbon contained in the fossil natural gas is stripped of, and converted into, a solid, 'carbon black.' 'Green hydrogen' is produced from 'green' electricity, i.e., renewable electricity.

Resource potentials determined in Chapters 2-4 are technical potentials, i.e. they are not limited by regulation or cost. They are smaller than the theoretical potential (100% of the resource) as they are limited by the available resource and resource recovery constraints. In the case of forest-based woody feedstock, recovery factors used assume that it is only possible to recover a portion of the theoretically determined resource, such as roadside residue. For RNG from anaerobic digestion, the potential determined in Chapter 2 considers that only sites near gas pipelines will be developed and that only a portion of the feedstock produced is available for digesters. The potential for blue hydrogen is limited by suitable geological formations where carbon dioxide stripped from natural gas can be securely sequestered.

The scenarios in Chapter 5 assume further restrictions, including build-out curves and technology readiness. They represent technically feasible outcomes whose realisation will depend on policies in B.C. and the interplay between markets in the province and in other jurisdictions. The achievable (as opposed to technical or theoretical) potential does likely lie in-between the Minimum and Maximum scenarios developed.

2.0 RENEWABLE GAS FROM ANAEROBIC DIGESTION

2.1 Description of Pathway

Inside air-tight tanks, naturally occurring microorganisms convert moist or liquid organic material into biogas and digestate. Biogas consists of methane (typically 55% – 65%), carbon dioxide (typically 35% – 45%), small amounts of water, hydrogen sulphide and other trace gases, such as nitrogen and oxygen. Biogas is upgraded to renewable natural gas (RNG) by removing carbon dioxide and other impurities. It is then injected into the local gas grid, or if there is no local grid, compressed and transported to a site where it can either be injected into the gas grid or used.

Digestate is the material removed from biogas plants after micro-organisms have finished converting most of the feedstock's dry matter into biogas. It contains most of the nitrogen, and all of the phosphorus and potassium of the input feedstock, and is considered a good fertilizer.

Biogas plants are most often categorised by the type of feedstock they digest. These categories are:

- Agricultural: biogas plants that digest livestock manure and other on-farm inputs, such as crop residues and energy crops. These plants may also digest some commercial and residential source separated organics (SSOs).
- Municipal: biogas plants that digest residential and/or commercial SSOs.
- Wastewater: biogas plants that digest sludge from wastewater treatment plants. These plants may also digest some commercial and residential SSOs.

RNG can also be produced from landfill gas (LFG). LFG, a mix of methane (typically 45 – 55%), carbon dioxide (typically 45 – 55%) and many impurities, is a by-product from decomposition of organic material buried in landfills. LFG (often classified as a type of biogas) is captured through a system of perforated pipes drilled into landfills. As with biogas, LFG can be upgraded to RNG by removing carbon dioxide and impurities. These impurities, including high levels of nitrogen and oxygen, make LFG more challenging than biogas to upgrade.

2.2 Technology Update

Biogas plants typically consist of four process stages, while LFG projects consist of only two process stages (i.e., the second and third process stage below). These are:

- Feedstock pre-treatment.
- Digester tanks or LFG capture.
- Biogas or LFG upgrading.
- Digestate management.

A multitude of mechanical feedstock pre-treatment technologies are commercially available. These technologies cut/shred feedstock into smaller pieces, or separate feedstock from non-organic material, such as plastic. Other feedstock pre-treatment technologies are rarely used, except in specific circumstance (e.g., thermal hydrolysis for specified risk material or highly contaminated feedstock). This is because pre-treating feedstock is often too costly, and/or biogas production from the feedstock is insufficient to justify the cost. There are no pre-treatment technologies near to commercialization (TRL 7/8) that could significantly increase biogas production from feedstock, or reduce pre-treatment costs.

Digester tanks are gas-tight, insulated tanks, placed below or above ground. While digester tanks differ in material (i.e., concrete or steel), shape and agitation (mixing of feedstock), they are all generally similar. No digester tank design is considered universally preferential or superior.

LFG is extracted from landfills using a series of wells and a blower/vacuum system. As with digester tanks, no LFG capture technology is widely considered to be better than others, nor are there any technologies near to commercialization (TRL 7/8) that could significantly increase LFG capture or reduce capture costs.

Upgrading biogas/LFG to RNG removes carbon dioxide and other impurities (such as hydrogen sulphide and water) to increase methane content from approximately 55 - 65% to > 95% or more. Several technologies are available for upgrading biogas/LFG to RNG, including membrane, water wash, chemical scrubbing, pressure swing adsorption and cryogenic upgraders. While the cost and performance of these technologies differ, the overall outcome (cost per gigajoule of produced RNG) is relatively similar. For this reason, all biogas/LFG upgrading technologies are considered similar in performance, and there are no technologies near to commercialization (TRL 7/8) that could significantly increase RNG production or reduce production costs.

In cases where nutrients in digestate are greater than needed in the immediate vicinity of biogas plants, nutrient recovery technologies are often used. Nutrient recovery technologies extract nutrients from digestate into a more concentrated form, reducing transportation costs. Dozens of nutrient recovery technologies are available, all designed to extract different types (nitrogen, phosphorus and/or potassium) and amounts of nutrients. Because different technologies are designed for different needs/purposes, no nutrient management technologies are deemed to be superior to others. Furthermore, there are no nutrient recovery technologies near commercialization (TRL 7/8) that could significantly reduce nutrient extraction costs.

Feedstock pre-treatment, digester, upgrading and nutrient recovery technologies have been commercially available for many years. During this time, small incremental improvements have been made to many of these technologies (such as lowering costs, improving performance and increasing durability). These improvements have resulted in very small increases in RNG production and/or lower production costs. There are no biogas technologies near commercialization (TRL 7/8) that could significantly increase the production of RNG (per unit of available feedstock), or significantly lower the cost of producing RNG ($ per gigajoule).

One pre-commercial technology that could significantly increase the production of RNG is ex-situ power to RNG.[10] This two-step process starts with the electrolytical production of hydrogen. The hydrogen is then combined with carbon dioxide from the exhaust stack of a biogas/LFG upgrader, and fed into a reactor tank with specialty microorganisms to convert hydrogen and carbon dioxide into RNG. However, because the use of electricity to produce hydrogen is considered below, the use of electricity to produce RNG through ex-situ power to RNG isn't considered in this study.

[10] Ex-situ power-to-RNG is different from in-situ power to RNG (which is TRL 5) because ex-situ power-to-RNG requires a separate reactor with specialty microorganisms in it. In-situ power to RNG feeds hydrogen and carbon dioxide into the same digester tank used for producing biogas from organic feedstock, where a wide range of non-specialty micro-organisms exist.

2.3 Feedstock Availability

For the purpose of this chapter, the following potential sources of feedstock were assessed:

- Agricultural: livestock manure, including dairy and beef cows, swine and poultry.
- Source-separated organics (SSOs): residential and commercial SSOs from food processors, grocery stores, etc., and homes (typically collected as part of a "green bin" program).
- Wastewater treatment plant: sludge from processing wastewater.
- Landfilled organics: organic material placed in landfills.

B.C.'s feedstock availability was estimated using the same assumptions that were used in the 2017 RNG Production Potential Study[11] (there called the short-term achievable potential).[12] To estimate feedstock availability for 2021, 2030 and 2050, estimated availability in the 2017 RNG Production Potential Study was extrapolated using predicted agricultural and population growth rates. The annual predicted agricultural growth rates used were 0% for beef, 1% for dairy, broilers and turkeys, and 2% for layers and hogs. Population growth rates for B.C., Canada and the U.S. were extrapolated using population data from the past 20 years. LFG potential was also based on the 2017 RNG Production Potential Study. This study used LFG model estimates from Golder Associates (2008).[13] It should be noted that while this approach is likely the most reasonable, estimating RNG potential into the future becomes less and less certain as feedstock availability and LFG production are calculated using predicted and historical growth rates.

2.4 Anerobic RNG production potential in B.C.

RNG production potential in B.C. for 2021 is estimated to be 8.9 petajoules per year (Table 2). This potential assumes that all wastewater treatment plants (WWTPs) and landfills flaring LFG or using biogas/LFG to produce heat or heat and electricity switch to RNG production.

Due to its high dry matter and energy density, food waste (unlike livestock manure and WWTP sludge) can be transported up to 150 km or more to a biogas plant. This means that food waste can be digested in agricultural, municipal or WWTP biogas plants, regardless of where it is produced. In the RNG potential estimates shown in Table 2, it is assumed that most food waste is digested in municipal biogas plants. This assumption was used because in theory, municipal biogas plants should be closer to food waste than agricultural and WWTP biogas plants.

However, food waste could just as easily go to agricultural or WWTP biogas plants. Therefore, while the following agricultural, municipal and WWTP production estimates for B.C. assume an RNG division of approximately 40% from agricultural, 50% from municipal and 10% from WWTP biogas plants, in reality this division could be 70% from agricultural, 10% from municipal and 20% from WWTP biogas plants (or any other combination therein). RNG from LFG is different, as these estimates are based on estimated methane production from food waste already in B.C. landfills. The potential for 2050 assumes that organic waste is still landfilled over the coming decade; landfill gas production will decrease eventually (after 2050) if organics are more and more diverted and used for anaerobic digestion.

[11] Hallbar Consulting, *Resource Supply Potential for Renewable Natural Gas in B.C. Public Version,* 2017.

[12] The only changes were that plant operating capacity was increased from 80% to 90%, while residential and commercial SSO availability was increased from 60% and 80% to 70% and 85% respectively. These changes were made to reflect growing maturity of B.C.'s biogas industry and greater participation in organics source separation.

[13] Golder Associates, Report on Inventory of Greenhouse Gas Generation from Landfills in British Columbia (2008).

In a 2012 B.C. RNG study,[14] theoretical RNG potential for FortisBC's Service Areas 1 and 2 (covering approximately 90% of B.C.'s population) from agricultural, residential and commercial SSOs was estimated to be 5.4 petajoules per year. This is only 0.6 petajoules lower than the 6.0 petajoules estimated in Table 2 (when LFG is excluded). Realistic RNG potential was estimated to be 1.93 – 2.38 petajoules per year. One possible reason that this study estimated much lower RNG potential than shown in Table 2 is because it assumed a maximum RNG sale price of $15.28 per gigajoule. If a higher price had been assumed, realistic RNG potential may have been much closer to the theoretical potential.

RNG production potential in B.C. for 2030 is estimated to be 9.5 petajoules per year. This is approximately one-third of FortisBC's 15% renewable gas target. The 8% growth in B.C.'s RNG potential between 2021 and 2030 is entirely due to industry (agricultural feedstock) and population (SSOs and WWTP sludge) growth estimates, and LFG production models.

RNG production potential in B.C. for 2050 is estimated to be 11.2 petajoules per year. As in 2030, the 27% growth in B.C.'s RNG potential between 2021 and 2050 is entirely due to industry (agriculture feedstock) and population (SSOs and WWTP sludge) growth estimates, and LFG production models.

Table 2 B.C. RNG Potential, in Petajoules (PJ) per Year

	Agricultural	Municipal	WWTP	LFG	Total
2021	2.4	3.1	0.48	2.9	**8.9**
2030	2.5	3.5	0.55	3.1	**9.5**
2050	2.8	4.6	0.69	3.1	**11.2**

2.5 Anerobic RNG Production Potential in All of Canada

RNG production is constrained by feedstock availability. As such, the challenge with estimating RNG potential is that provincially-aggregated feedstock data (e.g., tonnes of manure or SSOs) can provide false perceptions. To estimate RNG potential with any level of confidence, detailed regional and municipal-level spatial feedstock data is required. This data must be overlayed with information known to impact biogas plant development.

For example, liquid manure (i.e., dairy and hog) cannot be transported far before transportation costs are greater than revenue from RNG production. Liquid manure is therefore unlikely to be available for biogas plants greater than 10 – 15 km away. Other feedstock, such as SSOs, may have competing uses (e.g., animal feed). Therefore, it may not be available for RNG production. Biogas plants also require power (a rough ballpark estimate is 1-2 kWh per cubic metre of RNG). As such, even a 100,000 gigajoules per year biogas plant requires ~300 – 600 kW of electricity. If three-phase power isn't available locally it can be very challenging to build a biogas plant.

Furthermore, biogas plants typically inject RNG into the gas pipeline. Biogas plants also produce digestate which must be managed (ideally spreading on nearby fields). While RNG can be compressed and transported for grid injection elsewhere, and while nutrient extraction technology can be used to transport nutrients to fields further away, the unavailability of a local gas grid and the requirement for nutrient extraction technology adds cost and can severely impact biogas plant economics.

Finally, while biogas plants are environmentally beneficial, they can still face community resistance if built too near communities (due to concerns with traffic, noise, odour, safety, etc.). Finding locations for biogas

[14] CH Four Biogas, Inc., *Biomethane Potential in FortisBC Service Areas 1 and 2,* December 2012.

plants that are sufficiently near feedstock (much of which comes from residential and commercial sources), yet far enough away from homes and businesses to avoid public opposition can be challenging.

The B.C. RNG production estimates above have been calculated using regional and municipal-level spatial feedstock data overlayed with information known to impact biogas plant development (including localised feedstock availability and competition, infrastructure and digestate management requirements). As such, they represent a realistic estimate of RNG production potential based not only on feedstock availability, but also on constraints known to impact biogas plant development.

Canada's livestock sectors are relatively evenly distributed across the country,[15] and B.C. and Canada's per capita commercial and residential SSOs and WWTP sludge production and capture rates are comparable. Population densities in all but the smallest provinces and territories are similar. Therefore, the above B.C. RNG production estimates have been extrapolated, with a moderate level of confidence, for the rest of Canada based on population size.

In 2021, RNG potential in Canada (including B.C.) is estimated in Table 3. Of Canadian RNG potential, 39% is estimated to be in Ontario, with 23%, 14% and 12% estimated to be in Quebec, B.C. and Alberta, respectively. All other Canadian provinces and territories account for the remaining 13% of RNG potential. As with RNG production potential in B.C., it is important to note that estimated RNG production between three of the sources (agricultural, municipal and WWTPs) in Table 3 is somewhat arbitrary. Because food waste is the greatest producer of RNG and can be transported up to 150 km or more to a biogas plant, the division of RNG between agricultural, municipal and WWTP biogas plants could be very different from that presented below.

Table 3 RNG Potential in Canada, in Petajoules per Year

	Agricultural	Municipal	WWTP	LFG	Total
2021	17.4	22.9	3.6	21.3	65.2
2030	18.2	25.2	4.0	22.3	69.7
2050	20.0	33.2	4.9	22.5	80.7

In 2030, RNG potential in Canada is estimated to be 69.7 petajoules per year. Of Canadian RNG potential, 39% is estimated to be in Ontario, with 22%, 14% and 13% estimated to be in Quebec, B.C. and Alberta respectively. All other Canadian provinces and territories account for the remaining 13% of RNG potential. The 7% growth in Canadian RNG potential between 2021 and 2030 is entirely due to industry (agriculture feedstock) and population (SSOs and WWTP sludge) growth estimates, and LFG production models.[16]

In 2050, RNG potential in Canada is estimated to be 80.7 petajoules per year. Of RNG potential, 40% is estimated to be in Ontario, with 20%, 14% and 15% estimated to be in Quebec, B.C. and Alberta respectively. All other Canadian provinces and territories account for the remaining 12% of RNG potential. As with 2030, the 24% growth in Canadian RNG potential between 2021 and 2050 is entirely due to industry (agriculture feedstock) and population (SSOs and WWTP sludge) growth estimates, and LFG production models.[16]

[15] While Quebec and Ontario have more dairy cows per capita, B.C. has a higher number of poultry, Manitoba a higher number of hogs, and Alberta a higher number of beef cattle per capita. The concentration of grains and oilseeds in the prairie provinces isn't relevant as crop residues and energy crops are excluded from this study.
[16] B.C. agricultural growth estimates and LFG production models were used to estimate national increases in agricultural feedstock and LFG availability, while provincial population growth estimates were used to estimate increases in national residential and commercial SSOs.

Other studies have also attempted to estimate Canadian RNG potential. For example, according to the 2010 Alberta Innovates Technology Futures study,[17] Canadian RNG potential from manure, SSOs, WWTPs and LFG is 165 petajoules per year (68.8 petajoules per year from manure, 5.6 petajoules per year from municipal SSOs, 7.2 petajoules per year from WWTP and 83.8 petajoules per year from LFG). This estimate is for technically feasible RNG potential, and doesn't take into account actual feedstock availability, location, etc. If these RNG estimates were assessed through a more realistic lens, taking into account actual rather than theoretical feedstock availability, estimated RNG potential would likely be 50% lower at 82.5 petajoules per year.

In 2013, the Canadian Biogas Association (CBA) released a biogas study[18] that estimated Canada's RNG potential to be 92 petajoules per year. While this estimate is significantly higher than the 65 petajoules per year estimated above, it includes crop residues, which are not included in the present estimate.[19] If crop residues are removed, and only 50% of livestock manure is considered to be available (a realistic assumption identified in the CBA study), RNG potential falls to 62.5 petajoules per year.

While RNG pathway potentials in the 2013 CBA study differ significantly from those estimated in this study(for example, the 2013 CBA study estimates 6.8 and 11 petajoules per year from WWTPs and landfills, respectively), the reason for this is due to assumed feedstock end use. Most feedstocks can be used in multiple RNG pathways. For example, SSOs can be digested in agricultural, municipal or WWTP biogas plants, or can be landfilled to produce LFG. Therefore, assumptions on where feedstock is used significantly impacts how much RNG is estimated from each pathway.

In a more recent study, Torchlight Bioresources estimated the Canadian RNG potential from livestock manure, biosolids, WWTP, urban organics and LFG to be 111.5 petajoules per year.[20] However, as the study notes, this is theoretical not realistic potential. Technical RNG potential, which would require an assumption that only '40-70% of potential feedstock' is available for RNG production, is estimated to be 44.6 – 78.1 petajoules per year. Table 4 compares the results of the above-mentioned studies. Discounting the Alberta study, the results are very similar in each.

Table 4 Canadian RNG Potentials Compared, in Petajoules per Year

	This Study	Alberta Innovates	CBA	Torchlight Bioresources	Range of All Studies
Current RNG Potential	65.2	82.5*	62.5	61.4**	61.4 – 82.5

* Deemed to be 50% lower than this theoretical potential identified in the Alberta study.
** Average taken from 44.6 – 78.1 petajoules per year range estimated by Torchlight.

[18] Canadian Biogas Association, *Canadian Biogas Study: Benefits to the Economy, Environment and Energy - Technical Document*, 2013.
[19] Crop residues have been excluded for several reasons. To reduce soil erosion and/or build-up organic matter, crop residues are often incorporated into the soil or, as with straw, used elsewhere (e.g., animal bedding or in mushroom production). For these reasons crop residues are often unavailable. Crop residues often have low spatial energy density and high fiber content. This means they can be costly to collect and transport, and require expensive pre-treatment. Finally, crop residue availability is highly variable, depending upon weather, crop rotation and seasonal variation, while they are also only available once or at certain times of the year. This makes them challenging to use because biogas plants require year-round feedstock availability and long-term storage is expensive.

2.6 Anerobic RNG Production Potential in the United States

B.C. RNG production estimates in this study were used to estimate RNG potential in Canada. This was done with a moderate level of confidence due to similarities in livestock distribution (and therefore manure production), SSOs production and capture rates, WWTP sludge production rates, and population densities across Canadian provinces.

Using the above B.C. RNG potentials to estimate U.S. RNG production potential is much less straightforward. Unlike in Canada, U.S. populations and livestock densities vary greatly. For example, California has 254 people, 4.4 dairy and 12.8 beef cows per km^2, while Wisconsin and Oregon have 44 and 109 people, 9.1 and 0.5 dairy cows and 24.6 and 5.0 beef cows per km^2 respectively.[21,22,23] This means that unlike Canada, availability of agricultural and SSO feedstocks for RNG production will vary greatly between U.S. states. Those with high populations and/or animals per km^2 will be able to collect and use a lot more feedstock than others (i.e., those with low populations and few animals per km^2).

Unlike in Canada, per capita SSOs capture rates in U.S. states are vastly different. Wisconsin and California, for example, have 0.6 and 1.9 composting facilities per 1,000 km^2, while Idaho and Texas have 0.02 and 0.05 per 1,000 km^2, respectively.[24] This means that some U.S. states (those with more compost facilities per square kilometre) will be able to collect much more SSO feedstock than others (those with less compost facilities per square kilometre). Despite this, and due to lack of available data elsewhere, the above B.C. RNG production estimates for 2021, 2030 and 2050 have been extrapolated, based on population size, to estimate RNG potential in the U.S. However, as just noted, this has been done with a low level of confidence.

Current RNG potential in the U.S. is estimated in Table 5. The 5% growth in U.S. RNG potential between 2021 and 2030 is entirely due to industry (agriculture feedstock) and population (SSOs and WWTP sludge) growth estimates, and LFG production models.[25] The 12% growth in U.S. RNG potential between 2021 and 2050 is also entirely due to industry (agriculture feedstock) and population (SSOs and WWTP sludge) growth estimates, and LFG production models.[25]

Table 5 RNG Potential in the U.S., in Petajoules per Year

	Agricultural	Municipal	WWTP	LFG	Total
2021	150	197	31	184	561
2030	154	213	34	189	590
2050	156	259	38	176	630

Other studies have also attempted to estimate U.S. RNG potential. For example, in 2011 the American Gas Foundation[26] estimated U.S. RNG potential (not including food waste) under non-aggressive and aggressive scenarios. Under the non-aggressive scenario, manure, WWTPs and LFG were estimated to

[22] Beef2Live: *Ranking of States with The Most Cattle,* September 26, 2021.

[23] U.S. Census Bureau, *Historical Population Density Data (1910-2020)*, April 26, 2021.

[24] BioCycle: *The State of Organics Recycling*, October 2017.

[25] B.C. agricultural growth estimates and LFG production models were used for estimating national increases in agricultural feedstock and LFG availability, while population growth estimates were used to estimate increases in national residential and commercial SSOs.

[26] American Gas Foundation, *The Potential for Renewable Gas: Biogas Derived from Biomass Feedstocks and Upgraded to Pipeline Quality,* September 2011.

have RNG potential of 156.1, 4.2 and 192 petajoules per year, respectively. These estimates are very similar to those presented above in Table 5.

In 2013, the National Renewable Energy Laboratory[27] estimated U.S. RNG of 110.4 petajoules per year from manure, 67 petajoules per year from commercial SSO, 135 petajoules per year from WWTP, and 142 petajoules per year from LFG. While the distribution of RNG potential is different from other estimates (likely due to the assumption that more commercial SSO will be sent to WWTPs then municipal biogas plants), total estimated RNG potential is again similar.

In 2019, the American Gas Foundation published an update to their 2011 study.[28] It estimated U.S. RNG potential under non-aggressive and aggressive scenarios in 2040. The non-aggressive scenario, which is 857.5 petajoules per year, is one-third greater than the RNG estimate for 2050 made here.

Table 6 US RNG Potential Compared, in Petajoules per Year

	This Study	American Gas Foundation (2011)		NREL	American Gas Foundation (2019)		Range of Studies
		Aggressive	*Non-Aggressive*		*Aggressive*	*Non-Aggressive*	
Current RNG Potential	561	352.4 (No food waste)	917.9 (no food waste)	455.2			352.4 – 461*
Future RNG Potential	630 (2050)				1,503.7 (2040)	857.5 (2040)	630 – 857.5*

* Using American Gas Foundation's non-aggressive scenarios.

2.7 Anerobic RNG Production Cost Curves for B.C.

2.7.1 Key Considerations

Estimating RNG production costs can be very challenging for three reasons. First, unlike renewable energy technologies that either require no biomass (e.g., wind, solar and hydro) or purchase homogenous feedstock (e.g., wood pellets), biogas plants accept a wide array of feedstock with varying quality (i.e., level of contamination) and characteristics (size, dry matter, viscosity, etc.). As such, biogas plants can require very different feedstock reception, handling, storage and processing equipment.

Second, unlike renewable energy technologies that have an established energy output per unit of technology or feedstock (e.g., kilowatts per square metre of solar panel or gigajoules per tonne pellets), biogas production of feedstock varies greatly. Some feedstocks produce ten times or more biogas per tonne than others. As such, biogas plants that are similar in size and scope can produce very different amounts of RNG.

Finally, unlike renewable energy technologies that produce no by-product (e.g., wind, solar and hydro) or very little by-product (e.g., ash from biomass plants), biogas plants produce digestate. Digestate is a low-nutrient concentration liquid (or solid if produced by a dry-batch biogas plant). If digestate cannot be used locally (e.g., spread on nearby fields), nutrient extraction technology or transportation (trucking) is often required. Both of these can add significant costs.

[27] National Research Energy Laboratory, *Energy Analysis: Biogas Potential in the United States*, October 2013.
[28] American Gas Foundation, *Renewable Sources of Natural Gas: Supply and Emissions Reduction Assessment*, December 2019.

No public data is available for RNG production costs in B.C. (biogas plants and landfills in B.C. don't make their production costs public). For this reason, estimated B.C. RNG production costs are based on the 2017 RNG Production Potential Study.[29] The 2017 RNG Production Potential Study estimated the total feedstock availability in B.C. and used realistic assumptions to determine what percentage of this feedstock could be available to biogas plants, and how much biogas this feedstock could produce.

It then looked at the size of municipalities and farms near available feedstock to determine how much feedstock would go to what type of biogas plant (municipal or agricultural), and how much RNG these plants would produce. All SSOs were assumed to go to municipal or agricultural biogas plants, while WWTPs were assumed to only digest sludge.

Once the type (municipal or agricultural) and size (gigajoules of RNG per year) of biogas plant was established, production costs ($ per gigajoule) were estimated using an industry cost-curve. This cost-curve, created using data from hundreds of biogas plants in Europe, provides an estimated cost of RNG production based on biogas plant size. As biogas plants increase in size (digest more feedstock), they are anticipated to benefit from economies of scale, and the cost of RNG production decreases. To fully understand all of the assumptions and methodology used to estimate RNG production costs, the reader is referred to the 2017 RNG Production Potential Study.[11]

Tip fee (or avoided cost) for SSOs is assumed to be $0 per tonne[30] because to meet all, or at least a high percentage of, estimated RNG potential, all available feedstock must be used. Therefore, while biogas plants are currently able to receive a tip fee of around $20-40 per tonne, it is expected that a significant increase in food waste demand will drive down the fee biogas plants are paid to take it. For 2030 and 2050, there are expectations that RNG equipment costs will come down by 5% and 10% respectively as a result of a more mature biogas sector.

2.7.2 B.C. Production Costs in 2021

Estimated B.C. RNG production costs in 2021 are shown in Figure 4. The reason there is no RNG potential for ≤$18 per gigajoule from agricultural and municipal biogas plants is due to digestate management costs assumed in populated areas (i.e., Lower Mainland and Vancouver Island). The difference in RNG potential between ≤$50 per gigajoule and the technical potential is because some biogas plants are assumed to be unable to secure SSOs. If SSOs were available , RNG production costs for these plants would decrease significantly, while technical RNG potential would increase.

RNG potential from WWTPs and landfills is much lower in cost than agricultural and municipal RNG because digester tanks, LFG capture equipment, etc. are not included in the RNG production cost estimates (this equipment is assumed to exist as WWTPs and landfills require this equipment even if they do not produce RNG). Therefore, the only cost included for RNG production for WWTP and landfills is the cost of biogas/LFG upgrading. If the cost of digester tanks, LFG capture equipment, etc. were included, WWTP and landfill RNG production costs would be significantly higher.

[29] Hallbar Consulting, *Resource Supply Potential for Renewable Natural Gas in B.C. Public Version,* 2017.

[30] Tip fee typically accounts for <15% of biogas plant revenue, so an assumption of a $0/tonne tip fees doesn't significantly impact RNG production costs.

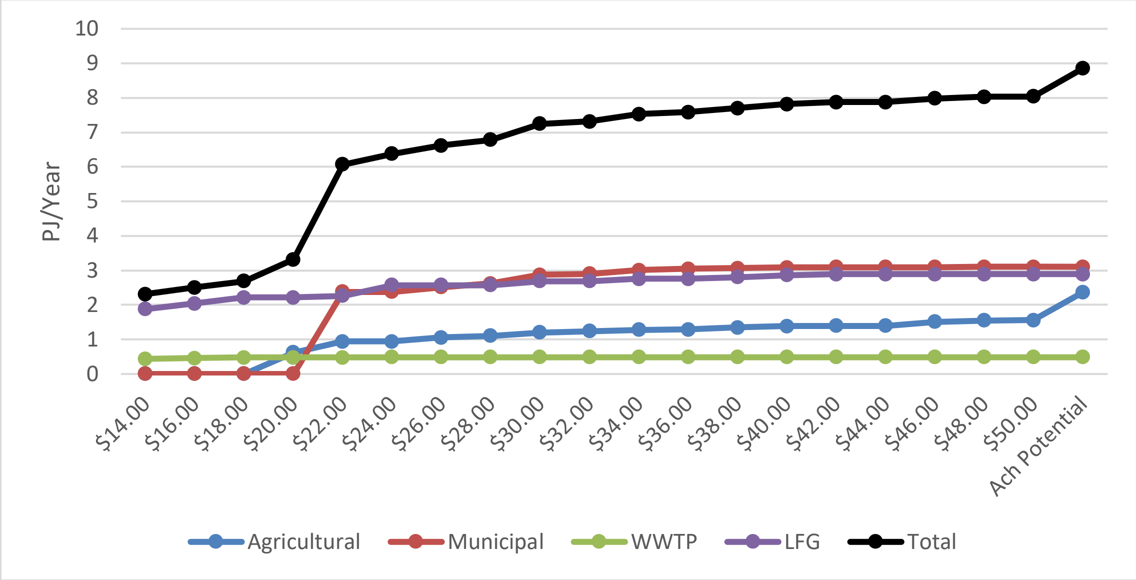

Figure 4 B.C. RNG Production Costs (2021)

2.7.3 B.C. Production Costs in 2030

Estimated B.C. RNG production costs in 2030 are shown in Figure 5.

- **Agricultural RNG** potential remains low, due to the assumption that most SSOs will be used in municipal biogas plants. As in 2021, there is no RNG potential for ≤$16 per gigajoule due to digestate management costs, while the difference in RNG potential between ≤$50 per gigajoule and technical potential is due to lack of SSOs.
- **Municipal RNG** potential is zero under $18 per gigajoule but increases to 3.3 petajoules per year for ≤ $31 per gigajoule. Technical RNG potential is 3.5 petajoules per year. As in 2021, there is no RNG potential for ≤$18 per gigajoule due to digestate management costs.
- **WWTP RNG** potential is small, even though some will be available for less than $16 per gigajoule.
- **Landfill RNG** potential is an important low-cost resource, with 2.2 petajoules available at $16 or less, and 2.9 petajoules per year for ≤ $31 per gigajoule. As in 2021, production costs for WWTP and landfill RNG only includes the cost of biogas/LFG upgrading.

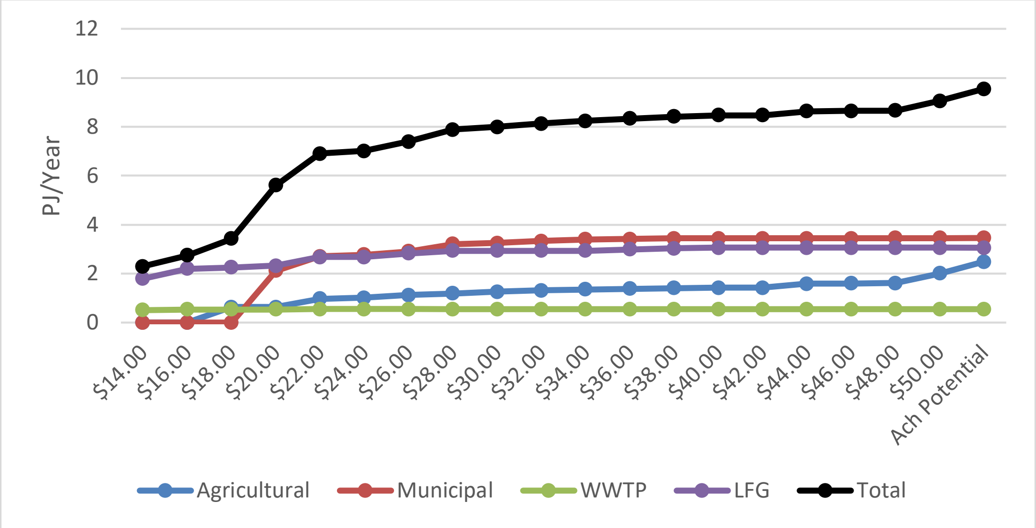

Figure 5 B.C. RNG Production Costs (2030)

2.7.4 B.C. Production Costs in 2050

Estimated B.C. RNG production costs in 2050 are shown in Figure 6.

- **Agricultural RNG** potential increases to a maximum of 2.2 petajoules for ≤50 per gigajoule. As before, there is no RNG potential under $16 per gigajoule due to digestate management costs, while the difference in RNG potential between ≤$50 per gigajoule and technical potential is due to lack of SSOs.
- **Municipal RNG** potential is significant, at 4.5 petajoules for ≤ $31 per gigajoule. There is no RNG potential for less than $14 per gigajoule due to digestate management costs.
- **WWTP RNG** potential is only slightly higher than in previous years.
- **Landfill RNG** potential is only slightly higher than in 2030, at 3.0 petajoules under $31 per gigajoule. As before, production costs for WWTP and landfill RNG only includes the cost of biogas/LFG upgrading.

Figure 7 combines the above data into a single graph that shows estimated RNG production costs for 2030, for the various sub-categories defined above. About 8 petajoules are available for ≤$30 per gigajoule. This represents the majority of the technical potential. Only a relatively small amount can be added by paying more for the RNG. Also, only a small additional amount becomes available by 2050, adding up to the total potential of 11 petajoules shown in Table 2 above.

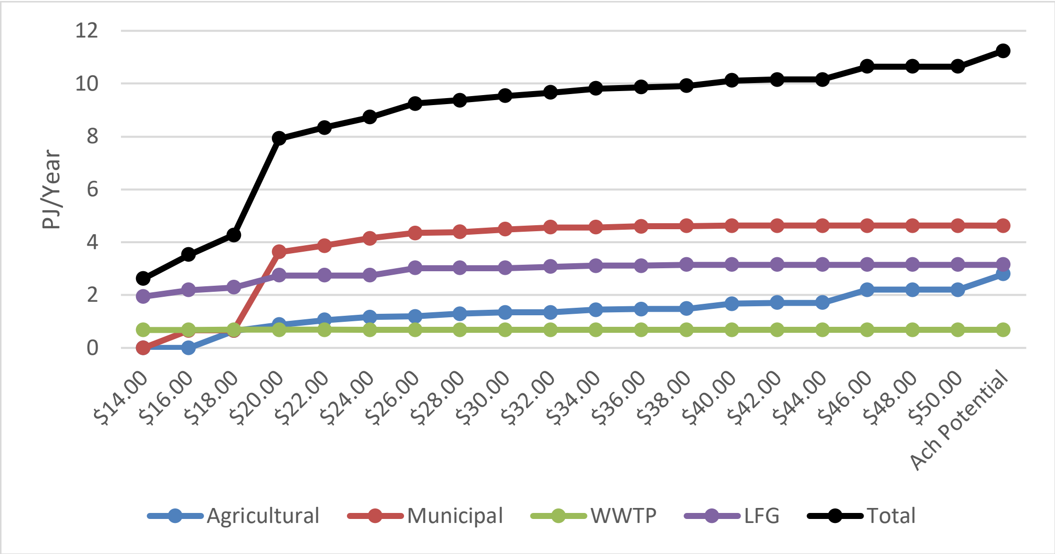

Figure 6 B.C. RNG Production Costs (2050)

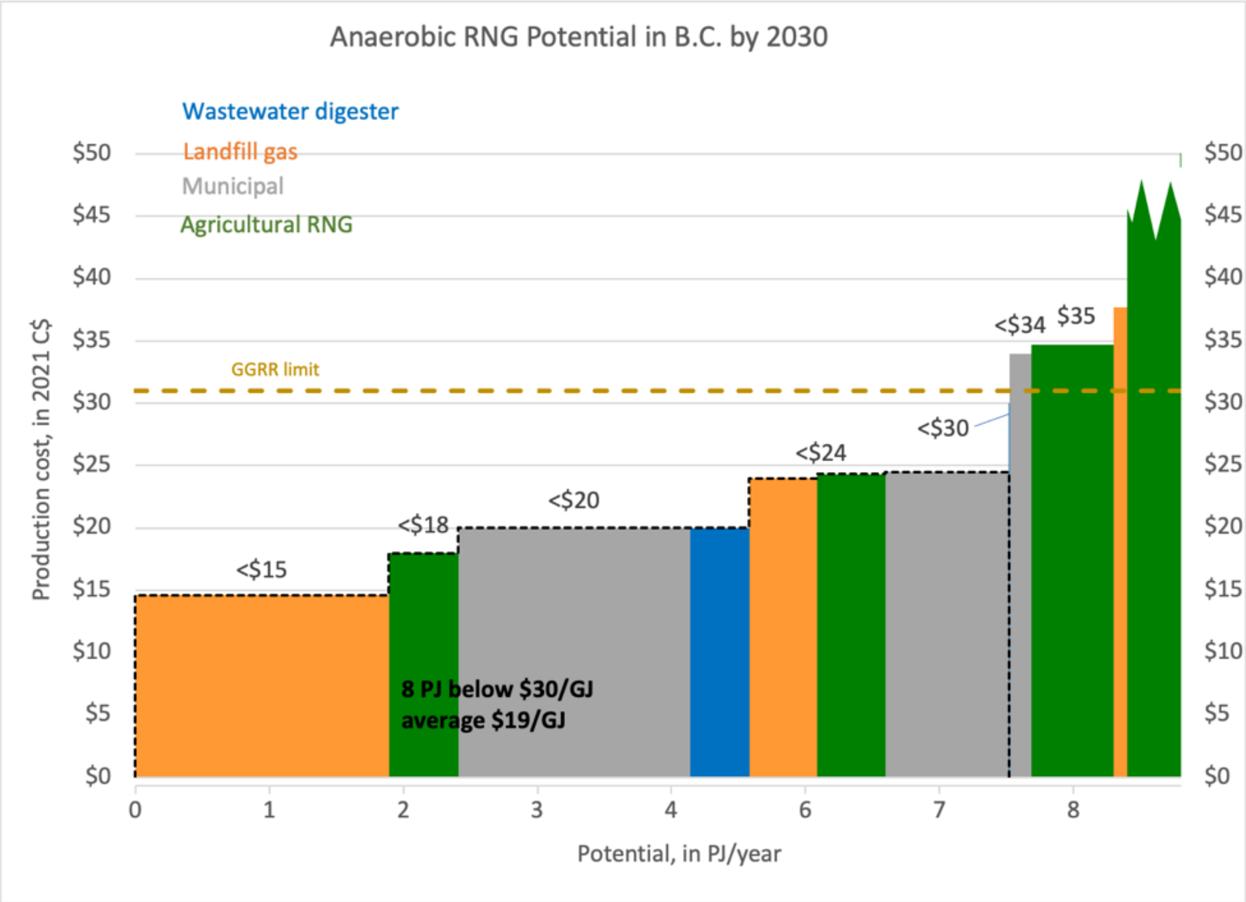

Figure 7 B.C. RNG Cost Curve for RNG from Anaerobic Digesters (in 2030)

2.8 Anerobic RNG Production Cost Curves in Canada

2.8.1 Key Considerations

The B.C. RNG production potential estimates above were used to estimate Canadian RNG potential. This was possible because Canada's livestock sectors are relatively evenly distributed, B.C. and Canada's per capita SSO and WWTP sludge production rates are the same, and population densities in all but the smallest provinces and territories are similar.

Using the B.C. RNG production cost estimates to calculate Canadian RNG production costs is more challenging. Typically, as biogas plants digest more feedstock or landfills capture more LFG (i.e., are larger), production costs per gigajoule of RNG decrease. This is because larger plants can benefit from economies of scale. Because Ontario and Quebec have significantly more feedstock than B.C., while Manitoba, Saskatchewan and the Atlantic provinces have significantly less feedstock, estimating Canadian RNG production costs using B.C. cost estimates may over- or under-estimate actual production costs.

Furthermore, the B.C. RNG production cost estimates were calculated by overlaying spatial feedstock data with local natural gas infrastructure. Gas infrastructure plays a key role in RNG production as it connects biogas plants and landfills with demand centres and end-users. The distribution of feedstock relative to the natural gas infrastructure in B.C. is not necessarily the same as in the rest of Canada. While RNG can be compressed and transported for grid injection elsewhere, doing so can increase RNG production costs by \$3 – \$6 per gigajoule or more.

Finally, different Canadian provinces have different policies and regulations that affect RNG production. Obstructive policies, whether intentional or not, can delay project development and result in the need for additional equipment, both of which affect RNG production costs. While this impact is less significant to production costs than project size and gas infrastructure availability, it can still be impactful.

2.7.5 Canadian RNG Production Costs in 2021, 2030 and 2050

Despite the challenges of unknown project size, gas infrastructure availability and provincial regulations, the following are Canadian RNG production cost estimates for 2021, 2030 and 2050. While these cost curves may not be as accurate as those for B.C., they still provide a good indication of Canadian RNG production costs (Figure 8).[31]

Of Canadian RNG potential in 2021, 2030 and 2050, > 65% of production for ≤\$18 per gigajoule is from WWTPs and LFG. This is because estimated production costs for WWTP and LFG RNG only include the cost of biogas/LFG upgrading. In 2021, 2030 and 2050, 85% of Canadian RNG potential is for ≤\$34 per gigajoule, ≤\$32 per gigajoule and ≤\$30 per gigajoule, respectively. From 2021 to 2050 the cost of RNG decreases due to both expectations that equipment costs will decrease (as the biogas/LFG market grows) and economies of scale will increase as a result to greater feedstock availability.

[31] Digestate management costs for agricultural biogas plant were only assumed for plants in B.C.'s Lower Mainland and Vancouver Island. Agricultural biogas plants in all other areas of Canada were assumed to have no digestate management costs.

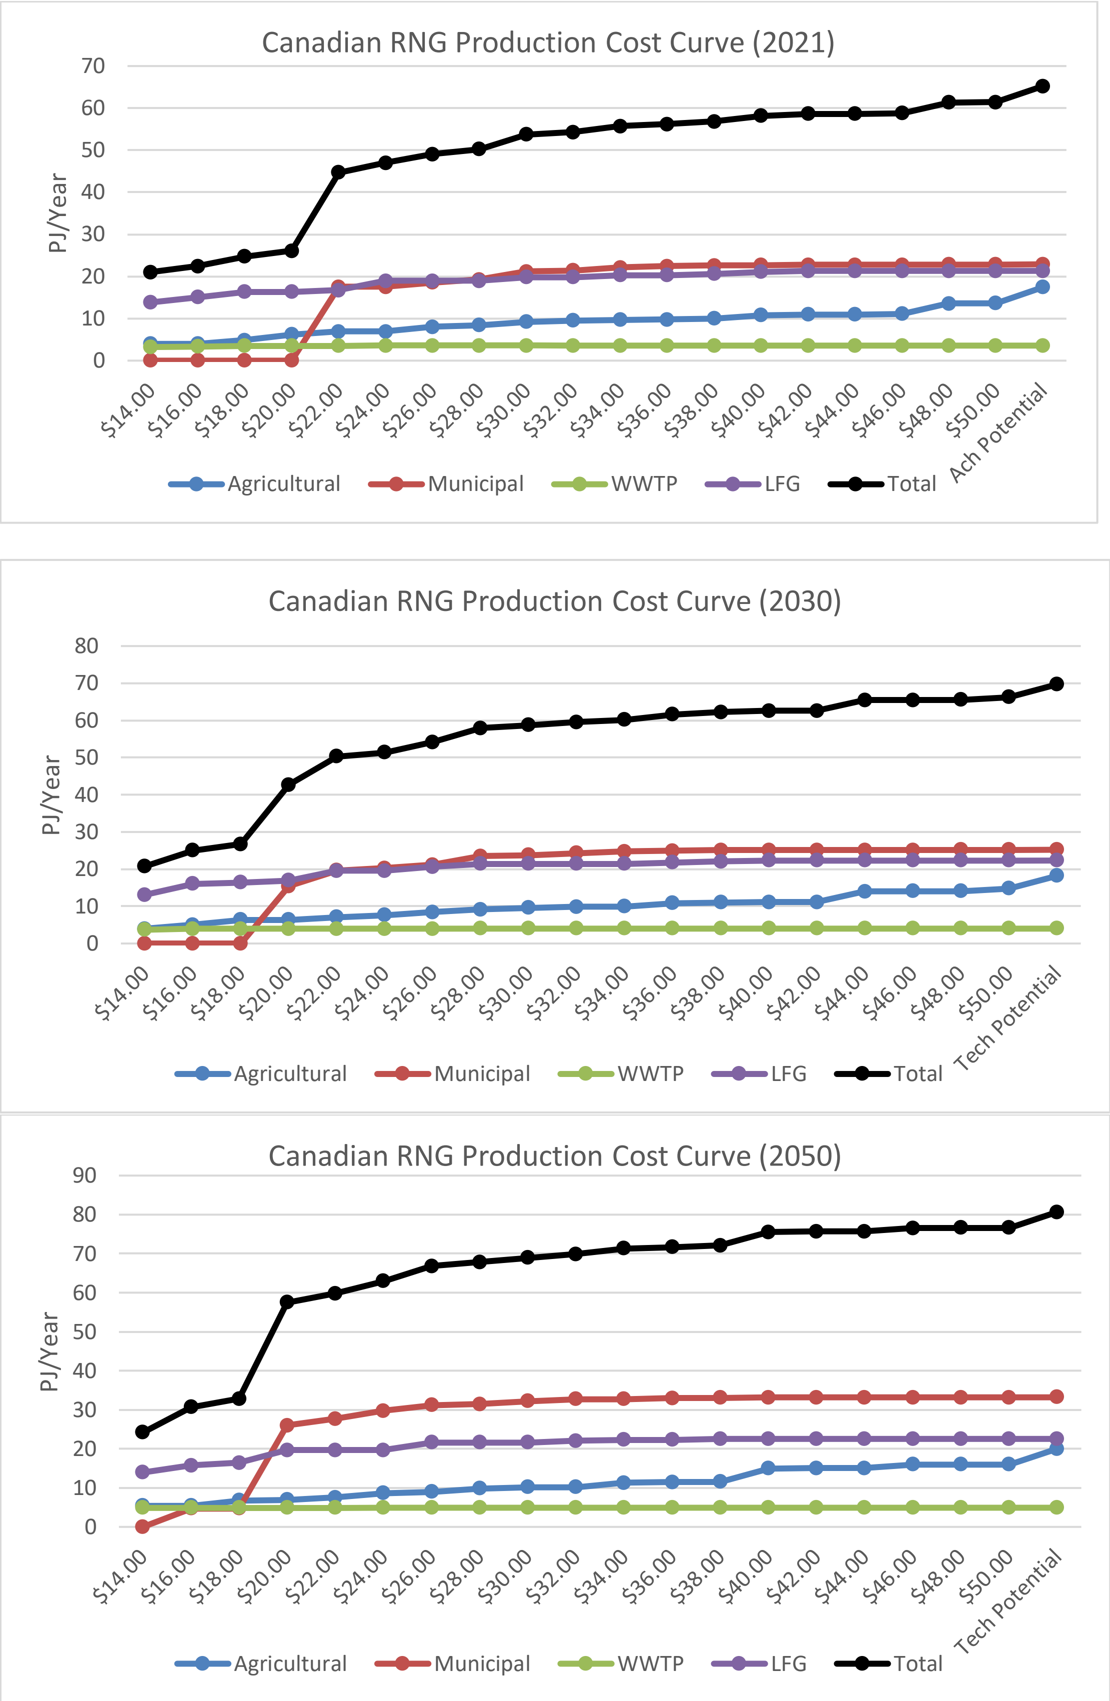

Figure 8 Canadian RNG Production Costs (2021, 2030 and 2050), in $/GJ

Other studies have also attempted to estimate the cost of Canadian RNG production. For example, the Torchlight Bioresources study[32] estimated RNG production costs ranging from $6 per gigajoule to almost $55 per gigajoule. RNG from a 0.1 petajoules per year biogas plant digesting hog manure and SSO was estimated to cost $53.90 per gigajoule, while RNG from LFG was estimated to cost $6.10 per gigajoule (best case) and $15.60 per gigajoule (most likely). While the estimated cost of $53.90 per gigajoule for agricultural RNG seems extremely high, the cost of $15.60 per gigajoule for LFG RNG is similar to that estimated above (70% of Canadian RNG from LFG is estimated to cost ≤$16 per gigajoule).

A study by Guidehouse[33] estimated current European RNG production costs to be €0.65 - €0.9 per cubic metre (~$26 - $36 per gigajoule), with RNG costs in 2050 estimated to be €0.47 - €0.57 per cubic metre (~$19 - $23 per gigajoule). While current RNG costs estimated by Guidehouse are slightly higher than the estimates above, this is likely for two reasons. First, the Guidehouse study considered the cost of biogas tanks and LFG capture equipment at WWTPs and landfills. Second, land availability in Europe is limited. Therefore, many European biogas plants require nutrient extraction technologies.

2.9 Anerobic RNG Production Cost Curves in U.S.

Using B.C. or Canadian RNG production cost estimates to estimate U.S. RNG production costs isn't possible. Canadian and U.S. agricultural sectors (both scale and density), population densities, policy structures and per capita commercial and residential SSOs capture rates aren't comparable. Furthermore, the U.S. currently has no standard market price for RNG. Instead, price is largely driven by the value of environmental commodities associated with the RNG from participating in the federal Renewable Fuel Standard and/or LCFS programs (see below). For this reason, the following RNG cost estimates were taken from previous studies by the American Gas Foundation.

The American Gas Foundation's 2011 study[34] estimated RNG production prices under a non-aggressive scenario state by state. RNG from animal manure was estimated to cost anywhere from C$8.1 – C$105.3 per gigajoule in Delaware and Alaska respectively, with an average cost of C$14.6 per gigajoule. RNG from WWTPs was estimated to cost anywhere from C$14.1 – C$40.8 per gigajoule in Illinois and Louisiana respectively, with an average cost of C$25.3 per gigajoule. RNG from LFG was estimated to cost anywhere from C$7.0 – C$18.8 per gigajoule in New York and Utah, respectively, with an average cost of C$9.7 per gigajoule.

In the American Gas Foundation's 2019 study,[35] RNG production cost ranges were again estimated, this time between C$24.4 – C$43.2 per gigajoule for biogas from animal manure, C$25.8 – C$37.6 per gigajoule from food waste, CD$9.8 – C$34.7 per gigajoule from WWTPs, and C$9.6 – C$25.4 per gigajoule from LFG. These ranges are somewhat comparable to the RNG production cost estimates above for both B.C. and Canada.

Table 7 Estimated RNG Production Costs (American Gas Foundation), in C$ per Gigajoule

	Agricultural		Food Waste		WWTP		Landfill	
Year	Low	High	Low	High	Low	High	Low	High
2011	$8.1	$105.3	N/A	N/A	$14.1	$40.8	$7.0	$18.8
2019	$24.4	$43.2	$25.8	$37.6	$9.8	$34.7	$9.6	$25.4

2.10 Competition for Anerobic RNG

The above work was carried out to estimate technical RNG production potential in B.C., Canada and the U.S. today, in 2030 and 2050. Work was also carried out to estimate how much this RNG would cost to produce. However, there can be a very large difference between costs (expenses incurred producing RNG) and prices (the amount RNG is sold for). This is because RNG isn't valued based on its energy content, but on environmental benefits generated through federal and provincial/state programs.

For example, B.C. has a Low Carbon Fuel Standard (LCFS), while Canada has the proposed Canadian Clean Fuel Standard. The U.S. has the federal Renewable Fuel Standard, and the California and Oregon LCFSs, with many more under development. Most of these programs[36] assign RNG a Carbon Intensity (CI) score. The lower (more negative) the CI score, the more RNG is sold for. This is because a smaller amount of highly negative CI RNG is needed to reduce a producer's overall fuel supply CI score.

Furthermore, because most LCFS programs use a lifecycle accounting framework methodology where upstream emissions are included, two similar biogas plants can have very different CI scores. For example, Farm A and Farm B both digest 200,000 tonnes per year of manure and consume similar energy inputs. As a result of these biogas plants, both farms prevent 10,000 tonnes per year of carbon dioxide equivalent being emitted into the atmosphere from manure storage (baseline emissions).

However, because Farm A has a longer retention time and superior agitation, it produces 100,000 gigajoules per year of RNG, while Farm B only produces 75,000 gigajoules per year. The outcome is that Farm B's RNG has a more negative CI score and will attract a higher price than Farm A's RNG (this is because the 10,000 tonnes per year of carbon dioxide equivalent not emitted from manure storage is divided by the number of megajoules of RNG produced). The price that Farm B receives for its RNG could be 30+% higher compared to the price Farm A receives.

If Farm A were to add food waste feedstock to the biogas plant, RNG production would increase significantly, while the tonnes per year of carbon dioxide not emitted from manure storage would stay the same. This means that the 10,000 tonnes per year of carbon dioxide equivalent would be divided by a much larger number of megajoules, and the farms' CI score would become even less negative, resulting in an even lower price for the RNG.

In 2021 Stifel Equity Research[37] estimated that over the past few years RNG from dairy manure and LFG has sold for an average price of C$129.1 per gigajoule and C$39.9 per gigajoule, respectively. This price is potentially up to three times higher than the production cost of the RNG. For example, the American Gas Foundation[38] estimated the maximum dairy manure and LFG RNG production costs to be <C$45 per gigajoule and <C$26 per gigajoule, respectively. Figure 9 shows typical CI scores for different types of renewable energy sold into the Californian LCFS market, with green dots denoting all types of compressed RNG, including manure, food waste, WWTPs and LFG. This means that due to its highly negative CI agricultural and to a lesser degree, municipal RNG can potentially be sold for several times what they actually cost to produce.

[36] The exception being the U.S. Renewable Fuel Standard, which creates renewable identification numbers which are purchased by those needing to meet their EPA-specified renewable volume obligation.

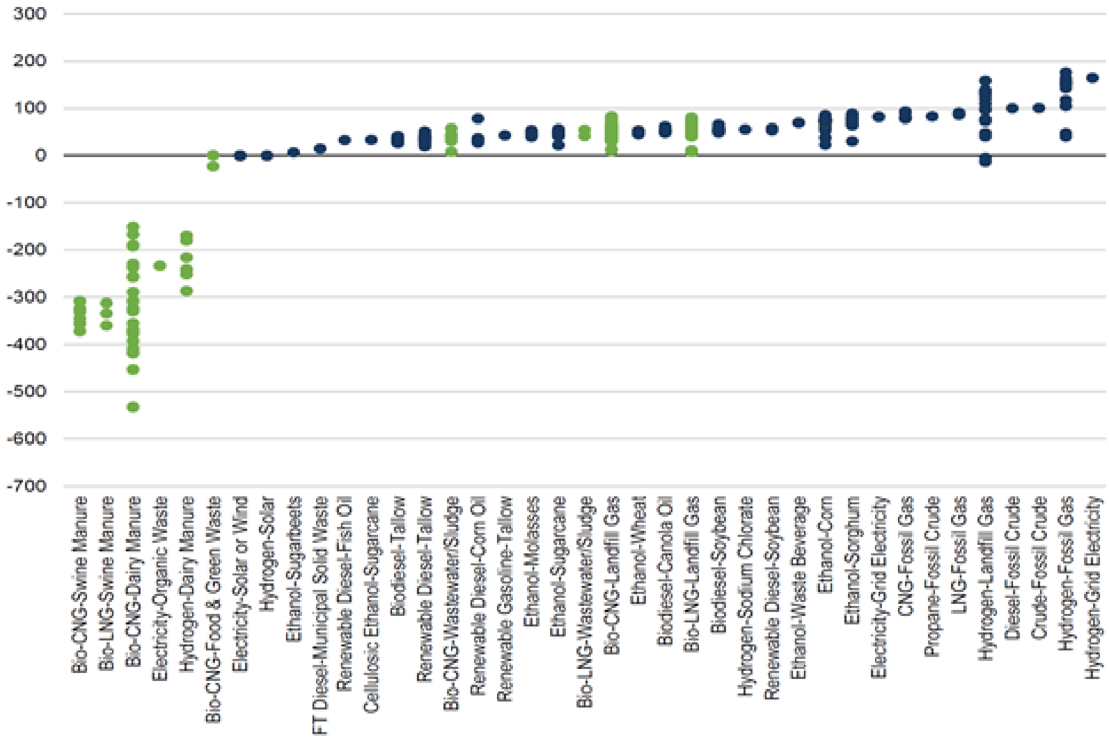
[38] American Gas Foundation, *Renewable Sources of Natural Gas: Supply and Emissions Reduction Assessment*, December 2019.



Note: Values determined based on the California LCFS methodology. Values for use in vehicles, based on high electricity use for gas compression, and adding emissions from truck transport.

Figure 9 Carbon Intensity Values of Certified Pathways, in in Grams per Megajoule[37]

To date, all B.C.-produced RNG has been contracted to FortisBC. This is likely for two key reasons. First, FortisBC is the largest local utility. This means injecting RNG into the local gas grid is relatively easy and more straightforward than selling RNG to another entity. Second, FortisBC offers up to 20-year (for agricultural projects) and 25-year (for municipal projects) biomethane purchase agreements (BPAs). Having a long-term BPA is often necessary to secure project financing. For these reasons, it is realistic to assume that, in the short-term, a very high percentage of RNG produced in B.C. could be available to FortisBC at or near production costs.[39] However, and depending upon the price of carbon, this percentage may decrease in the long term as the B.C. LCFS, Canadian Clean Fuel Standard and other programs mature, creating competing demand for B.C.-produced, low-carbon RNG.

Across Canada, FortisBC is successfully purchasing RNG. While FortisBC isn't the local utility for these projects, it can offer long-term BPAs. As a result, a high percentage of RNG produced in Canada could be available to FortisBC at or near production costs in the short-term. However, this percentage could fall drastically in the long-term if other Canadian utilities start offering BPAs similar to those offered by FortisBC. Furthermore, and as in B.C., the price of RNG could increase drastically when the Canadian Clean Fuel Standard or other provincial or state-based LCFS regulations are created.

Estimating the percentage of U.S. RNG that could be available at cost rather than at price is incredibly challenging. Within the U.S., FortisBC isn't the local utility but it does offer long-term BPAs. Despite this,

[39] While Pacific Northern Gas (PNG) is also able to offer long-term BPAs for RNG, the PNG natural gas lines are in Northern B.C. where livestock and population densities are low. The amount of B.C. RNG that could be produced in areas where PNG has a gas line is relatively small compared to where FortisBC has gas lines.

and as shown in Figure 9, agricultural and municipal biogas plants are typically able to achieve highly negative CI scores. This makes it unlikely that FortisBC will acquire much agricultural or municipal RNG from the U.S. at or near production costs. According to Section 2.6 above, up to two-thirds of U.S. RNG is estimated to come from agricultural and municipal biogas plants.

For these reasons, it is realistic to assume that in the short-term a medium to low percentage of RNG produced in the U.S. could be available to FortisBC at or near production cost. In the long-term, this percentage could fall if U.S. utilities start offering BPAs similar to those offered by FortisBC, while changes to the federal Renewable Fuel Standard and California and Oregon LCFS, and/or introduction of new state LCFSs could cause this percentage to fall even further.

2.11 Markets

Currently the main buyer of RNG in Canada is FortisBC (although other utilities and companies are also starting to purchase RNG). Other markets for RNG do, however, exist. These markets, which may attract RNG from projects within, and more likely, outside of B.C., include:

- The U.S. RNG certificate market is an opportunity that offers high pricing, especially for low CI agricultural and municipal RNG, and is already attracting projects development in the U.S.
- RNG can be used as a transportation fuel. This is a lucrative market, though it is often restricted to fleets running locally on RNG.
- As soon as the federal Clean Fuel Standard is enacted, demand from other gas retailers will follow. Quebec is also mandating its gas retailers to buy 10% renewable gas by 2030 and Energir is therefore buying LFG for pipeline injection.[40]

2.12 Infrastructure Needs

The equipment and technology necessary to build and operate biogas plants/LFG capture systems are all commercially available. Despite this, and at times, the existing gas infrastructure can be a limiting factor. If certain feedstock is concentrated in an area unserved by natural gas,[41] or if the existing natural gas infrastructure isn't able to accept RNG (especially during summer months, when natural gas demand is low), RNG must be compressed and transported for grid injection elsewhere. Compression and transportation can increase RNG production costs by $3 – $6 per gigajoule or more (depending upon project size and distance RNG must be transported). As Figure 10 shows, many landfills and WWTP are close to the gas pipeline. This is also true for most large urban areas, but isn't true for all farms that produce feedstock for RNG production.

Therefore, developing the full potential of RNG production with B.C., Canada and the U.S., will require expansion of the natural gas infrastructure to areas currently too far from the grid to inject any gas. Alternatively, and as done in Sweden where many biogas plants are located well away from any natural gas infrastructure, greater emphasis and support is needed to reduce the cost of RNG compression and transportation.

[40] https://www.ledevoir.com/economie/632010/le-gaz-naturel-renouvelable-dans-la-mire-d-energir-et-de-waste-management (Accessed September 1, 2021).

[41] Especially liquid, low dry matter feedstock, such as manure (i.e., dairy and hog), which typically cannot be transported far before transportation costs are greater than revenue from RNG production.

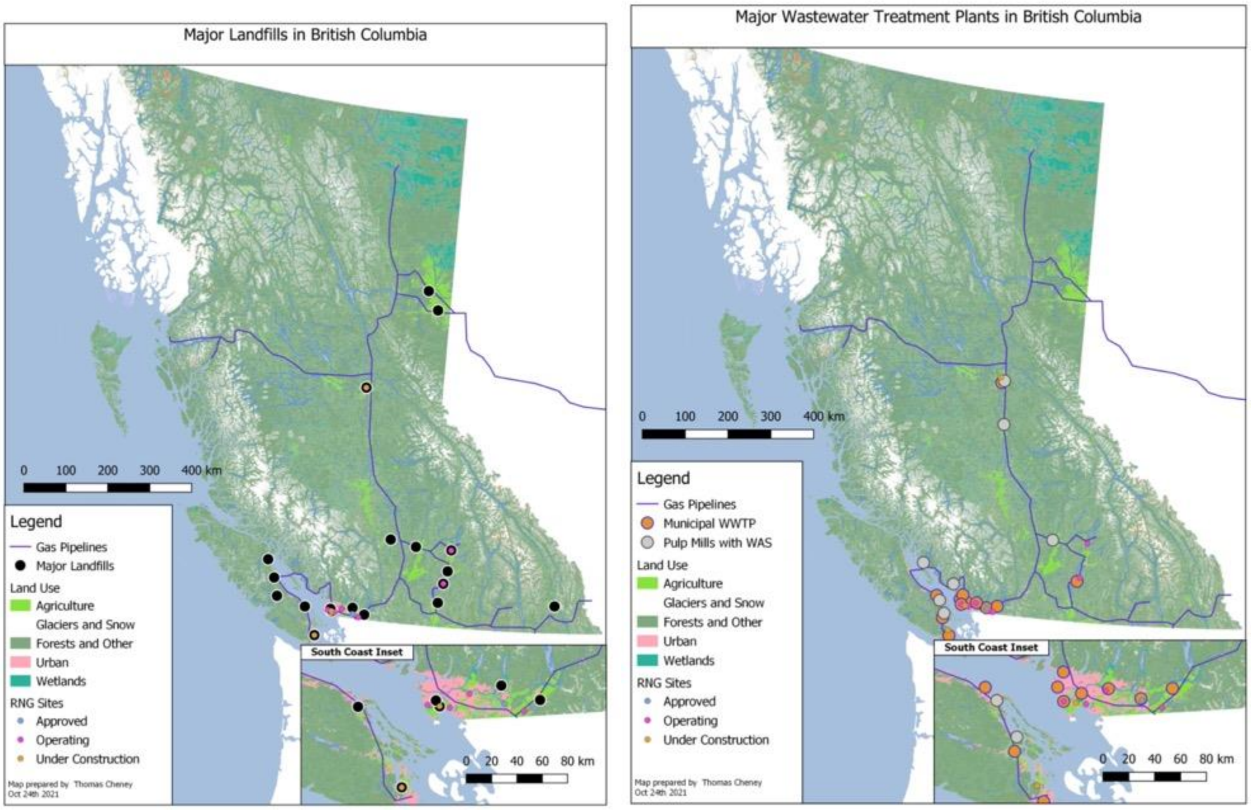


Figure 10 Locations of Major Landfills and WWTP in British Columbia

2.13 Recommendations

FortisBC is the first natural gas utility in Canada and one of the first in North America to purchase RNG. FortisBC also offers long-term BPAs. Having a long-term BPA is often necessary to secure project financing. For these reasons, FortisBC is able to purchase RNG across North America, and compete with federal and provincial/state fuel standards. However, as other Canadian and even U.S. gas utilities start offering BPAs similar to those offered by FortisBC, the 'first-mover' advantage that FortisBC currently has will start to erode.

Furthermore, as more fuel standards are developed, or as existing fuel standards mature, the attractiveness of these markets for RNG producers may increase (e.g., price stability and trust may increase, and/or fuel suppliers or intermediary companies may start offering long-term contracts). As such, FortisBC should leverage their current 'first-mover' advantage by procuring as much RNG as they can in the short-term, before the level of competition and the cost of RNG increases.

When it comes to procuring RNG, the choice for type (e.g., agricultural, municipal, WWTP or LFG) will depend upon a multitude of factors. The most important of these factors currently is cost. However, if/when there is a transition from requiring FortisBC to acquire 'renewable content' to acquiring gases with a certain CI score, the choice of RNG will depend upon CI calculations used. If a life cycle accounting methodology is used where credit is given for avoided methane from manure storage or food waste landfill diversion, then agricultural and municipal RNG will likely be the most attractive. Aligning these methodologies between jurisdictions is important to prevent that different GHG accounting methods may create higher value for a RNG type outside of B.C., leading to out-of-province sales.

3.0 THERMOCHEMICAL CONVERSION OF FOREST RESOURCES

This chapter deals with thermo-chemical conversion such as gasification of woody biomass. The gas generated may be upgraded to be injected into the pipeline or may be used directly at the point of production, replacing natural gas. We assume that all forest biomass available can be used by the various gasification and other technologies. It is understood that woody biomass comes in different dimensions and qualities (see Appendix C). For example, hog fuel may have higher ash content than other wood but this can be dealt with by using more potent syngas cleaning technologies. Salt contamination in coastal areas can be a problem for some processes and may then require salt removal (e.g., pre-washing) in order to use such material. Emerging technologies, such as supercritical water processing, may remove the need to pre-treat feedstock in. the future (see Appendix A).

3.1 Forest Biomass Resource Assessment

3.1.1. *Total Available Woody Biomass*

The estimates in this section are taken from the report *'Revitalization of the B.C. Bioenergy Sector*,' produced for BCBN in 2019. They are based on a commercial fibre supply model that uses the Annual Allowable Cut (AAC), mill activity, imports, and exports of fibre between regions, and estimates surplus residue at mills and in the forest. The main conclusions from this work were:

Based on the analysis in Appendix C,

combines availability data on the various wood feedstock types that have been quantified, adding typical cost ranges (see also Section 3.1.3). About half the long-term resource would come from standing trees (roundwood) at elevated pricing. The most significant low-cost resources include feedstock potentially becoming available from expiring contracts with BC Hydro for power production and feedstock currently used for wood pellet production. At the same time, these streams remain highly speculative as it is not certain that they will become available. Unused mill residue – a low-cost resource – provides a small amount throughout. Harvesting residue is one resource that is not yet fully exploited but also has limited availability unless harvesting rates increase above current levels.

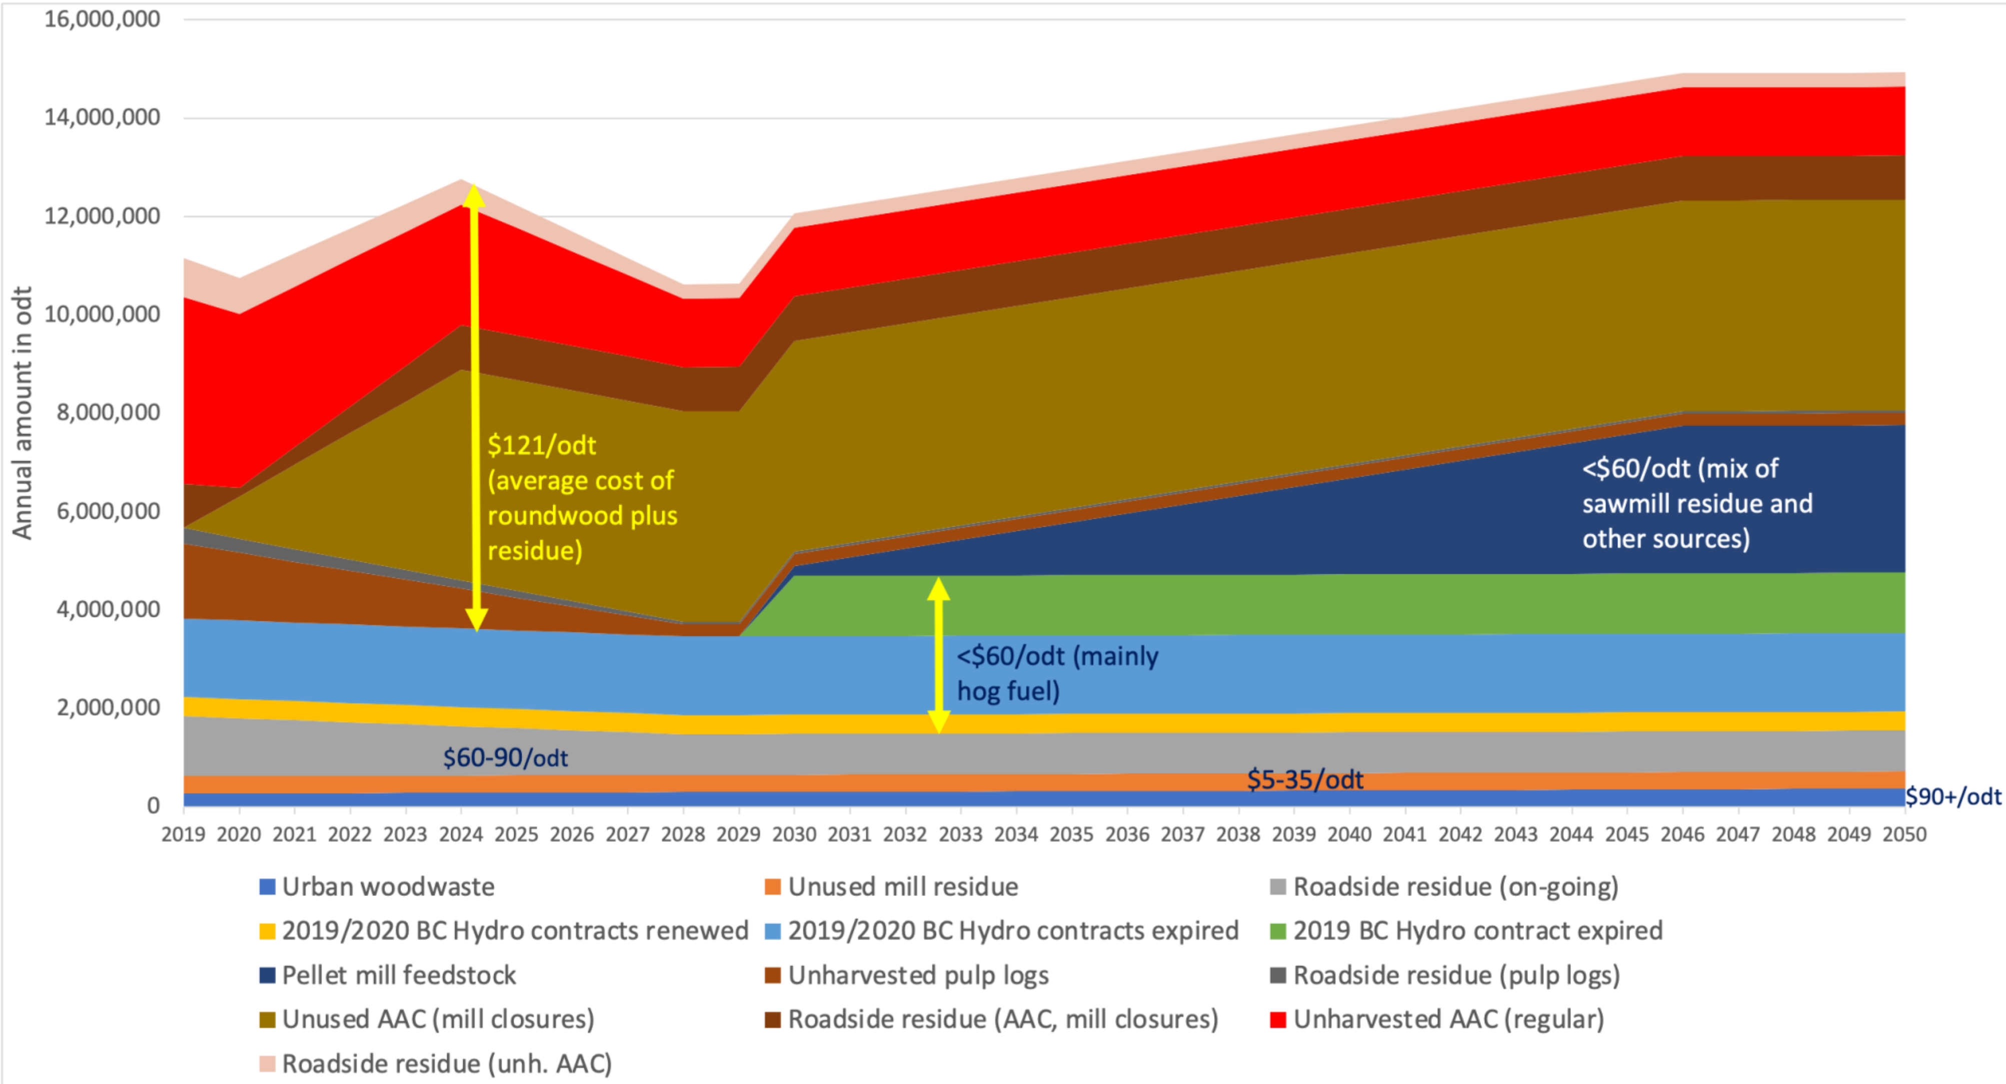

Figure 11 Assumed Amounts and Changes in Availability of Wood Fibre between 2019 and 2050

Table 8 summarizes the graph above in numbers. The largest amounts of wood available are also the most expensive to retrieve, i.e., standing trees from unused AAC. Together with the roadside residue generated from harvesting additional trees, the estimated cost of this biomass in the model is $121 per dry tonne – about twice the amount assumed for the low-cost fibre resources.

The inclusion of residue currently used for pellet production implies a conversion of this industry towards renewable gas production for local use instead of pellet exports. Such changes may be very gradual and may remain incomplete. Only some of this potential may be available.

The AAC may be further reduced due to beetle kills or wildfires, or conservation issues, such as the desire to protect old-growth forests. This would affect both AAC and residue production. Previously mentioned caveats also apply, such as how much harvesting residue may be available. It is not entirely clear if BC Hydro contracts with mills exporting excess power will be extended in 2028. Some of these uncertainties are expressed as different scenarios in the next chapter.

Converting the total amount of wood available in 2030 (217 petajoules) to hydrogen at an efficiency of 66% would result in about 143 petajoules of gas. This amount does not consider alternative uses for this biomass, either from new sawmills, for chemicals production, or pellet production. The use of lignin is not included because there are more effective ways of using biomass. Not counting the most expensive resource, i.e., unharvested AAC (and related roadside residue), the total gas production potential is then only 60 petajoules in 2030.

Table 8 Total Available Forest Biomass (Technical Potential) in B.C. and Gas Production Potential

	2021-2023		2030		2050	
Source	**Million odt**	**PJ**	**Million odt**	***PJ***	**Million odt**	***PJ***
Unharvested AAC	3,792,151	69	1,394,417	26	1,394,417	26
Roadside residue related to above	796,352	15	292,828	5	292,828	5
AAC from mill closures	4,282,789	78	4,282,789	78	4,282,789	78
Roadside residue related to above	899,385	16	899,385	16	899,385	16
Unharvested pulp logs	1,519,373	28	246,751	5	246,751	5
Roadside residue related to above	319,068	6	51,818	1	51,818	1
Unused roadside residue	1,223,419	22	831,315	15	831,315	15
Unused mill residue	349,080	6	346,199	6	346,199	6
Conversion of pellet plants	0	0	0	0	*>3,000,000*	>55
Expiring BC Hydro contracts	387,856	7	3,212,437	59	3,212,437	59
Urban wood waste (CLD)	270,000	5	300,000	5	*364,000*	7
TOTAL	**13,839,473**	**253**	**11,857,939**	**217**	**>13,839,473**	**>273**

Assumptions: Harvesting continues at recent levels, only adjusted by known and expected mill closures. Mills will continue to use residue at current amounts to sustain their operations. Nothing from BC Hydro contracts will be available before 2029.

Pellet mills have long-term contracts and are only deemed to transition towards renewable gas production after 2030. Population growth in B.C. is about 1% per year (for estimating urban wood waste).

Unused roadside residue is conservatively estimated. A higher amount may be available based on sources discussed above. Additional roadside residue from new activities is estimated as 21% of the mass of round logs.

Grey numbers identify the most expensive resource (standing trees).

3.1.2. *Conclusions on Wood Fibre Availability*

Large amounts of wood fibre are, or may become, available in B.C., including unharvested trees (most), harvesting residue, and mill residue. Yet, only limited amounts are easily accessible and currently available at low pricing (see next section). As already found in 2019, almost no mill residue is currently available for new projects. The pellet and pulp and paper industries are focusing on harvesting residue to obtain additional residue. This residue is being recovered in only a few areas, partly because of the difficulties of retrieving fibre beyond a certain distance from the road. Other reasons are the costs of recovering fibre after the primary harvest. Finally, there are legal constraints with tenure holders restricting third-party access to waste fibre. The 2019 estimate of around 1.2 million tonnes is still deemed accurate, although recovered amounts have recently started to increase and will therefore soon reduce the remaining potential. On the other hand, improved and integrated harvesting approaches may increase the availability of such residue over the coming decade.

Accessing more residual fibre will require improved supply chains that integrate tree harvesting and residue recovery and use best available technologies to reduce the cost of residue recovery. Some opportunities may exist where no pulp or pellet mills currently exist to recover additional harvesting residue for new energy projects. Costs may then be affordable, given the shorter transport distances.

Another element that would increase fibre availability are clearer regulations regarding the allocation of forestry residue and the responsibilities of the tenure holder versus the residual fibre user. If a third party is given access to a tenure holder's harvesting area, using the same logging roads, liabilities should remain with the third party and not the license holder. Failing to resolve such issues increases risk for sawmills and has led to unnecessary red tape and difficulties in accessing residue. Continued funding through e.g., the Forest Enhancement Society is needed to develop and improve related supply chains.

Another new mechanism, currently being tested in the Fort Nelson area, is the takeover of abandoned TSAs, where sawmills or other mills have been shut down. This can open access to large sources of fibre but also requires a complete business concept that makes use of both non-merchantable and merchantable wood to maximize revenue and allow projects to become bankable and operate profitably.

Summarizing thoughts on availability, it is important to understand that:

- Little unallocated mill residue is available throughout B.C. and only one or two new projects may be able to rely mainly on such resources.
- The mill residue previously used for excess power production at pulp and paper mills until 2019 is unlikely to become available for new projects. Sawmill closures have created a shortage of residuals. This biomass will likely be redistributed among existing users.
- Roadside residue appears to be the main opportunity for new projects but is already partially being used by pulp and pellet mills. Estimates of its availability vary by about a factor of two between models. Recovery becomes costly as the terrain becomes more rugged and distances to the user increase. Its availability is linked to harvesting techniques, such as skidding (most residue left in the forest) versus forwarding (more residue taken to the roadside). Changes in harvesting practices may be necessary to increase recoverable amounts.
- New stand-alone facilities to produce RNG or hydrogen will likely have to rely on more than one resource, such as some mill waste and some roadside residue, to secure their feedstock. This limits opportunities for locating such plants.

- Whole-tree harvesting, including non-merchantable wood, on abandoned TSAs where sawmills are no longer active may be a new opportunity as long as there is a high enough share of sawlogs in the stands to be cut that can be cost-effectively sold to sawmills. This concept is being tried in Fort Nelson but may not be directly transferable to other regions with limited pulp markets.
- Whole-tree harvesting for energy production may lead to a backlash from environmental groups – the scientific consensus is that harvesting is sustainable as long as a portion (usually around 20-30%) of the non-stemwood is left on the cut block but the B.C. community may still not accept large-scale operations of this type for fear of its impact on landscape and biodiversity.

3.1.3. *Feedstock Cost*

Typical feedstock costs, or the ability to pay, varies with industries. Pulp mills will pay up to about $100 per dry tonne for wood residue - possibly more for marginal amounts. Pellet mills produce a product of much lesser value and mainly rely on residue, only using small amounts of roundwood. They have typical feedstock costs of $50 per dry tonne but may also pay more for marginal amounts. Power plants usually use low-cost feedstock that costs no more than $35 per dry tonne.

Table 9 provides an overview of feedstock costs in 2015. Since then, harvested costs have increased around 30%, especially in the B.C. Interior. Stumpage fees were at about $0.25 per cubic metre in 2014 but have since increased to $20 (end of 2019).[42] Wildfires and beetle kills have reduced the resource to such a degree that longer hauls are necessary to obtain the same amount of wood. Standing timber would therefore likely cost in the area of $225 per dry tonne (delivered) today. During the second quarter of 2021, Interior sawlog pricing was reported as $128 per cubic metre for spruce-pine-fir (SPF) species and $50 ($123 per dry tonne) for pulp logs.[43]

The 2019 CFS report indicates costs of $5-15 per dry tonne for hog fuel, around $100 for residual wood chips ($120 on the coast), $40-55 per cubic metre ($98-134 per dry tonne) for pulp logs, $25-40 for sawdust. And $70-90 per dry tonne for delivered roadside residue (2018 pricing).[44]

Table 9 2015 Estimated Feedstock Procurement Costs in B.C.[45]

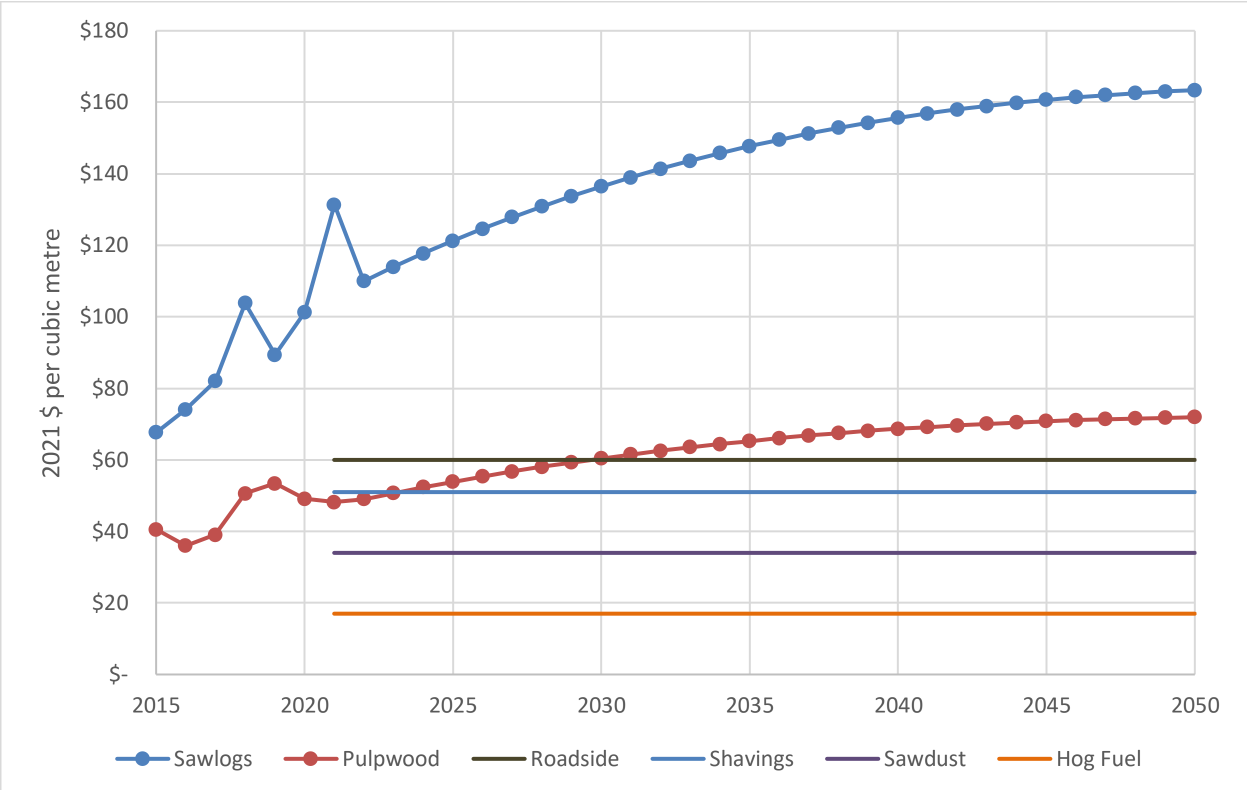
Fibre supply by source		Dry shavings	Saw-dust	Roadside residue	Hog fuel	Standing timber	Total/ average
	% supply	5%	5%	35%	5%	50%	100%
Regional fibre cost	in $/odt	$35	$20	%5	$5	$113	$61.25
Average delivery cost	in $/odt	$10	$10	$50	$10	$60	$49
Total delivered cost	**in $/odt**	**$45**	**$30**	**$55**	**$15**	**$173**	**$110.25**
	in $/m³	**418**	**$12**	**$22**	**$6**	**$71**	**$45.00**

[42]Jim Girvan and Russ Taylor (Fall 2020) "Can Stumpage Reform Save the B.C. Interior Forest Industry). *Truck Loggers*. from https://issuu.com/truckloggers/docs/truckloggerbc_fall_2020_final_lowres/s/11119030 (Accessed September 8, 2021).
[43] B.C. Interior Log Market Report for the three-month period of April 1, 2021 to June 30, 2021. Timber Pricing Branch, Ministry of Forests, Lands, Natural Resource Operations and Rural Development, Province of British Columbia, July 2021.
[44] B.C. Regional Surplus Biomass Fibre Supply Forecast. Industrial Forest Service Inc., March 2019.
[45] Wood Based Biomass in British Columbia and its Potential for New Electricity Generation. Industrial Forest Service Inc., July 2015.

The actual delivered cost of biomass depends on both harvesting and transport costs, plus any treatment at the plant that may be necessary (grinding, milling, de-barking, drying). No general cost can therefore be determined without taking the location and pre-processing requirements into account. Generally, roadside residue costs increase with distance and only a portion will be economically available. FPInnovations set the maximum cost at $60 per dry tonne and determined for various TSAs the amount deemed to be available at that cost, assuming a specific processing site. More can be recovered at a higher cost. The Forest Enhancement Society of B.C. provides one way of bringing down the delivered cost and increasing recovery rates. They contribute an average of $14 per dry tonne, allowing for a delivered cost of about $74 per tonne on average, for an amount of around 1.25 million cubic metres per year.[233]

Figure 12 shows the cost curves for woody feedstock in B.C., based on past trends, in 2021 Canadian dollars, not considering inflation. We assume that:

- Sawlog costs are based on SPF costs (Interior), although slightly lower costs are reported for other species, such as hemlock. Pricing includes logging road construction and replanting and has increased from $66 in 2014 to $128 per cubic metre in 2021 (average of $92 in 2014 to $166 in coastal TSAs), according to the Timber Pricing Branch. Some of the costs will also relate to increases in stumpage, which increased by 75% in the province's interior between 2020 and 2021. Cost increases in our model start at 5% per year in 2016, and decrease to a more modest 2% per year by 2050. Mill closures may reduce competition for logs and therefore lead to lower pricing. This cost represents the case where new facilities would access unharvested stands on their own account, as opposed to buying residue. Some economies can be expected due to whole-tree harvesting and are not accounted for in this cost.
- The cost of pulp logs increased from $40 to $50 per cubic metre since 2014, i.e., over seven years. This is about twice the 2% historical inflation rate, i.e., a 2% cost increase for pulp logs is presumed based on 2021 dollars. Cost increases in our model mirror the recent cost increases for sawlogs.
- Roadside residue costs rise with inflation. They are expected to remain constant in real dollars, at $60 per dry tonne on average. Yet, cost reductions due to supply chain improvements will lead to higher total amounts recovered.
- The cost of other residue is inflated at 2% per year to 2021 pricing from the 2015 pricing shown in Table 9, and deemed to continue to increase with inflation.



Note: Costs are expected to increase with inflation. This chart shows developments net of inflation

Figure 12 Expected Increases in Delivered Fibre Cost by Category, 2021-2050, in 2021$

3.2 Allocation of Resources

The forestry resources quantified above can be used for several of the technology pathways discussed below. Some of them therefore stand in direct competition for the same resources. Either one technology will win out over others, they will share the resource, or a staggered transition from one to another will occur. In any case, the total potential for each cannot be greater than the total wood resource. A brief outline describes the most likely outcomes:

- Lignin may be removed from black liquor to de-bottleneck recovery boilers but, once removed, higher-value markets are likely to be sought for this product. Although the energy value of lignin is fairly high at $30 per gigajoule, its use in lime kilns would require major modifications that deter its use. Recovery boilers will have to replace lignin with alternative fuels, such as hog fuel, to maintain an energy balance.

- Syngas will likely be produced at most B.C. mills using natural gas in lime kilns. This technology is deemed commercially available, even though it is still new. It is expected to be deployed gradually, starting with demonstration projects in the coming two years.[64] The scope of these gasifiers will be limited to the lime kilns and will therefore only consume a portion of the woody feedstock available, and only replace a portion of natural gas use at mills. Once established, it will likely continue for many years, possibly through 2050. Gasifiers could be used at cement kilns, veneer plants and others but we do not explore this in this report.

- Hydrogen from wood is a pre-commercial technology not yet proven at scale. It is not expected to be implemented before 2030 except for demonstration projects. It is considered to be less complex and cheaper than RNG production from wood and is therefore allocated the remaining resources not used up by syngas production. It is possible that hydrogen production may replace syngas production at some mills, or that stand-alone or separate hydrogen production will occur.

- RNG is not expected to be produced from wood due to the higher complexity of the technology and its very high capital costs. This may change after 2030 as new technologies mature, at which time it would compete with hydrogen production from wood. These dynamics are difficult to predict and hydrogen and RNG production may then be interchangeable alternatives. This is less relevant to this analysis, given the similar energy conversion efficiencies of these technologies.
- Alternative uses of forestry resources may occur but are not considered here. The production of platform chemicals or the continued or additional use for pellet production, for example, may affect the total resource available for renewable gas production.

3.3 Syngas Production from Solid Biomass

3.3.1 *Description of pathway and technology*

Syngas is the primary product of gasification (carried out at temperatures between 800-1000°C), and a co-product of pyrolysis (carried out at temperatures between 300-500°C). Gasification is a thermochemical process that uses a partially oxidized environment to generate syngas, which a mixture of H_2, CO, CO_2, and CH_4, as well as other small hydrocarbons. Oxidizing agents used in the gasification process include steam, oxygen, and air. While air is a cheap oxidizing agent, it produces syngas with lower LHV and HHV values - for biomass, HHV typically ranges between 4-7 megajoules per cubic metre.[46] The use of different oxidizing agents can deliver syngas with significantly higher HHVs - 10-18 megajoules per cubic metre for steam, and 12-28 megajoules per cubic metre for oxygen.[47]

The process of gasification of solid biomass requires the material to be dried (generally below 30% MC), reduced in size to particles or chips, combusted in the absence of oxygen (pyrolyzed), and oxidized to produce syngas. Of approximately 250 gasification facilities operating worldwide, only 10% use solid biomass as a feedstock.[47] While gasification technology itself is proven and operational (i.e. technology readiness levels (TRLs) of 7+), recent work by Binder et al. suggests that across total process chains TRLs are much lower, between TRL 5 (for dual fluidized bed technology) and TRL 3 (sorption enhanced reforming technology).[48] This is due to the lack of operational demonstrations which link all aspects of biomass recovery, processing, gasification, and gas product recovery. As such, lower TRLs would apply to new greenfield construction rather than adding gasifiers to existing pulp and paper mills. An overview of current technologies and their technology status is provided in Appendix A.

[48] Binder et al. (2018). Hydrogen from biomass gasification. IEA Bioenergy Task 33, December 2018.

3.3.2 *Cost Curves*

Syngas has multiple applications. Relatively few reports focus on syngas as a primary product, as most gasification processes are being optimized for hydrogen or for RNG production. Table 10 provides several sources informing about costs related to syngas from wood.

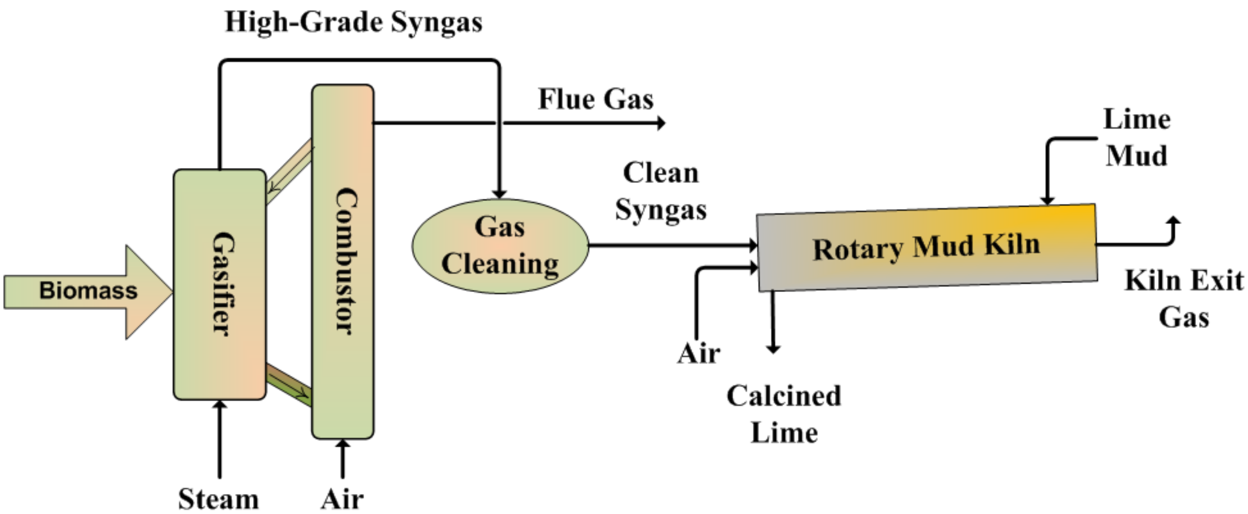
Table 10 Previous Cost Estimates on Syngas Production

Facility	Technology	Size	Energy yield	Gas cost	Capital cost	Source
Conceptual	Dual fluidized bed steam gasification	17.5 tpy		$1.22/m³ $17/GJ	$12.5 M US	Kim et al. 2011
Conceptual	Single-step air-steam gasification	600 ktpy	12 PJ/y	$6.45/m³ $92/GJ	n.d.	Nakyai and Seabea 2019.
Conceptual	Downdraft fixed bed gasification	27 ktpy	0.26 PJ/y		$13.82 M US	Mustafa et al. 2017
Lime kiln	Conventional circulating fluidized beds, or novel fixed bed	50 ktpy	0.8 PJ/y		$40-50 M US	Browne et al. 2019[227]

Capital costs for syngas production are variable, but seem to range between $1-2 million per 1,000 tonnes of material processed. Capital costs drop as plant size increases, so doubling plant size from about 25,000 to 50,000 results in a decrease of 50% in CAPEX. The capital costs used in this report are taken from Browne et al. because this reflects the B.C. situation and because they reflect the slightly lower costs associated with larger throughput.

This chapter describes the use of syngas in lime kilns of kraft pulp mills. Lime kilns are the last stage of recovering spent chemicals. To create the chemical calcination reaction with lime, kilns need to be operated at high temperatures. This is achieved by burning natural gas directly into the kilns. Across B.C., almost 6,000 gigajoules of natural gas are used in lime kilns.

Syngas can be a substitute for natural gas, more so than solid biomass, because its physical and chemical properties require little modification upstream and downstream of the existing lime kilns. In fact, medium calorific syngas could likely be used in parallel to natural gas, providing increased redundancy and a reduced conversion risk compared to other fuels, such as lignin (see chapter 3.6 below). The pathway is illustrated in Figure 13 below.



Source: Highbury Energy

Figure 13 Process Flow for the Production and Use of Syngas in Lime Kilns of Kraft Pulp Mills

Table 11 presents the default input parameters used to model gas costs. The capital cost was developed above. Operating cost parameters are based on Browne (2019.)[227] Capital costs are assumed to decrease over time due to technology improvements; the technology is fairly well understood and costs will likely drop in a fairly linear fashion. The default cost of wood is $60 per dry tonne but it is important to note that these costs could rise. While investment costs are substantive, feedstock costs are critical to the cost of these operations.

Table 11 Default Cost Parameters, Syngas from Wood for Use in Lime Kilns, in 2021$

Cost parameter	Value	Share	Comments
Annual biomass input	50,000 odt		Commercial-scale plant
Feedstock cost	$60/odt		Minimum scenario and first block of Maximum scenario
Gas yield	75%		Based on feedstock input, HHV
Capital cost	$50 million		In 2021
Capital cost	$35 million		In 2030 (-30%)
Capital cost	$25 million		In 2050 (-50%)
Amortization	$5.6 million	45%	20 years, 9.2%
Feedstock cost	$3.0 million	24%	
Personnel cost			
Labour, 9 FTE	$0.5 million	4%	
Management, 3 FTE	$0.3 million	2%	
Electricity	$0.5 million	4%	7.5 GWh/year (estimated value)
Natural gas	$0.02 million	0%	2,000 GJ/year (estimated value)
Other costs	2.5 million	20%	5% of CAPEX
TOTAL OPEX	$13 million	100%	
Gas production cost	$18/GJ		In 2021

Figure 14 depicts modelled syngas costs for use at B.C. lime kilns. We base our initial assumptions on Browne's 2019 report on syngas options for B.C. These costs evolve over time with reductions in capital offset in part by increases in feedstock costs. The primary cost of syngas systems is the cost of biomass used in the process, while capital costs are substantively lower. We use an average conversion efficiency of 70% on an energy input-output basis. The efficiency for syngas from biomass in the literature ranges between 0.42 to 0.88 gigajoules per gigajoule, so these efficiencies reflect the median conversion efficiency of systems available.

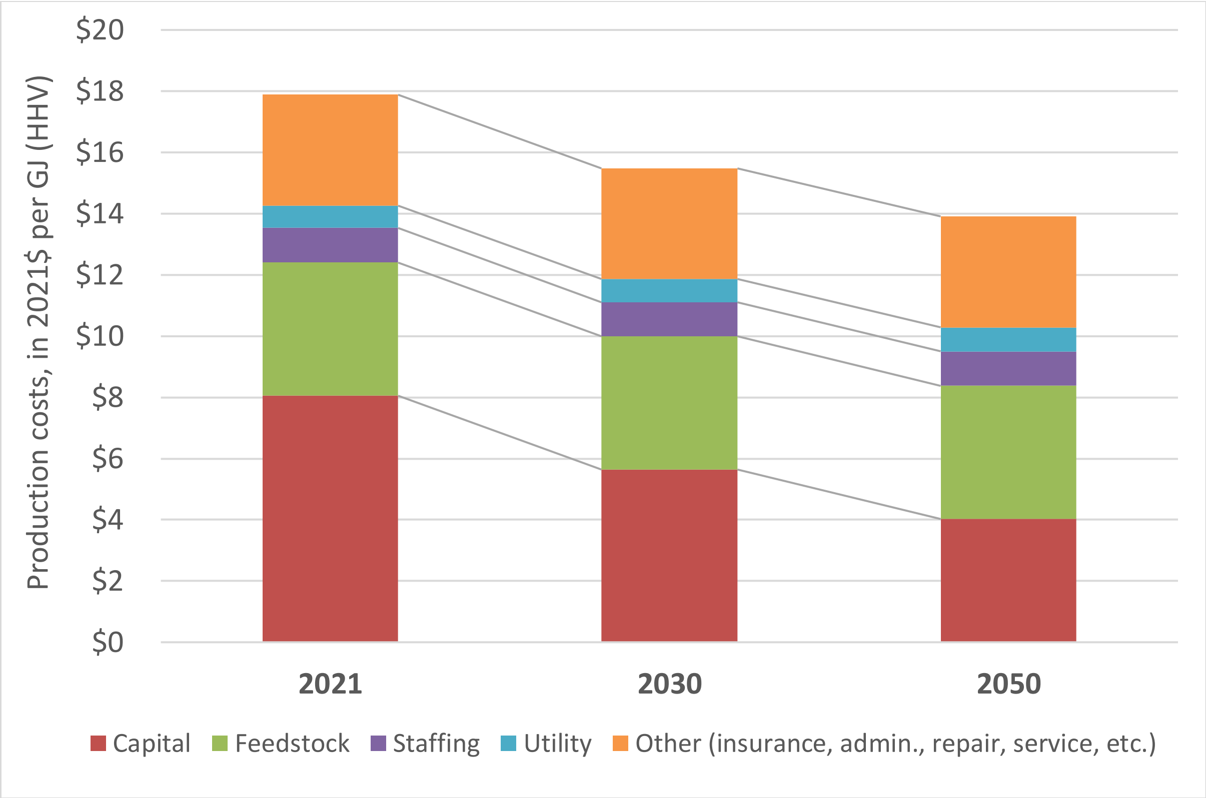


Figure 14 Modelled Cost for Syngas Use in a Pulp Mill's Lime Kiln

3.3.3 *Carbon intensity of syngas from biomass*

The use of syngas in energy production provides significant reductions in CO_2 emissions compared to natural gas on a life-cycle basis. Use of fossil fuels in the harvest and transport of biomass, and in the plant itself, contributes to emissions. Browne estimates that production of 0.8 petajoules per year of syngas would reduce GHG emissions associated with natural gas use by 41 kilotonnes CO_2e per year, in B.C.[227] Based on the model used to estimate the production costs above, B.C. values for natural gas-, electricity-, and feedstock-related GHG emissions for the production of syngas result in a CI of 3.2 grams per megajoule.

3.3.4 *Markets*

Producing syngas at existing pulp and paper facilities provides an opportunity to reduce natural gas consumption in lime kilns within these facilities. Browne estimated the impact of converting the three largest lime kilns in the province to syngas. He suggested that approximately 150,000 dry tonnes of biomass would be required per year to displace 2.4 petajoules per year of natural gas. He found that with a capital cost of US$40-50 million per conversion, and with variable operating costs of between US$5-10 per gigajoule, payback periods could be as low as 3-5 years (at $30 per gigajoule). Browne assumes that many of the capital costs for gasifiers are fixed.[227] Assuming this to be true, the market for syngas in B.C. is limited to a short list of facilities, and would consume about 150,000 dry tonnes per year. Browne considered the smaller kilns (nine in total) to be too small for economically feasible conversion. In total, these mills could consume up to 225,000 dry tonnes per year of biomass, and displace a total of 3.65 petajoules per year. Thus, the full potential of lime kiln substitution is 6.05 petajoules and would consume 475,000 dry tonnes per year of biomass.

3.3.5 *Infrastructure Needs*

Developing syngas for use in lime kilns will result in substantive savings, particularly with larger kilns. The technology is well understood and the economic feasibility for the three largest plants (150,000 dry tonnes per year in total) is strong. Expanded use of this technology with smaller lime kilns is more problematic as the capital costs are high, even for small facilities, and thus the cost of syngas goes up on a per unit basis. The best use case will focus on the largest plants and allow other biomass to be used for other renewable gas applications as discussed in following sections.

3.4 Hydrogen Production from Solid Biomass

3.4.1. *Description of Pathway and Technology Update*

As described in the previous section, gasification (or pyrolysis) produces hydrogen and CO among other gas species. These gases can be recovered through adsorption or via membrane separation.[49] CO can be further combined with H_2O via a water-gas shift reaction to produce additional hydrogen, CO_2, and a small amount of heat. The water-gas shift reaction is used to clean up syngas and produce a clean mix of CO_2, CO, and hydrogen (syngas) which can then be separated to provide a pure hydrogen stream. Key technological challenges common to most platforms include the production of better membranes to separate the gases, process simplification and high biomass costs. Commercial projects are now being planned using plasma-enhanced thermal catalytic technology, as pioneered by SGH2. An overview of current technologies and their technology status is provided in Appendix A.

3.4.2. *Cost Curves*

Examples of cost estimates in the literature are shown in Table 12. Capital costs for hydrogen-producing gasification systems are highly variable as a number of new technologies are being explored. In this study, we chose recent figures published by Binder for a large-scale dual fluidized bed gasifier, with throughput of approximately 50 tonnes per day, which reflects recent cost estimates for an established technology. We expect that capital costs for a 140,000 dry tonnes year facility will be approximately $160 million.

Table 13 presents the default input parameters used to model gas costs. The capital costs are developed above. Operating cost parameters are based on Binder et al. (2018). Capital costs are assumed to decrease over time due to technology improvements, especially after 2030. The default cost of wood is $60 per dry tonne, representing low costs. In this model, feedstock is the dominant cost, as the technology is scaled to a very large size. Note that the large plant size would suggest that transport of feedstock may become a substantive cost, which would be reflected in higher feedstock costs on a per-tonne basis.

Gas cost	$23/GJ		In 2021

Figure 14 depicts modelled hydrogen costs in B.C. The recent ZEN/BCBN report estimates the cost of hydrogen from biomass to be $2.14 per kilogram, based on a $180 per tonne feedstock cost and incorporating carbon capture and storage costs, which are included to offset non-biogenic emissions.[93] Incorporating all costs, this is about $8-12 per gigajoule. Although the assumed feedstock cost is much

[50] Ellingson (2020). World's largest green hydrogen project coming to Lancaster. https://www.bizjournals.com/losangeles/news/2020/05/19/worlds-largest-green-hydrogen-project-lancaster.html

lower, the model used for the present report shows somewhat higher costs per gigajoule, though still lower than those for RNG (see next section). Initial costs are predicated on high capital costs associated with early-stage plants, with related utility and operating costs (about $22 per gigajoule in total). The cost estimates towards 2050 bring capital costs closer to the Zen figures, at about $18 per gigajoule. An average conversion efficiency 0.67 gigajoules per gigajoule (feedstock input to gas output) was used. Efficiency ranges for hydrogen in the literature cited in this section range from between 0.56 and 0.67 gigajoules per gigajoule so we have opted for the most efficient conversion technology we are aware of.

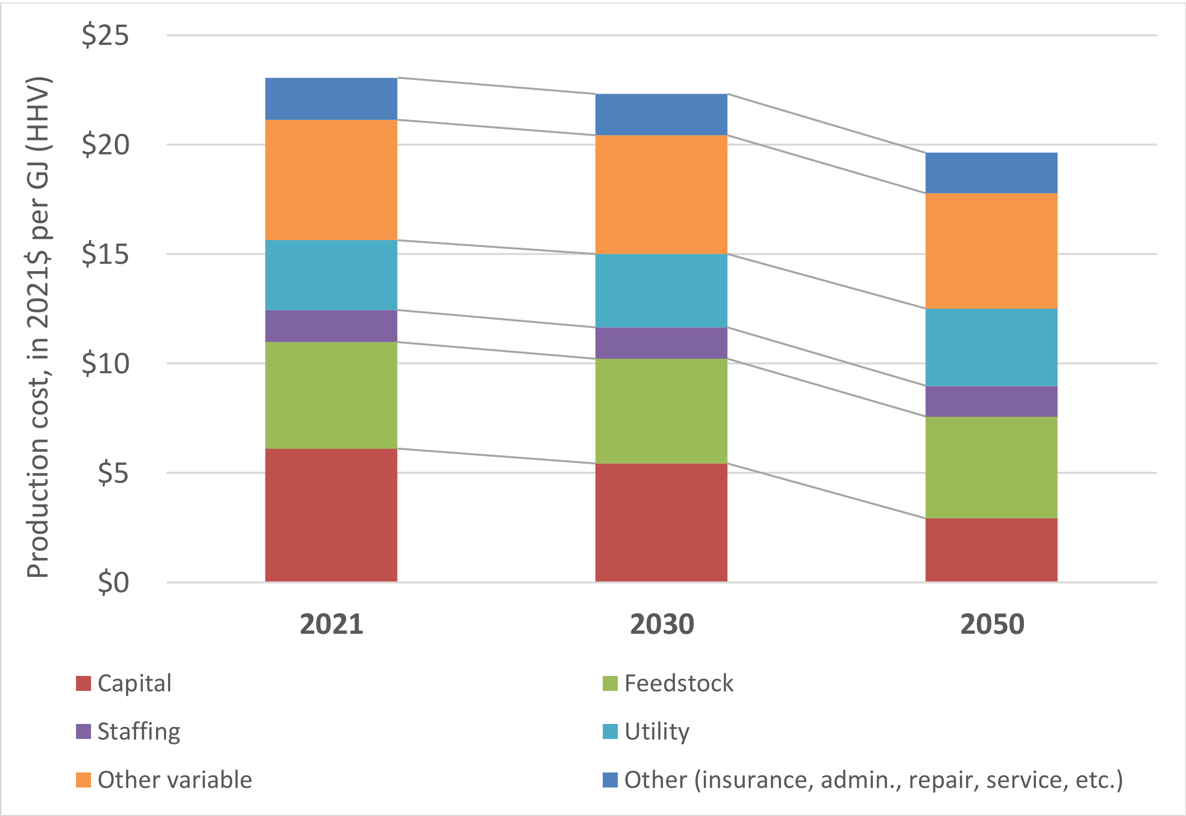

Figure 15 Modelled Hydrogen-from-Biomass Production Costs

3.4.3. *Carbon Intensity of Hydrogen from Wood*

Hydrogen from biomass has significant challenges. The very low hydrogen content in biomass itself (5-10%, tending to the lower end of this spectrum), means that most hydrogen produced is actually sourced from the water used in steam reformation. Conversely, the energy efficiency of steam reformation can be very high (56%).[51]

Biomass-sourced hydrogen has no direct GHG footprint. GHGs are still generated during the harvest and transport of biomass, and through the use of grid electricity and some natural gas in its production. Note that some technologies (e.g. SGH2) claim avoided (negative) GHG emissions of -188 grams CO_2e per megajoule H_2 (likely because of avoided landfilling).[52] The Hydrogen Council estimates the CI of hydrogen

[51] Milne et al. (2001) Hydrogen from biomass: State of the art and research challenges. IEA Hydrogen Task 16.
[52] SGH2 (2021). Technology. https://www.sgh2energy.com/technology/#hic

from wood as 1.7 kilograms per kilogram of hydrogen (12 grams per megajoule), which is the value assumed for this report.[53]

3.4.4. *Markets*

Sales of hydrogen into the gas network will depend on both updated policy targets and the cost of hydrogen produced from woody feedstock. As with other renewable gases from biomass, there is competition for wood feedstock, including cogeneration in mills, pellet production, and potentially renewable liquid fuels. By 2030, and possibly in subsequent years, several syngas projects are expected to be implemented and given priority over the more expensive and less mature hydrogen production technologies (see Section 3.2). Most hog fuel and roadside residues are likely to be used for syngas production by then, resulting in a theoretical total of up to 6 petajoules per year.

A large portion of the readily available woody biomass is currently used in power boilers of pulp mills. The power is partly used by the pulp mill and excess is fed into BC Hydro's grid under power purchase agreements that will expire before 2030. If this feedstock currently bound up in BC Hydro contracts for power exports to the grid (see Table 69 in Appendix A) becomes available and if there is a transition from pellet production to gas production in B.C., sufficient additional material will become available to also produce substantial amounts of hydrogen (see Chapter 5.0). A policy that reserves a certain amount of renewable gas for woody resources may create a captive market for hydrogen and/or RNG from wood (see Section 3.5).[227]

3.4.5. *Infrastructure Needs*

Developing hydrogen from biomass using gasification followed by a water-shift reaction will require significant development of new gasification infrastructure in B.C. Browne's report suggests that gasifiers capable of processing about 150,000 dry tonnes of biomass per year can be cost-effective, which in turn suggests that about eight facilities across the province would be sufficient to handle the 1.2 million tonnes of available biomass that we estimate from roadside residue. Facility locations would be determined via analysis of the gas grid and proximity to wood supply. Work also needs to be carried out on carbon capture and sequestration technologies to maximize the benefit of these processes.[93]

3.5 RNG from Woody Feedstock

3.5.1. *Description of pathway and technology overview*

The production of RNG from wood generally follows a stepped process that first gasifies the wood, cleans the syngas and then subjects it to a water-shift reaction (addition of steam) to add more hydrogen. Once the molar CO-H_2 ratio is about 1:3, a methanation reaction turns the syngas into a mixture with a high share of methane. Subsequent purification and compression provide pipeline-grade gas. Although these processes by themselves are all commercial, their combination is still pre-commercial. As opposed to syngas production to displace natura gas on-site, producing methane from woody feedstock requires some economies of scale. A much larger and more costly process will be needed to replace all natural gas used at a pulp and paper mill, and to insert additional gas into the pipeline system.

Appendix A identifies key technology providers for each of the main process steps (gasification, water-shift, methanation, and gas cleaning). The technologies from Sweden (GoBiGas/Valmet), the Netherlands (ECN) and the Austrian FICFB gasifier concepts are currently considered to be the best contenders for

[53] Hydrogen decarbonization pathways: A life-cycle assessment. Hydrogen Council, January 2021

gasification and gas cleaning. Methanation units can be provided by Haldor Topsoe, BASF or WOOD (Vesta). The University of Karlsruhe and ECN have also developed such technologies.

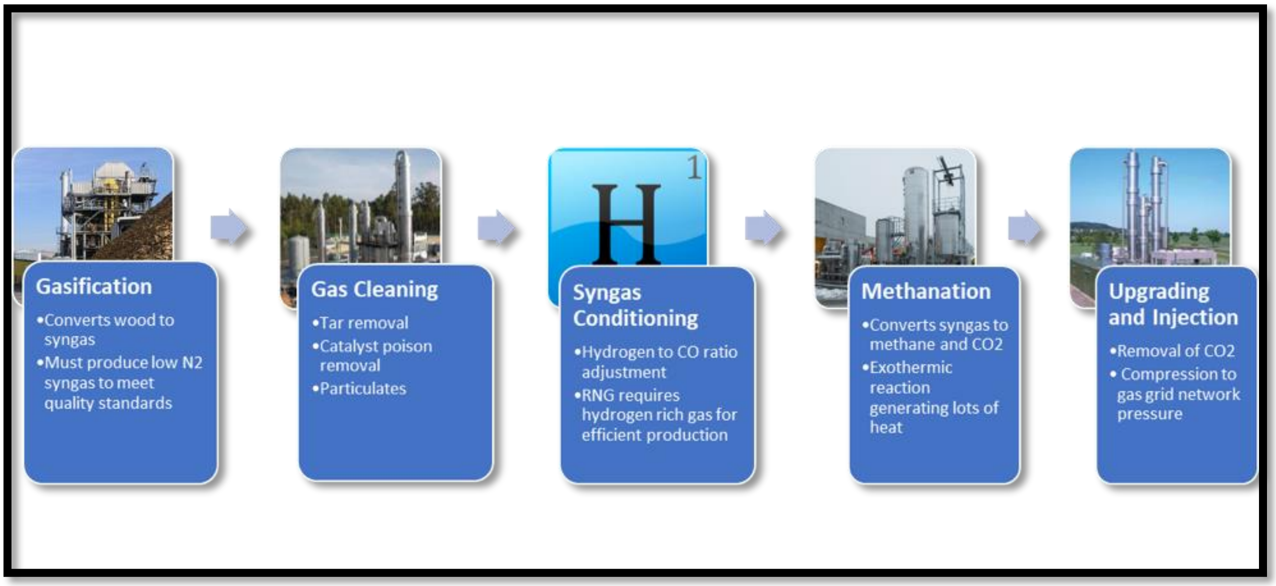

Figure 16 Generic Syngas to RNG Process

Biological methanation is an emerging technology that may soon replace the need for a chemical methanation step. Biological methanation occurs at low temperatures and pressures, similar to conventional anerobic digestion, rather than the high pressures and temperatures needed for conventional methanation.[54] Furthermore, biomethanation of syngas can yield significant savings as some contaminants, such as sulphur, do not need to be removed, meaning that the tar removal, water gas shift and guard beds can be avoided.[55] Tar removal, although likely to a lesser extent, is still necessary for biological syngas methanation. Challenges with biomethanation processes include the low solubility of syngas and the relatively low production rate.[56] The efficiency, at 50-65%,[57] is lower than catalytic methanation, which has a biomass-to-RNG efficiency of 65%-70%. Typically, syngas with high hydrogen content is best for biological methanation. Vancouver-based Highbury Energy is investigating biological methanation as a wood-to-RNG pathway. A small slipstream project testing biomethanation of syngas occurred at the gasifier in Güssing (Austria). The technology does not appear to be commercially proven with syngas but developments should be monitored.

Another potential paradigm changer is the pre-commercial process from G4 Insights. This Vancouver-based company proposes a simplified tar-free methane production process called hydropyrolysis that has considerably lower capital costs than the conventional gasification concept and is thought to be able to reduce the costs of methane production from woody feedstock. The process works by heating the biomass in a hydrogen atmosphere into char and a pyrolysis gas, the latter of which is then catalytically reacted to form methane. The mixture of methane, H2, syngas, water and carbon dioxide are separated. The methane is injected into the grid or used on-site. Some of the mixture is fed back to a char-fired reformer & PSA to generate and purify the necessary hydrogen.

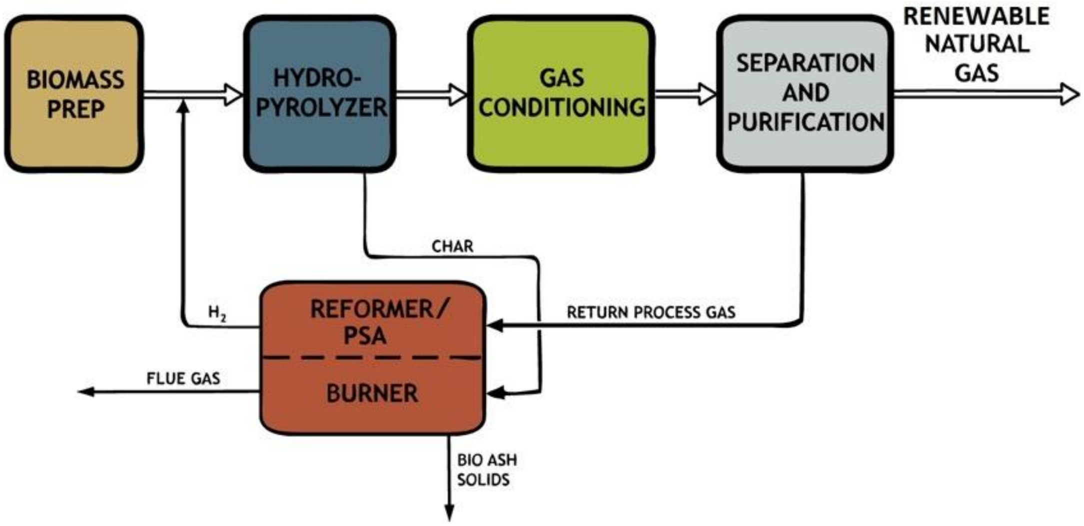

Figure 17 Pyrocatalytic Hydrogenation Wood to Methane Process

Emerging technologies around supercritical water may also open new avenues in wood methanation. Supercritical water uses the special solvent capacity of water with organic feedstocks when it is heated to a temperature greater than 374°C and pressurized above 22.1 megapascal.[58] Key advantages of supercritical water gasification include a higher carbon conversion capability and the ability to use wet feedstocks such as sewage sludge and other slurries without a significant energy penalty while Hydrothermal gasification or liquefaction can complement AD plants that have biosolids or digestate disposal issues as microplastics, some heavy metals, and pathogens are reduced or eliminated. Struvite, a desirable form of fertilizer can also be produced, aiding the nitrogen and phosphorous control benefits of the technology.[59] The efficiency is estimated to be 60-70%. Process heat recovery and conventional plant sizes are expected to be in the range of 2-3 tonnes dry mass per hour and to operate at temperatures of 600-700°C.[60]

As for the syngas produced, supercritical water gasification produces methane. The syngas can be fed into an anaerobic digester or be upgraded like conventional biogas.[61] Treatech's technology can generate

[61] SINTEF Norway.(May 7th, 2021). "BioSynGas - Next generation Biogas production through the Synergetic Integration of Gasification"

around 150% more methane than anaerobic digestion. RNG can also be produced from a similar hydrothermal liquefaction process as a by-product, with 3.6 gigajoules being produced per tonne of dry feedstock. HTL plants are being developed in Vancouver and Prince George and could represent an additional RNG source as well as being a liquid fuel generator. The TRL of this technology is around 3-7 according to GRTgaz, the largest and most advanced appearing to be with SCW systems having a 2 tonnes per hour demonstrator in the Netherlands.[62]

3.5.2. *Production Cost Parameters*

For the production of RNG from wood, both capital and feedstock costs are key parameters. Table 14 summarizes the estimates made in a previous report for an RNG plant with a wood input of 200,000 dry tonnes per year, assuming a 67% energy yield based on wood input. The design includes a Carbona gasifier and a Halder Topsoe methanation unit. For operating costs (leaving out debt service), feedstock represents about a quarter, with other variable costs accounting for almost a third of OPEX. The payback determined with these costs is over 60 years. According to the study, an RNG gas price of $50 per gigajoule would be required to bring this to ten years unless subsidies can be obtained. Capital costs have a great impact on the economic performance of the plant: a 30% cost increase means the ROI at a gas price of $50 per gigajoule would drop from 19% to 15%.

Table 14 Cost Structure of Biomass-to-RNG Conversion,* as per Browne (2019)[227]

CAPEX	Million C$ (2018)	OPEX	Million C$ (2018)
Gasification	117	**Wood ($61.2/odt)**	12
Methanation	85	**Other variables**	15
Construction	184	**Labor & maintenance**	8.7
EPC fee	15	**Fixed**	10
Engineering	8		
Permits & consulting	4		
Commissioning & start-up	17		
General & administrative	4.7		
TOTAL	**410**	**TOTAL**	**46**

* 200,000 odt per year feedstock intake

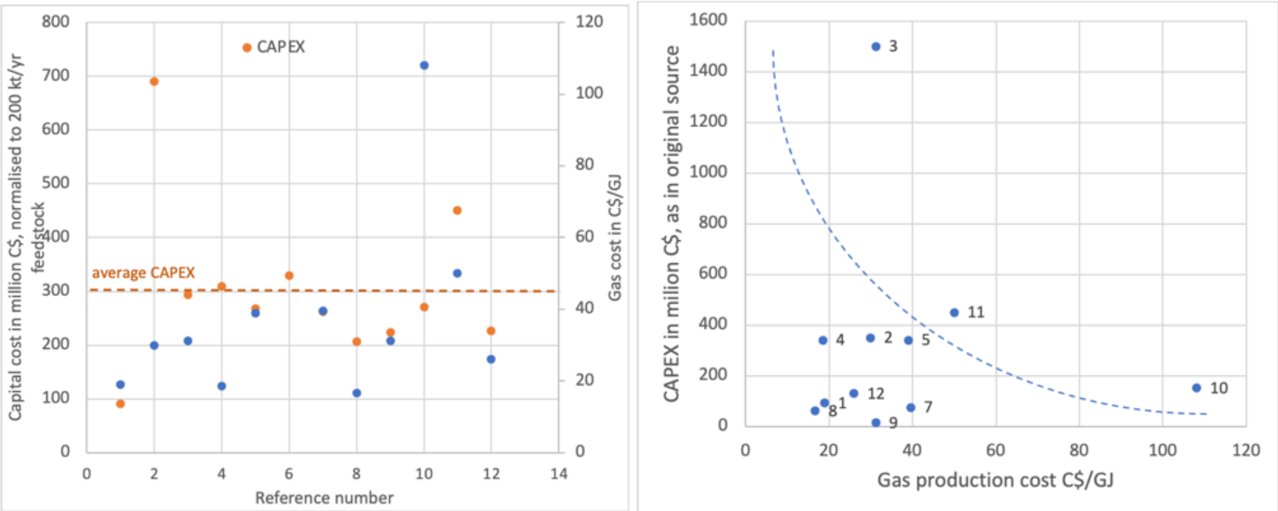
Since the methanation step is exothermic, this energy can be used as process energy. In theory, it could be used to dry pulp or lumber (depending on the site). RNG production will also increase power consumption at the mill considerably. To simplify the challenge, the approach followed here assumes that excess heat is used to produce additional power to reduce power imports from the grid.[65]

3.5.3. *Capital and Production Costs*

Figure 18 shows cost estimates for RNG production from wood. The sources for the figure are identified in Appendix B, by number (Table 60). The left graph normalises the literature values to 200,000 dry tonnes of wood input, making some assumptions about wood energy values and economies of scale for each plant (scale factor 0.8). The graph shows a wide spread of results, with capital costs varying by a factor of seven and gas costs varying from $20 to more than $100 per gigajoule. Gas cost estimates for the GoBiGas, ECN and two conceptual estimates concur with the estimate in Appendix B: at between C$30-40 per gigajoule. The REN Energy facility planned for Fruitvale, B.C. seems to be an outlier as it would only cost $130 million.63 It would use over 100,000 tonnes of wood waste, and produce about one petajoule of RNG.

[62] https://www.igu.org/wp-content/uploads/2019/09/SG1.2-Hydrothermal-Gasification.pdf (October 12th, 2021).
[63] https://www.canadianbiomassmagazine.ca/a-first-for-north-america-fortisbc-ren-energy-to-produce-rng-from-wood-waste/ (Accessed September 16, 2021).

Presumably, it would produce RNG at under $31 per gigajoule to qualify for a purchasing agreement with Fortis. The large spread of cost estimates indicates that the uncertainty regarding production costs of RNG from wood remains very high. The right graph plots the original CAPEX numbers of each source against the resulting gas costs. However, no logical cost curve showing economies of scale can be derived from this data.



Note: See Table 60 in Appendix B for sources of each data point. Data normalised to 200,000 odt per year

Figure 18 Normalized Cost Estimates for CAPEX and Gas Cost (RNG from Wood)

Capital cost estimates seem to converge around 200 to 400 million dollars for a plant with 200,000 dry tonnes of annual input. The cost estimate from the previous section therefore seems very conservative. For this report, $300 million in capital costs has been assumed. This is in line with the numbers developed for syngas and for hydrogen production in the previous sections. For 2030, no material change in capital or production costs is expected. After 2030, assuming that emerging technologies such as G4 Insights may become commercialized, a capital cost decrease of about 50% can be postulated. Because little is known about the G4 Insights process, the other operating parameters were not changed for this estimate. This may lead to a high cost estimate as the one-step process can be expected to have lower utility and personnel costs.

Based on the above, Table 15 presents the default input parameters used to model gas costs. The capital cost was developed above. Operating cost parameters are based on Browne (2019).[227] Capital costs are assumed to decrease over time due to technology improvements, especially after 2030. The default cost of wood is $60 per dry tonne but higher costs have also been modelled. High amortization costs clearly dominate operating costs, even with the somewhat generous assumption of a 20-year payback. Feedstock is the second most important cost but is considerably less important than amortization.

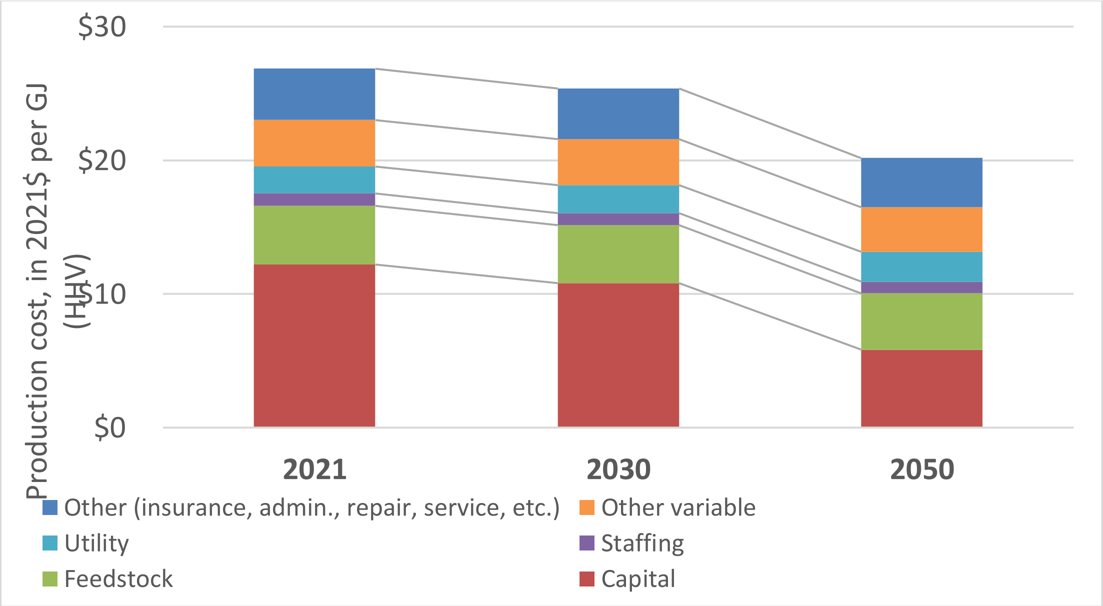
Figure 19 is the model output for RNG production costs from wood today and over the coming three decades. Capital costs are the main cost factor initially. Capital subsidies or better borrowing terms can positively influence gas production costs. The 20-year amortization period assumed is not acceptable to the forest products industry, which is known to seek amortization periods of only a few years for any investment.[64] This implies that subsidies or third-party financing (e.g., through a gas utility) would be required to implement such projects. Although feedstock is an important factor, it is only responsible for about 10% of production costs. Somewhat higher feedstock costs will therefore not have a strong impact on RNG cost.

[64] Bob Lindstrom, BC Pulp and Paper Alliance, in a conversation on Sep 27, 2021

Larger mills would likely implement syngas production during the first decade, removing around 150,000 dry tonnes from the available resource. With increased recovery of harvesting residue, about 1.2 million tonnes of this material would be available for new RNG production. This is sufficient for six facilities with an annual input of 200,000 dry tonnes, each producing 2.55 petajoules of gas per year (12.76 gigajoule per dry tonne.)[227]

Table 15 Default Cost Parameters, RNG from Wood, in 2021$

Cost parameters	Value	Share	Comments
Annual biomass input	200,000 odt		Commercial-scale plant
Feedstock cost	$60/odt		Minimum scenario and first block of Maximum scenario
Gas yield	67%		Based on feedstock input, LHV
Capital cost	$300 million		In 2021
Capital cost	$270 million		In 2030 (-10%)
Capital cost	$150 million		In 2050 (-50%)
Amortization	$33,333,633	45%	20 years, 9.2%
Feedstock cost	$12,000,000	16%	
Personnel cost		4%	
Labour, 26 FTE	$2,080,000		
Management, 3 FTE	$450,000		
Electricity	$5,124,600	7%	78,840 MWh per year
Natural gas	$376,631	1%	47,328 GJ per year
Other variable costs	$9,498,769	13%	
Other costs	$10,500,000	14%	4% of CAPEX
TOTAL OPEX	$73,363,633	100%	
Gas cost	$27/GJ		In 2021



* Feedstock cost at $60/odt

Figure 19 Anticipated Production Cost Development for RNG from Wood

3.5.4. *Carbon Intensity of RNG*

Counting wood feedstock as carbon neutral because it does not contain any fossil carbon, the feedstock procurement and process emissions still lead to emissions that need to be accounted for to arrive at a carbon intensity for RNG made from wood. For the Stockton site in the U.K., a GHG intensity of 16.8 grams per megajoule was determined.[65] This calculation took into account grid electricity emissions but also provided emission credits for the excess electricity produced in this case. These would likely cancel each other out in B.C. Another result assessed a process using the WoodRoll technology and arrived at 12 to 15 grams per megajoule for facilities of 4.8 and 18 MW capacity, respectively.[66] This includes credits for district heating that would rarely be available to a plant in B.C. Leaving out this credit but removing emissions from electricity use would lead to a very similar outcome as in the previous study. G4 Insights determined the GHG intensity of methane made from wood in California to replace motor vehicle fuels and arrived at 14 grams per megajoule.[67] The latter would imply that the GHG emission intensity will not be impacted in a major way by the technology used, since G4 Insights may be an emerging technology replacing the more conventional gasification approach. Any reductions are likely to be incremental, due to overall lower GHG emissions from transport and other sectors.

3.5.5. *Markets*

Total demand for renewable gases for injection into the provincial pipeline network is at least 15% (on a gigajoule basis) by 2030, based on the current renewable gas target set out in the CleanBC Plan. Additional potential could exist for local projects, where the gas produced would be used directly, or for exporting RNG through certificate trading, e.g., with the Californian LCFS market.

For renewable methane, the market after 2030 is theoretically equal to the total natural gas use in B.C. but actual sales into the gas network will depend on both updated policy targets and the cost of RNG produced from woody feedstock.

There is also competition for the woody feedstock itself. Alternative markets for woody feedstock exist in the power generation sector, including cogeneration at mills, which may become more attractive after 2032, when BC Hydro expects electricity production to start facing shortfalls. Competition may also come from pulp mills (for roadside residue), wood pellet mills and new concepts around producing renewable liquid fuels for direct use in vehicles or for sale to B.C. refineries. The markets that will ultimately develop and the ability of producers to pay for the woody feedstock will determine how additional feedstock will be allocated.

3.5.6. *Infrastructure Needs*

The existing 15 pulp and paper mills, where some of the feedstock will be available as hog fuel, are prime sites for the installation of RNG production facilities. They are generally close to the natural gas grid (see Figure 45 in Appendix C) and offer colocation benefits in terms of lower personnel requirements and shared infrastructure with existing mills. The estimated cost per facility is $300 million. With 26 new facilities for the Maximum scenario (Section 5.4), the total investment would come to $7.8 billion. These costs do not include additional pipeline or transport costs to take the RNG produced to an injection point. If any of the plants were to be situated at a distance from the pipeline network, additional costs would ensue.

3.6 Lignin as a Replacement Fuel for Natural Gas in the Pulp Industry

3.6.1. *Description of pathway and technology overview*

The GGRR has been amended to enable the gas utilities to work with pulp mills to displace natural gas used at their sites. Lignin is a by-product of the chemical pulping process and when extracted, can be used as a fuel in lime kilns at kraft mills. Wood fibre consists of cellulose, hemicellulose, and lignin. Cellulose is the main component used for pulp. Lignin has been traditionally burned, partly as a fuel, partly to get rid of an unwanted by-product, and to recover the pulping chemicals. Instead of burning lignin as black liquor in recovery boilers it can also be extracted from the spent chemicals.

Because lignin has a high calorific value it can be used to replace natural gas used in a pulp mill's lime kiln. Even though many kraft pulp mills produce surplus steam, lime kilns are typically fuelled by natural gas. This final stage of recovering the original chemical (NaOH) is done in direct-fired rotary kilns that cannot be heated by steam. Dried and ground to a fine powder, lignin can be injected into the kiln just like natural gas, even though the sulfur content of untreated lignin is generally high, derating the kiln capacity and causing corrosion and unwanted effluents.

Lignin can be further processed and sold to offsite markets as a high-grade solid fuel or as a feedstock for bioplastics, resin, etc. Onsite and offsite use as a natural gas replacement is discussed below. Both pathways compete with using lignin as a feedstock for various chemical processes that generally fetch higher market prices than when used or sold as a fuel.

Lignin extraction also has impacts on a pulp mill's energy balance and output capacity. These implications can be understood by looking at the various processes involved. In the chemical pulping process, cellulose is extracted by 'cooking' the wood fibre in caustic chemicals called 'white liquor.' The white liquor turns black as lignin is dissolved in it. By evaporating the water and burning the resulting 'black liquor,' the original chemicals are recovered and, after calcining in the lime kiln, can be reused. Many of these processes require steam or natural gas (Figure 20).

Most chemical pulp mills use lignin as a fuel to heat and power various processes.[68] Extracting lignin creates a fuel shortage that needs to be made up for by additional biomass. The energy balance of the specific pulp mill determines how much lignin can be extracted before lower-cost wood fuel needs to be brought in to fuel a power and steam boiler. A mill would have to have a proper heat / mass balance done to determine the impact and benefits of lignin extraction.[69] Looking only at one of the two pathways would neglect the overall systemic impact of lignin extraction (Figure 21).

Pathway 1 - Lignin replacing natural gas in a lime kiln:
To create the chemical reaction with lime and for maintenance reasons, lime kilns need to be operated at high temperatures and are typically heated by natural gas burners. Wood cannot not be used as a fuel, unless it is completely dried and finely ground or gasified. Dry lignin, however, can be burned in injection burners with the flame injected directly into the kiln. Stora Enso in Finland fires kraft lignin as a fuel in its lime kiln to reduce natural gas use by 70%.[70]

Pathway 2 - Lignin replacing natural gas in other undetermined energy producing processes:

[70] Pulp & Paper Canada. 2013. Stora Enso upgrading Sunila mill to produce lignin.

Because lignin has a high calorific value (26 gigajoules per tonne, HHV), it is a denser and more valuable fuel than conventional woody biomass (17 to 19 gigajoules per tonne, HHV). Like the onsite lime kiln, it can be burned with some technical modifications in the secondary wood processing industry, e.g., in direct-fired lumber drying kilns, veneer dryers or as a supplemental fuel in wood-burning processes of the paper industry.

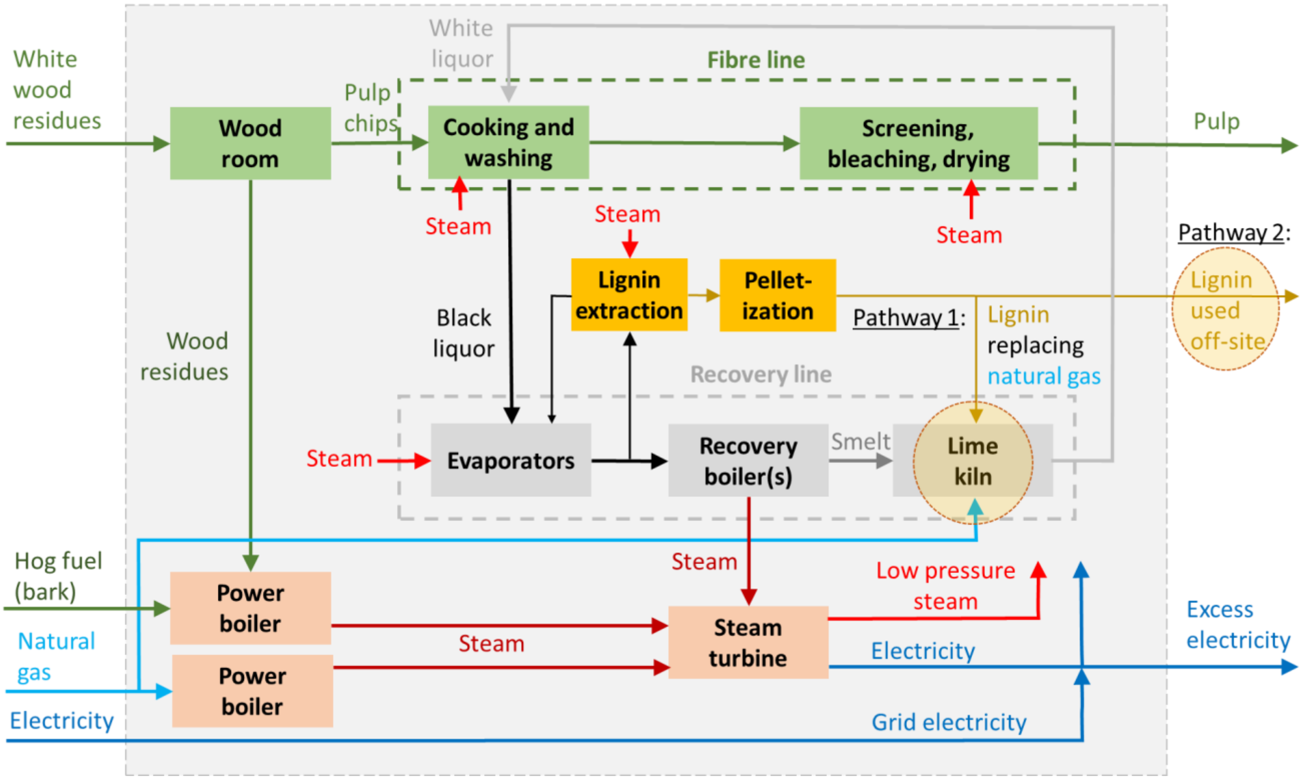

Figure 20 Processes and Energy Flows in a Pulp Mill[71]

The capacity of a kraft pulp mill is typically limited by the size of its recovery boiler, the most expensive part of a kraft mill.[72] Extracting lignin requires that <u>less</u> black liquor be burned in the recovery boiler, thereby allowing increased pulp output. This lignin, then, is no longer available as a fuel to heat other processes. Typically, no more than 15% of lignin can be extracted before additional heat sources are needed, such as low-value bark burned in a power boiler.[68] At a market value of $800 per tonne,[80] equivalent to $31 per gigajoule (HHV), it would be more profitable to sell lignin as a chemical feedstock and purchase additional natural gas at $8 per gigajoule than to burn lignin on site. Instead of burning high-value lignin, low-value biomass may be gasified to heat lime kilns.

[72] Bruce Process Consulting for Alberta Environment. 2008. Technical and Regulatory Review and Benchmarking of Air Emissions from Alberta Kraft Pulp Mills.

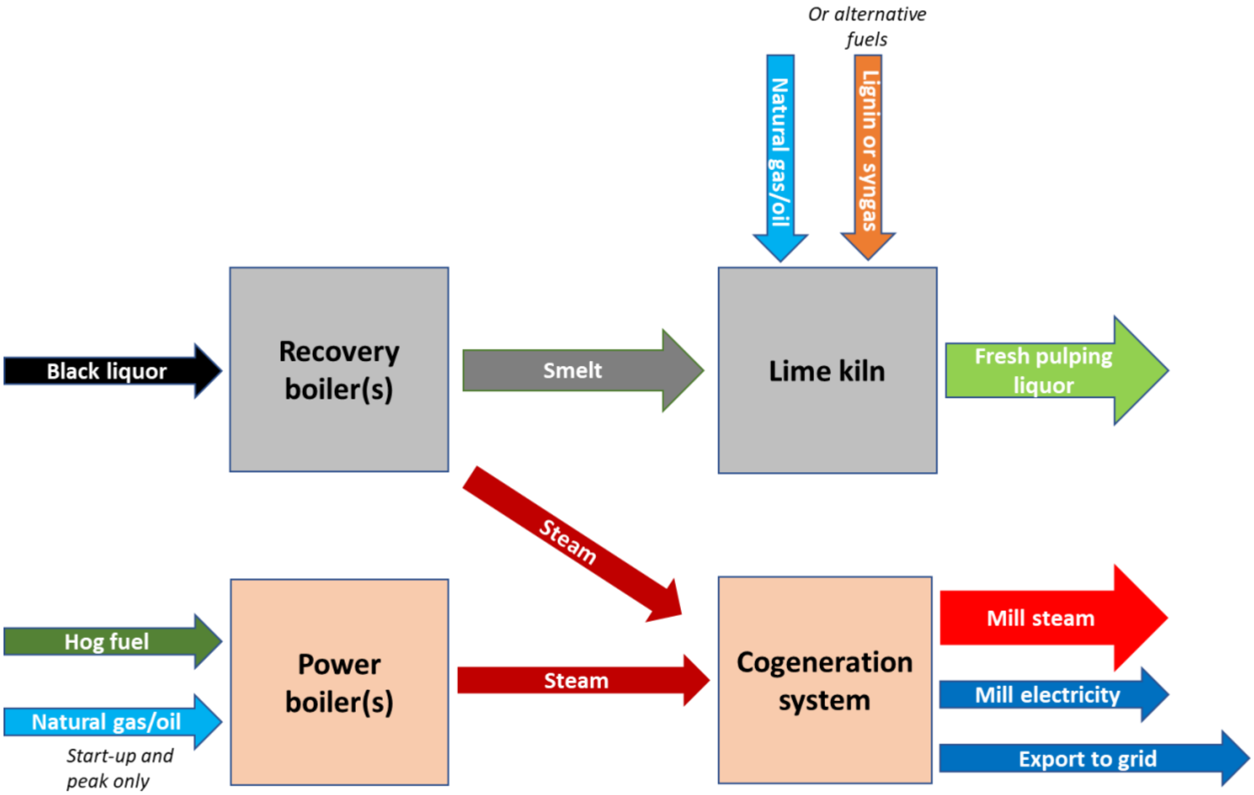

Figure 21 Energy Systems in Kraft Pulp Mills

Typically, around 1.5 tonnes of black liquor solids, consisting of lignin, hemicellulose and pulping chemicals, are created per tonne of pulp (cellulose) produced. Of the black liquor, around 15% to 25% of lignin (roughly 0.18 tonnes of lignin per tonne of pulp, at 10% moisture content)[73] can be extracted without compromising the operation of the recovery boiler. An average-sized kraft pulp mill in B.C. with a daily capacity of 1,100 tonnes of pulp can thus produce around 45,000 tonnes of lignin a year.[74]

The basic process of extracting lignin from black liquor is acidifying the caustic liquor and thereby precipitating the lignin contained in it. Washing, filtration and pelletization are downstream process steps. FPInnovations, combined with NORAM Engineering, refined the process by first oxidizing the liquor to prevent the release of hydrogen sulfate (H_2S), a toxic and foul-smelling gas. Secondly, the oxidation process reduces alkali content and thereby the need for carbon dioxide and sulfuric acid. Heat exchangers recover the heat created from the oxidation of the black liquor.

A competing technology is the LignoBoost system developed in Sweden.[75] A key difference between the LignoBoost and the LignoForce systems is that the latter oxidizes some of the reduced sulphur compounds. Oxidized black liquor has lower ash content and increased particle size of the precipitated lignin, making it easier to be filtered out. The LignoBoost system claims to have lower capital and operational costs. The LignoBoost system is marketed by Valmet and is commercially deployed at the

Domtar Pulp plant in Plymouth, N.C. and Stora Enso's Sunila mill in Finland, producing 25,000 and 50,000 tonnes of lignin a year, respectively.[76]

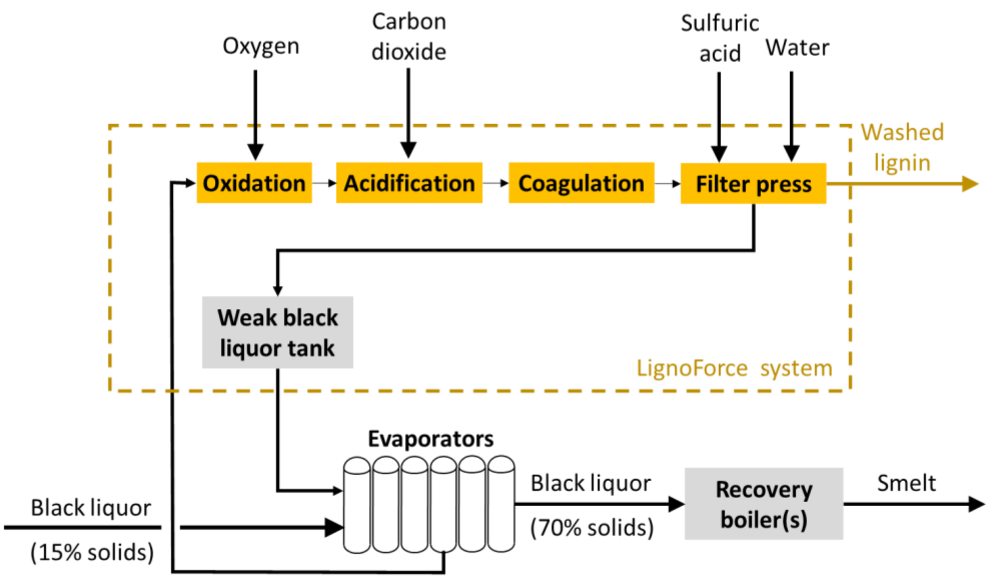

Figure 22 Schematic of the *LignoForce* Technology

One promising pre-commercial approach to producing lignin in a stand-alone plant comes from Pure Lignin Environmental Technology based in Kelowna, B.C. The process produces three separate products: cellulose, lignin and sweet liquor that can be used in the production of cellulosic ethanol. This nitric acid process increases yields compared to the traditional kraft process. A key advantage of the technology is its ability to use any type of biomass, including grasses, husks and waste wood, as feedstock. There is no commercial-scale plant in operation yet. A 50-tonne-per-day plant is said to yield a return on investment of 35%.[77] The company still appears to be at the demonstration stage with a one-vessel portable unit.[78]

3.6.2. *B.C. Potential for Excess Lignin Use*

Currently, no lignin extraction exists at any pulp mill in B.C. West Fraser operates four pulp mills in B.C. and Alberta. The company employed the LignoForce technology at its kraft mill in Hinton, AB. The technology could be replicated at other kraft mills in B.C. Each pulp mill would have the potential to produce more than twice the amount of lignin required to fuel their respective lime kilns. Theoretically, B.C. kraft mills could replace approximately 5.1 petajoules of natural gas and export the remaining 264,000 tonnes of surplus lignin off-site (Table 16).

Pulp mills do not produce more steam than they need for internal purposes. Removing lignin from this balance requires that an equivalent amount of energy is replaced, e.g., in the form of biomass. Instead of burning lignin in the recovery boiler, additional 'hog fuel' needs to go into the power boiler. That hog fuel needs to be imported, preferably from the region or area that the mill is located in. Additional fibre, however, may not be available. The forecast of fibre availability changes depending on the fibre model used or the region or area or zone the mill is located in. Some forecast a deficit for 2029 in certain areas and a surplus in other areas. Trucking woody residue from one area to another is an option and has been done in the past, albeit at a cost. Transportation and handling costs may exceed the value of the fibre, especially if the distance exceeds 200 kilometers one-way. The model underlying the cost projections below assumes that no import or export of fibre is done within assigned regions, areas or zones.

The theoretical potential shown in Table 16 is then constrained by the availability of fibre in the area or region that the mill is located in. Instead of 6 petajoules, the technical or resource potential is only 1.4 to 2.2 petajoules, i.e., a fraction (22% to 47%) of the theoretical potential. Figure 23 below shows the technical potential depending on the fibre model used.

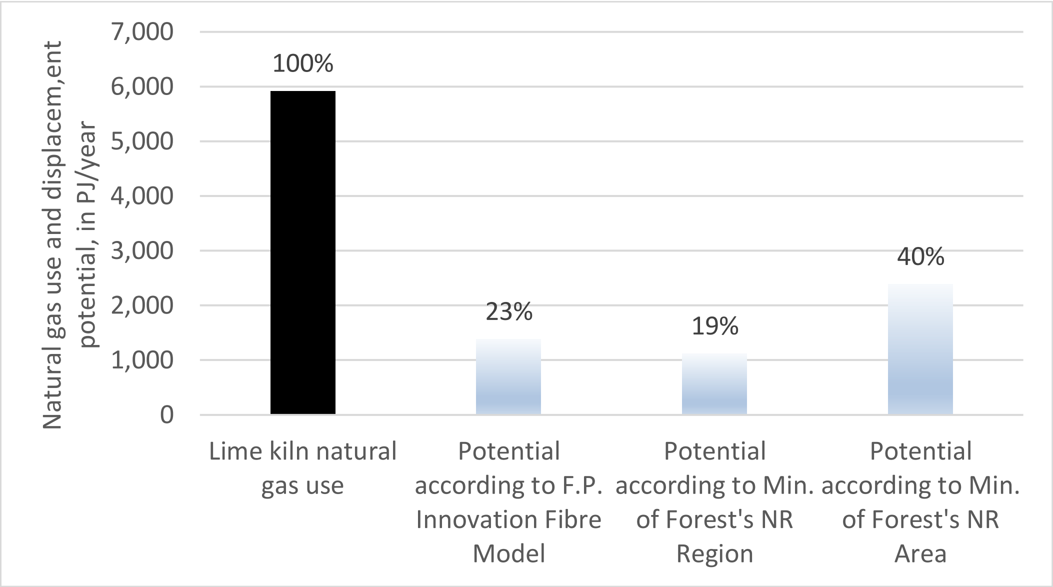

Figure 23 Technical or Resource Potential for Displacing Natural Gas in B.C. Kraft Mills

3.6.3. *Cost Curves*

The cost model shows that assuming the same feedstock costs, heating a pulp mill's limekiln with lignin is more expensive than heating it with syngas ($19 instead of $14 per gigajoule in 2030). This would apply even more when using lignin as a fuel off-site when transport costs are added in. Wherever lignin can be used as a fuel, syngas or even wood pellets likely achieve lower production costs. Moreover, lignin is likely to fetch higher prices when sold as a feedstock for non-energy markets. Current (2021) market prices for sulfate lignin are around $800 per dry tonne (Adt)[80], equivalent to $35 per gigajoule (LHV). Lignin, even in its unrefined form, is too valuable a product to use as a fuel (Figure 24).

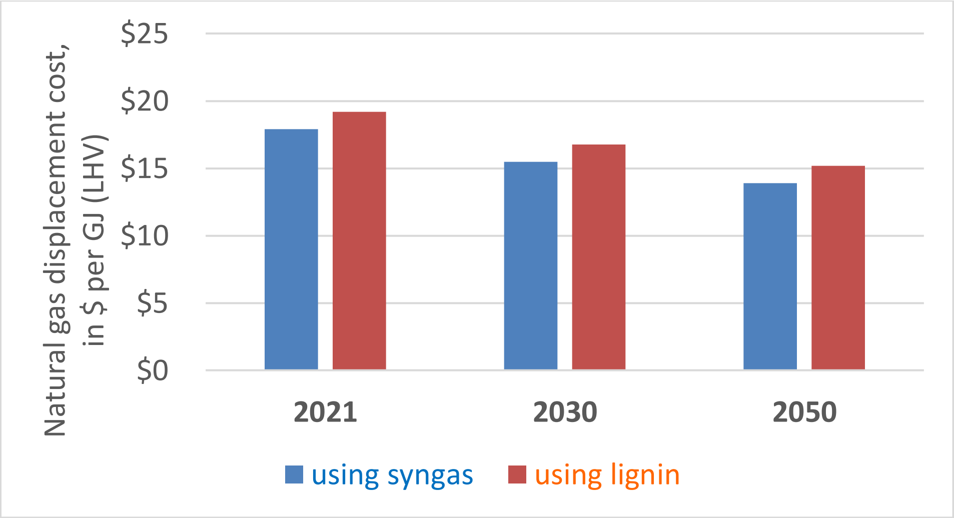

Figure 24 Cost of Replacing Natural Gas in Lime Kilns with Syngas and Lignin

80 https://www.forest2market.com/blog/more-rd-activities-open-up-lignins-feedstock-potential (Accessed September 1st, 2021).

3.6.4. *Carbon Intensity of Lignin Fuel*

Extracting lignin from a pulp mill's energy balance requires replacing it with biomass with an equivalent calorific value. Because lignin has a higher energy density (23 gigajoules per ADt, 26 gigajoules per dry tonne) compared to waste wood or hog fuel (10 gigajoules per green tonne, 18.3 gigajoules per dry tonne), a larger volume of wood fuel needs to be imported than the lignin extracted. Additionally, grid electricity has a small carbon footprint. Using the B.C. grid emission factor, less than 3 kilograms per gigajoule of calorific value would be emitted, 5% of the burner tip emissions of natural gas. Total carbon abatement would range between 54,000 and 118,000 tonnes of CO_2e per year, depending on the fibre availability model used.

Figure 25 Impacts of Lignin Diversion on Kraft Mill Energy Demands and GHG Emissions

Fuel	Amount		GHG emission factor[81]		Annual GHG emissions	
Feedstock (*wood to offset steam losses*)	45,000	odt/year	40.32	kg CO_2e/odt	1,814	t of CO_2e
Electricity	2,500	MWh/yr.	10.80	kg CO_2e/MWh	27	t of CO_2e
Avoided carbon emissions	n/a					
TOTAL			**2.67**	**kg CO_2e/GJ (HHV)**	**1,841**	**t of CO_2e**

3.6.5. *Markets*

Markets for lignin can be separated into energy use and non-energy use. The former is marginal in Canada. Beyond fuel, lignin has a wide variety of uses and applications, including opportunities to displace traditional fossil-based chemicals and products. There has been significant investment in lignin over the past 20 years. Historically, the lignin market for commercial application has been around 60,000 tonnes per year. Major markets for lignin include:[82]

- Adhesives
- Plastic/packaging materials
- Insulation
- Carbon fibre

Different lignin applications have various levels of commercialization. Thermoplastic and packaging applications are the most mature. Resins are an emerging application explored by West Fraser. Currently, lignin can replace up to a quarter of the polyurethane in foams. For carbon fibre applications, lignin-based materials can substitute for 50% to 100% of the fossil-fuel-based material used for carbon fibre[82] and is being investigated as an alternative way to reduce battery weight for lithium ion batteries.[83] Opportunities also exist to use lignin to replace the carbon black used for tires and other reinforced rubber products.[68]

3.6.6. *Infrastructure Needs*

Lignin has the potential to be used as a high-grade fuel where flame temperatures matter. Replacing natural gas in lime kilns is a potential niche application. Converting the existing gas burner with a solid fuel suspension burner is technically more challenging than burning syngas in the same kiln. The burner would have to be exchanged and the flame might have a different shape, resulting in spatially different temperature gradients inside the kiln. This might affect the chemical reaction time, the wear of the refractory, maintenance, and downstream flue gas volumes. The flue gas treatment system, especially the particulate precipitators, would likely have to be changed. This is notably more expensive than using a medium calorific gas, such as syngas from a wood gasifier that would keep the existing equipment in place.

Currently, suspension burners are used where finely ground wood fibre is available, e.g., sander dust at particle board plants. The fine particles instantly ignite as they are injected into the hot combustion chamber, dryer or kiln. Start-up of suspension burners generally requires fossil fuel to heat up the refractory beyond the flash point of the solid fuel used, generally above 300°C. Suspension burners are best used in applications that operate 24/7 without interruption. This tends to be the case in large-scale applications, such as in the pulp and paper industry, the cement industry or petrochemical industry. These operate continuously throughout the year. The sheer amount of lignin that would be needed to fuel these industries and the associated need for fuel storage, however, makes heavy industry an unlikely candidate for using lignin as a fuel.

For transport, lignin is usually compressed into pellets, see Figure 26 below. The material can then be transported in the same vessels as pellets of grain. 'Black pellets' made with, or entirely of, lignin have been used as a fuel in other parts of the world, for example in Russia where lignin is abundant as a by-product of wood alcohol production.[84]

In the Canadian context, the authors of this report consider lignin to be too valuable a product to use as a fuel. An exception may be adding lignin to enhance the calorific value and improve the physical properties of wood or herbaceous pellets used as a fuel. Wood is a sturdy material because lignin is the natural binder. In wood pellets, lignin is the material that creates dense, durable pellets. To get the same quality from pellets produced using plants with lower lignin content, such as straw, a binder must be added during the process. Lignin is a natural resin that can also be used to improve the quality of biomass pellets. Pellets without binding agent may decompose during conveying and storage, forming hazardous gases such as carbon monoxide and hexanal. Adding lignin to pellets may reduce safety concerns and occupational health problems such as wood dust exposure, fire and explosion risks. However, the increase in fuel value has to be balanced with the cost of adding lignin.

[84] Bioenergy International, "Lignin Pellets – from residual product to valuable biofuel," May 2020, Accessed on September 26, 2021 at https://bioenergyinternational.com/pellets-solid-fuels/lignin-pellets-from-residual-product-to-valuable-biofuel

Figure 26 Lignin Pellets[85]

3.7 Recommendations on the Use of Woody Feedstock

While B.C. is a largely forested province, the amount of accessible and attainable woody feedstock has declined in the past year, partly as a consequence of drawing down mountain pine beetle-killed stands and partly due to disturbances, including wildfires. The Ministry of Forests has reduced the Annual Allowable Cut to approximately half the amount available before the infestation. With the projected mill closures, the amount of mill and forestry waste will be reduced further.

In the near term, the best strategy to displace fossil methane in the forest resources industry is to use syngas for use in lime kilns. This can only displace a portion of natural gas use by the industry but still has considerable potential. It will require less feedstock (around 50,000 dry tonnes per year for the largest kilns) and considerably less investment. The gas is also likely to be produced at a lower cost than pipeline-grade methane or hydrogen. These still require technology development to become commercial.

In the longer term, hydrogen or RNG production from solid biomass is an option that can potentially displace large amounts of fossil gas. Just six full-scale RNG plants may displace more than five petajoules of demand, and recovery and use of all available biomass (an unlikely scenario) could deliver as much as 145 petajoules in the form of hydrogen or methane. Although the required technologies to achieve this exist, they are not proven technologies so demonstration and further refinement are required. Based on previous work on the GoBiGas plant and other such ventures, the most suitable technologies need to be combined and operated at a smaller scale. Once this is achieved and the process has been shown to operate successfully on a continuous basis, a full-scale plant could be built. Given the high capital cost of these plants, utility and/or government partnerships are likely necessary to realize this potential. As the technology matures and, possibly, more advanced technologies with lower capital costs become available after 2030, gas costs from these pathways are expected to decrease.

4.0 HYDROGEN FROM NON-BIOMASS RESOURCES

4.1 Description of Pathways: Blue, Green, Turquoise and Waste Hydrogen

4.1.1 The Hydrogen Opportunity

Approximately 70 million tonnes per annum of hydrogen are currently manufactured globally. The vast majority is used for industrial purposes, namely the manufacture of ammonia and the upgrading of liquid fuels in refineries. It is estimated that 95% of global hydrogen produced comes from steam methane reformation (SMR) of natural gas, resulting in a relatively high carbon intensity for the hydrogen generated. Multiple pathways exist to produce low carbon intensity hydrogen. An introduction to nomenclature that has been adopted follows.

4.1.2 Green Hydrogen

The most common description of green hydrogen is its production by the electrolysis of water, using emission-free power generation sources. Other green hydrogen manufacturing technologies exist, such as the production of hydrogen in nuclear reactors. These generally have low TRLs. The term 'green hydrogen' usually presupposes the use of renewable electricity from wind, photovoltaic, geothermal and hydro power as the energy sources for the electrolysis. These energy sources have low carbon intensities, in some cases close to zero.

4.1.3 Blue Hydrogen

The production of grey hydrogen via steam methane reforming (SMR) technologies is currently the most cost competitive and common hydrogen production process used globally. This hydrogen is used mainly for the production of ammonia for fertilizers and the upgrading of petroleum products in refineries and has high carbon intensity. When the CO_2 stream from grey hydrogen production is captured, and sequestered or used, the resulting hydrogen is called blue hydrogen. The sequestration, capture and use of CO_2 can occur through a number of pathways that include the injection of the CO_2 deep into the Earth's crust. An example is the Shell Quest Project.[86] This report will only assess the potential for blue hydrogen and not grey hydrogen.

Autothermal reforming (ATR) is a technology used to produce hydrogen for methanol and ammonia production. It is being proposed as a way to produce low carbon intensity blue hydrogen from natural gas because it allows carbon capture at higher rates than conventional SMR, and at a lower cost.[87]

4.1.4 Turquoise Hydrogen

Turquoise hydrogen is a more recent addition to the description for hydrogen that is produced by breaking down methane within a natural gas stream into hydrogen and solid amorphous carbon. The process is called pyrolysis and has the potential to produce a relatively low carbon intensity hydrogen. This is because most of the carbon by-product in the process is solid (black) carbon that mainly displaces carbon produced from other fossil sources. There are a number of natural gas pyrolysis technologies. Pyrolysis hydrogen production technologies use electricity to drive the processes and would be of benefit in B.C. given BC Hydro's low CI electricity. The use of amorphous black carbon is relatively common within industries around the world for applications such as the manufacture of rubber for tires, the use as pigment blacks in polymers and in printing blacks.

---

[86] Shell Quest Project. https://www.shell.ca/en_ca/about-us/projects-and-sites/quest-carbon-capture-and-storage-project.html (Accessed September 7, 2021).

[87] Pembina Institute. Carbon intensity of blue hydrogen production. August 2021 revised.

4.1.5 Waste Hydrogen

Waste hydrogen is produced at two plant locations in B.C. The North Vancouver Chemtrade plant is a chloralkali facility that focuses on the production of chlorine for numerous applications. Chemtrade has sodium chlorate production facilities, based in Prince George. Approximately 18,500 kilograms of hydrogen per day, for both plants together, is produced as a by-product. Hydra Energy has partnered with Chemtrade to use some of the waste hydrogen to power dual-fuel Class 8 trucks.[88]

Pipeline injection of any waste hydrogen would potentially require increased natural gas use to replace the hydrogen that is not emitted into the atmosphere but is used to produce heat for the Chemtrade plants. Thus, minimal or no GHG reduction benefits would accrue when using all the waste hydrogen produced. Only a portion may be available as low-carbon hydrogen for pipeline injection.

4.2 Technology update

Table 17 provides a brief overview of hydrogen production technologies. Essentially, all elements of blue and green hydrogen production are commercial, with only incremental improvements expected in the near term. Some new technologies, such as plasma pyrolysis, are expected to contribute to turquoise hydrogen production in the coming decade. More detail can be found in Appendix A.

Table 17 Overview of Hydrogen Production Technologies

Technology	Improvements/Benefits	Limitations/Challenges	Key players and Game Changers
Electrolysis: PEM	Improvement in membrane current density and lowering platinum loadings. Capex and efficiency improvements. The benefit is the fast dynamic response capability for demand-side response grid stabilisation opportunities.	Efficiency not significantly improved and thus Opex. Electricity costs are the largest component of the total cost of ownership. Capex would be negatively affected as well	Suzhou Jingli, Siemens, Areva H2gen, ITM Power, Erredue SpA , H2B2, Elchemtech, CUMMINS, NEL Hydrogen, Plug Power
Electrolysis: Alkali membrane	Improvements in Capex reduction. Alkali membrane electrolysis is a mature technology. Benefit is the low Capex per MW	Insignificant cost reduction improvements. No further dynamic response improvements.	CUMMINS, NEL Hydrogen, Teledyne Energy Systems, McPhy, Yangzhou Chungdean Hydrogen Equipment, Asahi Kasei, Verde LLC, ThyssenKrupp, Toshiba
Electrolysis: SOEC	The benefits of SOEC include the high efficiency: 30% above incumbent technologies.	SOEC is not yet commercialised. TRL of ~6. Operates at high temperatures of around 700°C and in a steady stage mode.	Haldor Topsoe, Ceres Power, Toshiba

[88] Hydra Energy. https://hydraenergy.com/news/chemtradepressrelease. (Accessed September 7, 2021).

Technology	Improvements/Benefits	Limitations/Challenges	Key players and Game Changers
ATR - CCUS	Improvement in CO_2 capture in ATR plants versus SMR technology and potential cost reduction according to a Pembina Institute report.	Not as common in the marketplace as SMR plants. GHG reduction benefits are marginal.	Air Products. New plant in Alberta planned for 2024
SMR - CCUS	Improvement in CCUS is key to the successful deployment of blue hydrogen. Both higher capture and sequestration percentages and associated costs are developing. Large SMR plants are deployed globally and produce hydrogen at a low cost of under US$2/kg. Increased efficiencies of small units that can provide smaller modularity benefits related location.	According to the Global CCS Institute[89] there are 25 technologies in various TRL stages. Which of these succeed is still unknown.	There are 26 CCUS plants in operation around the world[90]
Partial Oxidation	Shell Gas Partial Oxidation (SGP). High TRL. More than 100 plants globally. Claimed 22% lower levelised cost of hydrogen for SGP technology compared with ATR.	Past market focus for this technology has not been on hydrogen production but to monetise low-value refinery residues, asphaltenes, heavy oils, gas or biomass by converting them into syngas	Shell
Methane pyrolysis	The various pyrolysis technologies offer a low cost of H_2 and opportunities to use and sell the solid carbon by-product	Mostly low TLR. Some have a high TRL.	

4.3 Feedstock and resource availability

4.3.1 B.C. Potential for Green Hydrogen Production

The primary parameters determining the potential for green hydrogen production via electrolysis include:

- The availability of renewable electricity. Focusing on BC Hydro's most recent draft 2021 Integrated Resource Plan (IRP)[91] that addresses both demand-side efficiency improvements and demand response programs, additional capacity needs are not foreseen until 2032 (however, a high electrification ['accelerated'] scenario indicates a need for power imports as early as 2025 and new power plants being added as of 2029, despite the commissioning of the Site C hydro facility, as per Table 18 in the plan's appendix). No mention is made in this draft report about the use of electricity

[89] Global CCS Institute, Technology Readiness and Costs of CCS (2021).
[90] Global CCS Institute, Global Status of CCS 2020.
[91] BC Hydro and Power Authority DRAFT 2021 Integrated Resource Plan. BC Hydro, June 2021

for the electrolytic hydrogen production. Transmission from electricity production sites or large sub-stations will play a role in site selection.

- Availability of potable water as an electrolyser feedstock. Each megawatt of electrolyser load capacity requires about 1.4 million litres of water per annum. This subject was addressed for a number of sites up to 300 MW plants.[92] Water availability was not an issue. The addition of a potable water filtration plant was the only requirement identified.
- Hydrogen injection into the natural gas grid is faced with a number of challenges and barriers that include:
    - Critical pipeline system components including embrittlement of steel.
    - End-user equipment tolerances and operating considerations.
    - Engineering assessments that would examine the safety, integrity and reliability of the gas company and end-user-owned assets.
    - Updates to pipeline standards and policy.
    - The establishment of mixed (hydrogen/methane) gas tariffs and insurance (the gas blend still needs to meet tariff requirements).
    - Pipeline capacity (including locating hydrogen-producing facilities near major pipelines to inject it into the B.C. grid).
    - Hydrogen separation technology.
    - Gas metering for blended gases, purity and requisite specifications.[93]
    - Finally, the upper hydrogen concentration limit in the B.C. grid needs to be determined.

The above leads to three possible concepts for implementing new green hydrogen production in B.C.:

1. One or more centralized on-grid facilities: BC Hydro indicated the ability to support 300 MW of electrolyser load capacity for green hydrogen production.[92.] According to recent discussions with BC Hydro, this can be increased if power demand is close to the new Site C dam or other large power generation plants. Beyond a few hundred megawatts of demand, BC Hydro could not to guarantee power deliveries for new plants in the coming decade. It may be possible to wheel electricity from other jurisdictions, but this may again depend on plant location and transmission capacities.
2. Wind or solar PV-generated electricity. Figure 28 indicates wind farm and gas network overlapping regions that may provide opportunities to build large (100-150 MW nameplate capacity) off-grid wind farms and electrolysers. Potential for consideration includes the B.C. mainland and offshore wind generation west of Vancouver Island. Off-shore wind farms may be very large, in the range of 300-700 MW. The limitations are then dictated both by the potential amount of hydrogen that can be injected into the natural gas grid and by the time required to get such facilities permitted, built and production commissioned.
3. A third opportunity is decentralized hydrogen production using large- and small-scale facilities such as the one being developed in Chetwynd[94] or the HTEC/Mitsui 5-megawatt project.[95] Grid-

[92] Centralized Renewable Hydrogen Production in B.C. – Final Public Report. G&S Budd Consulting Ltd., July 2019.
[93] BC Hydrogen Study. ZEN Clean Energy Solutions, July 2019.
[94] https://biv.com/article/2020/01/green-hydrogen-plant-project-has-investor (Accessed September 8, 2021).
[95] https://www.htec.ca/htec-has-partnered-with-mitsui-co-canada-ltd-to-develop-electrolytic-hydrogen-production-project-in-british-columbia-that-will-provide-fuel-to-htecs-network-of-fueling-stations-and-hel/ (Accessed September 8, 2021).

connected facilities of this or a smaller size can rely on both hydro power from the grid, and solar or wind power from a nearby facility, putting less strain on the power grid. They could be developed in various regions and inject into the local grid, albeit at somewhat higher costs because of lower economies of scale.

Table 18 outlines the resulting estimates for new green hydrogen production potential in B.C. by 2030 and by 2050 (cumulative). The current (2021) BC Hydro draft Resource Plan extends to the year 2041 and does not consider any major new power production for hydrogen consumption. The addition of large amounts of demand would likely require adapting the resource plan. The possibility of wheeling electricity from other jurisdictions is not considered here but could potentially allow for the construction of additional electrolyser capacities. About 700 MW of electrolyser capacity is required to reach the provisional volumetric variable of 5% hydrogen in the pipeline network. Note that some power plants, such as wind-based generators, have nameplate capacities that are considerably larger than their average output. For example, 100 MW of average electrolyser output from wind will likely require wind farms of at least 250 MW nameplate capacity.

The 2030 technical potential for centralized grid-connected hydrogen production is based on opportunities to use grid electricity at locations that are relatively near BC Hydro power plant sites and major sub-stations. By 2050, BC Hydro can contract for new generation capacities (or import more power) and will then be able to connect additional green hydrogen plants. The exact amounts would depend on Utilities Commission approval and direct negotiations with BC Hydro.

The estimate for total resource potential considers information provided in the ZEN Hydrogen Study that estimates 5.4 GW of wind potential.[93] With the sites tentatively indicated in Figure 28, several large off-grid wind farms seem feasible in the Interior, along the gas pipeline network. Also considering offshore locations for very large wind farms (300-700 MW), this would amount to a total of 1450 to 2000 MW of installed wind power capacity. This would result in up to 800 MW of net average power output,[96] using a 40% capacity factor. Some of this potential may also be developed as on-grid facilities. Given long lead times, only one or two on-shore and no off-shore wind farms are deemed feasible by 2030. Beyond 2030, the potential for on-grid electrolyser farms will ultimately be determined by policy and Utilities Commission directives since BC Hydro or the private sector could add considerable new renewable generation. This may increase overall power pricing and therefore needs regulatory support. Five hundred MW of new electrolyser net capacity (about 1250 MW of wind farms) between 2030 and 2050 is deemed to be a reasonable estimate in this respect. Wheeling of low-carbon electricity from other jurisdictions may also be a possibility to increase on-grid electrolyser capacities. This option is not explored here but the technical potential depends on both legal constraints and transmission and interconnection hub capacities.

For small-scale, decentralized on-grid hydrogen production, the estimate assumes a plant size of 10 MW with up to five sites being developed by 2030 and up to 30 sites by 2050. Decentralized facilities may be built near the gas distribution grid, with lower input pressures. They could be linked to local renewable energy generation to supply some of the electricity needed. Larger facilities elsewhere may feed power into the grid commensurate with increased local demand. They may be close to hydrogen users in the Lower Fraser Valley. These potential estimates can be modified based on cost evaluations and the establishment of potential sites intended for the injection of hydrogen into the natural gas grid.

[96] Real output will fluctuate with the wind resource. In an off-grid situation, this would require either adding battery storage to ensure stable power supplies at the average level or otherwise, building electrolyser farms with capacities close to the maximum output of the wind farm in order to minimise curtailment. In an on-grid situation, the grid can serve as a "battery", thus reducing the capital investment required.

Table 18 Estimated Green Hydrogen Production Potential in B.C. (Electrolyser Capacity)

Concept	By 2030	By 2050 Technical potential	Total Resource potential
Centralized grid connected	300 - 500 MW*	1000 MW	2100 MW net** (from wind) Additional potential exists from e.g., geothermal, photovoltaic
Centralized off-grid	60 MW	600-800 MW	
Decentralized grid connected	10 - 50 MW	300 MW	
Total	**370 – 610 MW**	**~1900 MW**	**>2100 MW**

* Current limit for new on-grid demand by 2030; ** assuming an average capacity factor of 40%.

Figure 27 indicates five areas where large off-grid wind power plants could be implemented, including an off-shore site that would need to be linked to Kitimat and two areas along the northern section of the Westcoast Energy Pipeline System. In addition, offshore wind power plants west of Vancouver Island could be implemented. As Vancouver Island requires a gas pipeline upgrade to increase capacities delivered, the upgrade could be used to install a larger pipeline that can carry hydrogen produced on the Island back to the mainland. This could occur in a reversed flow if production capacities are large enough or through a parallel hydrogen pipeline. A large (500 MW) offshore wind farm could provide the electricity for electrolytic hydrogen production. The areas indicated appear to be good candidates, but this high-level overview does not replace the need for detailed resource assessments and an examination of siting conditions and other requirements to determine suitable locations. For example, the gas flow currently goes to Vancouver Island and Kitimat. Hydrogen injected may then either be used locally or may cause the flow to be inverted, which may pose engineering and cost challenges not considered here.

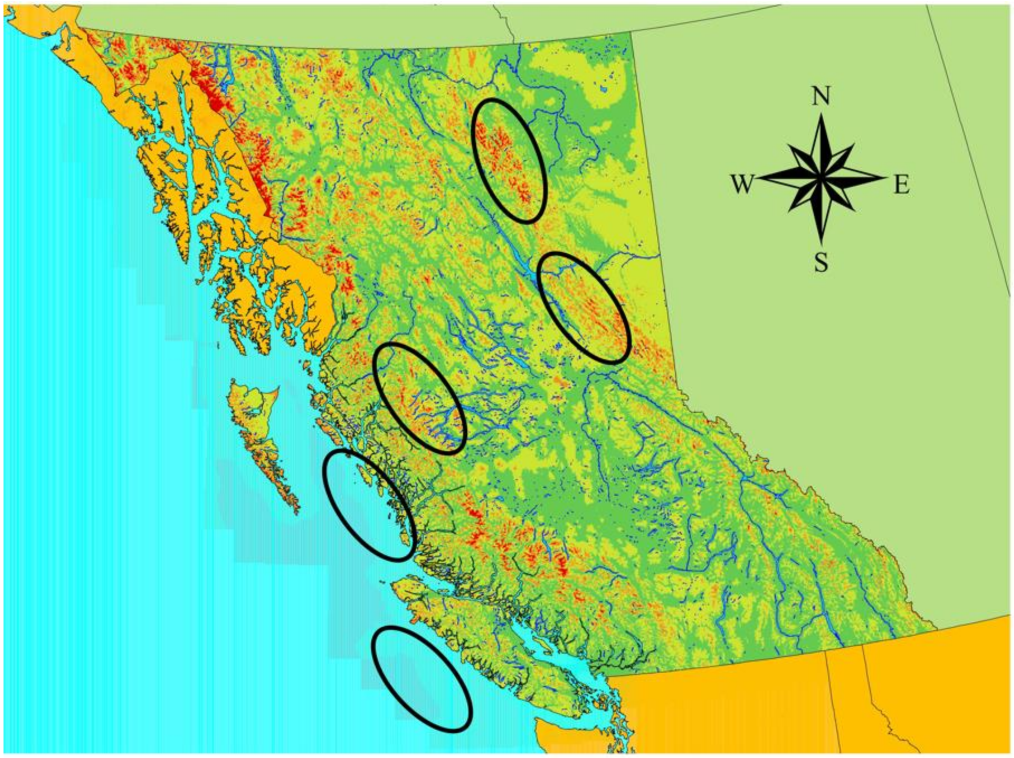

Figure 27 Promising Regions for New Wind Farms Supporting Large-Scale Green Hydrogen Production

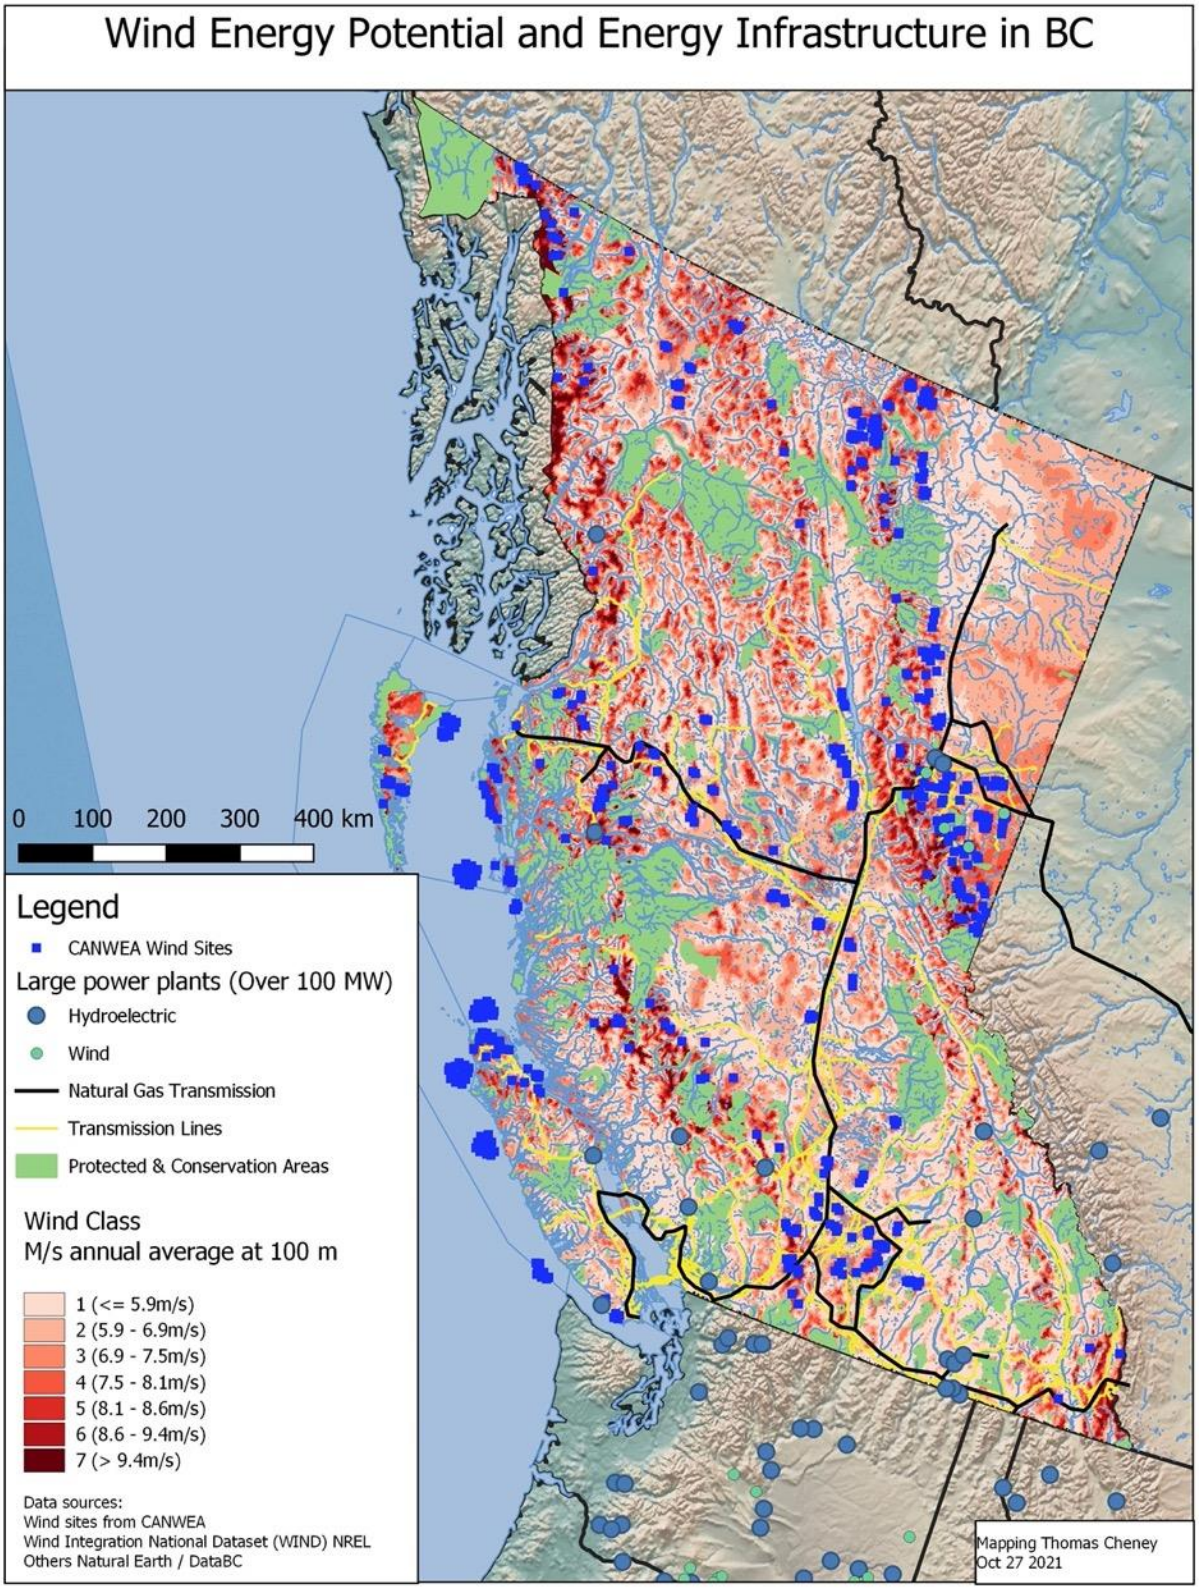

Figure 28 B.C. Predicted Wind Speeds and Potential Locations for Large Wind Farms Near the Gas Pipeline Network

For grid connected, large-scale hydrogen production, locations near large hydro facilities in the province's north appear to be ideal, in line with the regions identified for larger wind farms in Figure 27. In addition, larger facilities could also produce for industrial (direct) use and for grid injection, capturing additional economies of scale. They could produce for use in other applications that include, by way of example, fuel cell powered mobility (not within the scope of this study). Opportunities to capture and sell the by-product electrolytic oxygen need to compete with a cost of less than US$50/t from air separation plants. Colocation opportunities may exist that could use either the hydrogen or any by-product oxygen, or both. The two refineries (Burnaby and Prince George) could provide opportunities as they use large amounts of hydrogen and may continue operating if they were to move towards biofuels, using plant-based lipids and possibly biocrude. The latter, however, would stand in competition to gas production from the same resources. Although most of ground transportation may no longer use liquid fuels by 2050, air and marine transport may still rely on renewable liquid fuels.

4.3.2 B.C. Potential for Blue Hydrogen Production

The two primary feedstock types required for the production of hydrogen using SMR or ATR technologies are natural gas and water. The potential for the production of blue hydrogen is dependent on a number of factors, including:

- Carbon capture and sequestration is required to meet the proposed B.C. carbon intensity threshold for low-carbon gases of 36.4 g CO_2e per megajoule. This will require that at least 60% of the CO_2 is sequestered or used, based on a carbon intensity of 90 g CO_2e per megajoule for grey hydrogen. Geological sequestration capacity in B.C. is deemed large, as suitable sites exist close to where gas production is taking place (Figure 29). Overall estimated sequestration capacities have been used to derive the blue hydrogen potentials in the ZEN report.
- The adoption of ATR technology instead of SMR offers a simpler production stream, with a high concentration of carbon dioxide, which allows a higher percentage of carbon emissions to be captured. Capture efficiency is estimated at 90 to 95% in the conversion process and at its best, a carbon intensity of 11 kilograms CO_2e per gigajoule of hydrogen is projected.[106] It is potentially a more cost-competitive solution. However, unlike SMR, ATR requires the supply of oxygen as a feedstock. This may offer co-location benefits for green hydrogen production using the by-product oxygen as feedstock for ATR blue hydrogen production.
- The cost of the CO_2 captured and sequestered needs to be considered. For every kilogram of hydrogen produced via SMR, approximately 9.5 kilograms of CO_2 is produced. If the cost to capture and sequester the CO_2 were US$60 per tonne, an additional cost of US$0.57 per kilogram results for the cost of hydrogen produced.
- In terms of hydrogen injection into natural gas pipelines, one limitation is the amount of hydrogen the pipeline can technically tolerate unless the pipeline is converted to transport high hydrogen blends or 100% H_2. The total amount of gas that can be injected at any particular site will have to be determined and is site-specific. Given that 90% of natural gas produced in B.C. is exported, any target for the B.C. market will only have a minor impact on the renewable gas content in the main transmission lines. It is, however, possible that decentralised production of hydrogen on the gas distribution grid may lead to high hydrogen concentrations near the point of injection and would then need to include variable hydrogen flow rates to maintain the target injection percentage, especially in the summer when gas consumption may be three to four times lower than during some winter days.
- The size of the SMR plant and location along any of the natural gas pipe branches influences potential. Large plants may be limited in terms of where and how much hydrogen can be injected into the grid. Potential locations must allow either the use of CO_2 or its injection into geologic formations underground. The capacity to sequester the CO_2 below the Earth's surface in northern B.C. must

therefore be considered and may become a limiting factor. Numerous smaller high-efficiency SMR units and small CCUS modular technologies that capture CO_2 are being developed (see Section D.2 in Appendix A). These units can be placed in locations that would avoid the limitations associated with the use of large SMR and CCUS.

The overall potential for blue hydrogen production is very high. All current gas production in B.C. could theoretically be replaced with blue hydrogen, since production is about ten times larger than provincial demand. It is, however, unrealistic to expect that this will happen. By 2030, few plants will likely have been constructed. This is because the technology is relatively new and because lengthy permitting periods expected for the first B.C. CO_2 injection projects. The scenarios therefore only include limited blue hydrogen production by 2030. After this date, the industry is more likely to grow and may then obtain a large market share for low-carbon gas. The scenarios assume that up to 30 full-scale facilities may be built in the two decades between 2030 and 2050. Total potential by 2050 is based on the ZEN Hydrogen report.[93]

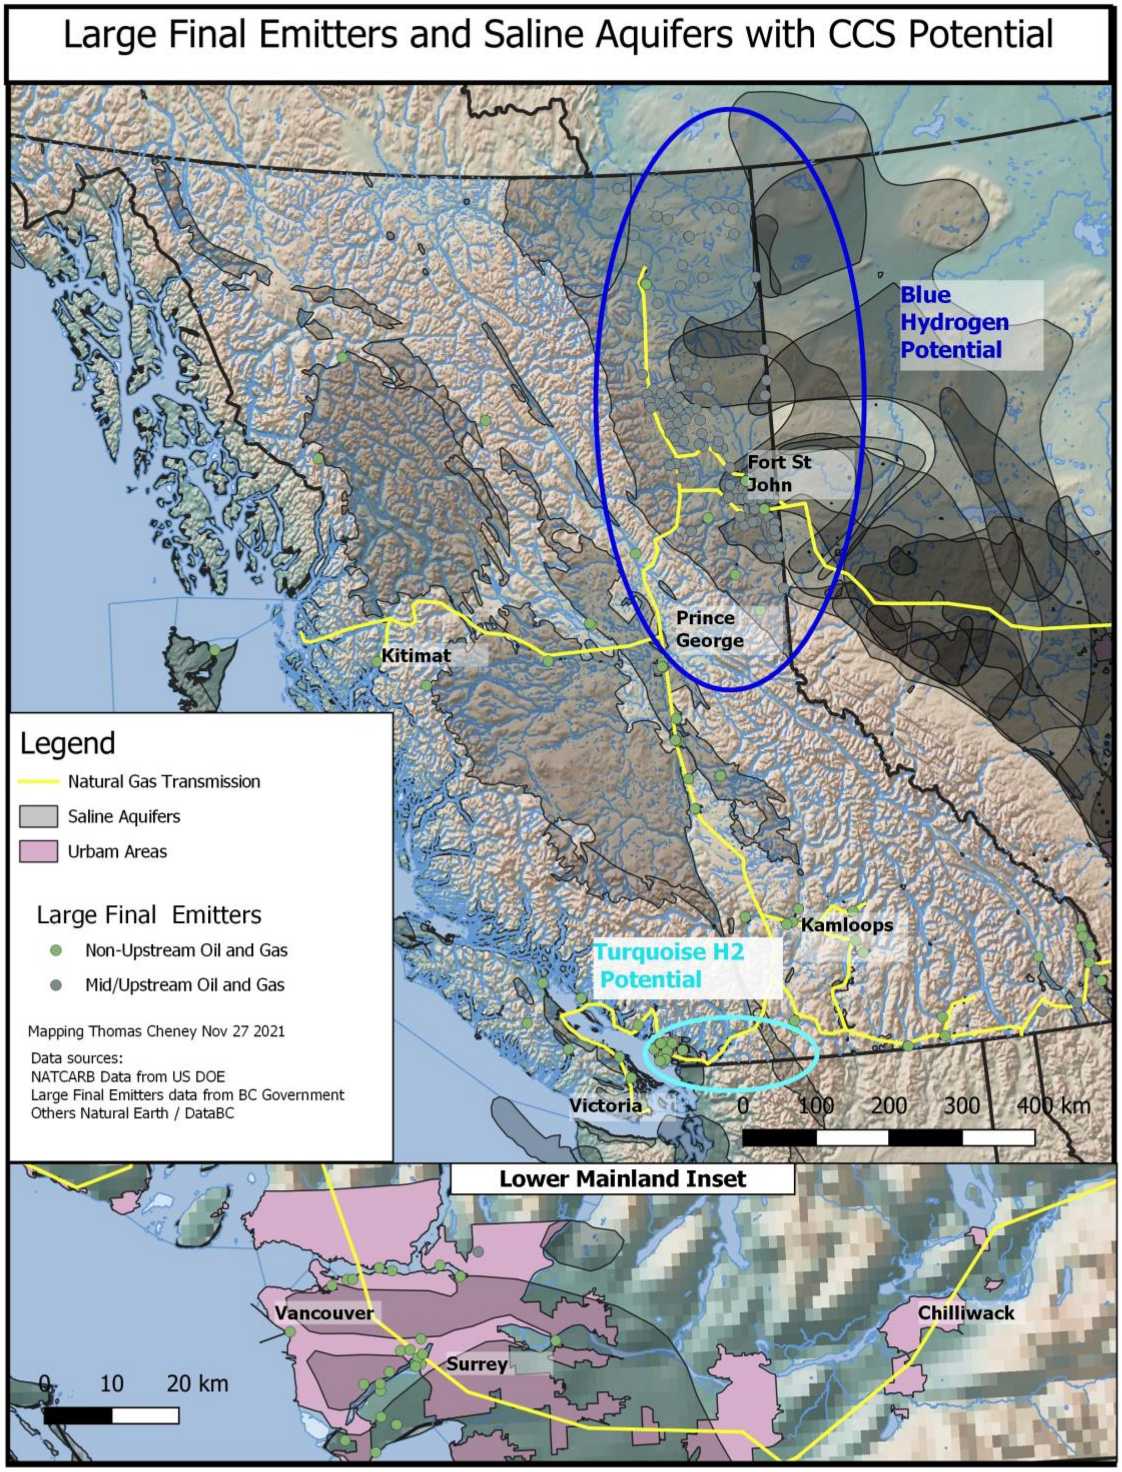
Figure 29 shows the northern area around Fort Nelson, where natural gas is produced, as the obvious region where blue hydrogen could be produced and injected, and where captured CO_2 could be injected into the ground. Turquoise hydrogen production, also indicated on the map, would more likely happen more downstream along the gas pipeline, near strategic export hubs (Kitimat, Vancouver) or near potential users of hydrogen or carbon black. This suggests that locations near refineries, where the hydrogen could be used directly, are also attractive.

4.3.3 B.C. Potential for Turquoise Hydrogen Production

A number of pyrolysis technologies have been considered in this report (Appendix A). These include plasma, fluidised bed, moving bed, molten salt and pulse methane pyrolysis. All technologies require natural gas as a prime feedstock. Using RNG would be a more costly alternative but could at the same time result in a negative-emission pathway if the carbon black produced is used in long-lived products. This section will focus on two technologies, Plasma Pyrolysis (Monolith Materials) and Pulse Methane Pyrolysis (EKONA Power). The former is chosen as this technology appears to be more advanced in terms of its TRL (see Appendix A). The potential to produce low-carbon-intensity hydrogen using a turquoise pathway depends on a number of factors, including:

- Similar to blue hydrogen, the location, plant size and allowable amount of hydrogen that can be injected into the grid, used in industrial hubs, or distributed through gas infrastructure and converted to 100% hydrogen are key.
- Methane pyrolysis yields solid carbon (high-value production output if sold as carbon black) with hydrogen as a (lower-value) by-product, which adds a revenue stream opportunity to sell the carbon as a pigment or rubber black. No CO_2 capture is necessary.
- The market for black carbon is large (US$18 billion per year and increasing[97]) so there is considerable potential for B.C. to produce this material while also making hydrogen. The projected market growth can be estimated as about 8 million tonnes by 2026. One facility in B.C. may only produce around 100,000 tonnes per year.
- The production cost of this process is close to zero once black carbon sales are factored in. Hydrogen could likely be sourced at no more than $10 per gigajoule from this source.

[97] https://www.alliedmarketresearch.com/carbon-black-market (Accessed September 30, 2021).



Promising regions for **blue hydrogen** and **turquoise hydrogen** production marked by ovals.

Figure 29 Potential CO_2 Sequestration Sites in B.C.

The potential for turquoise hydrogen, as with blue hydrogen, is very large. This resource could provide a large share of the low-carbon gas required to help achieve BC's 2030 and 2050 GHG reduction targets. In the ZEN report,[93] its potential is estimated at 92 petajoules – almost half the current B.C. gas consumption. As with green hydrogen, however, the realization of this potential will depend on the ability to source enough electricity – unless thermal pyrolysis is used as the production method. One plasma pyrolysis plant may use around 40-50 megawatts of power; 90 petajoules of hydrogen output per year would require the construction of 18 such plants, amounting to additional power demand of around 800 megawatts. Since the technology is new, the scenarios in Chapter 5.0 assume that few plants can be built by 2030. After that date, the potential is based on the ZEN Hydrogen study.

4.4 Cost Curves

4.4.1 Green Hydrogen

Figure 30 shows the cost curves resulting for electrolytic hydrogen. Costs are higher than C$31 per gigajoule throughout, and incremental cost reductions and efficiency improvements are cancelled out by expected increases in electricity pricing. Producing hydrogen off-grid will entail considerably higher costs. The latter vary greatly between on-shore (around US$1.5 million per megawatt) and off-shore wind farms (around US$5 million per megawatt). Since both are envisaged for B.C. to obtain sizeable numbers, a cost of around US$3 million per megawatt was used. The very high CAPEX for wind turbines and oversized electrolyser farms combined with the intermittent output of wind turbines (capacity factor assumed to be 40%) lead to very high costs of hydrogen produced off-grid, despite independence from grid electricity. For on-grid hydrogen production, electricity costs are the most important cost factor and changes in electricity pricing will heavily influence hydrogen costs. For off-grid, the power generation assets are owned by the producer and the capital costs for these assets and the electrolyser farm become the most important cost element, yet maintenance and operating costs are also significant. The predicted cost scenarios for green hydrogen are based on an electricity price of C$65 per megawatt-hour, including demand charges (see Section 5.1). Lower electricity costs will cause a significant reduction in the unit cost estimation for the green hydrogen produced. Future green hydrogen cost improvements will be due to developments in:

- Electrolyser Capex reduction,
- Improvements to electrolyser stack and system efficiencies,
- Decreases in operating and maintenance costs,
- Longer durability, and electrolyser system operational lifetime.

Table 19 Key Cost Impacts, On-Grid Green Hydrogen Production

Year	Status and improvements	Challenges
2021	The electrolyser capex (incl. balance of plant but excl. storage) is estimated at C$1,400/kW	Cost of electricity
2030	For this period, it is expected that further improvements will be made to the cost associated with the list above.	Inadequate supply of available renewable electricity. Cost of electricity.
2050	For this period, further improvements are expected to be made to the costs associated with the list above. PEM electrolyser target costs have been studied in the UK for a planned mega electrolyser production facility.[98]	Inadequate supply of available renewable electricity.[91] Cost of electricity.

For capital costs, the assumptions from the ZEN report were retained for 2021. Future cost reductions may be significant. A U.S. source predicts costs of only US$400 per kilowatt.[99] Strong capital cost

[98] Gigastack Bulk Supply of Renewable Hydrogen Public Report. February 2020.

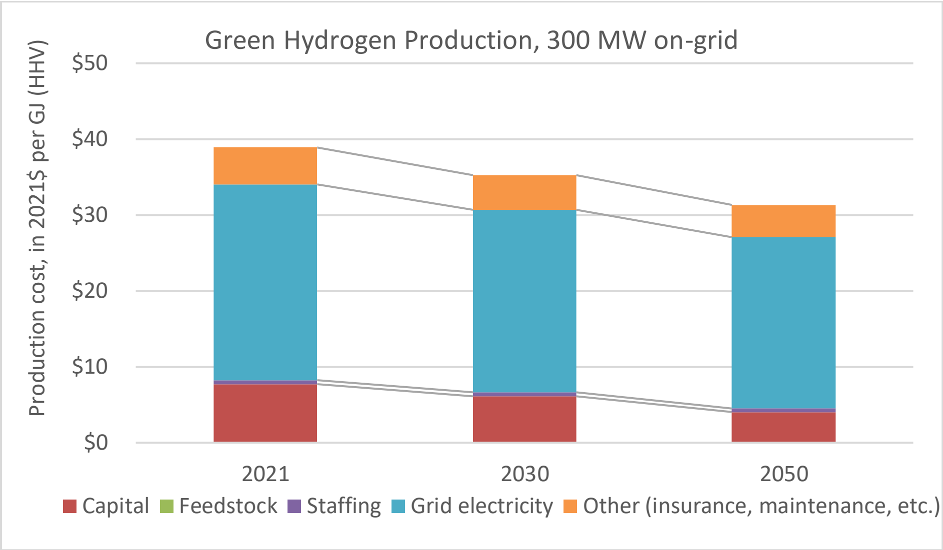
[99] Roadmap to the U.S. Hydrogen Economy – Reducing Emission and driving growth across the nation. Fuel Cell and Hydrogen Energy Association, March 2020.

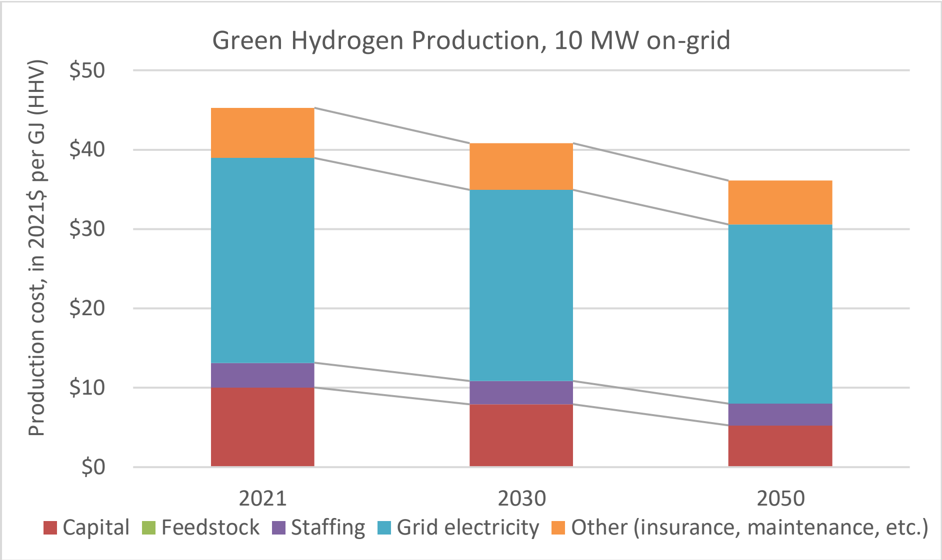
reductions for 2030 (15%) and 2050 (40%) were therefore assumed. Another important variable is electrolyser efficiency. Currently, PEM electrolysers can achieve a power-to-hydrogen conversion efficiency of up to 72%.[100] Default assumptions are 70% for 2021, 75% for 2030 and 80% for 2050. Additional assumptions for a small (10 MW) and off-grid plant can be found in the Excel model.

Table 20 Default Cost Parameters, On-Grid Green Hydrogen, in 2021$

Cost parameter	Value	Share	Comments
Electrolyser plant	300 MW		Very large
Conversion efficiency	70%		Electricity to hydrogen, GJ/GJ
Gas yield	6.48 PJ		
Capital cost	$420 million		In 2021
Capital cost	$357 million		In 2030 (-15%)
Capital cost	$252 million		In 2050 (-40%)
Amortization	$46.7 million	20%	20 years, 9.2%
Opex personnel costs		1%	
Labour, 36 FTE	$2.90 million		
Management, 2 FTE	$0.30 million		
Opex electricity	$156.00 million	66%	2,400,000 MWh per year at $65/MWh
Opex other costs	$29.40 million	12%	7% of CAPEX for maintenance, insurance, etc.
TOTAL OPEX	$235.25 million	100%	
Gas cost	$39/GJ		In 2021

[100] Hydrogen Program Plan. U.S. Department of Energy, November 2020 (footnote 80).





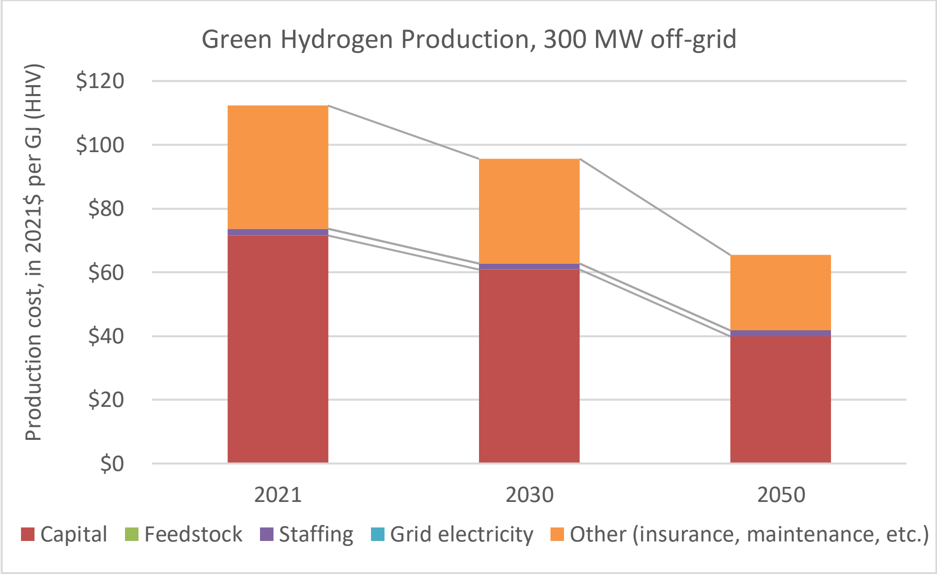


Figure 30 Cost Curves for Electrolytic Hydrogen Production

4.4.2 Blue, Turquoise and Waste Hydrogen Cost Curves

For blue hydrogen, the natural gas price is key after the cost of carbon sequestration. Presuming these plants will be built at the well, where natural gas costs are lowest and sequestration opportunities exist, any increases in natural gas pricing will negatively affect hydrogen costs. This is buffered by the expectation that sequestration costs will fall over time. Capital costs are the most important cost factor, due to the need to implement both SMR reactors and the carbon capture, compression, and sequestration infrastructure. Other models, such as the use of CO_2 in tertiary oil and gas fields, or other uses of CO_2, would strongly reduce the sequestration cost but are not likely going to be sufficiently available for the large amounts of blue hydrogen anticipated.

The conversion efficiency of natural gas to hydrogen is assumed to increase to 85% by 2050.[101] Carbon capture costs are modelled as decreasing from $75 a tonne of CO_2 in 2021, by 10% by 2030 and 25% by 2050. Capital costs will decrease more slowly at 9% by 2030 and 20% by 20% by 2050. Gas costs at the well are deemed to increase only with inflation. No carbon tax applies since natural gas is (mainly) used as a feedstock. The resulting cost of $3 per kilogram (US$2.30 per kilogram), although somewhat higher than in the ZEN study ($2.14 per kilogram), lies within the range of previous estimates.[102] The plant size of 100 tonnes per day has been retained from the ZEN report and was chosen to compare to turquoise hydrogen production; actual projects may be considerably larger.

Table 21 Default Cost Parameters, Blue Hydrogen, in 2021$

Cost parameter	Value	Share	Comments
Conversion efficiency	75%		Methane to hydrogen, GJ/GJ
Gas yield	100 tonnes/day		As hydrogen (5 PJ per year)
Capital cost	$300 million		In 2021
Capital cost	$273 million		In 2030 (-9%)
Capital cost	$240 million		In 2050 (-20%)
Amortization	$33.3 million	32%	20 years, 9.2%
Opex personnel costs Labour, 42 FTE Management, 2 FTE	 $3.4 million $0.3 million	3%	
Opex electricity	$2.3 million	2%	35,000 MWh per year at $65/MWh
Opex natural gas	$25.6 million	25%	6.6 PJ of natural gas at $3.87/GJ
Carbon capt./sequestr.	$23.6 million	23%	$75 per tonne of CO_2[103]
Other OPEX	$15 million	14%	5% of CAPEX
TOTAL OPEX	**$103.5 million**	**100%**	
Gas cost	$21/GJ		In 2021 ($2.96/kg)

For turquoise hydrogen, feedstock costs (natural gas) remain the most important factor. No capture or sequestration is required, making the process easier to locate and operate. Yet, the conversion efficiency is lower than with SMR, which increases overall production costs. Carbon black sales may, however, almost entirely compensate for the cost of production. Producing the correct grade of carbon and establishing sales channels will be key. Given the carbon in the feedstock is not emitted but turned into carbon black, likely displacing fossil carbon black sources, turquoise hydrogen production is not impacted by increasing carbon taxes (methane use as a feedstock is not subject to the carbon tax). If on the

[101] Hydrogen in a low-carbon economy. Committee on Climate Change (UK), November 2018
[102] GLOBAL STATUS OF CCS 2020. Global CCS Institute, November 2020 (Table 3)
[103] See https://www.iea.org/commentaries/is-carbon-capture-too-expensive (Accessed October 29, 2021)

distribution grid, facilities would, in theory, be affected by increasing gas pricing as is anticipated with increasing amounts of renewable and low-carbon gases being injected (see Section 5.1). It is, however, presumed here that a low gas price is offered to turquoise hydrogen producers that will only change with inflation. This is estimated by taking the current Rate 5 commodity charge plus storage and transportation charges, resulting in a gas price of only $4.70 per gigajoule. Whereas the hydrogen conversion efficiency is deemed to remain constant over time, the increasing amount of hydrogen in the gas pipeline will lead to lower rates of carbon black output, although somewhat more hydrogen is then injected into the pipeline by 2050. Alternatively, the development of hydrogen at scale in B.C. could include dedicated natural gas pipelines to deliver methane feedstock to processing facilities such as these.

Table 22 Default Cost Parameters, Turquoise Hydrogen, in 2021$

Cost parameter	Value	Share	Comments
Conversion efficiency	57%		Methane to hydrogen, GJ/GJ
Gas yield	5 PJ/year		As hydrogen
Capital cost	$153 million		In 2021
Capital cost	$139 million		In 2030 (-9%)
Capital cost	$122 million		In 2050 (-20%)
Amortization	$17.0 million	18%	20 years, 9.2%
Opex personnel costs		3%	
Labour, 30 FTE	$2.40 million		
Management, 2 FTE	$0.30 million		
Opex electricity	$22.8 million	25%	350,000 MWh per year at $65/MWh
Opex natural gas	$41.2 million	46%	8,769,600 GJ of natural gas at $4.7/GJ
Other OPEX	$7.6 million	8%	5% of CAPEX
TOTAL OPEX	$91.3 million	100%	
Carbon black revenue	-$89.6 million	-98%	112,000 tonnes at $800 per tonne
Gas cost	$0.3/GJ		In 2021

Turquoise hydrogen is a special case due to the co-production of carbon black. Depending on its exact texture and quality, carbon black can fetch considerable value in the market. It has been conservatively assumed that a value of C$800 per tonne is attainable.[104] This is sufficient to cancel out almost all of the operating cost of a new plant, leading to very low hydrogen production costs. Natural gas is the main cost parameter but somewhat higher pricing could be absorbed.

One concern with turquoise hydrogen is the anticipated change of gas composition in pipelines. If significant amounts of hydrogen will be injected, turquoise hydrogen facilities will not be able to generate the same amount of carbon black as before, which may affect their financial viability. A detailed technical analysis of this problem would be beyond the scope of this study, but it is assumed that with moderate amounts of hydrogen, the process would simply become somewhat less efficient and would produce more hydrogen as a by-product. Increasing amounts of hydrogen in the gas distribution network could also affect other industries using natural gas as a feedstock but no such industries, such as fertiliser production, were identified during the research for this report. For the cost estimate, it has been assumed that hydrogen in pipelines will amount to 2% by 2030 and 40% by 2050. This leads to somewhat less carbon black revenue but also to increased hydrogen sales. It is assumed that the hydrogen in pipeline gas would simply be injected back into the same after processing, together with the hydrogen produced by the

[104] Pricing was around US$800 in 2021, see https://www.chemanalyst.com/Pricing-data/carbon-black-42 (Accessed October 28, 2021)

process. Alternatively, plants could be situated on gas transmission pipelines where the hydrogen content may be lower than at locations on the distribution grid.

Waste hydrogen is produced at several facilities in B.C. but is generally already being used for plant process heat and as an energy vector for heavy duty truck applications, a Hydra Energy Chemtrade project. Therefore, only a small portion may be available for pipeline injection. If the gas is currently vented, the costs of harnessing the resource are fairly small (some conditioning and compression). It is the most cost-effective resource but also very limited in its potential.

Although the production costs for turquoise and waste/by-product hydrogen are estimated as less than $10 per gigajoule, it is deemed unlikely that this hydrogen would be offered on the market for less than $10. For the cost curves in Chapter 5.0, the calculated amounts were used but it is not expected that this would be the actual cost of purchasing this hydrogen.

Table 23 Default Cost Parameters, Waste Hydrogen, in 2021$

Cost parameter	Value	Share	Comments
Gas yield	0.9 PJ		All figures used based on ZEN (2019)
Capital cost	$19.3 million		In 2021 (no change for later years since no more potential)
Amortization	$2.1 million	57%	20 years, 9.2%
TOTAL OPEX	$3.7 million	43%	Labour and maintenance
Gas cost	$4/GJ		In 2021

Figure 31 shows the gas cost estimates for the present year, 2030, and 2050. The cost is lowest for turquoise hydrogen (due to the revenue generated from selling carbon black), followed by waste hydrogen and then, blue hydrogen

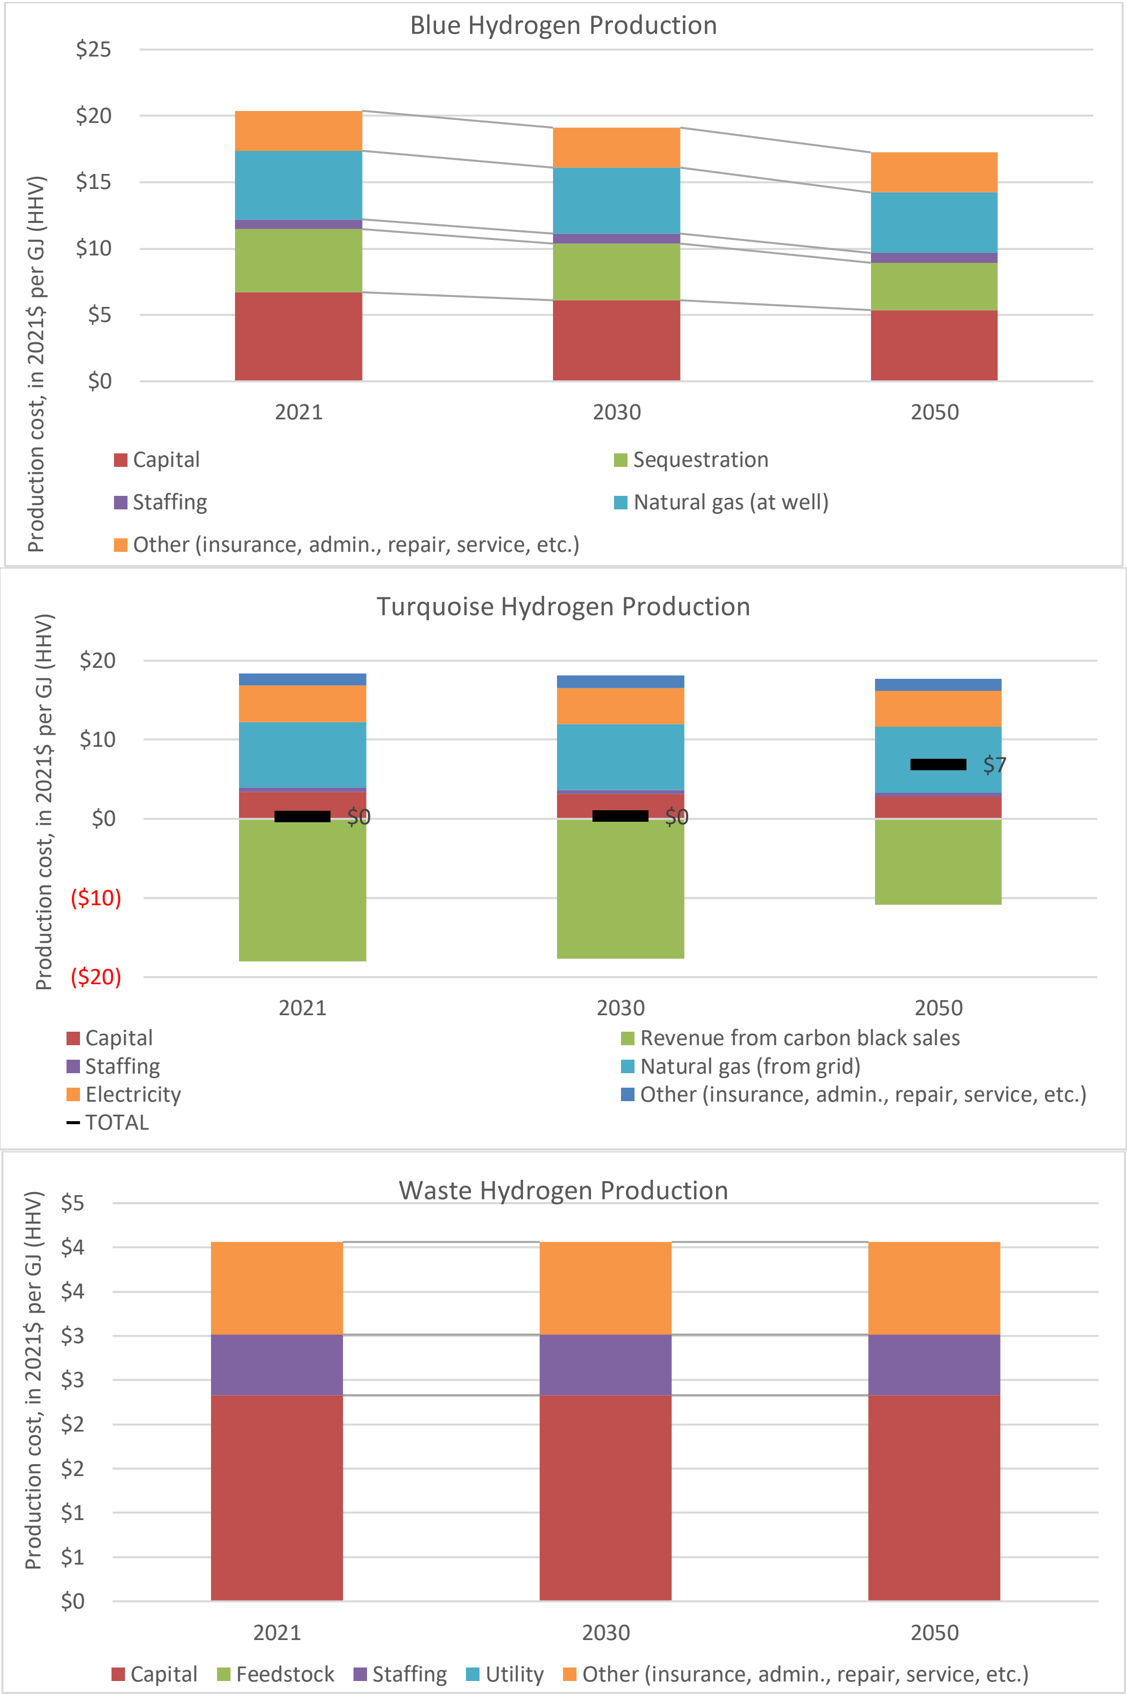

Figure 31 Cost Curves for Non-Electrolytic Hydrogen Production

4.5 Carbon Intensity of Hydrogen from Non-Biomass Sources

Table 24 shows additional values for the four types of hydrogen available in B.C. For blue hydrogen, the actual value will depend on the carbon capture efficiency. The value shown here indicates about 80% of CO_2 being captured, i.e., lower values may be achieved with more efficient technology. The life-cycle emission value for natural gas with and without carbon capture remains contested, however, as indicated in Section 5.5 below.

Table 24 Literature Values for Hydrogen Carbon Intensity

Type	Value	Source
Green	15.6 g CO_2e/MJ	Based on GHGenius[105]
	0.0 g CO_2e/MJ	ZEN (2019), off-grid
	3.3 g CO_2e/MJ	Pembina (2021)[106], wind electricity. Only plant construction
	27.4 g CO_2e/MJ	ZEN (2019), on-grid
Blue	22.4 g CO_2e/MJ	ZEN (2019), 80% capture efficiency
	14.0 g CO_2e/MJ	Pembina (2021), SMR, high performance
	10.6 g CO_2e/MJ	Pembina (2021), ATR, high performance
	26.3 g CO_2e/MJ	BC Hydrogen Strategy, 90% capture eff.[107]
	50 g CO_2e/MJ	Timmerberg (2020)[108]
Turquoise	12.5 g CO_2e/MJ	ZEN (2019), Plasma pyrolysis
Waste	10.5 g CO_2e/MJ	ZEN (2019)

4.6 Markets

The primary markets in B.C. for renewable hydrogen are:

- Pipeline injection to reduce the carbon intensity of retailed natural gas in B.C. To attain (a theoretical) 5% hydrogen by volume in the B.C. natural gas grid, 100,000 tonnes of hydrogen need to be produced and injected into the grid. If this were green hydrogen, it would require an approximate total of 700 MW of electric output to operate the electrolysers.
- The second segment is the transportation market and includes light-, medium- and heavy-duty on-road vehicles, city buses and ferries, to name a few. The Zen Hydrogen Study recommended transportation as second on their list of future demand for hydrogen, albeit over a longer period of time. The focus of this study does not include the transportation market.
- Large industrial users may buy or produce renewable and low-carbon hydrogen. This could include oil refineries and other industries that are large hydrogen users. They could produce hydrogen for on-site use and possibly for export, or a third party could produce for both markets.
- A national or interprovincial strategy to create dedicated hydrogen transport infrastructure could allow for the sale of pure hydrogen across larger portions of Canada, as well as internationally through B.C. ports, or to Western U.S. jurisdictions through pipelines. Market dynamics would then no longer be constrained by the B.C: market but would be driven by large-scale U.S: and overseas demand. Such

[105] GHGenius501d-5, www.ghgenius.ca. Numbers are for BC Hydro's integrated grid. Electricity and green hydrogen produced in the Fort Nelson grid has a much higher carbon intensity.
[106] Gorski, Jan *et al.*: Carbon intensity of blue hydrogen production - Accounting for technology and upstream emissions. Pembina Institute, August 2021.
[107] B.C. Hydrogen Strategy - A sustainable pathway for B.C.'s energy transition. CleanBC, July 2021.
[108] Timmerberg, Sebastian et al.: Hydrogen and hydrogen-derived fuels through methane decomposition of natural gas – GHG emissions and costs. Energy Conversion and Management: X Vol 7, September 2020.

infrastructure could also allow for long-term storage of hydrogen in order to stabilise the electricity grid and provide more seasonal flexibility with hydrogen delivery. In the absence of dedicated hydrogen pipelines, liquid organic hydrogen carriers (e.g., methyl cyclohexane) or liquefied hydrogen could be exported by ship to U.S. or Asian markets from B.C. Physical export or the sale of hydrogen certificates into extra-provincial markets represents a potential threat to the ability to use the gas locally if pricing is higher outside of B.C.

4.7 Infrastructure Needs

The main infrastructure for low-carbon hydrogen use is already in place: the natural gas grid. The limit to hydrogen content in the gas pipeline is currently undetermined. B.C. exports 90% of its natural gas production. Even if all B.C.'s natural gas consumption was converted to hydrogen, the average hydrogen content in the main transmission lines would be only 10% or less.

The co-location of hydrogen production at other industrial sites that could potentially use hydrogen – for example near cement plants and refineries – offers infrastructure benefits. Section 6.3.5 of this report also notes this. Additional infrastructure needed includes electrolysers, power generation assets, and other production assets linked to blue and turquoise hydrogen, as indicated in Table 25.

Table 25 Infrastructure and Planning Requirements to Increase Hydrogen Production

Requirements	Status
Additional renewable electricity production assets	BC Hydro currently developing a new integrated resource plan.
Electrolyser farms	Installation of large-scale production sites on-grid or off-grid. For off-grid sites, additional investment is required to generate electricity (PV, wind). Off-shore sites will potentially require long cable connections to the mainland.
Site local water feed for electrolysers	Filtration plants will need to be invested in.
BC Environmental Management Act. Site and plant environmental assessment and permitting will need to be undertaken for large electrolyser plants	Electrolysers use integrated water purification including ion exchange and reverse osmosis filtration processes. Feed water and grey waste water effluent will need to be addressed.
Steam methane reforming facilities	Commercial technology that needs to be financed and deployed in several locations, often near proven sites for carbon sequestration.
Carbon sequestration infrastructure	CO_2 capture units (amine-based or other technologies), compression and injection into the ground.
Methane pyrolysis plants	Production of carbon black and hydrogen near hydrogen users and/or the natural gas grid.

4.8 Recommendations

The cost curves can inform the best strategy for procuring renewable and low-carbon hydrogen from B.C. or elsewhere. Generally, hydrogen from outside the province is not expected to be cheaper, given the low electricity and gas costs in B.C. The exception would be any waste hydrogen that is currently vented, or turquoise hydrogen. If the aim is to keep costs low, available sources of waste and turquoise hydrogen should be secured first. A strategy should be developed to attract investors to B.C. who will demonstrate and then commercially produce turquoise hydrogen and by-product carbon that could be sold into the carbon black markets. The production of green and turquoise hydrogen should preferably be situated near large consumers, such as the refineries in Prince George and Burnaby. This can make use of existing infrastructure and possibly, personnel, will maximise the value of the hydrogen as it can be delivered in its pure form, and offers possibilities to better manage pipeline injection of surplus hydrogen produced that is not used on-site, thus reducing impacts on the local gas distribution pipelines.

For blue hydrogen, incentives may be needed to construct a first production site by 2030. Since carbon sequestration is likely required, permitting is expected to take several years. This may be a demonstration facility or a full-scale facility. Alternatively, the effort could focus on building a CCUS facility if a market for the CO_2 can be identified. This would avoid the need for sequestering the CO_2 and would improve economics through sale of CO_2.

The production cost of green hydrogen is currently above the GGRR price limit of $31 per gigajoule. This may change if the price ceiling is modified so that an *average* price can be used that allows more than $31 per gigajoule for some projects to be paid, or if the current policy is changed towards a carbon intensity-based target which allows for higher pricing. Green hydrogen may also become more competitive if power tariffs are implemented that reflect the ability of large-scale electrolysis to balance the power market, use constrained wind, and provide long-term (seasonal) energy storage opportunities. Given the very high potential for blue hydrogen, green hydrogen is only deemed competitive if it is incentivised through a portfolio standard approach. Implementing electrolytic hydrogen production where the by-product, oxygen, can be used will slightly improve economics. At an estimated value of $50 per tonne of oxygen, hydrogen costs could be reduced by about $2.80 per gigajoule. This is insufficient to achieve a cost of below $31 per gigajoule for green hydrogen but niche opportunities may exist where this is possible if oxygen costs are higher.

The high cost of off-grid hydrogen production strongly suggests that on-grid wind farms or other renewable electricity production technologies should be given preference for green hydrogen production. Strongly increasing green hydrogen production will require an adjustment to the BC Hydro Resource Plan to accommodate large new sources of intermittent power production and large-scale green hydrogen production.

Time-of-use electricity prices would offer benefits as hydrogen could be produced when wholesale grid pricing is zero or negative, for load balancing. Current electricity pricing structures provide no incentive for energy storage, and there is no need for such grid balancing in B.C. at this point in time as it can be handled by adjusting hydro output. This may, however, change after 2030 if large amounts of intermittent renewable power production is added to the B.C. grid.

5.0 SUPPLY PORTFOLIOS

This chapter develops scenarios that model the cost and availability of a portfolio of renewable and low-carbon gas production pathways described in the chapters above. These scenarios are not to be confused with, or taken as, a forecast. Rather, they are models that represent a possible outcome based on a set of criteria. The underlying Excel-based model considers possible factors or drivers, the interactions between pathways, and their relative contribution to the targets by 2030 and by 2050.

The model is simplistic and high-level and would need to be refined to achieve specific goals and milestones. The scenarios are based on several assumptions, mainly related to costs and the availability of resources, build-up rates, and technology readiness of each pathway.

5.1 General Assumptions

General assumptions apply to all pathways and were made to model the cost of the various renewable and low-carbon gases in 2030 and 2050, as depicted in Table 26. These cost assumptions can be modified in the model to determine their relative impact on the cost of production. The amounts are given in 2021$ – i.e., inflation is not considered but costs reflect changes above the inflation level. For natural gas, future costs were based on the "Diversified" scenario developed in the Guidehouse report. For users on the distribution grid, the Fortis Rate 5 (Lower Mainland/Southern Interior) was used. The retail cost accounts for increasing amounts of renewable and low-carbon gases in the distribution grid. For electricity costs, BC Hydro's latest Revenue Requirements Application to the BCUC indicates a bill decrease of 1.4% in 2022, then an increase of 2% in 2023 and another increase of 2.7% in 2024. In 2025, due to Site C being commissioned, another 5-6% rate increase is expected. After that, assuming that rates grow with inflation, these assumptions reflect price increases in line with 2% inflation for the entire decade. After 2030, an annual increase commensurate with inflation is assumed to continue.

Table 26 Default Cost Assumptions, in 2021$

Cost Factor	2021	2030*	2050*
Electricity	$65/MWh	+0%	+0%
Natural gas, retail (Rate 5)**	$7.96/GJ	$14.09/GJ	$21.43/GJ
Natural gas, at the well	$3.68/GJ	$3.68/GJ	$3.68/GJ
Natural gas retail demand in B.C.	200 PJ/year	200 PJ/year	186 PJ/year[109]
Renewable and low-carbon gas share in B.C. gas grid[109]	0%	15%	73%
Pipeline gas carbon intensity	49.9 g/MJ	42.4 g/MJ	20 g/MJ
Capital costs, non-biomass hydrogen	100%	-9 to -15%	-19 to -40%
Capital costs, gas from biomass	100%	-10 to -30%	-50%
Capital costs, anaerobic RNG	100%	Incremental	Incremental
WACC	9.2%	9.2%	9.2%
Loan term	20 years	20 years	20 years
Carbon tax	$45/t	$130/t***	$130/t
Wood feedstock cost (residue, average)	$60/odt	$60/odt	$60/odt
Wood feedstock cost, add. harvest	-	-	$121/odt

* In relation to 2021; ** Incl. carbon tax; *** Corresponds to $170/t in 2021, at 3% inflation

[109] Pathways for British Columbia to Achieve its GHG Reduction Goals. Guidehouse, August 2020 (Diversified Pathway).

Electricity costs include demand charges but do not consider BC Hydro's lower CleanBC Industrial Electrification Rates,[110] which are deemed to benefit the project developer and investors, but not the purchaser of renewable gases.

The B.C. carbon tax does not apply when natural gas is used as a feedstock, as opposed to a fuel.[111] This means that for turquoise and blue hydrogen production, where natural gas is the feedstock, no carbon tax applies on any volumes of CO_2 emitted at the production stage. On the other hand, wood gasification and steam reforming using natural gas are subject to the tax since the gas is used as a process fuel.

An important assumption relates to feedstock costs for gas production from wood. In line with Section 3.1.3, the cost of residue is assumed to increase with inflation, whereas the costs of pulp and sawlogs continue to increase above the inflation rate. $60 per dry tonne is taken as a conservative number for residue costs - an average between mill residue and increasing amounts of harvesting residue. This cost is also applied to any wood residue currently used for either power production for BC Hydro or for pellet manufacturing.

Additional wood could be harvested but would then require the use of standing trees within the AAC limit. This has been estimated to roughly double feedstock costs for gas production, as an average between pulp quality logs and the resulting roadside residue, also assumed to be available at a cost of $60 per dry tonne. Only about 30% of new stands harvested this way are assumed to be used for renewable gas production; most of the harvested volumes would be sold as sawlogs.

5.2 Technology Readiness

The pathways discussed in this report vary in technology readiness (see also Appendix A). The build-out rate of mature pathways will be faster than of those with little or no commercial-scale implementations. Precommercial technologies is unlikely to be mature by 2030. Unless enormous resources are poured into decarbonization, their full technical potential is likely to be reached only by 2050. With respect to the three major pathways, the following can be said:

- **Anaerobic digestion:** By and large, RNG from anerobic digestion is a well-developed technology that could grow quickly.
- **Woody biomass:** Renewable gas production from woody feedstock is not commercial technology. Technologies need to mature, with demonstration projects being built and evaluated before full technical potential can be realized. We assume a slower build-out for these pathways, with only demonstration projects producing hydrogen or RNG from wood happening before 2030. Syngas for lime kiln projects could proceed more rapidly.
- **Hydrogen from non-biomass resources:** While electrolysis is a well-known technology, large industrial-scale applications are only just being deployed. Blue hydrogen (carbon capture and sequestration) and turquoise hydrogen have to mature even further.

5.3 Resource Potential

Previous chapters describe the technical resource potential of each of the three main renewable and low-carbon gas sources: anaerobic digestion, wood gasification, and non-biomass hydrogen production. The

[110] https://app.bchydro.com/accounts-billing/rates-energy-use/electricity-rates/electrification-rates.html (Accessed November 26, 2021)

[111] https://www2.gov.bc.ca/gov/content/taxes/sales-taxes/motor-fuel-carbon-tax/business/exemptions (Accessed October 14, 2021

numbers provided in these chapters are technical potentials that need to be translated into what is realistic or desirable for B.C. Consequently, two scenarios reflecting a maximum and a minimum resource potential are developed below. What is actually achievable in B.C. with appropriate policies and investment may lie in-between these two extremes. Ultimately, the criteria to gauge potential for in-province renewable and low-carbon gas production must also consider the cost of each pathway and the relative availability of each resource. Other criteria, such as carbon intensity values for different gases or fuels, may also be taken into account.

For anaerobically produced RNG, resource potential has been assessed in detail and is well known. Scenarios for 2030 and 2050 are mainly a function of the cost associated with each pathway. For anaerobically produced RNG, the Minimum scenario only considers projects that cost less than $31 per gigajoule, the current threshold the GGRR has set to protect ratepayers from excessive rate increases. Also, only a portion of the technical potential can be realized. The Maximum scenario allows for projects that are up to $50 per gigajoule.

The potential for green hydrogen largely depends on the availability of (green) electricity. BC Hydro's long-term resource planning suggests that around 300-500 MW may be available for low-carbon fuel production. Additional or alternative sources may include on-grid power production from renewables, such as wind power.

The potential for blue hydrogen is mainly constrained by the availability of suitable geological features and abandoned wells that could be used to sequester CO_2. Turquoise hydrogen produces carbon black and can only be produced cost effectively where there are markets for this by-product. The market for carbon black is large and growing. Sufficient natural gas is available within B.C. to supply both pathways. Currently, only 10% of B.C.'s natural gas production is used provincially; the rest is exported.[112]

The supply potential of renewable gas from wood biomass is constrained by resource availability and its distribution within the province. The demand for syngas in a particular area might not match feedstock supply. Trucking woody feedstock from parts of the province that have surplus fibre may not be viable or even desirable as the energy contained in it is rather low, and trucking costs would be high. Only the Maximum scenario makes use of whole logs (beyond some unharvested pulp logs used in both scenarios). Only low-cost residue is used in the Minimum scenario. In the Maximum scenario, we assume that low-cost resources from expiring BC Hydro contracts and transitioning of mill waste from wood pellet to gas production takes place.

The numbers used for the two scenarios for wood resources are made explicit in Table 27. Both scenarios have time horizons for 2030 and 2050. The amount of wood has been converted to gas production potential using an input-output (feedstock/gas) calorific conversion rate of 67%, representative of the main technologies to be used.

[112] https://www.capp.ca/explore/natural-gas-and-the-lng-opportunity-in-british-columbia/ (Accessed October 6, 2021).

Table 27 Renewable Gas from Woody Biomass Produced in B.C. in Each Scenario (PJ per year, HHV)

Wood Resource	MINIMUM SCENARIO		MAXIMUM SCENARIO	
	2030	2050	2030	2050
Unharvested AAC	-	-	4.6	4.6
Roadside residue related to above	-	-	2.1	4.0
AAC from mill closures	-	-	14	14
Roadside residue related to above	-	-	6.5	11
Unharvested pulp logs	3.6	3.6	4.0	4.0
Roadside residue related to above	0.4	0.6	0.4	0.6
Unused Roadside residue	6.0	10	5.9	10
Mill residue not used	4.8	4.8	4.8	4.8
Conversion of pellet plants	-	-	-	44
Expiring BC Hydro contracts	-	-	47	47
Urban wood waste (CLD)	-	-	-	-
TOTAL	**15**	**19**	**89**	**143**

The table above shows that in the Minimum scenario, insufficient wood is available to reach a 15% renewable gas target (equivalent to about 30 petajoules) with wood alone. On the other hand, there are, in theory, sufficient resources overall to reach the 15% renewable gas target in 2030 and to produce up to 143 petajoules of gas in the Maximum scenario. Table 28 summarizes the assumptions underlying the subsequent tables.

Table 28 Assumptions on Wood Availability for Minimum and Maximum Scenarios

Minimum Scenario	Maximum Scenario
- BC Hydro power purchase agreements with pulp mills extended, limiting availability of mill residues for renewable and low carbon gas production - All lime kilns converted to syngas by 2050. - No whole-tree harvesting for energy occurring due to high cost or difficulty harvesting. - Demonstrations for hydrogen and possibly RNG at pulp mills by 2030. - Urban wood waste already used by others. - 50% of unused roadside residue recovered by 2030, 85% by 2050. - Pellet plants continue to operate and export after 2030.	- Substantial amounts of lower-cost biomass transitioning from BC Hydro power purchase agreements and pellet mills will buffer costs from increased use of roundwood. - All kraft mill lime kilns converted to syngas by 2050. - Hydrogen and RNG production are implemented at almost all mills, possibly some stand-alone facilities. - Max. about 30% of standing trees on a cutblock used for energy, the rest for sawmills or new uses (bioproducts). - Mixed cost of roundwood and associated roadside residue is $121 per dry tonne by 2050. - Max. 75% of unused AAC can be accessed by 2050 (remoteness, terrain, etc.). - Max. 85% of unused roadside residue recovered. - Pellet plant feedstock transitioned to gas production after 2030. - BC Hydro power purchase agreements expire around 2029 and Hydro sources electricity from wind and solar. - Urban wood waste already used by others.

Based on the above assumptions, Table 29 and Table 30 lay down the resource potentials assumed to exist in each scenario, for the years 2030 and 2050. This includes assumptions about demonstration and build-up of new gas production facilities.

Table 29 Assumptions for Gas Production in 2030 and 2050, in PJ/yr (Minimum Scenario)

Gas Type	2030	2050	Rationale
Green hydrogen (large on-grid)	0.0	8.3	Slower ramp-up than Maximum scenario
Green hydrogen (small on-grid)	0.8	1.9	Slower ramp-up than Maximum scenario
Green hydrogen (large off-grid)	0.0	2.4	A single 300 MW off-grid wind farm after 2030
Blue hydrogen	14.2	46.8	Limited by permitting and regulatory restraints
Turquoise hydrogen	1.5	15.4	Slower ramp-up than Maximum scenario
Waste hydrogen	0.9	0.9	Identical to Maximum scenario
Syngas in lime kilns	1.4	5.9	Identical to Maximum scenario
Lignin in lime kilns	0.0	0.0	Lignin a more expensive fuel than syngas
Syngas to hydrogen	0.3	13.4	No change to forestry practices. BC Hydro PPAs are extended. No use of wood pellet feedstock. Only low-cost residue used.
Syngas to RNG	0.0	0.0	Technology not advancing as expected
Agricultural RNG	0.9	1.2	Potential for production cost below \$31/GJ; 70% of 2030 technical potential (90% of 2050 potential).
Municipal RNG	2.3	4.0	
Waste water treatment gas	0.4	0.6	
Landfill gas	2.1	2.7	
TOTAL	**24.7**	**103.8**	

Table 30 Assumptions for Gas Production in 2030 and 2050, in PJ/yr (Maximum Scenario)

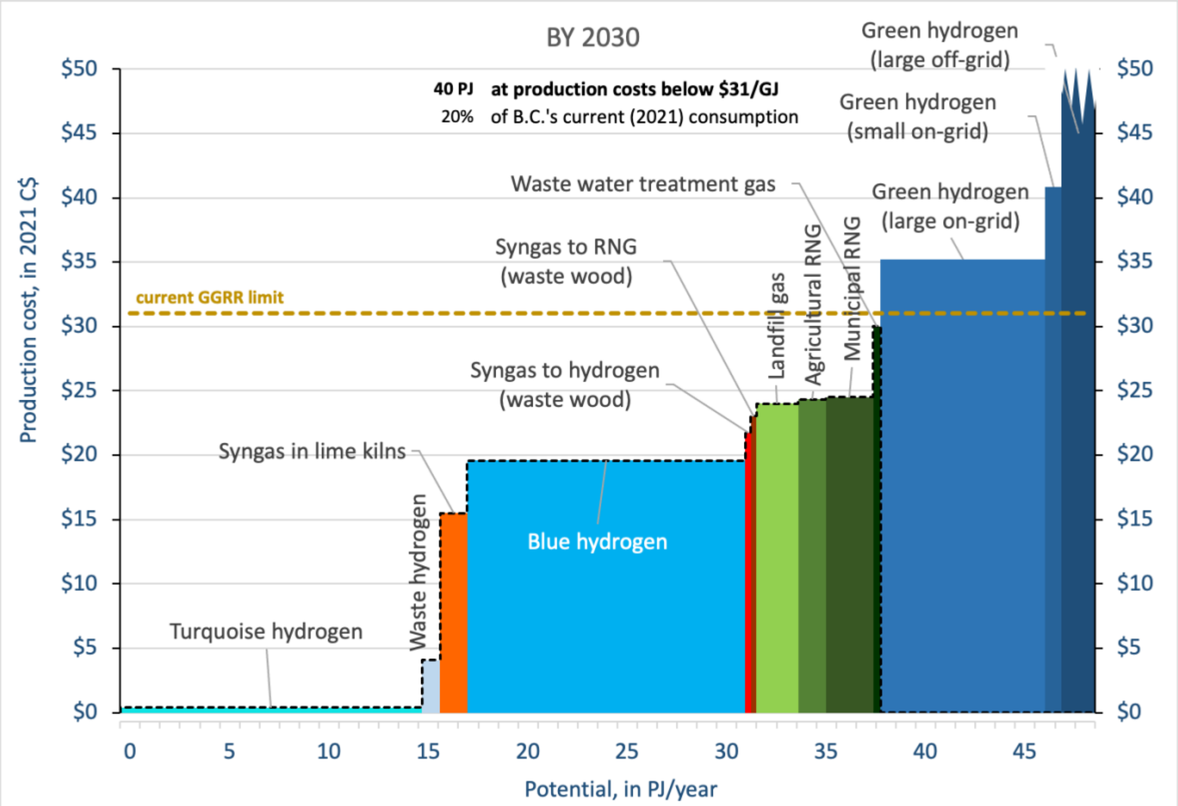
Gas Type	2030	2050	Rationale
Green hydrogen (large on-grid)	8.4	21.0	Converted to petajoules from Table 18
Green hydrogen (small on-grid)	0.8	6.3	Converted to petajoules from Table 18
Green hydrogen (large off-grid)	1.7	12.6	Converted to petajoules from Table 18
Blue hydrogen	14.2	156	From ZEN (2019) report, Figure 28 (in 2050)
Turquoise hydrogen	15.4	92.2	From ZEN (2019) report, Figure 28 (in 2050)
Waste hydrogen	0.9	0.9	From ZEN (2019) report, Figure 28
Syngas in lime kilns	1.4	5.9	100% of lime kilns are converted to syngas by 2050. BC Hydro contracts are not extended.
Lignin in lime kilns	0.0	0.0	Lignin a more expensive fuel than syngas
Syngas to hydrogen	0.3	64.9	Increased forest residue recovery. BC Hydro contracts are not extended. Pellet feedstock transitions towards gas production. 36 plants (or less if larger plant size), also using standing trees
Syngas to RNG	0.3	74.2	One demo by 2030. 26 full-size plants by 2050. Use of some roundwood
Agricultural RNG	1.4	2.0	Potential for production cost below \$50/GJ. 70% of 2030 technical potential (90% of 2050 potential).
Municipal RNG	2.4	4.2	
Waste water treatment gas	0.4	0.6	
Landfill gas	2.1	2.8	
TOTAL	**49.7**	**444**	

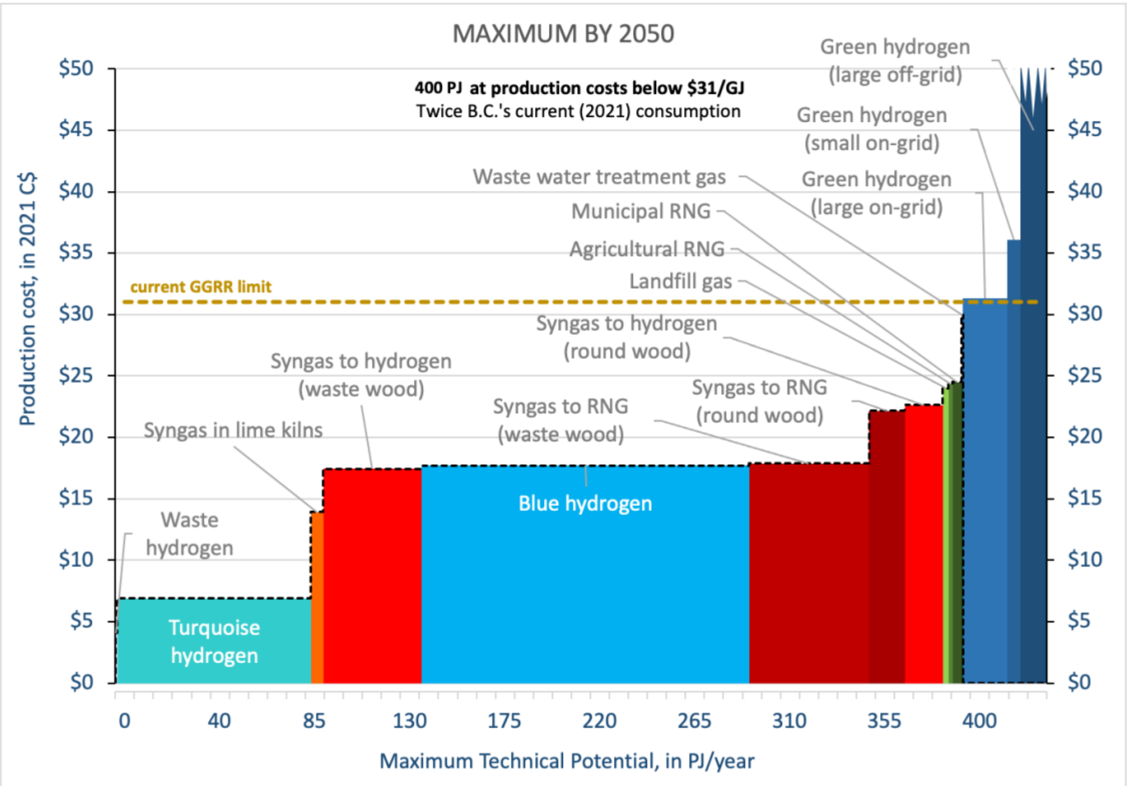
The potentials shown above result in the cost curves displayed in Figure 32 and Figure 33. The (horizontal) x-axis indicates the potential in petajoules per year and the (vertical) y-axis shows the production cost for each pathway. The lowest-cost pathway is shown on the left. The potential increases as higher-cost options are considered, resulting in a stepped curve. Eventually, the costs per gigajoule surpass the $31 threshold that the GGRR requires. The viable potential under the current regulatory framework is limited to the area in the graph that is outlined by a dashed line. Note that, to keep the graphs legible, the size of the x-axis is not the same.

There would be a gradual increase in production over time, which for some pathways only begins after 2030. For anaerobically produced RNG, the potential for 2030 developed in Section 2.4 has been reduced to 70% (90% by 2050) as developing the total potential is not realistic. Syngas production from woody feedstock is assumed to continue through 2050 even if new hydrogen or RNG production is added to mills.

Maximum scenario: the 2030 target of 15% renewable gas can be reached using only in-province resources if low-carbon gas becomes eligible. The target would be reached with a mix of gases, mainly blue hydrogen (construction of about 300 tonnes of blue hydrogen production capacity before 2030) and anaerobically produced RNG. By 2050, 100% of natural gas currently retailed in B.C. could be replaced with provincial renewable and low-carbon gas, still remaining within the $31 (2021$) cost threshold. The resulting gas mix includes a large share of blue hydrogen, high biomass use, and also the construction of carbon black production facilities that produce turquoise hydrogen. For gases from woody biomass, production sites exceed the number of existing mills, suggesting that some greenfield plants would have to be built and substantial amounts of roundwood would be used. More than the current provincial demand could be produced with provincial resources, possibly allowing for exports.

Minimum scenario: compared to the Maximum scenario, the 2030 target cannot be reached with provincial resources. If low-carbon gases are eligible and if action is taken now to implement blue hydrogen production, only 24 out of 30 petajoules per year required are produced in province. B.C: gas utilities would have to purchase 6 gigajoules a year of RNG from out-of-province resources. By 2050, the total available renewable and low-carbon gas levels off at around 100 petajoules, i.e. only about half of current natural gas distributed through pipelines can be displaced. Renewable and low-carbon gas imports would be necessary to fully decarbonize provincial gas usage unless B.C. gas consumption is reduced drastically. The lower gas production levels in this scenario are due to more pessimistic assumptions with respect to woody feedstock availability and built-out rates, as well as technology development (e.g., no RNG production from wood).





Note: To keep the graphs legible the size of the x-axis for 2030 are not the same as for 2050

5.4 Supply Portfolios

5.4.1 Criteria for developing portfolios

The cost curves above show both costs and potential. These numbers are, in part, based on predictions and are subject to changes such as technology development and resource availability. The cost curves can be used to gauge the contribution that each pathway may make, and at what cost. Apart from the cost threshold of $31 per gigajoule (indexed with inflation), other criteria policy makers might want to consider include:

- **Geographical origin:** Gas produced outside B.C. will not have the same provincial social and economic benefits as gas produced within the province.
- **GHG footprint:** The government might set a minimum life cycle carbon intensity for gas to qualify for displacing natural gas. This could give preference to gases that have much lower – even negative – carbon intensities than others, possibly accelerating GHG reductions (Section 5.5).
- **Industry sector:** Renewable and low-carbon gas production may be promoted depending on the potential and need for job creation and how competitive the industry is.
- **Co-benefits**: Some pathways create co-benefits in addition to renewable gas. These co-benefits, which can include local employment, rural diversification and odour and nutrient management, may be considered when choosing which renewable and low-carbon gases to acquire.
- **Social acceptance:** Some pathways may be more acceptable than others. For example, social acceptance may be lower for carbon sequestration projects than for green hydrogen, or for large-scale wood gasification projects versus small-scale digesters. Buyers need to weigh the advantages of each and may have to engage in education efforts to defend purchasing decisions if they are faced with critiques in the media.
- **Speed of development:** As discussed above, some types of projects may require much longer lead times. This would apply to off-shore wind projects used to power electrolysers, or to blue hydrogen projects that need to inject carbon dioxide into the ground. Other types of projects may be developed more easily and quickly, especially to meet the 2030 targets.
- **Investment needs:** Some pathways require substantial investments for project development. A full-scale RNG production facility using woody feedstock may cost more than $300 million to build, which is more difficult to realize than smaller projects under $100 million, such as syngas production, or under $30 million, such as anaerobic digestion.
- **Technology status:** Pre-commercial pathways need to be supported with further R&D. Demonstration projects should be realized before 2030, possibly with public support, but near-term solutions lie in technologies that are already fully commercial today.
- **Diversity and hedging:** It may be advantageous to diversify the production portfolio, including several sources of renewable and low-carbon gases. This will reduce the risk of relying on a single source that may become more expensive or may even cease to exist over time, and will support the parallel development of new industries in several sectors.
- **Potential and replicability:** Some pathways have more potential than others in terms of how much gas can be produced.

5.4.2 Possible Supply Portfolios

Table 31 qualitatively compares the renewable and low-carbon gas pathways. Some clear messages can be derived:

- Green hydrogen remains too expensive for immediate consideration.
- Turquoise hydrogen is of great interest but not yet commercial.
- Waste hydrogen is also of great interest but very limited in terms of its resource potential.
- Syngas production from wood is the most achievable and lowest-cost option for using woody biomass.
- Wood-based pathways offer more social benefits than those based on electrolysis or blue hydrogen.
- Agricultural RNG is attractive based on several parameters but has limited potential.
- Anaerobic pathways are the most developed technologically and also relatively easy to develop.

Table 31 Qualitative Comparison of Renewable and Low-Carbon Gas Pathways

Pathway	Gas Cost	Invest-ment	GHG	Sector	Co-Benefits	Social	Speed	TRL	Poten-tial	Overall score
Green hydrogen (large on-grid)	--	-	+	o	o	+	+	+	+	**o**
Green hydrogen (small on-grid)	--	o	+	o	o	+	+	+	+	**o**
Green hydrogen (large off-grid)	---	--	+	o	+	+	--	+	++	**-**
Blue hydrogen	+	-	o*	+	-	-	--	+	++	**o**
Turquoise hydrogen	++	+	o*	++	-	+	-	-	+	**o**
Waste hydrogen	++	++	o	o	-	+	+	++	--	**++**
Syngas in lime kilns	o	+	+	+	o	+	o	+	+	**+**
Syngas to hydrogen	-	-	o	+	o	o	--	-	++	**o**
Syngas to RNG	-	--	o	+	o	o	--	-	++	**o**
Agricultural RNG	o	+	++*	+	++	o	+	++	+	**+**
Municipal RNG	o	+	+*	o	+	o	+	++	+	**+**
Wastewater treatment gas	+/o	+	+*	o	o	+	+	++	o	**+**
Landfill gas	+	++	+*	o	o	+	+	++	o	**+**

---- extreme; -- very bad; - bad; o neutral or small impact; + good; ++ very good

* Exact carbon intensity is disputed; see Section 5.5

In combination with the cost curves developed above, the supply portfolios for 2030 and 2050 could be structured as shown in Table 32. Options to facilitate these outcomes will be discussed in Chapter 6.0.

Another question is what role imported gases will play. This is discussed in the following section. As mentioned above among the criteria, a portfolio approach is desirable both in terms of creating more opportunities inside B.C. and offering more resilience for gas retailers that need to comply with government mandates. The breadth of this diversity will depend on the ability to pay for the gas – i.e., whether the $31 per gigajoule threshold is hard or flexible – to accommodate some of the more expensive sources. It is presumed below that such flexibility may not occur before 2030 and/or that more expensive sources may become more affordable after that date.

Table 32 Potential Supply Portfolios of Renewable and Low-Carbon Gases

	2030	2050
Primary sources	Waste hydrogen Anaerobically produced RNG Syngas in lime kilns Blue hydrogen	Turquoise hydrogen Syngas in lime kilns Hydrogen (or RNG) from wood Anaerobically produced RNG Waste hydrogen
Secondary sources	Turquoise hydrogen Hydrogen from wood (demonstration)	Blue hydrogen Green hydrogen

5.4.3 In-Province Versus Out-of-Province Supplies

FortisBC is currently buying RNG produced outside of B.C. (e.g., Lethbridge, AB and Des Moines, Iowa) for an existing voluntary market.[113] This option is in line with other jurisdictions, such as California, that use a certificate trading system to 'move' RNG between jurisdictions by separating and selling the environmental benefits of these gases. Buyers can then claim these benefits for their own gas use whereas, at the injection point, the RNG is treated as if it was generic natural gas. The green benefits therefore accrue where the buyer uses natural gas, not where the producer injects it, geographically decoupling RNG production and use.

While avoiding trade barriers, this system may leave most of the socio-economic benefits from renewable and low-carbon gas production outside of B.C. However, it can be harnessed to obtain low-cost RNG (e.g., from landfill gas sites) or hydrogen to protect B.C. ratepayers from exposure to high renewable and low-carbon gas pricing. It may also enable sourcing RNG with very low, or even negative, carbon intensities. This would be an advantage for reaching provincial and corporate GHG targets more quickly. Yet, sourcing all, or a large portion of, gases from outside B.C. will economically benefit producers in other jurisdictions, rather than keeping ratepayers' money inside the province. Some balance between imports and local production is therefore desirable.

As outlined in Chapter 2.0, the potential for anaerobic RNG production in the rest of Canada and the U.S. is large enough to cover all of B.C.'s gas needs. Both qualify as vendors of renewable gas because they are connected to B.C. through the continental gas grid. The Canadian potential (including B.C.) is deemed to be about 70 petajoules by 2030 and 80 petajoules by 2050. U.S. potential is deemed to be close to 600 petajoules in 2030 and about 630 petajoules in 2050. This means the entire 2030 B.C. target could, in theory, be procured inside Canada and any 2050 target could be complied with using Canadian and U.S. sources.

B.C. utilities are unlikely to secure as much of this gas as they wish to due to competition. In the U.S., several jurisdictions have implemented renewable gas policies and have created lucrative markets for RNG certificates (see Section 5.5). In Canada, Quebec is currently seeing uptake of RNG from landfill gas. Any first-mover advantage that B.C. gas utilities currently have may therefore disappear soon. Table 33 provides a comparison between the advantages and limitations of importing renewable and low-carbon

[113] https://www.fortisbc.com/services/sustainable-energy-options/renewable-natural-gas/meet-our-renewable-natural-gas-suppliers#tab-7 (Accessed October 5, 2021).

gases. The choice mainly relates to sourcing lower-cost, assured gas production outside B.C. versus creating more social and economic benefits inside the province.

Table 33 Renewable and Low-Carbon Gas Procurement in B.C. versus Imports

	Aspect	Purchase gas certioficates outside British Columbia	Develop renewable and low-carbon gas projects inside British Columbia
0.	Potential	Currently far in excess of required targets.	Sufficient to meet 15% by 2030 CleanBC target within $31/GJ threshold. Can theoretically replace entire B.C. gas consumption by 2050.
1.	Cost	Reduced cost to ratepayers if credits are purchased soon and for a long period.	Some of the gas purchased will cost more than out-of-province.
2.	Project portfolio	'Low-hanging fruit' will be developed first – mainly RNG from anaerobic digestion and landfills.	Range of pathways will be developed because B.C. offers better conditions than many other jurisdictions.
3.	Competition	Competition with other utilities and venture capital.	Less competition due to Fortis predominance as a gas utility in B.C.
4.	Control	Limited control over resources outside B.C. Credits may go to other bidders after initial contracting period.	Good control of biomass and electricity-based projects, some control over organic waste.
5.	Resilience to high price carbon markets	Some resilience if B.C. utilities are 'early movers'. High exposure to markets as regulatory framework is developed in other jurisdictions.	High resilience because B.C. utilities have right of first refusal.
6.	Impact on competing resource users	Low	Industries such as the pellet industry will see increased competition for 'energy wood.'
7.	Technology development	Limited incentives for technology development.	Developers and venture capital have incentive to develop and mature technologies.
8.	Compatibility with other B.C. government policies	Incompatible with desire to strengthen forest products industry and develop provincial renewable and low-carbon gas production.	Demand for electricity from B.C. Hydro will increase. Low-grade wood waste may be used for energy rather than higher-value products.
9.	Demand side management	Low gas prices discourage energy savings.	Increased gas prices will foster demand-side management.
10.	Cash flow	Net outflow of ratepayer money.	Ratepayer money stays inside B.C. Potential inflow of capital from out-of-province.

Table 34 takes a conservative approach for the potential of imported gases. A portion of RNG may be secured in the coming years as other jurisdictions ramp up their own renewable and low-carbon gas policies. After 2030, possibly, earlier, the first-mover advantage may cease to exist, and only incremental amounts may be secured. This is especially true in the U.S., where very high RNG certificate pricing has been observed together with rapidly increasing sales volumes.[114] This may price RNG out of reach for Canadian utilities. There is also the question of renewing RNG sales contracts after the 20-year procurement contract ends. A 20-year term is reasonable for the life expectancy of most RNG plants. At renewal, pricing is likely to adjust to market conditions, which may feature higher prices than at the start of such projects.

For hydrogen, low-cost resources such as waste hydrogen will likely be quickly secured by U.S. buyers. Turquoise hydrogen and other electricity-based gases would likely cost more in the U.S. than in B.C., and no imports are assumed. This leaves mainly blue hydrogen potential for imports. Since there is great potential inside B.C. for such gas, import needs are limited. They may still occur if B.C. production is slow to commence or if costs are lower outside of B.C. (e.g., where good sequestration opportunities exist). For the table, it is assumed that two large sources (100 tonnes per day) may be secured outside B.C. by 2030 and another two by 2050. The current wording of the GGRR does, however, not appear to allow for hydrogen imports as it requires that the gas must be delivered through the B.C. gas distribution system or directly used by a client to replace natural gas.[5]

Table 34 Anaerobic RNG and Hydrogen Import Potential

	Technical Potential, 2030	Achievable, 2030		Achievable, 2050	
Rest of Canada	60 PJ	10%	6 PJ	15%	10 PJ
U.S.	590 PJ	5%	30 PJ	7%	44 PJ
Blue hydrogen	Very large		8.4 PJ		17 PJ

The above assumptions are conservative and a more aggressive approach may deliver different results. Yet, even with these conservative assumptions, the resource outside B.C. will be more than sufficient to comply with the 2030 target. For 2050, an aggressive strategy would have to be in place to secure enough renewable and low-carbon gas production in competition with other jurisdictions. However, if certificate pricing remains high or increases, this may not be a profitable strategy.

With pricing of environmental credits over US$200 per tonne of CO_2 in recent years,[115] the value of renewable and low-carbon gases can be very high in the U.S. Table 35 provides a range of market values for different renewable and low-carbon gases, based on their carbon intensities (Cis). The higher CI value is typical for blue hydrogen, for example, whereas low positive values may apply to gases derived from solid biomass, and negative values refer to agricultural and municipal RNG. With a carbon intensity for natural gas of 60 kilograms per gigajoule (see next section), a gas that has an intensity of 30 kilograms per gigajoule would displace 30 kilograms per gigajoule. At C$260 per tonne of CO_2 under the California LCFS, this would reflect a value of $7.80 per gigajoule. Renewable Identification Number (RIN) pricing for R3 RINs (for RNG) have been about US$2.50 per RIN since 2020.[116] This corresponds to about C$38 per gigajoule – well above the current B.C. threshold of $31.[117]

[117] https://www.waste360.com/gas-energy/where-renewable-natural-gas-moving-forward-and-what-will-mean-industry-and-states-part-2 (Accessed October 5, 2021).

Table 35 Current U.S. RNG Certificate Pricing, in C$*

Gas Carbon Intensity	RIN Value	LCFS Credit Value**	Total
30 g/GJ	$38	$7.8/GJ	$46/GJ
5 g/GJ		$14.3/GJ	$52/GJ
-100 g/GJ		$41.6/GJ	$80/GJ
-400 g/GJ		$117/GJ	$155/GJ

* Converted from US$ at a rate of C$1.3/US$

** Depends heavily upon the California Low-Carbon Fuel Standard Credit price, which has been as low as US$71/tonne in June 2017 and as high as US$217/tonne in February 2020. The price in October 2021 was US$158/tonne.[118]

The important takeaway from this table is that at current pricing levels, it is impossible for B.C. utilities to buy even gases with a comparatively high CI through certificate trading as pricing is higher than the C$31 per gigajoule threshold. This may change in the future but the best strategy is to source the gas from projects through long-term purchasing agreements at the investment stage. This implies high transaction costs and a limitation to greenfield projects or projects that have previously sold their gas into different markets (e.g., using biogas for power generation). Blue hydrogen does not fall under the RIN system but would earn LCFS credits in the U.S.

A strategy for gas utilities in B.C. is to secure renewable and low-carbon gas supplies outside the province to hedge against the risk of insufficient resources below the ceiling price in B.C. by 2030. This is a no-regrets strategy since utilities can sell surplus credits into the gas credit market later if there are enough low-cost gas sources in the province. If credit pricing remains high, this may mean that profits can be obtained from such activity, which could in turn reduce the cost of gas for B.C. ratepayers. Sourcing renewable and low-carbon gases provincially should still be a priority as it creates the support structures that establish this industry in B.C.

5.5 Carbon intensity and emission reductions of supply portfolios

The potential that this report has established is based on petajoules of renewable and low-carbon gas rather than tonnes of CO_2e displaced. A policy switch away from energy and towards carbon abatement as a measuring parameter would have to look at a different metric to measure compliance with GHG targets. This section assesses the carbon mitigation that can be achieved with the existing potential.

The various pathways differ in their use of resources and thereby in the amount of greenhouse gases (GHG) emitted. The spreadsheet model factors in carbon credits from the displacement of GHGs that would occur in the absence of the project. Using GHG emission factors published by the B.C. Ministry of Environment and Climate Change Strategy (MECCS)[119] and other data, the model determines the carbon intensity of each pathway. Literature values are also used to determine the reported range of carbon intensities. The carbon intensity can vary significantly from one pathway to another, or even between projects within the same pathways, especially when methane is emitted, a powerful GHG with a high global warming potential.

Carbon emissions of <u>agricultural and municipal RNG</u>: Most pathways described in this report have a GHG footprint lower than that of natural gas. Agricultural RNG, especially from projects involving liquid manure (such as dairy and hog farms), even has a strong negative carbon intensity as it captures methane that

[118] Source: California Low Carbon Fuel Standard Credit price | Neste.

[119] BC Ministry of Environment and Climate Change Strategy, « B.C. Best Practices Methodology for Quantifying Greenhouse Gas Emissions, 2020 », Victoria, B.C., April 2021.

would have escaped from manure stored in open pits.[120] Some of the carbon intensities reported do not include GHG emissions that happen outside the digester. Digestate is removed from the digester while anaerobic reactions continue to produce uncaptured methane for a while. Many life-cycle analyses include some emissions from digestate in the actual facility and some from spreading digestate on the land. The 'GHG Genius' model used by the government may not include the latest data and may exclude some emissions associated with digestate.[121]

Carbon emissions of RNG from landfill gas and WWTPs: At times, landfill gas and WWTP RNG projects reportedly have higher CI scores than natural gas in B.C. This is because most CI data for landfill gas and WWTP RNG projects comes from the California LCFS, which counts GHG emissions during RNG production and from the transportation and compression of RNG to approximately 3,600 PSI (248 bar) for use as vehicle fuel. As such, if landfill gas and WWTP RNG projects are built in U.S. states with high CI electricity, the CI of the RNG can be quite high.

Carbon emissions of natural gas: Similarly, fugitive emissions from the extraction of natural gas, especially related to hydraulic fracturing, may result in significantly higher GHG emissions than stated. The burner tip emission intensity of natural gas (close to 50 kg per gigajoule) needs to be augmented with upstream emissions, currently estimated at between 6 and 12 kilograms per gigajoule for B.C. natural gas.[122] Recent remote measurements indicate that this may still be an underestimation by a factor of two as some fugitive emissions have not been captured in previous ground surveys.[123] Any uncertainties with respect to natural gas also apply to natural gas-derived low-carbon gases.

Carbon emissions of blue hydrogen: Converting methane into hydrogen is an overall endothermic process, that is, heat/steam must be supplied to the process for the reaction to proceed. This steam is usually produced using natural gas as a fuel. The CO_2 emissions from the steam boiler may or may not be captured and sequestered. Powerful compressors are used to inject and sequester the captured CO_2 into geological formations. These pumps may be fuelled by green electricity or by natural gas. Hydrogen has a lower calorific value than natural gas (12.7 gigajoules per standard cubic metre as opposed to 39 gigajoules per standard cubic metre) requiring more pump energy per gigajoule to deliver gas through the pipeline to the end user. Most natural gas compressor stations are powered by gas-powered combustion engines,[124] which vent exhaust emissions into the atmosphere.

Blue hydrogen merits a closer look due to the uncertainties and technology pathways that can lead to significant differences in carbon intensities. The Pembina Institute evaluated the carbon intensity of blue hydrogen produced with different technology pathways. In that they found that existing steam methane reforming (SMR) technologies employed like at the Quest upgrader in Alberta leads to a modest reduction in carbon intensity.[125] Other studies suggest even higher GHG emissions for blue hydrogen than for natural

[120] This is considered for the California LCFS but currently not for the B.C. LCFS, which may lead to very different carbon credit values from the same source.

[125] Gorsky et al., Pembina Institute, "Carbon intensity of blue hydrogen production", Aug 2021, accessed on Jan 28, 2022 at https://www.pembina.org/pub/carbon-intensity-blue-hydrogen-production

gas.[126,127] Pembina's report states that "*there are a wide range of carbon intensities for blue hydrogen, depending on the choice of technology (SMR or ATR), carbon capture rate, emissions associated with imported electricity, and the emissions from natural gas production (which vary by production basin).*"

A robust regulatory framework that addresses upstream GHG emissions sources like fugitive methane and supports best available technologies is important to ensuring that blue hydrogen production pathways are as low-carbon as possible to align with long-term GHG reduction goals.

Carbon emissions of wood-fuelled gas: Using roundwood for energy purposes accelerates the emission of carbon contained in the wood, and creates a carbon dept that must be paid back through regrowing felled trees over time. This is because there is essentially no residence time for carbon in the final product (i.e. the fuel) before energy is created, as opposed to lumber which might remain in solid form for decades or centuries before disposal. For mill and harvesting residue, convention typically attributes the majority of emissions to the harvested wood products, such as dimensional lumber or pulp. The residue is then counted as close to carbon neutral. In the Maximum scenario, some roundwood is harvested to produce RNG or hydrogen. The initial carbon removal that is reported as a loss in the Canadian GHG inventory when a tree is cut would then be attributable to this portion of the feedstock. RNG made from wood then has a similar carbon footprint as natural gas, since the carbon in the RNG produced is counted as an emission. Unlike with natural gas, however, trees regrow over time and the carbon debt is then paid off as the same amount of CO_2 is sequestered as harvested stands are renewed. The B.C. carbon stock accounting system is not yet set up to capture these processes fully. Over a 50-to-100-year timeframe, roundwood is also carbon neutral. It will be a policy decision as to how temporary emissions from roundwood for energy are accounted for, and whether and how the repayment of carbon debt enters the equation.

The examples above show that refining emission factors and quantification protocols is still on-going and substantial uncertainties exist with the GHG profile of some of the pathways discussed in this study. The factors published by MECCS, largely used in this study, may reflect neither the latest science on the full upstream emissions of natural gas exploration nor the downstream emissions of biogas production. As science improves, carbon accounting protocols will change. MECCS updates its "B.C. Best Practices Methodology for Quantifying Greenhouse Gas Emissions" on an annual or bi-annual basis.

A climate change strategy that is largely based on blue and turquoise hydrogen or on anaerobic digestion might be at risk of having to correct the carbon intensities of these pathways over time. This may become important as the Government of B.C. is contemplating switching from targets pegged to energy production to those related to GHG intensity. Figure 34 provides the carbon intensities used in this report (solid green bar) and the range that could be gleaned from some published studies.

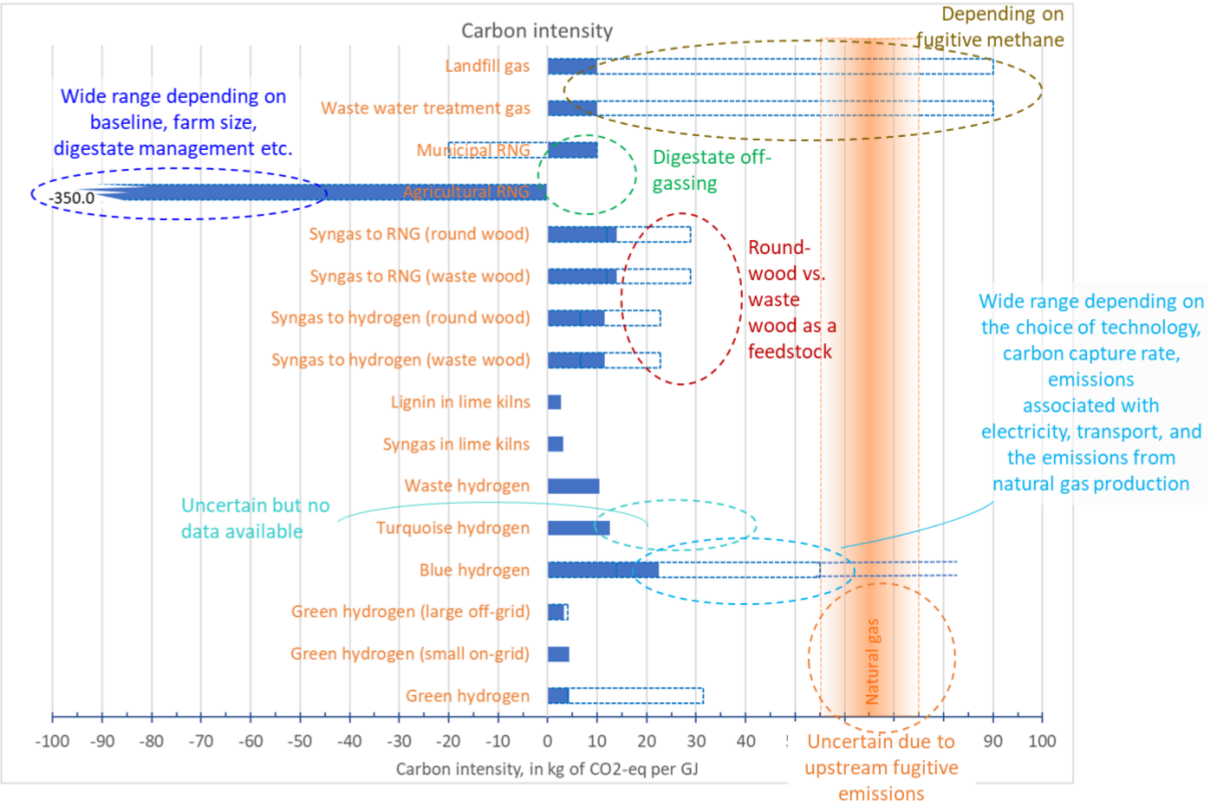
Figure 34 Carbon Intensities of Renewable and Low-Carbon Gas Pathways as reported in literature



Notes:

- Dashed bars indicate the range of factors stated in various publications.
- Error bars represent uncertainty with respect to life-cycle GHG emissions for various pathways.
- For anaerobic RNG, uncertainty arises with both accounting methodologies (including avoided emissions from lagoons in the agricultural sector, consideration of methane off-gassing from digestate), fugitive emissions (e.g., leakage from repeated gas transfers), as well as indirect emissions (compression to high pressures for use in transportation using more or less green electricity).
- Different conversion technologies and energy types used for gas production from wood will result in different CI values.
- For green hydrogen, the CI of the electricity used determines the CI of the hydrogen produced.
- For both natural gas and or turquoise and blue hydrogen, upstream emissions from gas production, conversion, sequestration and transport, as well as CO_2 leakage from geological storage can have impacts.
- No data is available for turquoise hydrogen but uncertainties will likely be in the same range as for natural gas.

6.0 CREATING THE B.C. RENEWABLE AND LOW-CARBON GAS INDUSTRY

6.1 Key considerations and Desired Outcomes

As discussed in Section 5.4.1, there are many considerations for the choice of renewable and low-carbon gas pathways for B.C. The B.C. Government wants to weigh three main considerations:

(a) Achieve the CleanBC *Roadmap to 2030* goals, including a minimum of 15% renewable being retailed in B.C. by 2030, reducing emissions while supporting a strong economy, supporting innovation, and implementing a cap on emissions for natural gas utilities.

(b) Keep the cost of pipeline gas affordable. Low gas prices are important to keep energy costs affordable in the province. Increasing energy costs disproportionately affects the poor and energy-intensive industries. Changes must be gradual and must occur in a considered way to be socially acceptable.

(c) Develop a bioeconomy within B.C., maximizing socio-economic benefits for the province. The renewable and low-carbon gas should be made in-province. Producing gas from local biomass can increase local benefits over the current situation, especially if wood fuel exports were redirected towards provincial renewable gas production. It could also stabilise the forest product industry if BC Hydro contracts expire without renewal around 2029. In addition, the gases produced should have a low (or negative) carbon intensity.

These considerations lead to the question of how best to support a transition towards renewable and low-carbon gas use in B.C. and what types of policies should be implemented, above and beyond those currently in place.

6.2 Best Policy Pratices in Other Jurisdictions

6.2.1 Main Policy Approaches

The promotion of anaerobic RNG and other renewable and low-carbon gas types, takes place across a broad spectrum of policy areas ranging from agricultural/forestry, waste, energy, climate, and general environmental policy. As illustrated in Figure 35, the RNG value chain can be affected and enhanced at several stages, including facilitating feedstock acquisition, creating a demand-pull using incentives or mandates, and a regulatory environment that supports RNG deployment.

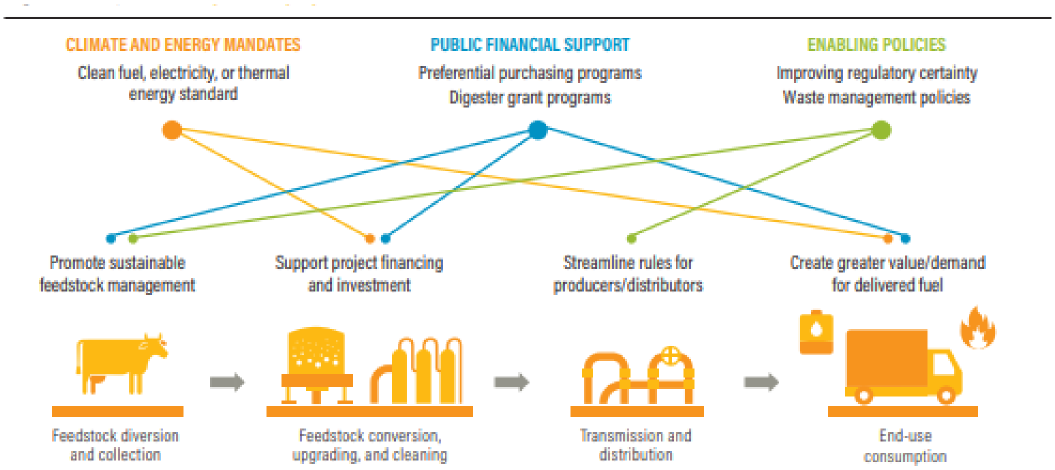


Figure 35 Policies Promoting the Development of RNG[128]

[128] Cyrs, Tom, John Feldmann, and Rebecca Gasper. 2020. "Renewable Natural Gas as a Climate Strategy: Guidance for State Policymakers." World Resources Institute. https://doi.org/10.46830/wriwp.19.00006.

Countries and states have created legislation regarding renewable energy to diversify their energy resources, promote provincial energy production and encourage economic development. Three approaches to promoting renewable energy have evolved over the last decades.

1. Renewable Portfolio Standards (RPS) or Clean Energy Standards (CES) are quantity-based schemes in which the regulator requires a specific amount or proportion of gas to come from renewable or 'clean' low-carbon sources. A carbon intensity standard is a variation of this approach.
2. Feed-in tariffs (FIT) guarantee all eligible producers a fixed price per gigajoule of gas fed into the grid. The tariffs are linked to standardized and simplified interconnection rules.
3. Public tenders: A certain amount (in gigajoules per year) or value (in $ of investment) for renewable or low-carbon gas is publicly tendered and sold to the lowest bidder or bidders with the highest volume.

Table 36 outlines key features of each instrument. All of them have been tried and tested in the electricity sector over the last decades. There are variations of, and supplementary policies for, each of them used in various jurisdictions. These are described below.

Table 36 Policy Instruments for Promoting Renewable and Low-Carbon Gas Production

	Renewable Portfolio Standard, Clean Energy Standard or LCFS	Feed-in tariff or premium system	Public tenders or auctions
Approach	Quota for renewable or low carbon gas or quota for maximum GHG intensity.	Set price for renewable or low-carbon gas fed into the grid, or premium/ bonus paid on top of fossil natural gas price.	Individual tenders for a certain type of renewable or low carbon gas. Reverse auction mechanism.
Mechanism	Volume-based	Incentive-based, can be restricted by total target volume.	Either volume or price-based.
Technology	Technology neutral. Only eligible technologies.	Technology specific. Carve-outs for specific technologies.	Technology-specific
Control of portfolio	Investors and producers decide which pathway/technology is used.	Government controls tariff for each pathway/ technology.	Tender specifies type and volume of gas, typically large projects only.
Target control	Penalty for not reaching target(s).	Markets and tariff decide uptake. Cap and floor for premiums	Penalty for winning and then not implementing capacity.
Certificate trading	Possible	Not possible.	Not possible.
Investment security	No investment security.	Stable cash flow insulates investors from revenue risks.	Binding investment limit. High risk for investors.
Adminis-trative effort	Low	Medium	High
Build-out / installed capacity	Build-out rate dependent on target.	Robust short-term growth and high build out if incentives adequate.	Many bids end up being too low and projects fail.

	Renewable Portfolio Standard, Clean Energy Standard or LCFS	Feed-in tariff or premium system	Public tenders or auctions
Local development	Certificate trading may not encourage local development.	Incentives for selective technologies can promote local and specific local development	Frequently larger bidders from out-of-province.
R&D	Lowest price technologies succeed. Little R&D.	Stimulates R&D input to reduce costs.	Lowest-price technologies succeed. Little R&D.
Cost-effective-ness	Least-cost instrument. Competition between technologies. Self-corrects. More efficient to reduce GHG emissions and cost to ratepayers.	Lack of competition leads to higher cost than RPS. Requires continual adjustment by government/utility board Low transaction cost and low risk leads to low financing cost.	Strong push for low costs but some projects then fail due to often higher than expected cost. High transaction costs.
Impact on ratepayers	Lower social risk than feed-in tariff.	Cost to ratepayer may be volatile.	Typically, lower than feed-in tariff
Key challenges	Low build-out pace.	Social acceptance might decline with increased costs to ratepayer.	Top-down approach often does not meet with reality on the ground. Monopolizes production. Political insecurity.
Compatibility with existing B.C. policies	15% renewable gas commitment Low-carbon fuel standard.	Eligible CI can be defined. Maximum cap for total or per category and per year can be defined.	BC Hydro approach to buying power from third parties.

6.2.2 Current B.C. Policy

B.C. currently has a favourable policy framework for RNG development, including market support. Both pipeline gas and vehicle fuel are supported by B.C.'s Renewable Portfolio Allowance and the LCFS. The B.C. commitment to source 15% of renewable gas in gas sales is currently the most ambitious in Canada, higher than the current 10% by 2030 target for renewables gases in Quebec, which has very similar natural gas retail demand to B.C.[129] The carbon tax of $45 per tonne of CO_2e is among the highest in North America and is scheduled to rise to $50 in 2022,[130] then to increase at least in line with federal rates. However, the

[129] https://www.quebec.ca/en/government/policies-orientations/plan-green-economy (accessed November 22, 2021)

[130] https://www2.gov.bc.ca/gov/content/environment/climate-change/clean-economy/carbon-tax (Accessed October 11, 2021).

LCFS and voluntary purchase program have been the key drivers of growth in RNG. Under the 2018 CleanBC Plan and the 2021 *Roadmap to 2030*,[131] several targets related to RNG were announced:[132]

- Minimum 15% renewable gas target by 2030.
- Increase in the Carbon Tax to $50 per tonne by 2022, then to meet or exceed federal tax levels,
- Tripling the LCFS from a 10% reduction in carbon intensity in 2020 to a 30% reduction by 2030.
- Aiming to get to 95% organic waste division and capturing 75% of landfill gas by 2030.
- A GHG emissions cap of approximately 6 Mt of CO_2e per year for 2030 for gas utilities.

Follow-up policies have included purchases of CNG buses which can easily be switched to RNG, and an Organic Infrastructure Fund, which provided $30 million of funding from various sources to improve organic waste management. Also, the Organic Matter Recycling Regulation Intentions paper calls for stricter environmental assessments and controlled atmosphere composting (negative air pressure, biofilters, leachate control for all composting facilities that consume over 15,000 tonnes of food waste or biosolids per year).[133]

At the local level, some municipalities are interested in reducing and perhaps eliminating residential natural gas use as part of their climate action strategy. Such jurisdictions include the City of Vancouver, which has the power to control its building code, and the City of North Vancouver, which allows a less strict step code adoption for natural-gas-free buildings.[134]

6.2.3 Canadian Clean Fuel Standard and Other Federal Policies

While originally planning to have separate streams for solid, gaseous and liquid fuels, the Canadian Government announced in 2020 that the Clean Fuel Standard will only apply to liquid fuels,[135] however RNG used in vehicles can be used to generate compliance credits. The Clean Fuel Standard will require a 13% reduction in fuel carbon intensity below 2016 values by 2030.[136]

The federal carbon tax is currently (2021) at $40 per tonne of CO_2e and will increase to $50 in April 2022. The government's intent is to increase it further, to $170 (nominal) per tonne in 2030.[137] This will apply to fossil natural gas in the pipeline, thus reducing the price differential between renewable and low-carbon gases and natural gas. This will also increase costs for renewable and low-carbon gas production where natural gas is used for process heat (some of the wood gasification processes).

6.2.4 U.S. Policies

Policies at the state level vary between states, with California having the most comprehensive set of policies. Most RNG policies have centred around its use as a vehicle fuel. This is primarily through its use in compressed natural gas vehicles, which currently have a 40% RNG market share in the U.S.

[131] B.C. Ministry of Environment (2021) CleanBC: Roadmap to 2030

[137] https://www.cbc.ca/news/politics/carbon-tax-hike-new-climate-plan-1.5837709 (Accessed October 11, 2021).

Some states have made significant changes, with Washington, Oregon, California and Nevada developing either voluntary or system-wide RNG policies. The combined Federal Renewable Fuel Standard credits (called 'Renewable Indentification Numbers' or 'RINs') and California's LCFS credit value adds up to around C$21 to C$107 dollars per gigajoule (see also Table 35), with most RNG being over C$31 per gigajoule. California's population and economy are larger than all of Canada and several other states have also implemented RNG policies. Considerable demand could be generated in these jurisdictions and B.C. utilities may only compete with difficulty. On the other hand, enhanced electrification and other low-carbon fuels may limit demand for RNG in the U.S. market. Nonetheless, with RNG being the first mass-produced advanced biofuel, competition with the U.S. is likely to increase in the long-haul trucking sector.[138]

LCFS programs are under discussion in the U.S. northeast and mid-Altantic[139] (Transportation and Climate Initiative). Minnesota, Colorado, Iowa, South Dakota and others are considering LCFS policies , which may significantly increase demand for low-carbon and renewable fuels. When all the proposed and existing LCFS policies are considered, demand for low-carbon-intensity fuels should increase significantly. This is noteworthy, as the Californian LCFS alone has sparked considerable RNG development across the continent, with RNG being purchased from as far away as Quebec. With increasing demand for renewable and low-carbon fuels, prices are expected to rise, particularly for very low and negative carbon intensity projects RNG. Any first-mover advantage that B.C. utilities may currently have when securing supplies of low-cost RNG will likely disappear over the coming years.[140]

State-level policies are also driving RNG demand for the natural gas utility sector. California, Washington, Oregon and Nevada are all developing either voluntary or mandatory procurement of RNG by their natural gas utilities. Other noteworthy policies include organics diversion mandates in some states (California, Connecticut and Massachusetts)[141] and low-interest loans for RNG projects in Iowa.[142] California also has a program to extend infrastructure to large clusters of dairy farms.[143] Wisconsin and Washington State have funded agricultural digesters to reduce agricultural impacts on lands and water. Finally, watershed nutrient trading is considered, which allows farmers to trade nutrient permits and thus provides economic support to solutions such as anerobic digestion.[128]

Table 37 provides an overview of the most relevant U.S. policies affecting renewable and low-carbon gas production and markets. One can cnoclude that competition for RNG and RNG certificates will increase further with time. Especially California's LCFS market provides higher financial gains than B.C.'s. Quebec also recently announded renewable gas portfolio targets that are comparable to those of B.C. There is a risk that provincially produced RNG will leave the province.

Table 37 Current U.S. Policies Pertaining to Renewable and Low-Carbon Gas[144,128]

State	Low-Carbon Fuel Standard	RNG Pipeline Sales	Infrastructure/Other
California	• State LCFS[145]	• Biomethane target under development. • Utilities' (Southwest Gas, SoCalGas and SDG&E) RNG purchases including eliminating price caps for the last two (voluntary program).	• Clusters for Dairy RNG, including infrastructure funding. • Organics landfilling regulations • Cap and Trade program at state level • Short-lived Climate Pollutants plan. • Ability for developers to establish grid connection and requirement for reasonable time period for utility. • Standardised interconnection procedures among gas utilities to facilitate RNG production • Dedicated pipelines to large, industrial dairy farm clusters
Washington	• State LCFS under development[146]	• Under development to allow either voluntary or system-wide RNG sales.[147]	
Oregon	• LCFS under development with a target of 25% below 2015 levels by 2030	• Target for 5% RNG with thermal energy credits under development. Some integration with state LCFS.	• Cap-and-reduce program for RNG to reduce GHG intensity of gas distributedin state.
Iowa			• Low-interest bonds for farm RNG development.
Nevada	• LCFS envisaged[148]	• Utilities allowed to sell RNG. Encourages RNG to be in supply portfolio.	

6.2.5 Recommendations for B.C.

B.C. has a robust framework for the development of RNG with strong price support for deployment. One threat to this leadership is competition from the California market due to the very lucrative combination of the federal Renewable Fuels Standard and state-level LCFS revenues. Acquiring RNG from out-of-province could become increasingly difficult, particularly for low or negative-carbon intensity RNG

products. B.C.'s first-mover advantage can be used to procure RNG from projects where it can be secured with 20-year contracts. This hedges against stronger than expected costs from locally produced gas. If locally-produced gas can then be procured, any excess gas credits can be sold into the open market. The following areas should also be addressed to expand renewable and low-carbon gas production in B.C.:

Feedstock:

1. Continue working on improving the ability to recover harvesting residue through subsidies (Forest Enhancement Society programs) and the supply chain, using better methods and technologies.
2. Implement meaningful cost mechanisms to motivate forest product companies to recover most of the harvesting residue.

Financial:

1. Low-interest financing could be provided for agricultural digesters (and other types of gas production), as done in Iowa.
2. Provide funding to support the additional cost of RNG deployment over composting or other organics/wastewater solids disposal options.
3. Work with agricultural organizations to promote cooperatively-owned or operated centralized RNG plants, including a possible sustainable agriculture payment scheme for digestate use and soil carbon enhancement.
4. Financially recognize the broader social and ecological benefits of anaerobic RNG production, as AD with nutrient management can play an important role in preventing nutrient overload on lands and waters, increasing soil carbon, reducing methane emissions, and providing a low-carbon fuel for the gas grid and NGVs.
5. Continue to support R&D and demonstrationand first commercial-scale facilities to produce low-carbon gas.
6. Create mechanisms to support renewable and low-carbon gas production at larger scales from woody feedstock, such as higher gas rates being paid during the first years of operation to shorten payback periods, or low-cost, long-term financing for capital-intensive projects.

Infrastructure:

1. Work within B.C. and with neighbouring jurisdictions to make the gas system hydrogen-ready.
2. Proactively plan for network meshing, reverse flows and other measures to integrate renewable and low-carbon gas.
3. Work with BC Hydro to ensure that enough new power generation capacity is available after 2029 to enable green and turquoise hydrogen production in B.C. Electrolytic hydrogen production could be linked to on-grid power production commensurate with new demand and based on facilitated grid access for new renewable power generation linked to, but not necessarily in close proximity to hydrogen production hubs.

Regulatory:

1. Prioritize AD over composting when treating separately collected organic waste.

2. Allow for an average renewable and low-carbon gas cost of $31 per gigajoule, instead of the $31 ceiling, to facilitate demonstration projects and green hydrogen at higher costs (without requring BCUC approval each time), as was proposed in a previous study.[227] This would enable increased provincial production during the initial years; the cost cap could then be reduced over time.
3. Consider a renewable gas feed-in tariff that assigns cost thresholds depending on the pathway used, similar to feed-in tariffs in the electricity sector. Mature low-cost pathways may have lower thresholds than technologies under development. These cost caps should be reduced over time as prices come down.
4. If the current percentage target is retained, define five-year carve-outs for each pathway that require gas utilities to buy gas from several different sources rather than only the lowest-cost ones.
5. Alternatively, a carbon cap that requires utilities to account for the life-cycle carbon intensity of renewable and low-carbon gases fed into the pipeline could lead to a more diversified mix where more expensive sources may still be preferred if they have low or negative CIs.
6. In the longer term, consider coupling green hydrogen production with grid balancing and for energy storage to remunerate such services with revenue created from hydrogen production and release on demand, to create incentives to add green hydrogen production.

Climate:

1. Examine means to incorporate climate benefits from lower nitrogen fertilizer use and increased soil carbon due to the use of digestate from anaerobic RNG production.
2. Align international GHG quantification protocols to better compete in the international market.
3. Review the carbon footprints of blue and turquoise hydrogen and the anaerobic pathways to ascertain their impacts in terms of GHG emission reductions.

Demand-side management and technology switching:

This study focuses on the supply potential for renewable and low-carbon gas production pathways. Pathways beyond renewable and low-carbon gas are outside the scope of this report. A more comprehensive approach would compare primary energy use of various pathways in a 'well-to-heat' manner. Currently, 45% of natural gas consumed in B.C. is used by the residential and commercial sector.[149] The residential sector alone uses around 48 petajoules per year of natural gas for low-temperature space heating.[150] This need for low-temperature heat can be met more effectively by pathways other than low-carbon gas.

For example, green hydrogen can be produced with a conversion efficiency of 65% to 75% of the electricity used. Methanation of syngas to produce RNG is expected to have 95% conversion efficiency. A downstream household may use renewable gas in its furnace or boiler at a seasonal efficiency of 80% to 85%. The total system efficiency multiplies to 46% to 61% of the electricity input. In comparison, an air-source heat pump used in the climate of southern coastal B.C., where most of the population is located,

[149] https://www.cer-rec.gc.ca/en/data-analysis/energy-markets/provincial-territorial-energy-profiles/provincial-territorial-energy-profiles-british-columbia.html (Accessed October 17, 2021).
[150] https://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/showTable.cfm?type=CP&sector=res&juris=bc&rn=8&page=0 (Accessed October 17, 2021).

can achieve a coefficient of performance (equivalent to an efficiency) of 300% to 350% of the electricity used, i.e. it is six to eight times more efficient than heating with gas.

The life expectancy of residential buildings in Canada ranges from 42 years for apartment buildings with less than five storeys to 65 years for single detached and row houses and 80 years for large apartment buildings.[151] Assuming an average age of the residential housing stock of 36 years[152] (in 2021), a large share of B.C.'s building stock will be replaced within the 29 years between 2021 and 2050. This offers opportunities to switch from natural gas to alternative forms of heating. The goal of 15% renewable gas may be achieved more easily by switching technologies than by switching to low-carbon gas.

6.3 Infrastructure, Innovation and Technology

6.3.1 A comprehensive approach

Summarizing the issues discussed above, several measures should be considered to fully enable a transition towards renewable and low-carbon gas that relies to a large degree on provincial resources. This includes:

- **Feedstock:** One key resource is forest harvesting residue. More than a million tonnes are available at an affordable cost today and more could be sourced with better technologies and supply chains. Whereas Scandinavian harvesting models may not be directly transferable to B.C. conditions, subsidies (or penalties) to enhance residue recovery and better approaches to recovering the material, such as integrated harvesting, are needed.
- **Electricity:** B.C. has significant potential for wind farm development, a resource that could be used for hydrogen production. Major investment in wind farms and related transmission infrastructure would be required if green hydrogen is to form a substantial part of a low-carbon, gas-production strategy.
- **Technology development:** Several technologies are still pre-commercial. Demonstration and further R&D are necessary to enable the production of hydrogen and/or RNG from woody feedstock. Further refinement and cost reductions are also necessary for green hydrogen. Turquoise hydrogen represents another interesting pathway that needs development support.
- **Pipeline infrastructure:** Continuing work is required to upgrade the existing natural gas pipeline network to accommodate increasing amounts of hydrogen. This should be started near hydrogen users, such as oil refineries in Burnaby and in Prince George or the ammonia plant in Trail.
- **Financing:** Capital costs to produce renewable and low-carbon gas can be very high. The forest products industry cannot accommodate long-term amortization of large investments. Systems to reduce these cost parameters through low-cost loans or other means could accelerate demonstration and deployment (see also Section 6.2.5).
- **Demand-side management and fuel switching**: The 15% renewable gas target for 2030 can be achieved easier and likely at a lower cost by reducing the demand for fossil natural gas. In the moderate climate of southern and coastal B.C., electric heat pumps can achieve GHG reductions more effectively than renewable and low-carbon gases. Similarly, pellet production and heating with pellets has a higher overall efficiency than the biomass-syngas-hydrogen-methane pathway. Switching natural gas use for low-temperature applications, such as building heat, to other fuels will reduce costs for achieving CleanBC targets. This applies especially to new construction. Vancouver City Council has

[151] https://www150.statcan.gc.ca/t1/tbl1/en/tv.action?pid=4610000801 (Accessed on Nov 27, 2021)

[152] https://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/showTable.cfm?type=HB&sector=res&juris=00&rn=11&page=0 (Accessed on Nov 27, 2021)

approved a bylaw that bans fossil fuel appliances for low-rise buildings as of 2022.[153,154] Fossil natural gas will be phased out completely by 2050.[155] This approach could be extended to all of B.C.

6.3.2 *Investment needs*

Table 38 illustrates the investment required to realize the envisaged transition. Investment needs are around $5 billion by 2050 in the Minimum scenario and around $20 billion in the Maximum scenario. This does not include expansions or upgrades to the gas distribution network, or new power generation sources (apart from the off-grid green hydrogen pathway). Most early investment would be for anaerobic digestion, a pathway that is commercially more mature than other technologies.

Results shown in the table are taken from an Excel model that includes the cost parameters shown in Chapters 2 to 4. The corresponding amount of gas produced can be read from Figure 32 and Figure 33 in Chapter 5. This model can be used to simulate different input parameters and to model sensitivity towards varying assumptions.

Table 38 Investment Requirements, in Million Dollars (Minimum scenario)

Pathway	CAPEX per plant, 2030	Number of new plants, 2030	Total cost, 2030	CAPEX per plant, 2050	Number of new plants, 2050	Total cost, 2050	Cumulative cost, 2030 + 2050
Green hydrogen (large on-grid)	$357	1	$476	$252	1	$280	$532
Green hydrogen (small on-grid)	$15	4	$62	$11	5	$55	$66
Green hydrogen (large off-grid)	$155	0	$0	$109	1	$109	$218
Blue hydrogen	$273	3	$780	$240	7	$1,57 7	$1,817
Turquoise hydrogen	$139	0	$43	$122	3	$341	$463
Waste hydrogen	$19	1	$19	$19	0	$0	$19
Syngas in lime kilns	$35	2	$70	$25	7	$164	$189

Table 39 Investment Requirements, in Million Dollars, Maximum Scenario

Pathway	CAPEX per plant, 2030	Number of new plants, 2030	Total cost, 2030	CAPEX per plant, 2050	Number of new plants, 2050	Total cost, 2050	Cumulative cost, 2030 + 2050
Green hydrogen (large on-grid)	$357	1	$476	$252	3	$840	$1,316
Green hydrogen (small on-grid)	$15	4	$64	$11	31	$341	$405
Green hydrogen (large off-grid)	$155	1	$102	$109	5	$540	$642
Blue hydrogen	$273	3	$780	$240	29	$6,857	$7,637
Turquoise hydrogen	$139	3	$431	$122	15	$1,894	$2,324
Waste hydrogen	$19	1	$19	$19	0	$0	$19
Syngas in lime kilns	$35	2	$70	$25	7*	$164	$234
Syngas to hydrogen	$144	0.1	$23	$80	36	$2,880	$2,903
Syngas to RNG	$270	0.1	$27	$150	26	$3,900	$3,927
Anaerobic RNG		*6.3 PJ*	$315 – 770		*3.3 PJ*	$165 – 413	$480 – 1,183
TOTAL			**$2,308 - 2,763**				**$19,889 - 20,592**

* Because of the large size assumed for a syngas plant, the total is smaller than the number of kraft mills in B.C.

Investment needs are large, and vary by a factor of four between the minimum and maximum scenarios, by 2050. The $20 billion of the Maximum scenario correspond to 6.7% of the annual provincial GDP of around $300 billion, or about ten times the annual investment in the B.C. building sector.[156] Asia-Pacific countries invested about $30 billion in B.C. between 2018 and 2020, a large portion of which was dedicated to the LNG terminal in Kitimat.[157] As such, the cost of conversion to renewable and low-carbon gas production lies within the bounds of past energy infrastructure investments.

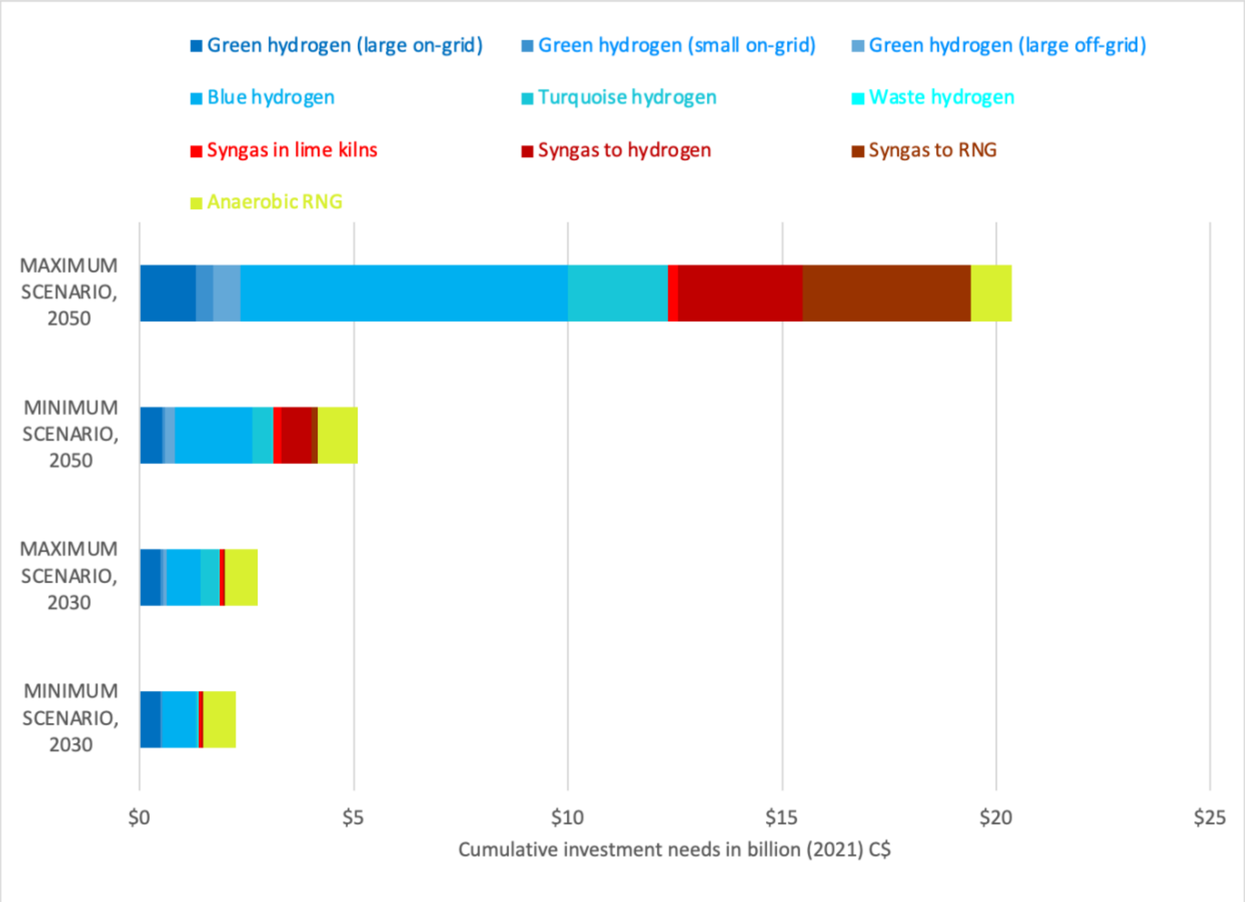

Figure 36 Cumulative Investment Needs by 2030 and 2050 in the Two Scenarios

6.3.3 Accounting for the Dynamics of a Changing Gas Production Industry

As the gas network transitions towards renewable and low-carbon gases, several aspects are changing at the same time:

- The average cost of gas from the pipeline will increase since the cost of renewable and low-carbon gases is higher than that of fossil natural gas.
- Carbon taxes are expected to increase over time, which will reduce the cost advantage of natural gas over renewable and low-carbon gases.
- The costs of renewable and low-carbon gases will decrease over time due to better and cheaper technologies.
- The carbon intensity of pipeline gas will decrease over time, as more renewable and low-carbon gases are injected – the share of fossil natural gas is expected to decrease, reducing the carbon intensity and amount of carbon tax to be paid per gigajoule.
- The pipeline gas composition will change as more hydrogen is added. This affects gas users (e.g., changed Wobbe index) and especially users that use methane as a chemical feedstock. This also concerns turquoise hydrogen production, which transforms natural gas into carbon black and hydrogen.

- Gas demand may be reduced as prices increase and if provincial strategies favour different heating technologies.

These developments have been considered at least in part in the cost model but can only be predicted with low certainty. The related uncertainties indicate the need for periodic review of the assumptions made. The latter can be modified in the Excel cost model, such that new developments can be integrated to model different outcomes.

6.3.4 Caveats With the Results of This Report

Several assumptions have gone into the preparation and underlying model of this report. These assumptions need to be verified and adapted. For users of this report, it is important to understand significant assumptions that were made for some of the pathways:

- **Anaerobic biogas:** The uncertainties are fairly minor and previous work has allowed for a fairly precise assessment of potentials, costs, and future developments. An important question is how much RNG produced in B.C. may be exported and how much RNG produced outside B.C. may be imported. This mainly depends on policies in B.C. and competing jurisdictions, and the RNG market value resulting from these policies. There is also some uncertainty about the true carbon intensity of anaerobically produced RNG, which may affect its future market potential. Any newly required technologies to reduce its carbon intensity could increase its cost. Finally, the potential by 2030 may not be realized unless there is a capital cost subsidy or other mechanism to deploy more production sites. Although the gas price offered is sufficiently high, it has not succeeded in motivating large numbers of farmers or municipalities to enter into purchase agreements with gas utilities.
- **Syngas:** The main assumption is that almost all mills can implement this technology, which is close to commercial. The potential is well understood and corresponds to current mill kiln energy demand. The main variable is the real cost of producing syngas and the reliability of the technology, which is improving quickly.
- **Wood resource:** This assessment relies on a set of assumptions, at least two of which can have major impacts on pricing and availability. These are: a) the amounts that will be available from BC Hydro PPAs expiring around 2029. It is unknown whether existing PPAs will be extended beyond this date. If they are extended, less low-cost material will become available and thus a strategy relying on large amounts of renewable gas from wood will have to account for much higher feedstock costs, including the use of some non-merchantable roundwood. Similarly, the assumption that after 2030, wood residue currently used to produce wood pellets for export may be redirected towards renewable gas production is uncertain. This material is fairly low-cost, at generally less than $60 per dry tonne, and if it does not become available, feedstock costs for future hydrogen and RNG plants will increase. Furthermore, uncertainties exist around future feedstock impacts from beetle infestations, fire damage, policy decisions impacting the AAC, and future mill closures or reopenings. At the time of writing, the treatment of old-growth forests in B.C. was under discussion and political decisions may significantly affect future AAC. All of this can have significant impacts on fibre availability and cost.
- **Hydrogen and RNG from wood:** These technologies are pre-commercial, so there is considerable risk with respect to both technology performance and related costs. Especially for RNG from wood, cost estimates vary widely.
- **Green hydrogen:** Whereas the cost parameters for green hydrogen are well understood, the future price of electricity is uncertain. Hydrogen production costs could fall after 2030 in 2021 dollars if power pricing does not increase with inflation. However, BC Hydro may need to buy more new renewable power after that date at higher costs to respond to increasing electrification demand and new users. This would leave electrolytical hydrogen one of the most expensive renewable and low-carbon gas

sources. Similar impacts would apply for turquoise hydrogen but to a much lesser degree, since this pathway has better economics than green hydrogen.

- **Blue hydrogen:** Significant uncertainty remains with respect to this pathways' carbon intensity. Future research may reveal that energy requirements for SMR, and fugitive emissions are more significant than current quantification protocols account for, which would decrease the value of blue hydrogen.
- **Turquoise hydrogen:** Similar concerns as with blue hydrogen apply to turquoise hydrogen. The technology is not mature yet and a GHG protocol needs to be developed that allocates carbon emissions between the carbon black and hydrogen products.
- **Future gas demand:** The B.C. retail market for pipeline gas beyond 2030 will depend on various developments in the industrial and building sectors, including annual growth, regulations, energy efficiency, and fuel switching. These developments may lead to shrinking pipeline gas sales in B.C. and other jurisdictions, changing the need for renewable and low-carbon gas production to reach the set targets.
- **New projects and industry changes:** Any new projects that compete for the same resources may have material impacts on the potentials identified above. For example, the CCU project announced by Huron Clean Energy will use over 300 MW of power from BC Hydro by 2025,[158] jeopardizing the addition of new electrolyser capacities through 2030 or longer. Similarly, closures of pulp and paper mills could reduce the potential for sourcing mill residue or for integrating hydrogen production plants with existing industrial operations.
- **Amortization periods:** The model uses a 20-year amortization period. This is not the usual approach for many projects. It also presupposes that a large portion of financing is provided through low-interest, long-term loans, to shorten paybacks for private equity investment. If such mechanisms are not functional, projects may not go ahead or gas pricing may be considerably higher than modelled.
- **Ownership:** The model assumes that plants are owned and operated by a private developer or an existing company, depending on the application. Each pathway has its own assumptions regarding staffing costs based on the most likely ownership model. Different ownership models may require different gas prices as they may have different cost structures.

6.3.5 Building the Renewable and Low-Carbon Gas Production Infrastructure

The transition towards renewable and low-carbon gas sources requires infrastructure upgrades. A strategy specific to infrastructure upgrades should be developed in collaboration with industry. This strategy needs to consider resource potential and related costs, as determined in the present study. Other factors to consider are geographic constraints, stakeholder interests, ratepayer impacts, regulatory issues, questions around gas imports versus provincial gas production, technical restraints to accommodate hydrogen into the gas network and competing uses for electric power and biomass resources.

This section highlights some basic considerations that can serve to inform such a strategy. This report does not recommend or suggest a 'winning' or preferred technology. Rather, actions are recommended that foster the development of all pathways considered (Table 40).

[158] https://www.alaskahighwaynews.ca/fort-st-john/carbon-capture-biofuel-plant-planned-for-bc-4514944 (Accessed October 22, 2021).

Table 40 Roadmap for Renewable and Low-Carbon Gas Pathways

	Phase 1: Develop Supply & Infrastructure 2020–2026	**Phase 2:** Commercial Expansion 2026–2030	**Phase 3:** Commercial Mainstream 2030–2050
Forestry & Feedstock	50% of roadside residue used for bioenergy.	85% of roadside residue used for bioenergy.	Integrated harvest of roundwood and residue in B.C.
Green Hydrogen	Continue R&D and observe technology developments.	Develop pilot demonstration project.	Focus on on-grid applications using new renewable energy generation.
Blue Hydrogen	Research fugitive methane emissions. Clarify hydrogen limits for existing pipelines.	Support the construction of first commercial production site near a refinery or sequestration site.	Source a portion of retailed gas from blue hydrogen.
Turquoise Hydrogen	Continue R&D and piloting of technology. Observe market developments for black carbon.	Support the construction of commercial production sites.	B.C. to become a major international player in terms of black carbon production linked to turquoise hydrogen.
Anaerobically produced RNG	The primary source of RNG in Phase 1. Continue to source RNG inside and outside B.C.	Landfill gas from all sites >1000 t/year is beneficially used. 70% of provincial potential is developed.	70% of all provincial landfill gas emissions captured and used. 90% of provincial potential is developed.
Syngas from wood	1-2 demonstration projects realised.	50% of lime kiln energy displaced by syngas.	100% of lime kiln energy displaced by syngas.
Syngas to Hydrogen or RNG	Continue R&D.	2+ demonstration projects implemented.	20-40 commercial sites developed in B.C.

Key questions to be answered for a strategy are: i) what is the timeline for recommended actions, and ii) where should new infrastructure be situated? A Geographic Information System (GIS) could be established that identifies resources, infrastructure capacities and demand from major consumers. This system will help identify the need for infrastructure upgrades. Table 41 highlights some of the elements to be considered in this GIS system.

Table 41 Development Considerations for Renewable and Low-Carbon Gas Resources in B.C.

Pathway	Location	Limitations	Comments
Green hydrogen (large on-grid)	Close to large hydrogen consumers or a natural gas transmission pipeline.	Limited by BC Hydro generation and transmission capacities.	Electricity rates too high for cost-effective production.
Green hydrogen (small on-grid)	Distributed, near loads.	Reduced impact on grid.	Electricity rates too high for cost-effective production.
Blue hydrogen	Northern B.C., near gas fields.	Long lead times.	Risk of not qualifying as a low carbon gas.
Turquoise hydrogen	Near hydrogen users, such as refineries.	Changing gas composition in grid may affect viability.	Pre-commercial Risk of not qualifying as a low carbon gas.
Waste hydrogen	Chemtrade / Hydra Energy, Prince George (see Section 4.1.5)	No other locations known.	Currently envisaged as a transportation fuel.
Syngas in lime kilns	Kraft mills	May also be used in paper mills, veneer mills, lumber drying kilns etc.	Commercial but not widely used.
Syngas to hydrogen	Pulp & paper mills, less greenfield.	Requires wood handling infrastructure.	Pre-commercial.
Syngas to RNG	Pulp & paper mills, less greenfield.	Requires wood handling infrastructure.	Pre-commercial, promising technology development.
Agricultural RNG	Lower Mainland, Vancouver Island, Peace County.	Low hanging fruit; stiff competition from other jurisdictions.	Highest carbon abatement potential.
Municipal RNG	Large urban centres	Often in cooperation with agricultural or WWTPs.	Hinges on effective organics collection system.
Waste water treatment gas	Large urban centres	Wastewater treatment plants with a 'critical mass.'	Should be made mandatory for new plants and upgrades of plants.
Landfill gas	Large urban centres	Needs at least 10 years of landfill.	Landfills produce less gas with diversion of organics

Table 42 provides a summary of ideas for a provincial strategy to foster renewable and low-carbon gas production. A full strategy would have to be created with industry input. Before engaging in strategy development, the government may want to take a more systemic approach by looking at energy use in the various sectors (residential, commercial, industrial, transport) to identify where and how overall efficiency can be increased (see Section 6.2.5) and how costs can be optimised by defining a strategy and related policies.

Table 42 Elements of a B.C. Renewable and Low-Carbon Gas Strategy

Sector	Goal	Regulation	Subsidies & Other
Forestry	• Make integrated harvesting the default approach in B.C. • More than half of all harvesting residue to be recovered by 2030.	• Create incentives to recover additional harvesting residue (e.g., increase stumpage when less is recovered). • Enhance mechanisms and funding to remove biomass from forests outside commercial harvesting, i.e., pre-commercial thinning or removal for fire prevention. • Slash burning to be (geographically) limited.	• Subsidize demonstration projects for integrated harvesting tailored to B.C. conditions. • Develop an internet platform to offer currently unharvested wood residue to potential buyers. • Work with treasury to quantify firefighting expenses and design a system to reward fire risk reduction. Develop plan to monetize benefits of increased residue harvesting.
Forest products sector	• Convert lime kilns to syngas. • Construct commercial-scale hydrogen and RNG production sites at mills. • Create new revenue streams to increase international competitivity.	• Develop rules and regulations that favour in-province renewable gas production over out-of-province purchases of RNG (for example, by offering a lower price per gigajoule for imports, due to decreased social benefits).	• Develop a new bioenergy & bioproducts strategy for B.C. • Support demonstration projects for hydrogen and RNG production from wood. • Resolve potential conflicts with mills losing the environmental benefits of renewable and low-carbon gas production and use when they sell the gas to a gas utility.
Hydrogen	• Build green hydrogen close to end users, such as refineries. • Upgrade natural gas network.	• Cannot play any major role unless \$31/GJ cost cap is removed or modified. • Allowing for monetisation of grid services (energy storage, grid balancing) could improve economics.	• Review of carbon intensity of natural gas production, incl. blue hydrogen production, is necessary.
Utilities Commission	• Protect consumers. • Lower the carbon intensity of gas retailed in B.C. • Maximise social and environmental benefits for B.C.	• Consider flexibility with financing, production, and with buying gas. • Mandate carbon footprint of pipeline gas. • Consider introducing feed-in tariffs for different gas types.	• Create new funding mechanisms for commercial-scale projects. • Allow gas utilities to buy renewable and low-carbon gases at an average of \$31/GJ (rather than a set maximum cost).

Sector	Goal	Regulation	Subsidies & Other
Gas utilities and gas transmitters	• Source increasing amounts of renewable and low-carbon gases. • Keep gas pricing affordable. • Hedge against high gas pricing.		• Engage with potential producers inside and outside B.C. to secure 20-year contracts. • Invite carbon black producers to B.C. by offering contracts for turquoise hydrogen. • Engage with BC Hydro and enter the queue for services early, to adjust planning for increasing amounts of electricity used for renewable gas production. • Engage with natural gas producers to facilitate blue hydrogen production.
Municipal biogas producers	• Maximise production and use in B.C.	• Widen municipal requirements to source-separate wood and organics from other waste. • Increase landfill gas use instead of flaring.	• Directly subsidize feasibility and FEED studies. • Provide bonds for WWTP upgrades and landfill gas capture. • Support demonstration of new and innovative technologies deemed to have a significant impact on advancement of biogas production in B.C.
Agricultural biogas producers	• Maximise production and use in B.C.	• Develop a Minister's Bylaw Standard for permitting agricultural digesters.	• Verify and align current GHG quantification protocols. • Reward local benefits from improved nutrient management. • Create a capital subsidy program for RNG production to accelerate deployment.
Municipal/ industrial organic waste management	• Maximise production and use in B.C.	• Require municipalities to consider anaerobic digestion when looking at compost facilities.	• Directly subsidize feasibility and FEED studies. • Provide bonds for municipalities building anaerobic digesters. • Provide support to help municipalities find long-term opportunities for land application of digestate nutrients.

Appendix A – BAT Lists

A. *Gasification of solid biomass and renewable production*

A.1 Renewable Gas Production from Solid Biomass

To produce a useful gas from biomass, the solid biomass needs to be gasified, and the resulting syngas needs to be conditioned. Unless the syngas is then used directly to replace fossil fuels, it then is further processed to maximize methane or hydrogen content. The main components of a typical facility would be:

- **Biomass pre-treatment:** depending on the gasifier type, it will require pre-treatment of the incoming biomass, such as drying and comminution. These processes are fully commercial and can be purchased to complete the other plant components.
- **Gasifier:** Several technologies exist, some of which are commercial. There was, however, no commercial biomass-to-hydrogen or -methane plant in operation at the time of writing.
- **Gas treatment:** The syngas contains a mixture of CO, H_2, CO_2, and CH_4, along with impurities and solids, and needs to be treated in order to be ready for the water-shift reaction. Several commercial gas treatment technologies (mainly, removal of tars and particulates) exist. They usually rely on gas cooling and then scrubbing or dry filtering of the syngas.
- **Water-shift reactor and methanation:** Commercial technologies exist but no commercial integration has yet taken place (see above). Compressors may be needed to achieve the required gas pressure to facilitate the reaction.
- **Hydrogen or methane separation:** Several commercial technologies exist, such as pressure-swing absorption, cryogenic or membrane technologies, and amine absorption (removal of CO_2).

A.2 Commercial Gasification Technologies

The main concerns with renewable gas production from solid biomass are the gasifier and subsequent gas treatment technologies, as well as how the entire plant is configured and operating as a whole. Gasification systems suitable for synthetic fuel product are provided by a variety of manufacturers. Several companies provide commercial, or are actively commercializing, indirectly-heated biomass gasification technologies. Table 43 presents an overview of key gasifier vendors, and their suitability to the various processes included in the project scope.

Table 43 Commercial Fluidized and Fixed Bed Gasifiers

Vendor	H_2	RNG	Lime Kiln	Products	Deployment
Synova	++	++	+	MILENA (Indirect)	Petten, NL; Portugal; India;
Enerkem	+	+	+	O_2 Blown gasifier, methanol, ethanol, jet, high octane gasoline.	Varennes, QC; Edmonton, AB; planned facilities in Tarragona, Spain and Rotterdam, Netherlands
Air Products (Texaco)	+	+	+	Over 60 Plants based on fossil fuels. Former Texaco technology	
Air Products (Shell)	+	+	+	50 plants worldwide, mainly coal	
Siemens	+	+	+	Dry feed system, can be used for a broad range of feedstock types	

Vendor	H_2	RNG	Lime Kiln	Products	Deployment
Concord Blue	++	++	+	Indirect gasifier similar to fluidized bed (called ‘falling bed’).	Owego, NY (MSW/Biomass); Omuta, Japan (Sewage Solids to H2); Mahad, India (Toxic Waste); Pune, India (MSW to Electricity
Valmet (CFB)	-	-	++	Air-blown gasifier used for cogeneration and lime kiln.	Vaskiluodon Voima Oy, Vaasa, Finland (Biomass syngas firing in coal power station); OKI Pulp Mill, Indonesia (Lime kiln); Aanekoski, Finland (Pulp mill lime kiln);
Repotec (Güssing)	++	++	+	Indirect CFB gasifier.	Güssing, Austria (Demonstrator/Cogeneration); GobiGas, Sweden with Valmet (Wood to RNG [mothballed]); Wajima, Japan (Thermal Power Generation); Senden, Germany (Gas Engine/ORC Combined Cycle Cogeneration)
Andritz	-	-	++	Carbon Circulating Fluidized Bed (Formerly Pyroflow)	Cheming, China (pulp mill lime kiln), Joutenso, Finland (pulp mill lime kiln), Tampere, Finland (Pilot Plant)
Air Liquide (Ruhr-Lurgi)	++	++	++	Direct fluidized bed (air/O2)	Sasol; Great Plains Synfuels, North Dakota; 101 total
Thyssen Krupp /Uhde	+	+	+	Winkler gasifier (pressurized)	70 plants (coal/pet coke)
Wood (Amec Foster Wheeler)	++	++	+	Direct fluidized bed	More than 9000 operating hours for a 12 MW gasifier (Värnamo, SE); project at Varkaus (FI) and 0.5 MW trial at VTT.[159]
Sunshine Kaidi New Energy Rentech-Silvagas	++	++	+	Indirectly heated dual-fluidized bed gasifier	One 40 MW demonstration in Burlington VT, proposed plant in Kemi, Finland
Agnion	++	++	-	Heat pipes (small-scale units only)	Developed by TU Munich
Air Products	+	+	+	Over 60 Plants based on fossil fuels. Former Texaco and then GE technology and 50 plants based on Shell technology (mainly coal)	
Exxon	+	++	-	Catalytic gasifiers	Only used with coal so far; no methanation necessary

[159] Schildhauer, Tilman and Boliaz, Serge: *Synthetic Natural Gas: From Coal, Dry Biomass, and Power-to-Gas Applications.* Wiley, 2016

Vendor	H_2	RNG	Lime Kiln	Products	Deployment
Nexterra	-	-	+	Fixed bed	
Synthesis Energy (U-Gas)	+	+	+	Fluidized bed gasifier directed at both coal and biomass markets developed in partnership with the Gas Technology Institute	Coal-based gasification projects in China and biomass demonstrations historically.
Siemens	+	+	+	Dry feed system, can be used for a broad range of feedstock types	
Thermochem Recovery International	++	++	++	Steam reforming technology	Commercial Demonstration at mill in Trenton, Ontario using black liquor for lime kiln firing

A.3 Pre-Commercial Gasifiers

Several new concepts are currently under development, and sometimes very close to commercialization. No unique gasifier concept has yet evolved that would dominate the market or even the R&D field, so future outcomes are as yet uncertain.

Table 44 Indirectly-heated fluidized bed gasification suppliers

Company Name	TRL	H_2	RNG	Lime Kiln	Products	Deployment
Highbury Energy Inc.	7	++	++	++	Indirect gasification with aims at Fischer-Tropsch liquid production. States that proprietary *in situ* tar removal process achieves 99% removal.	
Taylor Energy (New York)	6	++	++	++	Three-chambered gasification system designed for woody MSW and biomass to produce syngas with 13 MJ/M3	Project planned in Montgomery, New York with 307 tpd
West Biofuels Gasification	8	++	++	++	Modified Repotec fluidized bed gasifier	Facility under construction in Hat Creek, CA for power generation

For larger-scale plants, a partial list of CFB oxygen-blown gasifiers is shown below. In some cases, the technologies have been designed for MSW feedstocks. Nonetheless, the high biomass component in this feedstock suggests that they are also viable for RNG production from wood feedstock.

Table 45 Directly-heated fluidized-bed gasification suppliers

Company Name	TRL	H_2	RNG	Lime Kiln	Products	Deployment
TCG Global	8	++	++	++	Air/O_2 blown gasifier; building 125,000 tonne per year wood input Fischer-Tropsch plant in Oregon.	Red Rock Biofuels in Oregon
Advanced Biofuel Solutions Ltd. (Radgas)	4-5	++	++	+	Syngas production from biomass/MSW with Metso Outotec Oy oxy-steam fluidized bed with plasma treatment	Swindon, UK
Andritz Carbona (BFB)	8	+	+	++	Air blown gasifier.	Skive, Denmark (Cogeneration with Engine);
Andritz Carbona (BFB) Sungas	8	++	++	+	O_2 blown gasifier.	GTI, Chicago (demonstrator); Coal-based projects in China
Renergi	6-7	-	-	-	Two-stage gasification (air, steam) with focus on MSW and low-temperature tar reforming	Demonstration (Australia); ARENA pegged TRL at 7-8 in 2019
Suny-Cobleskill / Caribou Biofuels	5-6	-	-	++	Inclined rotary gasifier; air-blown	
Endeavour Energia	5-6	++	++	++	Fluidized-bed O2, steam-blown gasifier	Demonstration scale (UK); cold commissioning supposed to be in 2020; designed for biomethane
Jet Sprouted Bed Gasification (Taylor Energy [California])	7	++	++	+	O2-blown gasification with intermittent pulse jets to enhance reaction rate	2 t/day tested in California

Providers of entrained-flow oxygen-blown gasifiers are listed below. Many of these are designed for fossil fuels, such as coal and pet coke, but could be adapted to run on biomass.

Table 46 Entrained-flow gasifier suppliers[160]

Company Name	TRL	H_2	RNG	Lime Kiln	Products	
Lulea Green Fuels (Formerly Chemrec)	7	++	+	++	Proven with air/O_2 Blows for lime kiln and methanol DME synthesis	Pitea, Sweden (Black liquor gasification for Lime Kiln [also formerly DME synthesis]); New Bern, NC (pulp mill lime kiln)
BioLiq	6	++	+	++	Pilot plant producing under 100 Litres of gasoline per hour	Demonstration in Germany
Meva Energy	7-8	-	-	-	Entrained flow cyclone gasifier based on research at Luleå University of Technology sized at around 5 MW.	Hortlax, Sweden
Multi-fuel Conversion (MFC) Technology from RWE	3-4	++	+	++	Lab-scale but aims to recover phosphorous from biosolids and lignite using oxygen blown entrained flow gasification sized up to 125 MW (fuel input).	130 Kg/h pilot under construction in n Niederaussem, Germany

Different concepts that may pursue alternatives to the traditional three gasifier technologies described above, such as including a pyrolysis step or supercritical water, are outlined below. Their technical maturity is generally low and they are not expected to become commercially available in the coming decade.

Table 47 Other gasifier technologies

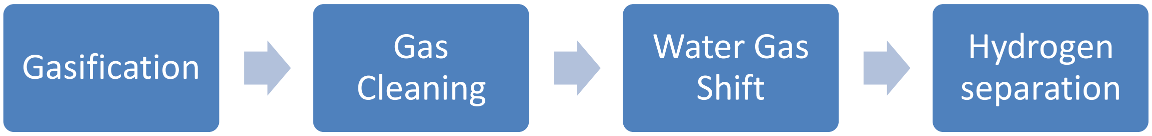
Company Name	TRL	H_2	RNG	Lime Kiln	Products	Examples
Cortus (WoodRoll)	8	++	++	+	WoodRoll Syngas units applying pyrolysis following by indirectly-heated, low-pressure, entrained-flow gasification of char.	Koping, Sweden (RNG/Syngas/Liquids Demo); Hogansas,Sweden (syngas for steel production)
Torrgas	6-7	++	++	+	Three step process involving torrefaction, low-temperature gasification and high-temperature gasification with biochar product.	700 kW demonstration and 13 MW planned plants
Wildfire Energy	3-4	+	0	+	Horizontal batch fixed bed gasification for power and hydrogen production. Oxygen blown trials planned for 2021.	Ipswich, Queensland, Australia

160 National Energy Technology Laboratory, "Entrained Flow Gasifiers." Website. https://www.netl.doe.gov/research/coal/energy-systems/gasification/gasifipedia/entrainedflow [Accessed September 20, 2019].

Plasco (Now OMNI)	5-6	++	++	+	Multi-stage gasification based on grate gasification , fixed bed and plasma reforming. Aimed at engine generator, hydrogen, & Chemicals markets . Can be on O_2 or air blown	Richmond, Ontario
G4 Insights	7-8	-	++	-	PyroCatalytic Hydropyrolysis which converts wood to CH_4 directly	Demo in Edmonton, AB
Genifuel	7?	++	++	-	Hydrothermal Processing to liquid fuels and RNG with 20% of input converted to methane and 60%+ to biocrude	Developed at PNNL and demonstration planned at Metro Vancouver WWTP
Kore Infrastructure	N/A	++	++	+	Pyrolysis of biosolids	Demonstration planned in Los Angeles, CA
Treatech	3	++	++	+	Hydrothermal gasification	

A.4 Gas Processing to Maximize Hydrogen Content

Wood to hydrogen production is done by water shift reaction of syngas; given the low hydrogen content of wood (around 6%), additional hydrogen is added in the form of water, which is split into hydrogen and oxygen, which reacts with the carbon in the syngas to form CO_2. To maximize hydrogen content, gasifiers are operated at very high temperatures above 1,200°C, requiring more expensive materials than gasifiers used for methane production, which operate at under 900°C. In order to simplify gas separation, direct gasification with oxygen or indirect fluidized bed gasifiers (such as FICFB or Milena) are preferred. Air-blown gasification, although low cost, is not suitable. Post gasification hydrogen content for most indirect gasification ranges from 25 to under 50%. Sorption enhanced reforming can remove CO_2 in the bed material, facilitating hydrogen volumetric contents of up to 75%. In all of the above cases, further processing is needed to achieve commercial hydrogen concentrations. Hydrogen is purified using either a pressure swing adsorption and membrane filters. Some experimental work in supercritical water gasification has also been completed. Another technology under development is the Ways2H technology. which combines preheating and O_2-based reforming to generate hydrogen (Figure 37).[161]



[161] Helena Tavares Kennedy (2021, April 4th) A Waste-to-Hydrogen Tokyo Facility Ready to Rock – Is 2021 the Year of Hydrogen? *Biofuels Digest.* Accessed August 18th, 2021

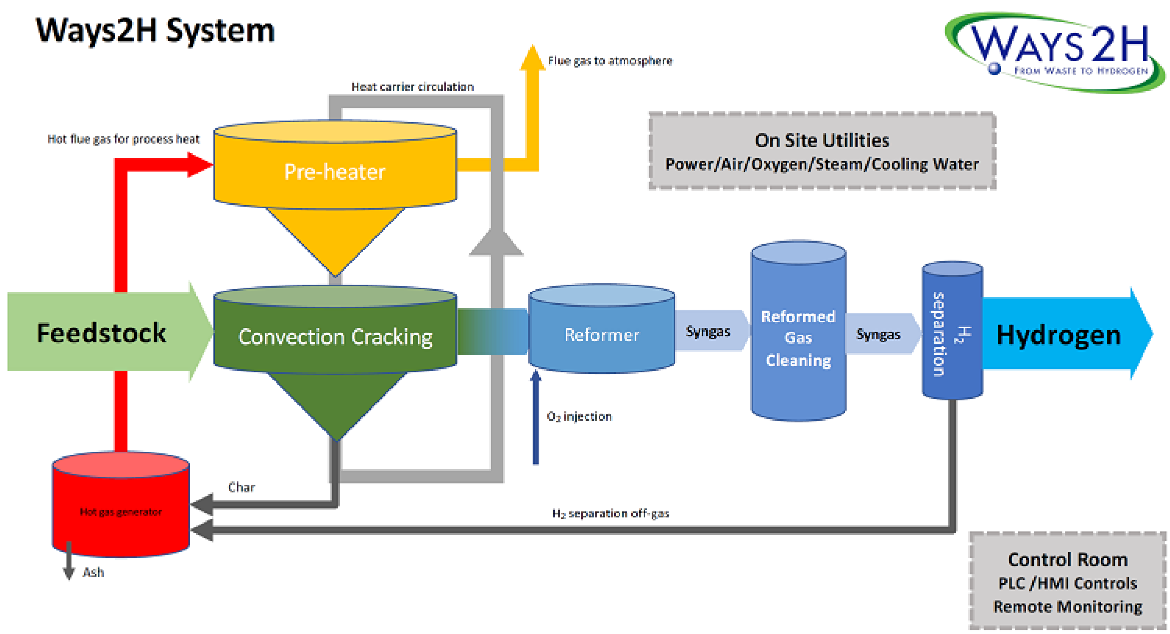


Figure 37 Process diagram of Ways2H Biomass to Hydrogen System

Table 48 lists current projects that attempt to produce hydrogen from solid biomass and MSW. Essentially, many of the technologies identified in the previous sections (gasifiers) can be used as part of such endeavours.

Table 48 Biomass to Hydrogen Systems

Vendor	Products	Deployment
Sungas Renwables	GTI fluidized bed gasification system with downstream gas cleaning and hydrogen production	Chicago Area, US
Hyper Project	Cranfield University based bulk hydrogen production project using Gas Technology Institute's sorption enhanced steam reforming process	Under development at Cranfield University, UK
Ways2H	Modular gasification technology using steam reforming of syngas	MSW-based project in Tokyo, Japan

A.5 Methanation

Pre-commercial systems: Once the syngas has been cleaned and particulates, water, sulfur and chlorine have been removed, it enters a water shift reactor. This reactor adds steam, which reacts with the carbon monoxide in the gas stream to form additional hydrogen, according to reaction (1). This hydrogen rich gas is then further processed into methane in an exothermic methanation step (2), followed by gas upgrading to pipeline standards.

(1) $CO + H_2O \leftrightarrow H_2 + CO_2$

(2) $CO + 3H \rightarrow CH_4 + H_2O$

Likewise, CO_2 can react with surplus hydrogen to form extra methane, resulting in a gas that consists of predominantly methane and some water vapour. Low temperatures (200°C) and high pressure (20-30 bar) are required to maximize methane content in the outgoing gas mixture. The Haldor Topsoe process converts H_2 and CO with a ratio of 3/1 into methane. It has a chemical efficiency of about 80 % and produces a product stream with up to 98% methane.[162] The molar ratio between hydrogen and CO needs to be close to 3 in order to maximize methane yields and minimize hydrogen in the gas. Generally, the mass yield of methane from biomass is around 0.33-0.35 kg per kg(dry),[163] which equates to 60-70% of energy. As the ratio in syngas is usually below 3, a water shift reactor needs to be added in order to adjust the ratio and maximize methane production.

The production of RNG from biomass through gasification is not commercial. Yet, numerous pilot and demonstration plants have been built – mainly in Europe. Two such project is being planned for B.C., i.e. the REN Energy project in the Kootenays and another one in Williams Lake. The best known and most successful (1200 operating hours) project has been the GoBiGas project in Sweden, which was mothballed in 2018 due to its economic underperformance, despite its relative technical success. ENGIE's Gaya project, which started in 2010 and has a demonstration unit operational since 2017, is also noteworthy. Based on the Güssing gasifier technology (FICFB), the Gaya site regroups several partners working together to make RNG production from biomass more efficient and more affordable. E.ON is also planning a commercial-size project in Sweden, using established technologies, and there are also several projects being planned in the U.S. Table 49 lists RNG projects using gasification, mainly from the past decade, as well as some planned projects. Note that although some projects are designated as TRL 8, this status could only be assumed to exist once the projects will have been commissioned successfully.

Table 49 Pre-commercial Methane Production from Biomass

Facility	TRL	Size	Technology	Deployment
GoBiGas, Gothenburg (SE)	7	20 MW (input)	Indirect gasification at atmospheric pressure (Valmet, Circulating Fluidized Bed), gas cleaning, methane production (via nickel catalyst) using Haldor Topsoe technology	One successful demonstration in Sweden, based on previous Chalmers tests
REN Energy (B.C.)	5	1 PJ/yr	Gasification at 900°C, methanation (technology unknown)	Planned for B.C.
Güssing (AT)	6	1 MW (input)	Dual fluidized bed steam gasifier (Fast Internal Circulation Fluidized Bed - FICFB), a two-stage gas cleaning system; no gas injection (internal use)	2009 Pilot was not further pursued at Güssing plant
Gaya Project (FR)	5	0.5 MW (input)	FICFB gasifier, proprietary metallic catalyst for methanation. 20 MW plant planned by ENGIE.[164]	R&D pilot (2015)
ECN (NL)	5	0.8 MW (input)	MILENA gasifier, OLGA gas cleaning and ECN's ESME methanation technology	Laboratory pilot

Facility	TRL	Size	Technology	Deployment
Swindon (UK)	5	1 MW (input)	Fluidized bed gasifier and plasma converter; uses refuse-derived fuel	Commercial facility planned (see below)
Advanced Biofuels Solutions Ltd	(8)	8000 tpy	ABSL RadGas and Wood VESTA; CO2 is separated and used. Uses both RDF and wood as feedstock; produces both hydrogen and RNG.	Planned for 2021[165]
Japan NEDO project	3	200 MW (input)	LPG production from biomass, using an entrained-flow biomass gasification and direct LPG synthesis process with hybrid catalyst.	4-year R&D project; apparently discontinued
Köping (SE)	5	0.5 MW	WoodRoll technology by Cortus Energy (gasifier), combined with catalytic methanation unit developed by Karlsruhe Institute of Technology	Pilot plant; first RNG produced in 2020[166]
E.ON Bio2G (SE)	(8)	345 MW	First commercial project; funding approved. Direct pressurized oxygen blown gasifier and the adiabatic TREMP (Haldor Topsoe) methanation	Decision to build not confirmed
Woodland (US)	4	1 MW (input)	FICFB gasifier	R&D project, lab scale
San Joaquin Renewables (US)	7	900 tpd	Oxygen-blown pressurized fluidized bed gasifier and methanation (catalytic BING process)	Successful pilot completed
Sungas Renewables (US)	6	1000 or 300 tpd	Bubbling fluidized bed gasifier by GTI	Successful pilot completed (Stockton, CA)
AMEC FW Vesta	(8)	315 MW (input)	AMEC CFB and VESTA methanation	Feasibility study only
Ambigo, Alkmaar (NL)	6	1 tph/4 MW	MILENA (indirect gasifier), OLGA gas cleaning, ESME methanation unit. Currently on hold.[167]	Planned demonstration project
Enerkem (CA)	4		Research facility since 2003; produced liquid fuels and RNG from a mix of feedstocks, including wood and straw	Pilot; no continuous operation
Great Point Energy (US)	5	1 tpd	Bluegas technology – catalytic gasification in fluidized bed gasifier (one-step methanation)	Company out of business since 2019[168]

Facility	TRL	Size	Technology	Deployment
IHI (JP)	5	6 tpd	TIGAR fluidized bed gasifier. Can use coal and biomass to produce methane. Successful pilot with biomass accomplished.[169]	Demonstration (50 tpd) planned for Indonesia
Transition Energy (CA)	7	n.a.	Based on GoBiGas technology	Proposed for Williams Lake
G4 Insights	5	6.7 MW (input)	Pyrocatalytic hydrogenation	Pilot at ATCO natural gas yard in EDmonton

Other emerging technologies: Although no wood-to-methane pathway is truly commercial, the above-mentioned demonstration projects have been successful in showing that the technology is technologically viable, albeit not commercially viable without stronger policies. Whereas gasification is still being perfected and appears to be the main pathway for short-term project development, hydrothermal gasification is one emerging technology that may offer advantages, mainly because it does not require pre-drying of biomass feedstock.

A catalytic hydrothermal gasification process was developed at the Paul Scherrer Institut (PSI) in Switzerland that allows for the production of methane from woody biomass. This process is carried out in an aqueous system at conditions near or above the critical point of water: 647 K (374°C) and 22.1 MPa. Whereas salts are highly soluble in subcritical water, they precipitate out in supercritical water. Supercritical water is more like an organic solvent. With a suitable device, the salts can be separated in a continuous way from the biomass stream prior to gasification. This has several advantages. Not only could salts poison the catalyst, but once separated in a concentrated form, they can also be used as nutrients. Products are clean water and SNG only – all possible hormones and bioactive proteins (e.g. prions) are destroyed. There is no solid residue that needs to be dried and burnt as hazardous waste.[170]

Supercritical water can also be harnessed for hydrogen production from biomass, such as bagasse.[171] The tolerance to water and salts suggests the technology could also be used with problematic feedstock, such as wastewater treatment sludge or industrial or agricultural wet residue otherwise used in anaerobic digesters, albeit it remains unclear what the required economies of scale would be. No demonstration plant has been constructed yet, which leaves this technology at a TRL around 3-4.

Syngas cleaning is another area of on-going R&D. Although commercial systems exist, they usually rely on a cool gas to be treated with filters or scrubbers (the Swedish Bio2G project also relies on high-temperature gas cleaning at around 600°C). The ability to remove contaminants from hot syngas instead of first cooling the gas has the potential to yield significant energy savings, thus reducing operating costs. RTI International has made progress in this area by developing a sorbent-based warm syngas cleanup process for H_2S and CO_2 removal that operates at 250–650°C. Others are using electric arcs to treat the syngas. Supercritical water would remove the need for additional gas cleaning.[172] Likewise, biological

conversion to methane could reduce gas cleaning needs; some emerging technologies such as Electrochaea and Viessmann are listed below (see also **Table 56**).

Strictly speaking of methanation units, several commercial technologies exist. The best known are listed in Table 50. As these commercial systems are integrated into a full methane production facility, however, much fine-tuning needs to take place and therefore, such facilities have a lower TRL as indicated above.

Table 50 Commercial Methanation Technologies

Vendor	TRL	Products	Deployment
BASF	9	BASF sells methanation catalysts which are used in coal to methane facilities in China	China (location unknown); Likely with DEMOSNG but this is not confirmed
WOOD	9	Vesta system designed to simplify processing by removing CO2 after methanation, facilitating better temperature control and eliminating the need for recycling compression. The VESTA process also avoids the need for H2/CO adjustment while reducing metal dusting and coking.	
Haldor-Topsoe	9	TREMP system is designed to recovery the energy from the exothermic methanation reactions while allowing high reaction temperatures as high as 700 C.	
Johnson Matthey	9	DAVY SNG production system provides dual methanation and CO shift.	Keshiketeng County, Inner Mongolia
Man ES	9	Man Energy Systems has power to gas based CO2+H2 methanation systems suitable for power to gas, and with modification, syngas	Audi Power to Gas system
Atmostat-Alcen	5	METAMOD System is a modular technology designed primarily to handle the high heat loads generated by methanation of carbon dioxide and hydrogen in power to gas while maintaining compactness. System uses a powdered catalyst with microchannels	No information available
Electrochaea GmbH	7/8	System that feeds hydrogen and carbon dioxide to methanogenic archaea microorganisms to create methane gas.	Foulum, Denmark; Avedore, Denmark; Solothurn, Switzerland
Ineratec	8	Modular containerized methanation systems usable for syngas and power to gas applications	Koping, Sweden
MicrobEnergy (Viessman)	7/8	System that feeds hydrogen and carbon dioxide or syngas to microorganisms to create methane gas.	

A.6 Carbon Sequestration Technologies

Table 51 presents an overview of projects related to carbon capture in the biomass energy field, including waste-to-energy plants. Generally, commercial technologies are available, such as amine-based technologies currently used for demonstration projects in the fossil fuel sector. Other (amine-free) technologies are also being explored (see Table 52). Several more projects are being proposed in the U.S. due to the 45Q federal tax credit, which rewards bioenergy projects with carbon sequestration with up to US$50 per tonne of CO_2 in extra income. Not included in this table are fossil-based CCS in Canada such as the QUEST project at the Scotford Upgrader or the Boundary Dam facility near Weyburn, Saskatchewan which produces CO_2 to be used for enhanced oil production (but see Table 58 further below). It should be noted that some of the CO_2 used by Cenovus comes from the Great Plains Synfuels coal SNG plant. Due to the purity of the waste gases, around 1/3rd of the carbon in the biomass can be captured with relative ease. Around ¼ of the carbon in the biomass is lost as flue gas (unless an oxyfuel process) and the remainder goes into the RNG.

Table 51 Carbon Capture Applied to Biomass Energy Systems

Project	Carbon Capture Technology	Deployment
DRAX (UK)	C-Capture (amine-free solvent)	1 tpd pilot plant
DRAX (UK)	Mitsubishi Heavy Industries (amine-based)	Planned for 2027
Fortum (NO)	Amine scrubbers, for storage in depleted North Sea oilfields	Planned for 2024
Stockholm Energi (SE)	Hot Potassium Carbonate (carbon scrubbing – chemical adsorption/pressure swing)	Pilot underway since 2019
Copenhagen ARC (DK)	Waste incinerator; CCS for injection in depleted oilfields	Demonstration planned for 2022
Twence (NL)	Aker capture technology (amine-based); waste-to-energy plant	Planned
Mikawa (JP)	Coal-to-biomass conversion of power plant; CCS for storage in depleted oilfields	Planned
ZEROS (US)	Texas oxyfuel combustion plant for waste; CO_2 for enhanced oil recovery	Planned
Bayou (US)	Velocys project; carbon sequestration from Fischer-Tropsch biofuel production process	Planned for 2025
Summit Carbon Solutions (US)	Proposal to connect ~30 ethanol plants in the Midwest US to a carbon capture and storage system projected to store 10 mt of CO2 per year	Announced in 2021
Ambigo (NL)	Selexol	Planned; realization uncertain

Table 52 Carbon Capture Technologies

Technology	Key points	Comments
Chemical (amine) scrubbing	• Commercial • Increases energy use • Creates toxic amine residue	Technology of choice for most commercial projects; can use lower-cost heat energy instead of electricity
Physical solvent scrubbing	• Suitable for syngas separation (oxy-fuel)	Not suitable for post-combustion due to minimum 30% CO_2 concentration requirement
Solid adsorption	• Demonstration	Can be pressure or temperature-swing adsorption
Membrane separation	• Suitable for syngas separation (oxy-fuel) • Better for small streams • High energy cost	Commercial hybrid membrane/amine technologies exist; Air Liquide uses membranes to get to 95% purity;[173] also used to remove CO_2 from natural gas. Uses electricity as the energy source (high cost)
Cryogenic	• Very high energy use	More suitable for food-grade CO_2
Enzymatic	• Canadian invention • Low energy consumption • No toxic chemicals	CO_2 Solutions captures CO_2 enzymatically as bicarbonate. The company had become insolvent and its IP was sold to an Italian company, Saipem S.P.A.[174]

In terms of CO_2 utilization, several Canadian projects are underway. The potential for these technologies depends on the size of the product market, and often whether a market exists close enough to the point of production. For example, *Air Liquide* is mainly targeting the food-grade CO_2 market worldwide. *Qantiam Technologies* are targeting methanol production from CO_2 and *CarbonCure* apply CO_2 for concrete curing. Montreal-based *Carbicrete* is curing ground steel slag with CO_2, which results in a concrete substitute. *Pondtech* is using the gas to cultivate algae and Quebec company *CO2 Solutions* uses enzymes to capture CO_2. *CleanO$_2$ Carbon Capture Technologies* converts CO_2 to sodium carbonate. *Capital Power* is using a technology to turn CO_2 into carbon nanotubes. Other potential uses would include curing concrete with CO_2, aggregate production, technical applications of CO_2 (e.g. as a working fluid), or formic acid production.

The above means that not only is it desirable to obtain a clean hydrogen or methane stream but also, a CO_2-rich gas stream can become a product to be sold. Applicable both to traditional biogas and synthetic RNG made through a gasification process, Table 53 compares various commercial gas upgrading technologies that can be used to convert a methane-rich gas stream to pipeline grade methane. More information on these technologies and additional comparisons can be found in the original source.

Table 53 Gas Upgrading Technologies[175]

Biogas Upgrading Process	Pressure (psig)	Temp (°C)	CH_4 Product Content	Methane Slip	Methane Recovery	Sulfur Pre-Treatment	Consumables
Pressure Swing Adsorption	14 – 145	5 – 30	95–98%	1–3.5%	60 – 98.5%	Required	Adsorbent
Alkaline Salt Solution Absorption	0	2 – 50	78 – 90%	0.78%	97 – 99%	Required / Preferred	Water; Alkaline
Amine Absorption	0 (< 150)	35 – 50	99%	0.04 – 0.1%	99.9%	Required / Preferred	Amine solution; Anti-fouling agent; Drying agent
Pressurized Water Scrubbing	100-300	20 – 40	93– 98%	1–3%	82.0 – 99.5	Not needed / Preferred	Water; Anti-fouling agent; Drying agent
Physical Solvent Scrubbing	58–116	10– 20	95– 98%	1.5–4%	87–99%	Not needed/ Preferred	Physical solvent
Membrane Separation	100 – 600	25–60	85– 99%	0.5 – 20%	75 – 99.5%	Preferred	Membranes
Cryogenic Distillation	260 – 435	-59 to -45	96– 98%	0.5–3%	98 – 99.9%	Preferred / Required	Glycol refrigerant
Supersonic Separation	1,088 – 1,450	45 – 68	95%	5%	95%	Not needed	

B. *Lignin Production and Use*

Lignin is a by-product of the chemical pulping process and is produced by kraft pulp mills in their process of separating the cellulose from wood. Lignin has been traditionally burned, partly as a fuel for the pulping process, partly to get rid of an unwanted by-product, and to recover the pulping chemicals. Instead of burning lignin it can also be extracted from the spent chemicals.

Because lignin has a high calorific value it can be used to replace natural gas used in a pulp mill's lime kiln. Alternatively, it can be processed and sold to offsite markets as a high-grade solid fuel. The report will describe two pathways: onsite or offsite use as a natural gas replacement. Both pathways compete with using lignin as a feedstock for various chemical processes that generally fetch higher market prices than when used or sold as a fuel.

Pathway 1 - Lignin replacing natural gas in a lime kiln: For maintenance reasons lime kilns need to be operate at temperatures at or bove 800°C and are typically heated by natural gas burners. Wood needs to be gasified to be burned in a lime kiln. Dry lignin, however, in the form of dust can be burned in injection burners with the flame injected directly into the kiln.

[175] Ong, Matthew *et al.*: Comparative Assessment of Technology Options for Biogas Clean-Up (Draft). California Biomass Collaborative, October 2014 (Table 17)

Pathway 2 - Lignin replacing natural gas in other undetermined energy producing processes: because lignin has a rather high calorific value (26 gigajoules/t HHV) it is a more valuable fuel than conventional woody biomass (17 to 19 gigajoules/t HHV). Just as for the onsite lime kiln it could be burned with little technical modifications in the secondary wood processing industry, e.g. in direct fired lumber drying kilns, veneer dryers or immersion heaters used in veneer mills.

Kraft lignin is an emerging product with potential in binders, bioplastics, carbon fibre, resins and other products. Kraft lignin has different properties than lignosulfonates produced by sulfite pulping or further sulfonation of kraft lignin. Markets for lignosulfonates include dispersants, oil well drilling fluids and as binding agents.

West Fraser currently operates a commercial facility in Hinton, Alberta. Most of the demand for lignin is for lignosulfonates, with volumes of around 88 million tonnes per year, with kraft and Organosolv Lignin being 9% and 2% of the market, respectively. The total market value of lignin products is estimated at US 730 million.[176]

Lignin of lower quality has energy potential beyond its current combustion in recovery boilers, such as for lime kilns and even export to other energy users, due its high energy value (26 MJ/Kg compared to 18 MJ/Kg for typical biomass fuels). Some research has also occurred into thermochemical treatments to develop aviation fuels from lignin feedstock.

Typically, up to 20% of the lignin can be removed without impacting the mill's operations significantly. Lignin removal can even boost production in recovery-boiler constrained plants by 25% and with operational changes, around 70% of the lignin can be removed.[177] However, some mills might require a small amount of additional fuel in the power boiler to offset the energy loss from lignin.

As kraft lignin does contain sulphur, impacts of sulphur dioxide and other-sulphur compounds need to be considered due to their acidification and odour potential. Lignin has been used as fuel in district heating plants in Sweden, suggesting it could be transported and used as a fuel to displace natural gas and other fuels. Lignin-rich pellets made from Russian woody methanol production by-products is traded as a coal substitute [178] in some European markets, including Verdo CHP plant in Randers, Denmark.[179] Table 54 identifies a few recent projects related to lignin extraction and use.

C. *Biogas and Landfill Gas*

C.1 Best Available Technologies

The production of Renewable Natural Gas (RNG) from organic material in digesters typically consists of four key process stages. These are:

1. Feedstock pre-treatment;
2. Digester tanks;
3. Biogas upgrading; and
4. Digestate management.

LFG projects consist of two key process stages. These are:

1. Landfill gas capture; and
2. Landfill gas upgrading.

Digester and landfill gas technologies are well-established, commercial technologies. The prediction of future trends can be based on existing technologies and incremental improvements. Feedstock pre-treatment technologies are fully commercial and can be deployed based on the specific feedstock qualities. They may be provided by anaerobic digester vendors as part of their product range, or may come from third-party providers within an overall engineering and design concept. Mechanical pre-treatment technologies enable biogas plants to accept food waste; food waste not only generates a large amount of biogas per tonne, but comes with a tip fee. For these reasons, mechanical feedstock pre-treatment technologies are often financially viable and could be considered BAT. Pre-treatment of feedstock that is difficult to digest is usually not economically feasible since the increased gas yields do not justify the pre-treatment expense.

Upgrading biogas/landfill gas to RNG is also commercial. This step removes carbon dioxide and other impurities (such as nitrogen, hydrogen sulphide and water) to increase methane content from approximately 55-65% to approximately 98%. Applicable technologies are listed in Table 53 above.

In cases where the nutrients in digestate are greater than the nutrient needs in the immediate vicinity of biogas plants, nutrient recovery technology is often used. Nutrient recovery technology extracts nutrients from digestate into a more concentrated form. The extracted nutrients can be transported away from the biogas plant more cheaply than digestate, while any remaining, nutrient-depleted liquid digestate can be spread locally.

There are dozens of different nutrient recovery technologies available, from simple large fibre removal (such as slope screen, screw press, rotary drum separator and roller press) to small fibre removal (such as dissolved air flotation, centrifuge, fiber filter and spiral filter) and almost complete nutrient recovery (such as mechanical vapour recompression and vacuum evaporation).

As with feedstock pre-treatment, digestate management technologies can be grouped into one of the following categories:

- Mechanical: such as screens, screw, belt presses, centrifuges and membranes;
- Chemical: such as flocculation and struvite precipitation; and
- Biological; such as ammonia stripping and use of nutrient accumulating organisms.

As with most feedstock pre-treatment technologies, nutrient recovery technologies are also considered uneconomical. The reason for this is that the end products of these technologies (a form of nutrient more concentrated than digestate) are almost always worth less than the cost to produce them. As such, nutrient recovery technologies are only used when absolutely necessary (i.e., when significant transportation cost savings are possible).

Table 55 lists several vendors of equipment relevant to RNG production that are active in Canada. These vendors will often sell equipment both for conventional biogas production and for gas upgrading to pipeline standards.

Table 55 Commercial Anaerobic Digester/RNG Systems*

Vendor	Products	Deployment
Air Liquide	Biogas/landfill gas upgraders	Widely deployed

C.2 Pre-Commercial Technology

While there are ultrasound, electrochemical, chemical, biological and combined process feedstock pre-treatment technologies being developed, these technologies are either TRL 6 or below, or are deemed to be uneconomical for the reasons provided above. Digester tanks and landfill gas capture systems are mature technology, and as such, subject to incremental improvements, and little sign of any significant pre-commercial technology developments.

Biogas/landfill gas upgraders are also mature technology, and while small advances are being made, these improvements are as a result of minor modifications to existing upgraders to improve energy consumption, reduce methane slip, etc., rather than development of new upgrading technology. The same is also true for digestate management technologies; improvements are as a result of minor modifications to existing technologies, rather than development of new technology.

One TRL 7/8 technology is ex-situ power to RNG technology. This two-step process starts with the production of hydrogen through water electrolysis using electricity. The hydrogen is then combined with carbon dioxide (from the exhaust stack of a biogas/landfill gas upgrader) and fed into a reactor with specialty micro-organisms that convert the hydrogen and carbon dioxide into RNG. This technology is different to in-situ power to gas (which is TRL 5) because it requires a separate reactor with specialty micro-organisms; in-situ power to gas feeds hydrogen and carbon dioxide into the same digester tank used for digesting organic feedstock, and where a wide range of micro-organisms exist.

The economic feasibility of ex-situ power to RNG technology depend heavily upon stranded electricity that has zero, or very low cost. This is electricity that has no use at time of production and cannot be easily stored, such as wind power in evenings or on particularly windy days. Once electricity has to be purchased for production of hydrogen through electrolysis, the economic feasibility of this technology quickly diminishes.[180] Therefore, until significant technology cost savings can be made, operational ex-situ power to RNG plants are financially viable only when inexpensive electricity is available.

As of 2019, there were an estimated 38 pilot and demonstration ex-situ power to RNG projects across 22 countries.[181] Of these, approximately half were able to inject RNG into the grid. Of these, a handful were of significant size (i.e., electrical load of electrolyser ≥ 1 MW electric) to be considered more than prototype demonstration. Most of these were conducted by research organizations or energy consortia. Of the most advanced and well-regarded technology supply companies, the following three stand out:

Table 56 Pre-commercial power-to-RNG technologies

Company Name	TRL	Products
Viessmann	7/8	Renewable natural gas
Uniper Energy Storage	7/8	Renewable natural gas
PFI Biotechnology	7/8	Renewable natural gas
Electrochea	7/8	Renewable natural gas

D. *Low-Carbon Hydrogen Production*

D.1 Green Hydrogen

The electrolysis of water is the primary manufacturing process used in the production of Green Hydrogen. The two most commonly used technologies are the alkali membrane and PEM technologies. Table 57

[180] For this reason, it is unlikely this technology will play a major role in BC. BC has hydro-electricity, which can be turned on/off to meet fluctuating demand, resulting in very little stranded electricity.
[181] Thema, M., Bauer, F., and Sterner, M. (2019). *Renewable and Sustainable Energy Reviews* 112, 775–787.

identifies commercial and pre-commercial technologies to produce green hydrogen, including several early-stage technologies.

Table 57 Green Hydrogen Production Technologies

Vendor	Products	TRL	Deployment
NEL Hydrogen	NEL Hydrogen, based in Norway, offers electrolysers that use two different types of membrane technologies. Alkali and Proton® PEM technologies[182].	9	NEL Hydrogen serves many different markets. By way of example but not limited to the production of ammonia fertiliser to hydrogen a coolant in power station electricity generation. NEL Hydrogen manufactures hydrogen refuelling stations that are deployed in numerous European countries, California, and other parts of the world.
ITM-Power	ITM is based in Sheffield in the UK. The organisation produces PEM technology electrolysers.	9	The company has partnered with Linde AG to serve large electrolyser market opportunities. ITM is constructing the largest PEM manufacturing plant in Sheffield, UK. It is planned to have a production capacity of 1GW per annum. The largest European electrolyser plant, 10MW was supplied recently by ITM to Shell GmbH in Germany. Delivering hydrogen to the Shell refinery. The REFYNE project.
CUMMINS	The organisation's electrolyser and fuel cell technologies base is in Mississauga Ontario. Cummins acquired Hydrogenics and manufactures, besides fuel cell systems both alkali and PEM electrolyser technologies.[183]	9	CUMMINS has supplied both alkali and PEM multi megawatt systems for numerous applications, and in the recent past for power to gas energy storage projects in Europe. The largest power to gas demonstration project in North America was conducted together with Enbridge in Markham, Ontario.[184] CUMMINS manufactured the largest PEM electrolyser plant assembly, 20MW, that was installed by Air Liquide in Bécancour, Quebec.
Siemens Energy	Siemens centre of excellence for PM electrolyser development is based in Munich, Germany.	9	Siemens Energy and Messer Group have entered into a cooperation agreement with the goal to work on green hydrogen projects in the 5-to-50-Megawatt (MW) range. The largest power to gas project in Mainz was supported by a Siemens PEM electrolyser.

Vendor	Products	TRL	Deployment
			Messer Ibérica has already submitted three clean hydrogen projects in the chemical complex of Tarragona to the Spanish government. These projects will have a total electrolyser capacity of 70 MW.
McPhy	This company is a manufacturer of alkali technology electrolysers and is based in La Motte-Fanjas, France. The organisation also supplies hydrogen refuelling equipment.	9	Numerous milestones of the deployment and growth of the company span the last decade and more.[185]
NeXT Hydrogen	This company is a manufacturer of alkali technology electrolysers and is based in Mississauga, Ontario	9	NeXT Hydrogen manufactures state of the art alkali technology electrolysers and has deployed units at Canadian Tire in Canada to produce hydrogen and power fuel cell powerplant forklifts.
Pre-Commercial Technologies			
Enapter	Enapter, headquartered in Italy uses an alkali electrode membrane (AEM) technology	≤ 6	AEM technology is used mainly for small electrolysers. 2 to 3kW
Ionomr	This company also used AEM technology and is based in Vancouver	≤ 6	AEM technology is used mainly for small electrolysers. 2 to 3kW.
Haldor Topsoe	Solid Oxide Electrolyser Cell (SOEC)	≤ 6	This technology is interesting in that it offers up to 30% greater efficiency than do the incumbent electrolyser technologies in use. The disadvantages include that the products operate at 700°C and most effectively in a steady state mode.
Early-Stage Technologies			
	Electrolysis from renewables.	9	Done.
	Thermo chemical water splitting solar	≤ 4	Thermochemical water splitting uses high temperatures that are concentrated from solar power to split water.
	Thermo chemical water splitting nuclear	≤ 4	Thermochemical water splitting uses high temperatures that are concentrated from the waste heat of nuclear power reactions.
	Photoelectrical water splitting	≤ 4	PEC water splitting process converts water to hydrogen and oxygen using specially designed semiconductor materials. The materials used in the PEC process are similar

Vendor	Products	TRL	Deployment
			semiconductor materials to those used in PV electricity generation.[186]
	Photobiological water splitting	≤ 4	Photobiological hydrogen production uses microorganisms and sunlight in a process to turn water into hydrogen.[187]

D.2 Blue Hydrogen

Blue hydrogen is produced from grey hydrogen that is manufactured using a process called steam methane reforming (SMR). It is essentially hydrogen that is created from any fossil fuel while capturing carbon dioxide. The main by-product of steam methane reforming is carbon dioxide and when this gas is separated from the SMR production stream, its capture, utilization and/or storage (CCUS) turns it into blue hydrogen. There are numerous pathways that have been and will be evaluated for the sequestration and utilization of the emitted bi-product carbon dioxide. Blue hydrogen is better described as a low carbon intensity hydrogen as the SMR process does not fully prevent the emission of greenhouse gases. Table 58 identifies commercial and pre-commercial blue hydrogen production technologies, as well as related carbon capture technologies.

Table 58 Blue Hydrogen Production and Carbon Capture Technologies

Vendor	Products and CCUS	TRL	Deployment
Numerous producers of grey hydrogen including the industrial gas companies by way of example but not limited to - Air products, Air Liquide, Praxair, Linde, and manufacturers of ammonia fertilisers.	Large SMR plants	9	The large SMR plants are found worldwide and produce about 60 million tonnes of hydrogen per annum. A smaller amount of hydrogen is produced from coal gasification. The primary use is the production of ammonia fertiliser and in oil refineries to upgrade the refining process.
There are several small modular SMR manufacturers. Including in the past some of the industrial gas companies, BayoTech (USA), ONEH2 (USA) and HyGear (Netherlands).	Small SMR products	9	These companies all offer small SMR units that are modular and offer remote and localization use siting opportunities.
Large Scale Carbon Capture Plants in Canada			
Canadian Natural Resources (CNR)	Horizon project, Alberta	9	CO2 captured and combined with the tailings feed into the settlement ponds to

D.3 Turquoise Hydrogen

Beyond green, blue and grey hydrogen we also now have a new member of the hydrogen rainbow family - turquoise hydrogen. This is a by-product of the pyrolysis of methane in natural gas. Pyrolysis splits this gas into hydrogen and solid carbon. Turquoise hydrogen is becoming more popular, and it is anticipated that this production technology can also offer competitive hydrogen at a low carbon intensity. This, however, still is dependent upon the high cost of the thermal process that is required for methane pyrolysis. The major benefit that this technology pathway may offer is the sale and supply of carbon black used in applications such as rubber pigments. The carbon black industry is very large and complex. About 80 million tonnes are currently produced globally, most of which is used in rubber applications. The organisations developing this technology pathway to manufacture very low carbon intensity hydrogen include both small start-up companies and large organisations, such as BASF. Figure 38 provides further information on turquoise hydrogen development.

Table 59 Turquoise Hydrogen Production Technologies

Vendor	Technology	TRL	Deployment
Monolith Materials. Based in Lincoln NE. Mitsubishi is one of Monolith's investors	Plasma Pyrolysis	9	Emphasis on the supply of hydrogen to various applications including clear ammonia production. Target markets for the solid carbon by-products includes tire, rubber and speciality blacks.[188] First commercial production unit started up in 2020.
Hazer Group. Based in Australia	Fluidised bed Pyrolysis	4-6	Start-up
BASF, Germany	Moving bed pyrolysis	7	A large German chemical company that has tested a lab scale production unit.

D.4 Waste Hydrogen

Waste hydrogen is defined as "hydrogen gas produced by a commercial process the primary purpose of which is not the production of hydrogen gas."[190] It is produced at two sites in B.C., both owned by Chemtrade. The first of which is in North Vancouver at their chlor-alkali plant that produces chlorine for numerous markets such as the production of sodium hypochlorite. The waste hydrogen produced amounts to approximately 10 tonnes per day. Organisations have in the past attempted to buy this hydrogen to liquify and deliver the gas for local consumption. In October 2005 it was announced that Sacre Davy Engineering[191] together with partners were awarded $12.2 million to construct a cryogenic hydrogen plant using the waste hydrogen. Insufficient demand was identified and the project was dropped.

Chemtrade also produces waste hydrogen at its Prince George sodium chlorate plant. Some of this hydrogen will be used by Hydra Energy that has developed a hydrogen diesel dual fuel Call 8 truck power plant. Hydra Energy has partnered with Chemtrade to capture, clean and deliver the hydrogen for mobility applications, including their retrofitted Class 8 trucks. It is estimated that the Prince George sodium chlorate plat emits about 10 tonnes of hydrogen per day.

Appendix B – RNG Cost References

Table 60 compares some recent cost estimates for RNG production from biomass. The numbers are only partially comparable as they are based on different parameters, i.e., feedstock energy input, feedstock amount, or output. Efficiencies are from output energy in relation to woody biomass input, omitting process energy inputs. Capital costs and gas costs have been normalized for better comparison in Figure 18.

Appendix C – Forest Biomass Resource Assessment

A. *Types of Forest Biomass*

B.C.'s forests provide woody feedstock for a variety of activities of the forest products industry, including sawlogs, pulp logs, and feedstock for wood pellet production. Table 61 describes log and residue streams and the terminology used. It is impossible to determine the amounts available of each residue stream exactly as they are often used jointly under existing fibre purchasing agreements.

Table 61 Types of Woody Feedstock

Fibre type	Description
Sawlogs	High-value trees that are used to manufacture dimensional wood products. The high value of these logs warrants the cost of building logging roads, felling and replanting. This resource is not used to produce energy but the residue from processing these logs is.
Pulp logs	Lower-value trees that can be harvested together with sawlogs. This is routinely done by forest product companies and the pulp logs are sold to pulp and paper mills at far lower pricing than sawlogs. Whenever pulp logs are not used by pulp and paper mills, they can be used to produce energy but are more expensive than other sources of fibre.
Chips	Wood chips can be made of pulp quality or for combustion in chip boilers. The latter remains exceptional in Canada, whereas large amounts of pulp chips are produced either by the pulp mills themselves or by saw or chip mills selling to pulp mills.
Roadside residue (or slash)	Also called harvesting residue, this fibre consists mainly of the limbs and tops of trees that are removed to obtain sawlog and pulp logs. Broken, small-diameter or deciduous trees are frequently part of 'slash piles.' This residue can be left in the forest but is often collected and piled up on the roadside. It is routinely burned, though sometimes recovered as a fuel for mills or as a feedstock for pellet production.
Mill residue	*Hog fuel* is the residue – mainly bark – left over from de-barking stems at pulp and paper mills. The term is also used to refer to any type of wood by-product or waste that can be burned for fuel but can't be categorized as chips, shavings, bark, or sawdust. It is high in ash and irregular in size. It is the lowest-value fuel and is often burned in recovery boilers at the mill where it is produced. Excess hog fuel is sold to other forest products companies at low pricing (sometimes for free). In coastal regions, bark may have been in contact with saltwater, which may require adapting processes or a pre-wash of such feedstock.
	Shavings from planer mills are a clean fuel that can be used for pellet or pulp production.
	White *sawdust* from sawmills is a sought-after residue for pellet production. It is more costly than hog fuel because of its higher quality (lower ash content, lower moisture).
	Mill residue data is not statistically collected in B.C. but can be estimated. It is only referred to as a combination of the above three streams in this report.
CLD	Construction, land clearing and demolition wood waste is a mixture of wood streams from construction activities. Removed trees to prepare the site, woody bits left over from construction, or wood separated out during deconstruction is included. Only clean wood can be used, which requires an efficient process to remove anything that is contaminated, covered with plastics or painted/treated wood. This separation process increases the cost of this fuel and it is often used in urban applications such as district heating, or by the cement industry if too contaminated.

B. *Previous Estimates*

The 2019 estimates in Table 62 are taken from the report *Revitalization of the B.C. Bioenergy Sector*, produced for BCBN in 2019. They are based on a commercial fibre supply model (the B.C. Fibre Model) taking the Annual Allowable Cut (AAC), mill activity, imports and exports of fibre between regions, to estimate surplus residue at mills and in the forest. The numbers represent the amounts available for new activity without negatively impacting existing uses of these resources by the forest products industry. The main conclusions from this work are:

- Little surplus mill residue is available in B.C. Some regions have a fibre deficit and are importing residue from neighbouring regions. Only small pockets with residue are still available in the western parts of the Skeena and Kootenay/Boundary Natural Resource Regions. These pockets may be exhausted by a single new project, such as a new pellet mill.
- Also, few pulp logs remain unharvested in most areas. By 2028, only small amounts will remain in few areas, which may be insufficient to sustain a new bioenergy facility on their own.
- The main resource available is forest roadside residue. Large amounts exist in some areas, especially when combined with other residue. Yet this resource is currently not fully recovered in B.C. There are issues with (physical and legal) access to and transport of this fibre so the cost will be higher than for mill residue. Fibre recovery zones have been set up to help use residuals for pulp wood and bioenergy. The amount indicated is based on costs up to $90 per dry tonne and omits regions that would require barging or other highly expensive transportation approaches.
- Stands of non-merchantable timber could be harvested for energy production. Most non-merchantable fibre consists of smaller trees with insufficient diameters to be used in mills. This may be recovered as roadside residue. As the AAC is usually defined for softwood, some regions – mainly in northern B.C. – have deciduous stands not covered in the AAC (in the South Peace, deciduous wood is already part of the AAC). These stands are not part of this inventory but may be obtained if close enough to relevant infrastructure. This would require a specific harvesting license from the Ministry.

The B.C. Fibre Model results are projected out to 2028. These results are further developed below, taking into account expected changes in the AAC and the impacts of recent mill closures. Whereas the B.C. Fibre Model uses specially-defined regions, the analysis in this report relies on the B.C. Resource Regions as commonly used in most government documentation and statistics (**Figure 39**).

TOTAL	3,792,151	1,394,417	1,519,373	246,751	1,223,419	831,315	349,080	346,199

Note: Negative numbers indicate a deficit of fibre. Wood has to be imported from other regions.

In total, the model projects that an equivalent of 126 petajoules of unallocated woody biomass is available in B.C. today (Table 63). The model predicts that this amount is reduced to 52 petajoules in 2029. These numbers refer to feedstock input and not to the amount of low-carbon fuel produced, which will vary by technology. Amounts available are strongly reduced for a mix of reasons, such as reduced AACs, expiring uplifts (temporary increases of the AAC to address the beetle epidemic), mill closures and the resulting redistribution of wood residue within the forest products industry.

Table 63 Total Woody Biomass Available in B.C. in 2019 and 2028

C. *Annual Allowable Cut through 2050*

Generally, the AAC is set for 10 years for each Timber Supply Area and Tree Farm Licence.[196] In most Resource Regions, Timber Supply Areas (TSAs) provide about ten times more volume than Tree Farm Licenses (TFLs). The exception is Vancouver Island, where TFLs provide most of the allowable cut. On average, the actual timber harvest has been almost 20% lower than the allowable cut, particularly on the coast.[197,198] Harvesting levels have been affected in the interior by the pine beetle infestation and wildfires. Whereas wildfires initially affected the dead pine beetle forests, the 2018 wildfires affected harvestable areas, especially the Cassiar (5.6% losses of harvestable areas), Lakes (5%), and Morice (2.9%) TSAs. This did not, however, lead the Ministry of Forests to revise the AAC.[199] Whether this will be necessary after the 2021 wildfire season remains to be seen. Recent wildfires have mainly affected the Cariboo and Thompson-Okanagan regions.[200]

Current government projections do not foresee any increase in the AAC before the year 2070 (Figure 40). The AAC is expected to fall to below 55 million cubic metres per year throughout this report's forecast horizon (2050).[201] This is equal to 88% of the 2021 AAC and 100% of the 2019 actual harvest (see below). Table 64 and Figure 41 show current AACs as of August 2021 and make projections to reflect the future harvesting level of around 40 million m^3 per year for the interior. These AACs consider the areas most affected by the pine beetle and by wildfires.

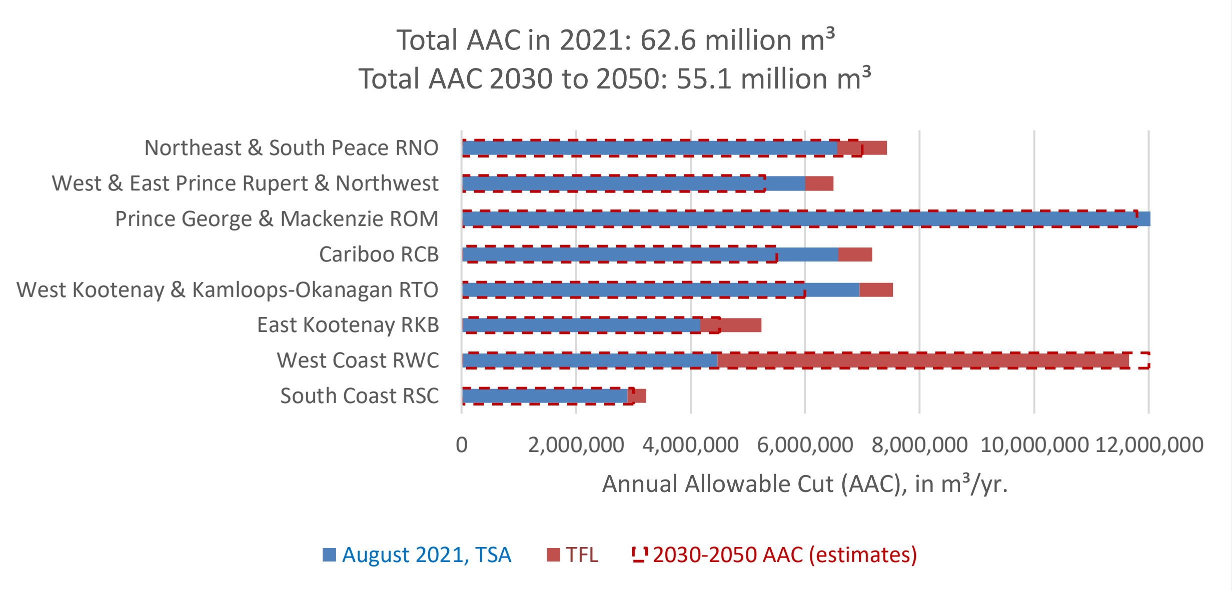

Figure 41 Annual Allowable Cut, Based on Table 64

As Table 65 indicates, the six largest forest products companies control almost half the allowable cut in B.C. This is important when trying to access harvesting residue, since users must negotiate with these companies to gain access to roadside residue.

[202] Ministry of Forests, Lands, and Natural Resource Operations - Apportionment System, August 12, 2021 – see https://www2.gov.bc.ca/gov/content/industry/forestry/forest-tenures/forest-tenure-administration/apportionment-commitment-reports-aac

D. *Mill Closures and Production Levels*

Statistics Canada noted a downward trend in lumber production from B.C. mills, see Figure 42. Although 2021 saw a strong increase in lumber pricing due to record housing starts, prices have recently dropped to low levels,[204] whereas delivered log pricing in B.C. remains high. The small margin between log prices and lumber caused Conifex Timber to curtail the MacKenzie mill in August 2021.[205] Several other producers curtailed production due to the numerous wildfires in the summer of 2021.[206] The strong increase in housing prices observed in 2021 may also reduce short-term demand for new homes. There is no reason to believe that B.C. mill output will reach previous levels in the coming years. Public discussion blames the decline on a set of issues affecting the cost of milling in B.C., including high stumpage fees, the pine beetle infestation, wildfires, and increased conservation efforts. Fibre costs in the B.C. interior increased by 33% between 2016 and 2019, with 25% of the delivered cost being due to stumpage fees.[207] The increasing fibre cost seems to indicate a transition towards lower harvesting rates.[208]

Since the 2019 report on the *Revitalization of the B.C. Bioenergy Industry*, several mills, including one pulp mill, have been closed or indefinitely curtailed (Table 66). According to independent forestry consultants, an additional four sawmill closures appear imminent on the coast and another five in the interior.[209] Proposed policies to curtail logging in old-growth forests and to protect caribou may result in a one-million-cubic-metre decrease in the coastal AAC and a three-million-cubic-metre decrease for the interior. These developments will affect the viability of pulp and pellet mills, as well as of biomass power plants.

Responsible for more than 68% of all wood consumed in B.C., sawmills remain the backbone of the forest products industry on which other mills depend. A reduction in sawmill output has impacts on downstream mills. Of the roundwood delivered to sawmills, only 45.8% become timber products in 2019,[217] 35.2% of sawmill feedstock was converted to residual chips for pulp mills and 17% was converted to sawdust and shavings used in pellet and panel mills. B.C. pulp mills processed over 22 million cubic metres of fibre, down 15% in 2019 from 2018. Of this total, pulp mills consumed about 15 million cubic metres of residual chips produced by sawmills and veneer mills, accounting for 67% of their fibre input. In addition to residual chips from sawmills, pulp mills used about 5.8 million cubic metres of whole-log chips, representing over 26% of their total fibre input. Pellet and panel mills also rely on sawmill residuals. In 2019, pellet and panel mills together processed 4.8 million cubic metres of fibre, mainly sawdust and shavings, down 5% from 2018.

Figure 43 shows the fibre flows between different players in the forestry industry of B.C. Industries depend on these fibre flows, mainly the pulp mills using chips from the sawmills and pellet mills using mainly sawdust and shavings. On the other hand, only 0.8 million cubic metres of harvesting residue is currently being used, against a remaining potential of 1.2 million tonnes (Table 62), or about 2.9 million cubic metres. The 12 B.C. veneer mills used 4.6 million cubic metres of logs. Other mills, such as shake and shingle mills, only used small amounts of fibre compared to other mill types (less than 2% of total log consumption).

Figure 44 and Figure 45 illustrate that pulp and paper mills and natural gas infrastructure are mostly near the interior working forest. Potential fibre supplies are remote for much of the coastal forest although much of the timber harvesting land base is on Vancouver Island or the south coast, close to potential users. Coastal wood is often hauled by water. Alternative logistics approaches might be needed to acquire additional feedstock suitable for gasification.

E. *Harvesting (Roadside) Residue*

Processing residues may also be augmented by roadside residue, which mainly refers to tops and branches generated during harvesting. This material may remain on the forest floor or be collected at the roadside, and a portion of the latter may be transported directly to mills to make wood products. Estimates of total roadside residue consumption were about 900,000 cubic metres in 2018[218] and 770,000 cubic metres in 2019. Whatever the total amount of residue is being consumed, the ratio of consumption by different sectors is constant, with pellet mills consuming about 64%, followed by chip mills (21%), and pulp mills (15%).

Harvesting residue has been estimated by FPInnovations (FPI) for 18 out of the 37 TSAs.[219] They determined that 2.89 million dry tonnes were available across these TSAs, representing a ratio of between 20.5% and 21.3% of the total sawlog harvest. Approximately 260,000 tonnes of estimated available residues are situated in the four coastal TSAs, and the remainder (2.63 million tonnes) are in the 14 TSAs in the interior. In the interior, FPI estimates that about 35% of this resource is economically recoverable at a cost of up to $60 per dry tonne at the plant gate. At coastal locations, only 16% are deemed recoverable at that cost. This adds up to one million tonnes of low-cost recoverable roadside residue. An additional 1.8 million tonnes may be recoverable at a cost above $60 per dry tonne. This is similar to the estimate of 1.2 million tonnes in Table 62. Note that the FPI estimates only extended to about half the total number of TSAs. Twenty percent of the total sawlog harvest across B.C. is likely to be available residues. A smaller subset is recoverable at costs acceptable to the industry. This suggests that in 2020, the total amount of available residues was as high as 3.12 million dry tonnes, based on a harvest level of approximately 37.7 million m^3.

Brian Titus of NRCan provided yet another estimate, quantifying roadside residue at a distance of 50 and 75 km from existing gas compressor stations along the pipeline network.[220] He arrived at 3.2 million dry tonnes for 50 km and 4 million tonnes for 75 km. This assessment overlaps with the FPI estimate of total available residues. It does not appear to consider existing uses of this material, or other costs such as road construction that might reduce this estimate. Uncertainties therefore remain, and improved recovery techniques and supply chains will make this resource more accessible and more affordable over time.

F. *Mill Residue Production and Consumption*

Table 67 summarizes the amounts of residue produced and consumed in B.C. for the year 2019. The great majority of mill residue is consumed within the forest products industry. Shake and shingle and other mills only consumed less than 2% of the fibre harvested (55 million cubic metres) and are left out of the table. Lumber mills accounted for almost 70% (68.2%) of harvested volumes in 2019, followed by veneer and OSB mills (11.1%) and chip and pulp mills (10.4%), which use whole tree chips for a portion of their input. Log exports were the fourth largest market for B.C. roundwood, at 8.4%.

Sawmills and veneer mills produced a total of 6.4 million m^3 of shavings and sawdust, as well as 15.7 million m^3 of chips. This meets most of the chip demand from the pulp and paper sector (22.1 million m^3),

with the remainder provided by whole log chips and some chip imports from the U.S., mainly coastal mills. Chip and pellet mills also consume increasing amounts of roadside residue as less mill residue is available because of sawmills closing their doors. Sawdust and shavings are mainly consumed by pellet mills. The numbers in the table suggest a sawdust/shavings surplus of about one million m^3. This may be because the amount was overestimated (the Mill List Survey does not collect data on the actual production of sawdust and shavings from lumber mills) or because these resources were used internally by industry, such as for on-site drying (activities like this are not captured in the mill survey). It is somewhat in line with the previous estimate that about 300,000 dry tonnes of mill residue remain unused in B.C. (Table 62).

Table 67 Mill Residue Production and Consumption in B.C. (2019)[217]

Mill type (number)	Residue type	Amount of residue, per year
Lumber Mills (69)	Sawdust & shavings	6.42 million m^3
Lumber Mills (69)	Pulp chips	13.29 million m^3
Veneer Mills (12)	Pulp chips	2.47 million m^3
Pulp Mills (15)	Hog fuel	4.7 million m^3
Pulp Mills (15)	Residual chips	15 million m^3 + 5.8 million m^3 of whole log chips
Pulp mills (15)	Sawdust	199,000 m^3
Pulp Mills (15)	Roadside residue	116,000 m^3
Chip Mills (24)	Roadside residue	162,000 m^3
Pulp & paper Mills (20)	Chip imports	1 million m^3
Pellet Mills (13)	Sawdust & shavings	4.4 million m^3
Pellet Mills (13)	Roadside residue	493,000 m^3
Panel Mills (27)	Sawdust	427,000 m^3

Black: production; red: consumption

Table 68 lists existing and planned wood pellet mills in B.C. These mills predominantly use mill waste (about 70% of their input). Only about one-quarter comes from whole logs.[217] New mills, such as the one planned for Fort Nelson, would change this picture and would use mainly roundwood, co-harvesting both sawlogs to be sold to mills and non-merchantable trees to be chipped and dried for wood pellet production.[221] This again confirms that little easily available fibre is available in B.C. for new ventures. The Fort Nelson project accesses an abandoned TSA that was previously controlled by one of the large sawmill companies. Where mills close and additional value can be obtained from co-harvesting both sawlogs and pulp or energy logs, the forest products industry may be revived through new energy-related projects. The role of bioenergy as an outlet for low-grade logs and residuals is particularly important in regions where there is no existing pulp production such as the northwest (e.g., Coast Mountain Natural Resource District and Kispiox/Nass areas).

Expiring contracts of pulp and paper mills with BC Hydro to export excess power to the grid have been identified as another potential source of fibre (hog fuel). As new contracts have been concluded since 2019 and until the end of 2021 at lower pricing and lower power output levels than before (around 80% of previous levels), the biomass previously used to generate the excess electricity can now be used for other purposes, potentially also to produce renewable gases. The amount of this biomass is substantial and has been estimated as high as 2.2 million dry tonnes (bark),[226] with potentially another 700,000 tonnes from dedicated power plants if the latter can no longer operate cost-effectively.[234] This estimate compares to an estimated 0.8-1.0 million dry tonnes from a report by Tom Browne, possibly increasing to 1.7 million tonnes by 2029 as more mills cease to export excess power (power-only generators are not considered in this estimate).[227] Table 69 summarizes the information available on these contracts and estimates the feedstock potentially becoming available for other uses.

Total potential if previous contracts expire and are not renewed				**3.2 million**

* These power plants come into full operation in 2018 and may have longer-term contracts with BC Hydro that only expire after 2030.

Almost 400,000 tonnes should be available today from modified BC Hydro contracts but over three million tonnes could become available in 2029 if the industry stopped exporting power, and if biomass power plants ceased to produce electricity. This does not take into account, however, that several sawmills have closed in recent years due to changing market conditions and changing fibre supply in various TSAs. The fibre balance in many regions has been affected. Pulp and paper mills, where cogeneration facilities are situated, may rely on at least some of this resource for their own needs, either as fuel or to produce additional wood chips. This may then affect their intake of roadside residue or hog fuel from other sources.

The 2019 Mill List[217] identifies 121 large and mid-sized lumber mills in B.C. As shown in Table 66, 14 sawmills already closed or have indefinitely suspended activities. If another nine mills are closing soon, this would mean that about 19% of B.C. mills active in 2019 will fall out of service. This, in turn, can be estimated to reduce residue production by 4.5 million cubic metres or about 1.8 million dry tonnes – about the amount potentially freed from reduced use for power production at mills. This would mean that, currently, a fibre shortage exists in B.C. and only a portion of the 3.2 million tonnes estimated in the table above may actually be available in 2029. Conversely, it is also possible that a large portion of lost production will be taken up by the remaining mills if the latter are currently running only one or two shifts per day and can now add additional shifts to increase their output. The impact of renegotiated BC Hydro contracts is therefore impossible to quantify, due to uncertainty around future negotiation outcomes, BC

[228] IPP Supply List – In Operation. BC Hydro, May 2021.

Hydro power requirements, and the internal demand of the forest products industry rebalancing in unpredictable ways.

G. *Other Sources of Wood*

Table 70 adds several more sources of wood that may contribute feedstock to a new biomass energy project. These sources are sometimes significant in size but they can also be variable or spread over a large area of B.C., so any given project may access smaller amounts of the totals estimated here. Wood from thinning around communities to reduce the fire hazard may occur regularly (i.e., thinning may have to be repeated every ten years) but is expensive to obtain. Subsidies are provided through the Forest Enhancement Society of B.C., yet the amounts recovered remain very small. Generally, a large portion of feedstock must be guaranteed for a long timeframe for a project to be bankable. This excludes many smaller or irregular resources from being counted on to start up a new project. Once in existence, however, a new facility can access a variety of these resources for part of its feedstock. The amounts of roadside residue available were estimated based on a yield of 21% of merchantable amounts.[229] Various innovations such as co-harvesting pulpwood and energy wood and yarding down to a 2" (5 cm) top is being considered in the Kootenays to use residuals that would otherwise be left on site, significantly boosting wood availability by over 20%. This approach is being employed by Celgar in the Kootenays which added specialized flail debarking technology to separate the white wood residuals from the bark. They plant to use the bark in a gasifier that will generate 1.2 million gigajoules of syngas.[230] However, road grades above 15% and cut slopes above five metres make secondary harvesting difficult with the current onsite chipping and grinding equipment. Biomass recovery on steep slopes appears to be limited without significant operational changes, such as those proposed by Celgar.

Table 70 Other Sources of Wood

Source	AAC	Roadside Residue, odt	Comments
Thinning for fire suppression (community interface, through FESBC).[231]	<40,000 m^3	16,000	124 wildfire risk reduction projects, 2016-2020; average contribution of $14 per m^3 roadside fibre recovered[232] <3% of a total of 1.25 million m^3.[233]
Heritage piles.	Unknown		Partially unusable if in state of decay.
Line and road maintenance.	Unknown		Likely thousands of tonnes, very dispersed.
Construction, demolition and land clearing.	270,000 odt[234]	270,000	Mainly in larger cities and often already being used by e.g., the cement industry or for district heating.
Sub-total		**>300,000**	Some currently used by others.
Newly available AAC due to mill closures.	10.5 million m^3	4.3 million	Roundwood; estimate based on anticipated mill closures.
		0.9 million	Roadside residue; estimate based on anticipated mill closures.
TOTAL		**>5.5 million**

H. *Concluding Remarks and Caveats*

A high-level estimate with respect to unused AAC can be made based on the assumption that 19% of mills are closing between 2019 and 2023 and that they have control over a commensurate amount of harvestable trees. If industry harvests about 55 million cubic metres, as indicated above for the year 2019, then there should be around four million tonnes of roundwood available from these TSAs that are no longer harvested. To that, about 21% of roadside residue could be added.

This compares to almost four million cubic metres of AAC not harvested in 2019 as previously determined (see Table 62). CFS expected most of this amount to be either used by 2028 due to increase mill output, or the AAC to be reduced. These developments may therefore affect the estimate made above, even if there were additional unharvested amounts as of 2019. The estimate appears to reflect the fact that about 10-20% of AAC is routinely not harvested in many TSAs so, in theory, more wood could be extracted from TSAs that are currently managed by sawmills. Harvesting whole trees is, however, the most expensive source of wood fibre available. It is not likely that the entire harvest would be used for gas production. Rather, valuable trees would be sold as sawlogs (with pulpwood) and only non-merchantable trees would be used, reducing the overall potential for gas production.

The results for roadside residue need to be taken with some caution. The factor determined by FPInnovations (21% of roundwood harvest) serves to identify recoverable amounts. Yet, it does not take into account regional differences (e.g., steep slopes may make recovery more difficult or uneconomic), harvesting practices (tree length vs. shortwood methods (skidding may result in much less residue being recovered than forwarding), existing uses, or actual harvesting levels. Available amounts will therefore be lower than estimated here and a local feedstock assessment is necessary to determine the amount available. The theoretically estimated amounts have therefore been reduced to 50% in 2030 and 85% by 2050 to define the Minimum and Maximum scenarios in Section 5.3. Also, harvesting residue should not be relied upon as the only resource for gas production since accessing it will often only be possible during a small window of time after the trees are harvested. This indicates that feedstock diversification should be the goal.

The results of the numbers developed above are combined graphically and in tabular format in Section 3.1.1 above. This technical potential is further developed into Minimum and Maximum scenarios in Chapter 5.0.

Appendix D-3

CAPACITY IMPACTS OF INTRODUCTING HYDROGEN OR HYDROGEN AND NATURAL GAS (OR RNG) BLENDS

APPENDIX D-3: CAPACITY IMPACTS OF INTRODUCING HYDROGEN OR HYDROGEN AND NATURAL GAS (OR RNG) BLENDS

FEI's framework to transition to a low-carbon energy future is its Clean Growth Pathway, discussed in Section 3 of the 2022 LTGRP. The Clean Growth Pathway is a diversified approach that is technology agnostic. At this point in the energy transition, it is important to maximize the number of decarbonization pathways available and explore business models that meet energy demands and maximize the use of existing assets, thereby avoiding the costs that would come with the complete reengineering of BC's energy sector. In the 2022 LTGRP, the Clean Growth Pathway is represented by the Diversified Energy (Planning) Scenario.

FEI is planning for gas supply resources made up of increasing amounts of renewable and low-carbon gas over the next 20 years and beyond. The components of this resource mix are expected to include RNG, hydrogen, natural gas, and smaller amounts of syngas and lignin, supplemented later in the planning period by CCUS. The amount of each resource to be acquired and delivered to customers throughout the planning period will ultimately be predicated by several variables, including:

- **Quantity and Timing of Resource Availability**: Although FEI has modelled the mix of renewable and low-carbon gas in certain proportions over time in the LTGRP planning scenario, the actual amount of each component that is acquired and delivered to customers could vary from the forecast amounts over the planning horizon based on a number of important factors, including resource costs and supply project opportunities and development. Renewable and low-carbon gases with the highest volume potential over the planning horizon are RNG and hydrogen. In particular, RNG is interchangeable[1] with natural gas and has wider availability so will make up a greater proportion of the resource mix in the near term. RNG will continue to be a large part of the resource mix throughout the planning horizon and beyond. While hydrogen resource development is underway, it is expected to become more widely available and make up an increasing proportion of the resource mix later in the planning horizon beyond 2030.
- **Resource Development and Delivery:** Many pathways exist for bringing the benefits of renewable and low-carbon gas to FEI's customers; however, there are several ways in which these resources can be developed and delivered to customers which will ultimately determine the capacity impact and the overall system upgrade scope and timing. The following discusses the various modes of production and delivery and explains some of the capacity impacts associated with each.
    i. **Off-System Supply and Off System Delivery:** Off-system supply is where FEI acquires renewable and low-carbon gases in other regions and the gas

[1] The physical properties of renewable natural gas, such as specific gravity, viscosity and heating value, etc., falls within the range of the physical properties of FEI's conventional sources of natural gas. The capacity impacts and gas supply resource needs are comparable, and both sources of methane can utilize the same upstream and on-system infrastructure.

transportation and consumption is conducted completely outside of FEI systems. This process achieves carbon reduction and credit for FEI customers with the environmental attributes associated with renewable and low-carbon gas. However, since FEI customers continue to physically receive conventional natural gas through FEI infrastructure the capacity requirements to meet peak demand forecasts remain the same on the FEI system. This capacity impact of off-system supply and delivery has the same neutral effect regardless of the form of the off-system energy delivered. The incorporation of these types of off-system supplies will play an important role while the transition to renewable and low-carbon gas occurs over the planning horizon until more on- or near-system resources that flow directly through FEI systems are developed.

ii. **CCUS:** processes for carbon capture at the customer location will not change the system capacity required to meet the peak demand. The process does not change the amount of conventional natural gas that would be flowing through the system to support customers using these processes.

iii. **On-System Hubs:** Local production and supply of renewable low-carbon gas will be developed. These local hubs, whether they produce RNG, or hydrogen or syngas and lignin will have some ability to free up pipeline capacity as the local demand served by this production no longer needs to be transported through the upstream transmission pipeline. For hubs that in addition to serving local demand inject RNG or electrolytic hydrogen (known as green production) into the transmission system as well there can be an additional capacity benefit on the system, however with hydrogen there can also be some offsetting capacity reduction where hydrogen blends are present in the transmission system or if conventional natural gas delivered through the upstream transmission pipeline is used as a feedstock for hydrogen production, by reformation or pyrolysis (known as blue or turquoise production respectively). The impacts of hydrogen blends on capacity are discussed further in Section 1.1 below.

iv. **Off-System Supply and On-System Delivery:** Off-system supply of RNG and hydrogen physically delivered into FEI transmission systems from upstream pipelines will produce no net change in FEI transmission system capacity to meet peak demand forecasts if the supply is RNG. If the supply is a blend of hydrogen, there will be some capacity reduction for the reasons discussed below in Section 1.1.

- **Location:** Given the length of the planning horizon, the geographic location where renewable and low-carbon supply production is physically delivered to FEI's customers is not yet known in detail. Production facilities for RNG and hydrogen supplies are expected to be developed both on FEI's system and, over time, in locations where these low-carbon gases can be injected into the existing upstream gas infrastructure. While many potential projects are in the concept and development stages, the location of all those that will proceed during the next 20 years is uncertain. In particular, the extent to which such resources are developed and delivered to customers on one portion of FEI's system will impact the amount of RNG and natural gas that will still need to be delivered on other portions of the system over the planning horizon.

Although FEI is securing about as many contracts for supply within BC as outside of BC, the larger producers, in the near term, are outside of the province. Therefore, in the early years of the planning horizon, FEI's supply will predominantly be acquired and used outside of FEI's service territory. As a result, during this early part of the planning horizon, the system capacity impacts will remain largely unchanged from what FEI would have otherwise anticipated without renewable gases, as the transmission and distribution systems continue to predominantly move conventional natural gas. By 2030 and through the end of the planning horizon, on-system delivery of renewable gases supplied within FEI systems or by upstream pipeline systems will expand.

As FEI incorporates renewable gases into the gas distribution and transmission systems, the physical properties of these gases, such as density and energy content per standard volume, can have an impact on capacity. Gases with physical properties within the range of conventional gas, such as RNG, will have no net impact on delivery capacity. Delivering hydrogen or a blend of hydrogen and natural gas or hydrogen and RNG, where the gas density and energy content are different from traditional natural gas supply, will change the energy delivery capacity. The following sections provide some additional detail and examples of the impacts on system capacity and infrastructure requirements of introducing hydrogen gas blends.

1.1 Hydrogen and Hydrogen / Natural Gas or RNG blends

FEI is planning for future pipelines to be hydrogen ready. In addition to selecting the optimum pipeline materials for construction, this means that the capacity of a pipeline that might initially deliver natural gas should be compatible with meeting the forecast energy delivery requirement when delivering hydrogen or hydrogen and natural gas blends.

For planning purposes, FEI uses an average gas heating value of around 39 megajoules per standard cubic meter (MJ/m^3) to determine the volumes of natural gas flowing through the system to meet customer peak demand. Hydrogen has a heating value of 12.1 MJ/m^3. As a result, if hydrogen is directly substituted for natural gas, around three times the volume of hydrogen must be delivered to customers to meet the same energy delivery of unit volume of natural gas. Blended mixtures of hydrogen and natural gas would fall in between in terms of the volume required to deliver the same energy to customers. This property difference in the pure gases or blends of the gases changes the energy delivery capacity in an existing transmission or distribution pipeline system. As the percentage of hydrogen flowing in the systems increases, the upgrades required to support future energy delivery requirements on the system will change. If a system is forecast to have a capacity deficit, higher blends of hydrogen supplied into the system will require system upgrades sooner, or at a lower system demand, than if the system were to deliver 100 percent natural gas.

The following example scenario is illustrative of the introduction of hydrogen into a hypothetical simple transmission system and a further example illustrates the introduction of hydrogen into an existing FEI distribution system. The examples provide some insight into the impacts hydrogen has on energy delivery systems, and the infrastructure planning considerations that need to be made to accommodate this renewable gas in FEI's transmission systems, and the capacity those systems currently possess to deliver hydrogen.

1.1.1 Hydrogen and Hydrogen / Natural Gas Through a Simple Transmission System

The following example illustrates a simple linear transmission system consisting of a 30-inch (NPS30) pipeline 240 km in length receiving gas at the upstream end at 1440 psig and delivering at the downstream end.

The critical parameter defining pipeline capacity of such a system is often the minimum delivery pressure required in the downstream systems; however, in some cases, it is limited or constrained by the velocity of gas within the pipeline. For this illustration, a delivery pressure of 500 psig or a maximum velocity of 24 meters per second (m/s) was chosen as a constraint.

For natural gas systems, sustained velocities of 20-24 m/s are typically considered in the maximum range for pipelines. FEI is currently exploring if higher allowed velocities are appropriate for hydrogen pipelines, however, in this example FEI shows how delivery capacity changes if such a maximum velocity is used to define the available capacity.

To summarize, the assumptions of this example are as follows:

- Pipeline Length: 240 kilometres
- Pipe Diameter: NPS30
- Upstream Supply Pressure: 1440 psig
- Minimum Delivery Pressure: 500 psig
- Maximum Gas Velocity: 24 m/s

In the table below, the last two lines indicate the available capacity to deliver 100 percent hydrogen using either delivery pressure or maximum gas velocity as a constraint.

Table D3-1: Pipeline Delivery of Natural Gas and Hydrogen

Hydrogen Blend (% By Volume)	Volume Delivery (MMscfd)	Energy Delivery Hydrogen (%)	Energy Delivery Natural Gas (%)	Energy Delivery Total (TJ/d)	Compressor Power (relative to 100% natural gas)	Capacity Limiting Constraint
0	871	0	100	960	100%	Delivery Pressure

Hydrogen Blend (% By Volume)	Volume Delivery (MMscfd)	Energy Delivery Hydrogen (%)	Energy Delivery Natural Gas (%)	Energy Delivery Total (TJ/d)	Compressor Power (relative to 100% natural gas)	Capacity Limiting Constraint
50	1095	23.8	76.2	791	141%	Delivery Pressure
100	1943	100	0	666	258%	Gas Velocity[1]
100	2347	100	0	805	308%	Delivery Pressure[2]

Notes:

[1] Gas velocity reaches 51 m/s
[2] Delivery pressure of 900 psig

The table illustrates how the energy delivery capacity reduces when hydrogen is blended with or replaces natural gas. Lines one through three in the table show how, as the blend of hydrogen in the gas stream increases, the volumetric flow in the pipeline also increases and the energy delivery decreases. The volume delivery increases by nearly 125 percent while the energy delivery decreases by just over 30 percent compared to the pipeline flowing 100 percent natural gas. The scenarios in lines one and two are limited by the minimum delivery pressure. Line three shows that the capacity constraint shifts from minimum delivery pressure to gas velocity. Line four shows how the energy delivery could increase in the pipeline if velocity is removed as a constraint and capacity is limited by only the minimum delivery pressure. In the scenario illustrated in line four, the gas velocity in the downstream end of the pipeline is 51 m/s. In that scenario, the energy delivery would decrease by less than 18 percent compared to the pipeline flowing 100 percent natural gas. As indicated earlier, FEI is currently exploring if higher allowed velocities are appropriate for hydrogen pipelines. While a velocity of 51 m/s is possibly excessive for a pipeline system, it is conceivable that allowed maximum velocities in future design of hydrogen pipelines will be higher than those used in natural gas pipeline design and can help mitigate the differences in capacity for pipelines carrying hydrogen or hydrogen/natural gas blends.

1.1.2 Hydrogen and Hydrogen / Natural Gas Through Distribution Systems

FEI distribution systems have capacity to deliver hydrogen and natural gas blends and with supporting capacity upgrades could deliver energy as 100 percent hydrogen. The following case study describes how the capacity of a distribution system is affected by the introduction of hydrogen. The example provided is based on the system serving Whistler, BC. Natural gas is supplied to gate stations in the south-central portion of the Whistler community through an NPS 8 pipeline from Squamish that is in turn supplied by the VITS transmission pipeline. This scenario assumes that that supply is supplemented or replaced by a hydrogen supply that is injected into that pipeline from a source near Whistler. The Whistler distribution system operates at a supply pressure at the local gate stations of 420 kPa, and as gas flows through the system to consumers, delivery pressure downstream falls below that. The farther from the gate station supply the customer resides, the lower the delivery pressure the customer would receive. The trigger for future distribution system improvement in the Whistler system is the system pressure in the northern part or "tail end" of the system in the neighbourhoods on the west end of Green Lake. When pressure at that location is projected to fall below 70 kPa under peak demand conditions, some form of capacity upgrade is required to restore higher pressure. Currently, the pressure in that portion of the system is projected to be greater than 190 kPa. Figure D3-1 below illustrates how the pressure would change at that critical location as higher and higher volumes of hydrogen are introduced. The analysis assumes the peak demand energy requirement of customers on the system is unchanged, that only the percent of hydrogen in the gas stream is changing and that the customers on the system have equipment capable of using any percentage blend of hydrogen and methane.

Figure D3-1: Whistler Distribution System Tail End Pressure vs. Volume Percent Hydrogen

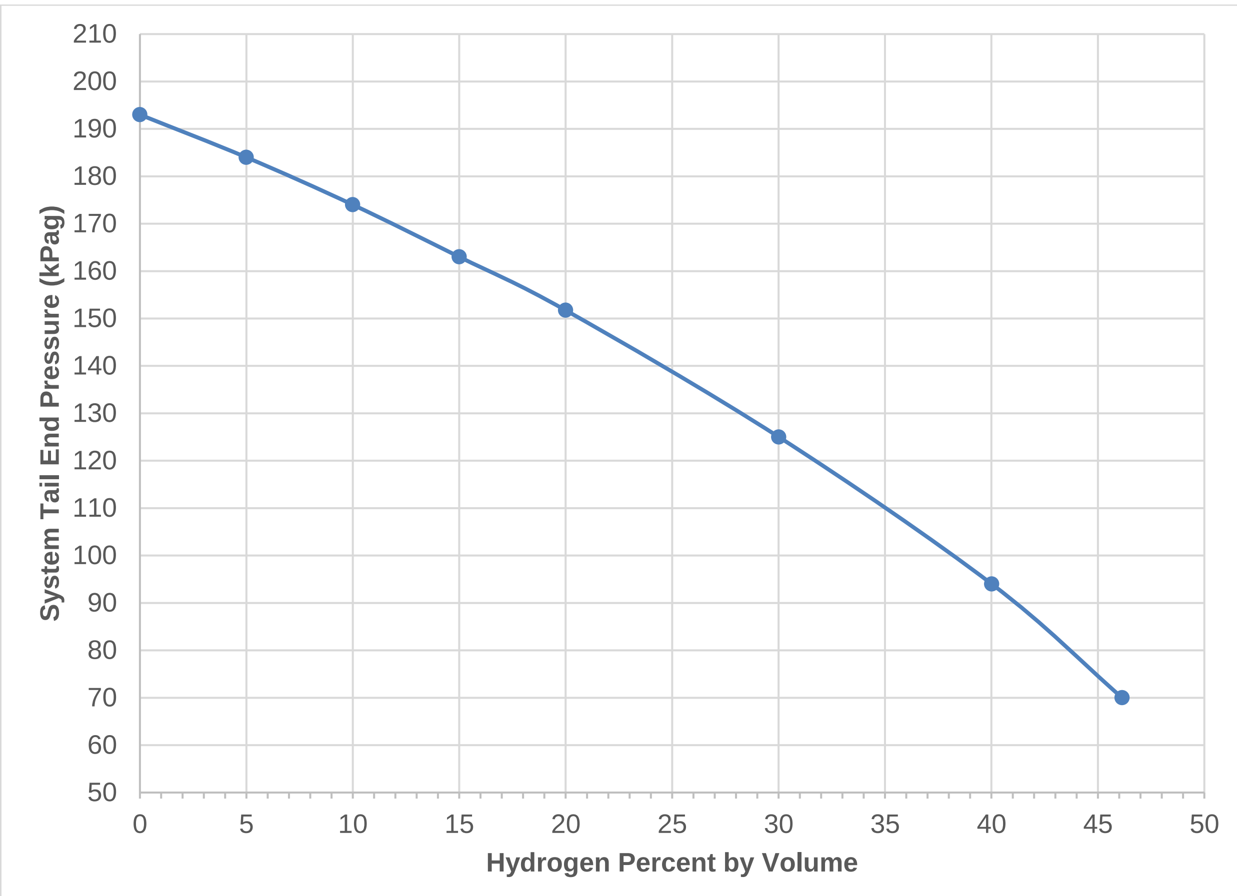

Figure D3-1 illustrates that the peak demand requirements of Whistler customers could be met without additional capacity upgrades required for blends of up to 45 percent by volume hydrogen blended with natural gas. At higher percent blends of hydrogen, the pressure for customers in the north of the system would fall below 70 kPa under peak demand and this would trigger FEI to install some distribution system upgrades to restore acceptable pressure to the area. A typical upgrade to the system would consist of a distribution main looping project that would reduce the pressure drop incurred as gas flows north in the system.

For the Whistler system, an upgrade that could restore sufficient pressure and accommodate higher percentages of hydrogen blends, up to 100 percent, could be accomplished by installing approximately 3300 metres of 8-inch distribution pressure main. This upgrade could allow the Whistler distribution system to meet the peak energy demand delivering pure hydrogen. The scale of such a project is shown highlighted in white (and circled) in Figure D3-2, in which the layout of the Whistler distribution system is presented to show that the project is a moderate upgrade to the system. A distribution project of this magnitude is not dissimilar in scale to projects FEI regularly includes in its distribution system upgrade plans and illustrates that existing distribution systems have the capacity to deliver hydrogen without extensive rebuilding.

Gas System Resiliency Plan

May 2022

Table of Contents

List of Figures

1. INTRODUCTION

FEI files this appendix in compliance with BCUC Order G-39-19, which accepted FEI's 2017 Long-Term Gas Resource Plan (LTGRP). In Order G-39-19, the BCUC Panel directed FEI to address security of supply concerns in its next LTGRP to respond to several concerns raised by the interveners (CEC/BCSEA) about the 2018 rupture of the Westcoast Energy Inc. (Westcoast)[1] T-South pipeline. Furthermore, in BCUC's acceptance of the Application for a Certificate of Public Convenience and Necessity for the Pattullo Gas Line Replacement Project (Order C-2-21), the BCUC provided a number of directives and suggestions for FEI to integrate into the 2022 LTGRP.

FEI has assessed various resiliency-enhancing options, in conjunction with external experts, and has concluded that the resiliency of its system is best enhanced through a portfolio of measures. Just as FEI's Annual Contracting Plan (ACP) combines assets with distinct attributes to meet the shape of FEI's load profile (Section 6 of the LTRGP), a portfolio approach to resiliency incorporates enhancements with distinct attributes that together provide a cost-effective approach to resiliency.

Broadly speaking, and as discussed further in Section 1.4 below, a resilient gas system relies on a combination of pipeline diversity, ample storage, and the ability to manage load when gas supply is constrained. In the medium term, FEI's proposed expansion of LNG storage and regasification capacity at the Tilbury facility (Tilbury Liquefied Natural Gas Storage Expansion (TLSE) project), and Advanced Metering Infrastructure (AMI) project, will add key components to FEI's portfolio approach to resiliency while providing other valuable benefits for customers. In the longer term, FEI is exploring possible regional pipeline expansions to address constrained transmission capacity, and reviewing its distribution system to identify locations that present a higher risk of supply disruption.

FEI's resiliency plan is organized as follows:

- Section 2 provides the background for FEI's gas system resiliency plan as a portfolio of measures as follows:
    - Section 2.1 distinguishes between integrity, reliability and resiliency;
    - Section 2.2 explains that high consequence events can still occur on the gas system, despite it being inherently more resilient than other energy systems; and
    - Section 2.3 identifies the key elements of a resilient gas system, namely: diverse pipelines in a regional pipeline infrastructure, ample storage, and load management capabilities and how each contributes to system resiliency in different ways.
- Section 3 describes the inherent resiliency of **FEI's distribution system**, which is comprised of transmission pressure (TP) lateral systems, intermediate pressure (IP)

[1] Westcoast is a subsidiary of Enbridge Inc.

systems and distribution pressure (DP) systems, and the potential enhancements to these systems being assessed by FEI;

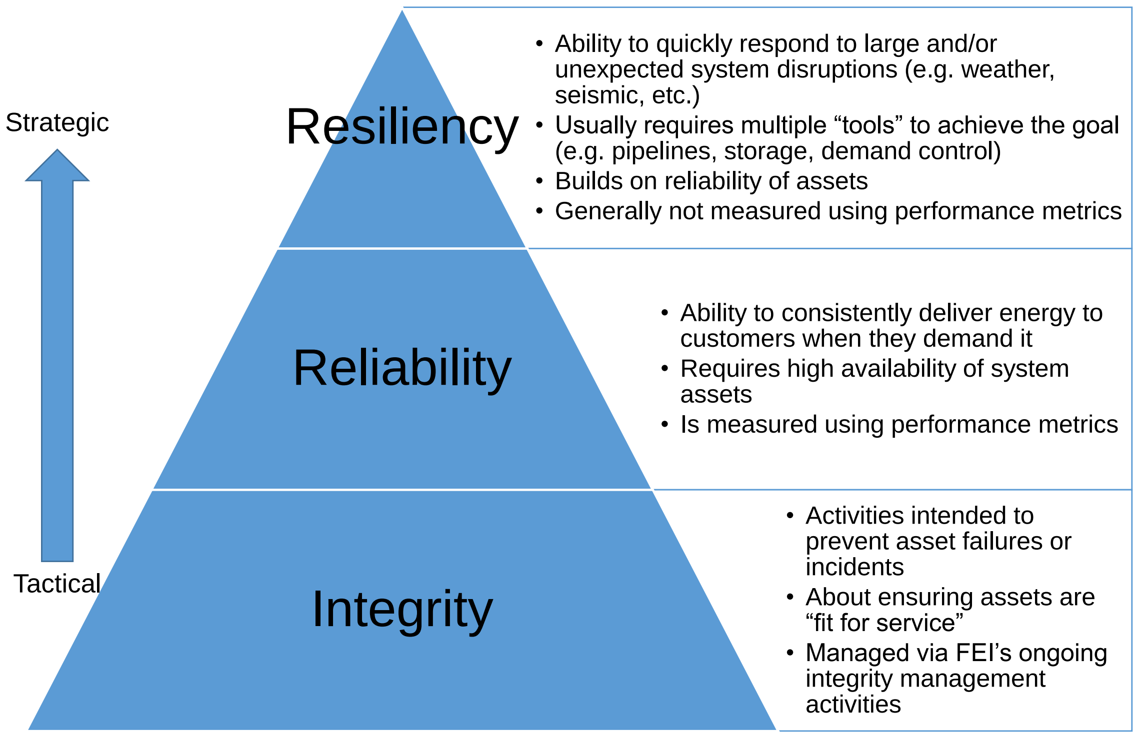
- Section 4 describes the existing resiliency of **FEI's transmission systems** including the consequences of disruption of upstream supply and the ongoing risk of supply disruption related to FEI's continued reliance on the Westcoast T-South system;
- Section 5 addresses **FEI's overall system resiliency** including the deployment of the TLSE and AMI projects, and exploration of diversified regional pipeline solutions including the proposed Regional Gas Supply Diversity (RGSD) project; and
- Section 6 provides a conclusion.

2. RESILIENCY AS A PORTFOLIO OF MEASURES

2.1 DISTINGUISHING BETWEEN INTEGRITY, RELIABILITY, AND RESILIENCY

Integrity, reliability, and resiliency are all necessary system attributes of providing service to customers. While the terms “reliability” and “resiliency” are sometimes used interchangeably, in the context of energy systems, they are not synonymous. Figure E-1 outlines these system attributes, how they differ but also how they inter-relate to each other.

Figure E-1: Integrity, Reliability and Resiliency as Building Blocks of Customer Service



2.1.1 Integrity: Having System Components Meet Design Specifications Throughout Their Lifecycle

As shown in Figure E-1 above, the integrity of system assets is foundational to the reliability and resiliency of the gas system. In the context of gas transmission and distribution, integrity refers to the ability of individual system components to meet their original design specifications, and to fulfil their intended purpose or application. The concept of integrity applies throughout the entire lifecycle of gas system assets, including planning, design, procurement, fabrication, construction, commissioning, operations, maintenance, and retirement.

FEI manages the integrity of its gas system assets in order to achieve its goal of having zero incidents on the system that result in significant consequences. Incidents of significant consequence interfere with the functionality gas system assets and may materially impact safety, the environment, and/or continuity of service to a large number of customers.

In the context of reliability and resiliency, integrity management is concerned with avoiding incidents, such as leaks or ruptures, that would undermine the ability of the assets to deliver service to customers. FEI uses tools and technology to detect and mitigate threats to system assets, such as corrosion, third-party damage, and external forces such as landslides, floods, and seismic events. Consistent with industry practice, FEI is continually seeking improved methods to address these threats, including increased use of electro-magnetic acoustic transducer in-line inspection (EMAT ILI). By reducing the likelihood of these threats resulting in incidents, integrity management ensures that it is highly likely that FEI's gas assets will be available to serve customers. Ultimately, ensuring FEI's gas assets remain fit for service is foundational to delivering safe and reliable service to customers.

2.1.2 Reliability: Adequacy and Security of Supply Throughout the Year

Reliability refers to designing and operating a system to ensure it meets the expected customer demand at all times and is a combination of two concepts: (1) adequacy, which refers to the ability to ensure a sufficient supply of energy; and (2) security, which refers to the ability to consistently deliver that supply to customers.

First, from the perspective of "adequacy", maintaining reliability requires that utility operators have sufficient resources to balance their energy supply capacity with customer demand throughout the year. This is necessary to ensure adequate energy supply during peak demand periods, while also being able to deal with the expected variability in customer demand during other times. To assist with this balance, energy can be stored directly (e.g., natural gas can be compressed, liquefied, or stored underground), or as a different form (e.g., in the electricity context, water held behind a hydroelectric dam).

Second, the "security" aspect of reliability depends on a combination of the concepts of integrity and redundancy. As discussed above, integrity is concerned with (among other things) preventing disruptions to service. Due to the nature of the assets and the success of integrity management in the natural gas industry, disruptions to natural gas service are relatively rare. In contrast, in the electric industry, where the integrity of electric assets is more difficult to maintain and disruptions are more frequent, redundancy is a mandatory requirement for a reliable system. While no mandatory redundancy requirements have been developed in the natural gas industry, gas assets such as storage and pipeline systems do nonetheless incorporate a level of redundancy in their design and operation. For example, multiple transmission pipelines within FEI's Coastal Transmission System have been looped for capacity purposes, which also provides redundancy as some transmission pipelines can be taken out of service without resulting in interruptions to downstream customers.

2.1.3 Resiliency: The Ability to Manage Through and Recover from Unexpected Events

Resiliency refers to the ability to prevent, withstand, and recover from system failures or unforeseen events. Resiliency is directly linked to the attributes of integrity and reliability in the sense that a system cannot be resilient without first having reliable components that serve their intended purpose. Resiliency also encompasses concepts such as preparing for, operating through, and recovering from significant disruptions, no matter the cause.

At a high level, the resiliency of a gas system is measured by its ability to deliver service, backed by physical assets, while preventing, withstanding and recovering from events that interrupt the flow of gas. FEI manages these risks through a portfolio of solutions that enables the utility to manage the risk of unforeseen events and their consequences. Embedded system resiliency enables the system to manage and recover from unexpected events more effectively and expeditiously.

Resiliency, as the ability to prevent, withstand, and recover from system failures or unforeseen events, is therefore critical for natural gas systems because the consequences of a lack of resiliency can be significant. In particular, insufficient resiliency poses a risk of an uncontrolled shutdown of the transmission or distribution system (also referred to as a pressure collapse). An uncontrolled shutdown or pressure collapse occurs when the pressure within a portion or all of the gas distribution system naturally decays to zero following a gas supply interruption. An uncontrolled shutdown is a serious scenario, both in terms of service disruptions and the resulting impacts on customers, and the potential for system safety concerns.

As discussed below, the overall resiliency of the system depends on the interplay between integrity, reliability, and resiliency in order to mitigate against serious events that impact FEI's ability to provide service to its customers.

2.1.4 Interplay Between the System Attributes of Integrity, Reliability and Resiliency

FEI's ability to safely, securely, and cost-effectively deliver energy to its customers is enabled through the interplay of the three necessary attributes integrity, reliability and resiliency. Resiliency is built on the foundation that a well-maintained (i.e., a system operated with appropriate integrity management) and reliable system is in place. Figure E-1 above depicts the concepts as building blocks of customer service. As discussed above:

- **Integrity** (Section 2.1.1) is ongoing, on a day-to-day basis, focusing on detecting and mitigating ongoing threats to system assets and is more "tactical" in nature.
- **Reliability** (Section 2.1.2) is built upon or includes system integrity and tends to be more of a strategic consideration (e.g., securing contracted assets for each gas year and through appropriate infrastructure capital planning).

- **Resiliency** (Section 2.1.3) is a higher-level strategic consideration that typically requires longer-term planning and solutions. It is concerned with the capability of the system to withstand a large and/or unforeseen event, such as an upstream pipeline failure. Resiliency depends on having an appropriate combination of physical assets that can provide continuity of service to FEI's customers.

2.2 GAS SYSTEMS EXHIBIT A MUCH HIGHER LEVEL OF RELIABILITY THAN ELECTRIC SYSTEMS, BUT FAILURES DO OCCUR

In general, gas transmission and distribution systems experience significantly fewer outages than electric networks.[2] However, when gas customer outages do occur, they tend to be longer in duration than electrical outages because the utility of the need to ensure isolation at each customer premise, repressurize, and safely relight customer appliances. The process currently remains a predominantly manual effort. Resiliency investments for the gas system are consequently focused on addressing what are typically low probability events. Even so, despite having a low probability, events can and do occur, and have the potential to give rise to significant consequences.

The vast majority of electric transmission in North America is via overhead power lines, which are more exposed to disruptive events, including: lightning, wind, ice, trees and third-party contacts. Consequently, electric power lines have considerably higher outage rates than underground gas lines.

Based on industry experience, on average, a typical 80 km overhead electric transmission circuit is expected to experience one unplanned outage event per year.[3] Since circuit outages are an expected occurrence in electric networks, asset redundancy is commonly employed to ensure compliance with minimum standards of reliability. The BC Mandatory Reliability Standards (MRS) require that the bulk electric system be planned and operated to withstand an unexpected outage of the single most critical system element, coincident with the forecast system peak load, while not experiencing any firm customer outages.[4] This is referred to as the N-1 reliability criterion and is based on North American industry standards. These industry standards were developed and mandated following two major Northeast blackouts, one in 1965 and one in 2003. In other words,

---

[2] Industry surveys and studies conducted by the US Gas Technology Institute have demonstrated gas customer average reliability/availability levels (due to unplanned causes) of 0.9999978. (Gas Technology Institute, Topical Report (July 19, 2018) "Assessment of Natural Gas and Electric Distribution Service Reliability," p. 10.) This is consistent with the service availability levels of the Canadian Gas Association when comparing outage incidents. In contrast, the comparable average availability for most electric customers in BC is approximately 0.99959. In other words, on average the gas system is 186 times more reliable than the electric system.

[3] North American Electric Reliability Corporation (NERC). "Outage Metrics, 2019 WECC AC Circuit." Total Circuit Outage Frequency of 1.97 per 100 mi·yr (for 200-299kV circuits). https://www.nerc.com/pa/RAPA/tads/Pages/OutageMetrics.aspx

[4] BCUC Order R-27-18 (June 28, 2018). "British Columbia Hydro and Power Authority Mandatory Reliability Standard TPL-001-4 Assessment Report." P. 8, Attachment D.

the cost of this necessary system redundancy is broadly accepted by electric operators and regulators in order to ensure adequate levels of customer service.

In contrast, large-diameter, high-pressure pipelines may operate for long periods without experiencing any unplanned outage events. As such, regional gas transmission systems are typically designed and operated to transport a contracted quantity of gas, as opposed to being explicitly planned to achieve an expected level of reliability. To FEI's knowledge, there are no specified regulatory requirements for gas system reliability in North America equivalent to the electric utility N-1 criterion. However, in interconnected gas networks with numerous supply points interspersed with multiple delivery points, a reliable network is a consequential outcome. Thus, in many areas of North America, the redundancy afforded by multiple gas supplies, storage, and transportation paths results in a more resilient system.

The rates of reliability would suggest that, on average, a typical natural gas customer would expect 69 seconds of service outage per year,[5] compared to almost four hours per year for a typical electric customer in BC (even with the high standards of redundancy on the electric system).[6] In practice, the vast majority of FEI's customers have never experienced a single natural gas outage, other than for planned reasons such as a meter exchange.

Ultimately, while gas pipeline failures are relatively rare occurrences, they can nonetheless be high consequence events. If a rupture followed by ignition occurs, the result may be significant property damage, or harm to individuals in the vicinity of the failure. Further, if there is insufficient transmission pipeline redundancy in the region, the reduced transportation capacity can potentially lead to gas shortages or outages to large numbers of downstream customers.

2.3 GAS SYSTEM RESILIENCY DEPENDS ON A COMBINATION OF DIVERSE PIPELINES, AMPLE STORAGE AND LOAD MANAGEMENT CAPABILITIES

At a foundational-level, and leaving aside adequacy of natural gas production and gathering (typically referred to as "upstream" systems), there are three elements that contribute to the resiliency of FEI's gas system:

1. **Diverse Pipelines and Supply:** Transmission pipelines can continuously transport a significant amount of gas supply to the market centres on a daily basis, and therefore, address customers' baseload and seasonal demand requirements. Having access to multiple regional pipelines, preferably separated geographically, to serve the distribution system improves a utility's ability to dependably collect and deliver gas supply to consumers. As described in Section 3.1 below, pipeline diversity within distribution

[5] Gas Technology Institute, Topical Report (July 19, 2018), "Assessment of Natural Gas and Electric Distribution Service Reliability." Online: https://www.gti.energy/wp-content/uploads/2018/11/Assessment-of-Natural-Gas-Electric-Distribution-Service-Reliability-TopicalReport-Jul2018.pdf

[6] "BC Hydro F2020 Annual Reporting of Reliability Indices", p. 3, https://www.bchydro.com/content/dam/BCHydro/customer-portal/documents/corporate/regulatory-planning-documents/revenue-requirements/2020-05-04-f05-f06-directive-26-f20120.pdf

systems is inherently more abundant and the majority of customers are situated so that supply to large numbers of customers is usually not reliant on a single gas line.

2. **Ample Storage:** Access to storage, preferably located on a utility's own system, allows a utility to manage expected or unexpected changes in supply for a period of time. Stored energy can bridge a shortfall in supply entering the utility system, or if necessary, provide time to shed load or implement a controlled shutdown of portions of the system to avoid pressure collapse. Two common gas storage methods are: (1) underground storage; and (2) LNG storage.

    - **Underground Storage:** uses natural geological formations to hold supply in gaseous form, and (as in FEI's case where underground storage is off-system) may require a functioning regional pipeline to transport stored natural gas to the utility distribution system.
    - **LNG Storage:** is held in aboveground storage facilities that are accompanied by adequate regasification capability (to convert the LNG back to gas for delivery to customers). On-system LNG storage has the benefit of being able to inject supply into the local transmission system close to the load centres and is not reliant on functioning regional pipeline infrastructure.

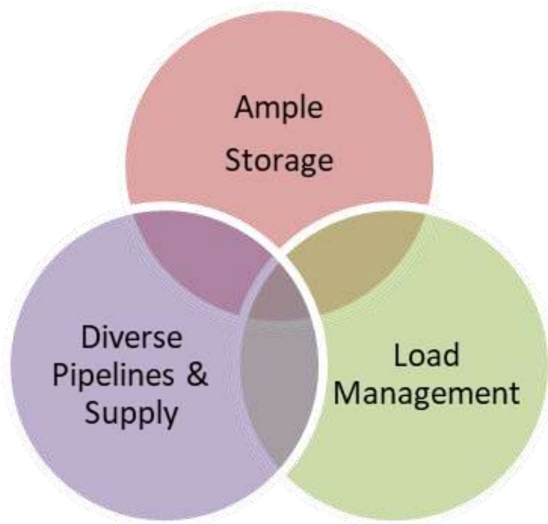
    While it is typically impractical to locate multiple storage sites within the distribution system, the presence of storage on portions of the local transmission system preventing system collapse and providing an interim supply provides a benefit to all downstream distribution systems.

3. **Load Management Capabilities:** The ability to manage load during a period of supply constraint allows an operator to shed load during a controlled shutdown, while ensuring the constrained supply of gas is maintained for the maximum number of customers. Until recently, FEI's only options for gas load curtailment were through broad public appeals to reduce consumption, or direct curtailment requests to large volume and/or interruptible customers. Under the former scenario, FEI has no way to ensure customer compliance, while under the latter scenario, the amount available to curtail may not be sufficient to prevent a system-wide pressure collapse. Moreover, neither are necessarily timely enough during a rapid-onset supply disruption.

    The pipeline diversity inherent to the distribution system means that isolating target customer segments or small targeted geographic locations, as part of a load shed plan, is impractical. This leaves the utility with certain larger scale measures (e.g., closing system valves or shutting-in stations supplying entire communities); however, these measures may not be sufficiently responsive. The deployment of new technology, such as AMI with remote-shutoff valves, will enable FEI to quickly, accurately, and directly target any required customer load shedding. As load management necessitates disrupting service to customers, it is ideally used in conjunction with other solutions (such as on-system storage) that can more directly address supply disruptions. FEI's ability to manage load is discussed further below.

As each of the three elements above adds resiliency in distinct, but complementary ways, FEI views resiliency as a combination of the above three elements, as depicted in Figure E-2.

Figure E-2: Key Elements of a Resilient Gas System



In practice, the overall resiliency of FEI's system is optimized through an appropriate combination of all three elements. For example:

- On-system LNG storage provides immediate response capabilities to ensure survival of FEI's system during a critical supply emergency.
- Diversifying regional pipeline infrastructure helps withstand longer-term interruptions or constraints, and in particular, would mitigate the risk posed by FEI's current reliance on the Westcoast T-South system.
- Load management (potentially facilitated by technology upgrades like FEI's AMI project) enables FEI to avoid an uncontrolled shutdown of the gas system in extreme events by initiating a controlled shutdown and restoration of the system as required.

As outlined above, establishing system resiliency enables the gas transmission and distribution systems to effectively respond to system disruptions and avoid or minimize the impacts of those disruptions on customers. FEI applies and leverages the three key elements of resilient gas systems on both the transmission and distribution system in a variety of ways in order to maintain and enhance the end-to-end resiliency of its system. In the following sections, FEI discusses the existing resiliency of FEI's distribution and transmission systems, and the resiliency of the overall system in the Pacific Northwest region.

3. DISTRIBUTION SYSTEM AND TP LATERAL SYSTEM RESILIENCY

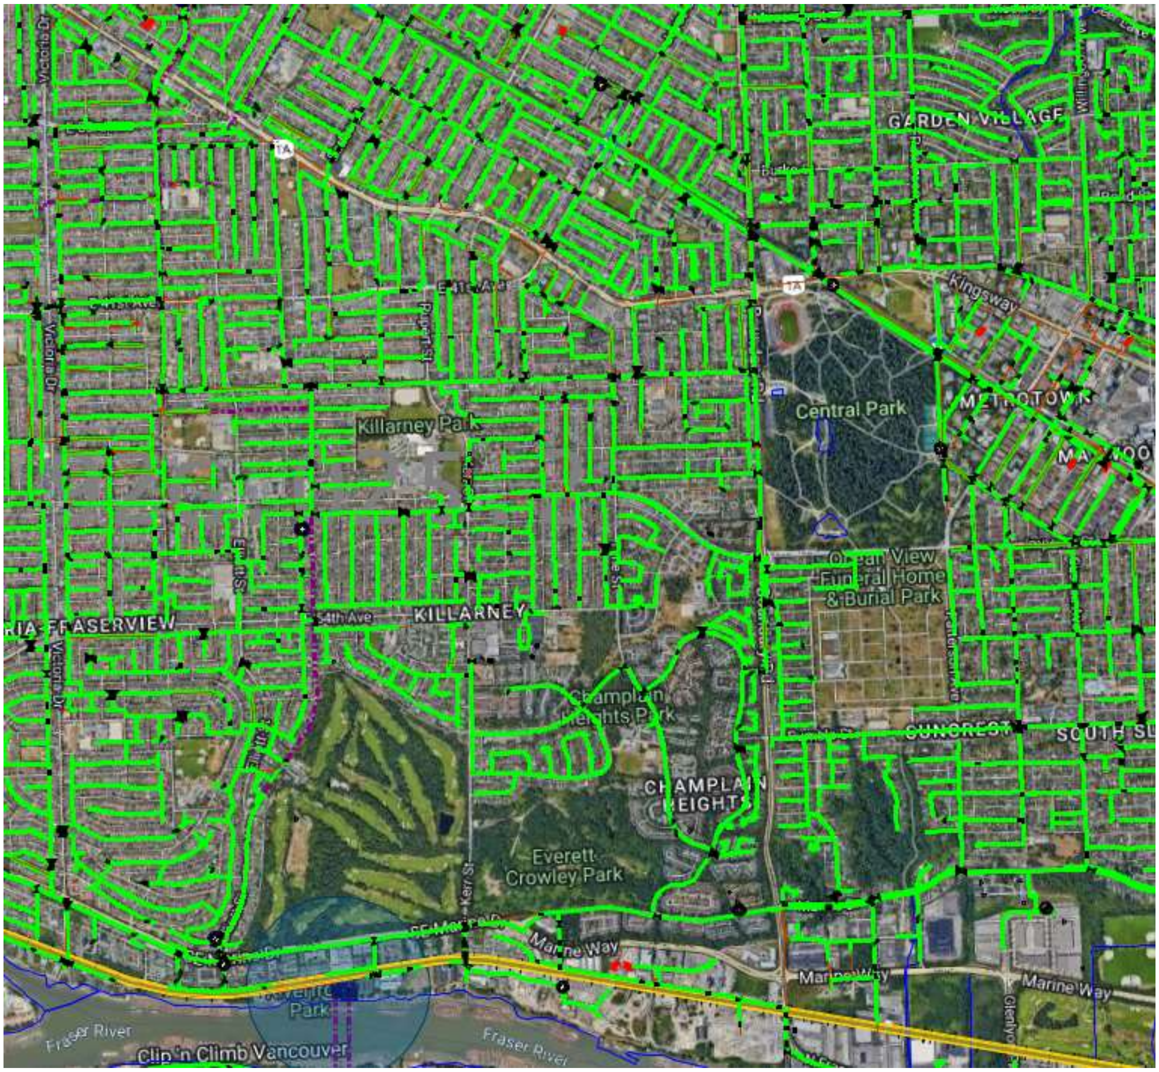
The distribution portion of a gas system is comprised of smaller gas lines that predominantly run within streets and laneways, delivering gas directly to customer premises. In the context of resiliency, FEI's distribution system comprises transmission pressure (TP) lateral,[7] intermediate pressure (IP), and distribution pressure (DP) systems. Each of these systems is considered to be part of the overall distribution system because they are highly integrated, and therefore, are capable of providing more significant support to each other than either can provide to upstream transmission systems.

As a highly interconnected system, FEI's network of gas lines are supplied by multiple gate or district stations which support the system. As a result, the distribution system has an inherent degree of resiliency, generally enabling FEI to maintain service to the majority of customers despite localized incidents on the system. For example, leaks or third-party damages rarely result in a significant supply interruptions, and when responding to and isolating damage within the system, measures can be taken by FEI's operations crews to ensure that customer impacts, if any, remain localized. As a result, FEI gas customers enjoy a very high degree of service reliability and most never experience an unplanned outage.

As a demonstration of the degree of interconnectedness in FEI's distribution system, Figure E-3 below shows gas lines (in green) located in the southern portion of Vancouver and Burnaby, and is a typical example of an urban distribution system layout.

[7] Transmission pressure (TP) laterals are pipeline branches from a transmission mainline that deliver gas at transmission pressure to one or more gate stations serving a local community distribution system or a customer station serving a larger commercial or industrial customer.

Figure E-3: Example of Distribution System Layout



3.1.1 Enhancing the Resiliency of the Distribution System and TP Lateral Systems

In this section, FEI discusses the steps it is taking to enhance the resiliency of these systems, including the development of a new resiliency-based criteria to identify and prioritize possible enhancement projects. FEI also outlines potential projects that could be developed enhance the resiliency of the distribution system, as well discussing the impacts of both recently completed and under-construction projects on resiliency in FEI's Lower Mainland system.

3.1.1.1 Development of Resiliency Criteria for the Distribution System and TP Lateral Systems

Despite the inherent resiliency of the distribution system, FEI is in the process of developing criteria to more clearly define projects where: (1) single points of failure would cause disruption to significant numbers of customers; and (2) the failure of supply would be unable to be restored in a timely manner. Such failures could result in a risk of significant number of customers being without supply for extended periods in winter conditions. As FEI is able to access the vast majority of the distribution system with relative ease, undertaking repairs and the restoration of supply is usually rapid and most often can be completed within a day or a few days (at most). Locations where repair and restoration of service cannot be completed quickly are almost exclusively related to major bridge or water crossing locations, resulting in resiliency-related risks. In some cases, small transmission lateral bridge and water crossings provide the sole source of gas supply to communities, and therefore present similar risks in the event of a supply failure. FEI is considering these types of locations in the criteria it is developing.

As part of the development of this criteria, FEI is reviewing the maximum capability of temporary "non-pipe" solutions (such as a CNG or LNG "virtual pipeline" supply alternatives) to support communities in a sustainable manner during winter conditions, while working to restore normal supply. Despite the probability of an event of this kind being relatively low, defining non-pipe capabilities and establishing the associated feasibility, timeliness of mobilization, and cost of implementation, will help FEI identify and define where opportunities to improve resiliency for non-resilient systems that are too large to be supported by non-pipe solutions if a failure occurs.

Moreover, because single feed crossings do not have the same probability or consequence of failure, establishing criteria to determine the risk associated with each location will allow FEI to prioritize addressing specific resiliency deficiencies within the distribution and lateral systems. As mentioned previously, FEI's DP and IP systems are already generally highly reliable and resilient, and the criteria FEI is developing are not expected to identify many locations where a project of significant scope or cost would result.

3.1.1.2 Metro Vancouver Distribution System Resiliency

As part of the Lower Mainland Intermediate Pressure System Upgrade (LMIPSU) project,[8] the integrity-driven need to replace an NPS 20 pipeline between Coquitlam and Vancouver also presented the unique, one-time, opportunity to increase the pipe size to NPS 30. This increased pipe size also enhanced the capacity, and therefore, the resiliency of supply to customers in the Vancouver, Burnaby, Coquitlam and North Shore areas. The BCUC was satisfied that the increased flexibility and resiliency benefits justified the added project costs associated with the increased pipe size:

> The Panel agrees that while not a mandatory requirement, restoring operational flexibility and improving system resiliency are worthy objectives for this project, and merit inclusion in the decision framework. Prior to the new NPS 30 being placed in service, customers in those areas were at risk of an outage if an upstream supply

[8] CPCN for the Lower Mainland Intermediate Pressure System Upgrade granted by the BCUC pursuant to Order C-11-15, dated October 16, 2015.

disruption occurred on FEI's Coastal Transmission System (CTS) or within the Metro Vancouver IP system.

The resiliency added through the LMIPSU project will be somewhat eroded once the existing Pattullo crossing is abandoned and replaced by the Pattullo Gasline Replacement (PGR) project, which was approved by the BCUC in June 2021. In Section 3.6 of the PGR CPCN Application, FEI described the impact the preferred alternative would have on the system resiliency recently gained through the LMIPSU project. In particular, replacing the Pattullo supply with a new pipeline, primarily supplied through Coquitlam Gate via the recently completed LMIPSU pipeline, erodes some distribution resiliency. Even so, after the PGR project enters service, the resiliency provided by the LMIPSU project will continue to be substantially higher than prior to its completion. Importantly, the system will continue to be able to accommodate a failure of supply at either of the two major gate stations serving the region, without loss of customers up to nearly the coldest day in a typical winter.

As discussed in responses to information requests during the regulatory review of the PGR project, in order to recover the eroded incremental resiliency, FEI would need to construct approximately 5 km of new IP pipeline in south Vancouver using 508mm (NPS 20) pipe. A project of this scope would be a significant undertaking, very similar to the scope of the PGR project itself.

As described above, while developing the criteria to identify other resiliency projects on the distribution system, FEI expects that these other proposed projects will address higher risk situations (e.g., where a failure would result in customers being without gas at any time of year should a failure of the single feed occur). As a result, while recovering the additional LMIPSU resiliency eroded as a result of the PGR project remains under consideration, FEI has not yet established the relative priority for the project, and therefore, at what point in the planning horizon the proposed project should proceed. For greater certainty, at this time, FEI does not intend to file an application for a project within the next five years to restore the distribution system resiliency that will be eroded when the PGR project is completed. Further consideration for the potential need and timing for any such project will be provided in a subsequent LTGRP application.

3.1.1.3 Major Distribution Pipeline Crossings

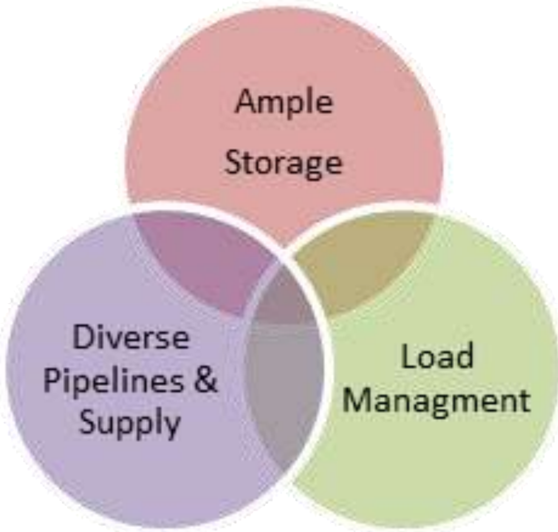
The risk of prolonged service interruptions to major distribution pipelines is almost exclusively limited to single feed gas lines at major water crossings where the line is inaccessible or otherwise extremely difficult to repair. Interruptions of this kind present a unique resiliency risk to the system. As such, FEI is examining options to improve resiliency at select points of the distribution systems, including at the Ironworkers Memorial Bridge in the Lower Mainland and at Okanagan Lake (between Kelowna and West Kelowna).

A single NPS 24 IP pipeline located on the Ironworkers Memorial Bridge provides the only gas supply to more than 45,000 customers in North Vancouver and West Vancouver. Loss of this crossing would result is an extensive outage for these customers. Similarly, in the Southern Interior region of the province, West Kelowna is supplied by a single NPS 8 IP pipeline that crosses Okanagan Lake between Kelowna and West Kelowna. While the system may require capacity upgrades later in the forecast period that could entail looping the lake crossing, this would only address capacity constraints and would not necessarily improve the resiliency of the distribution system. Therefore, FEI is in the process of studying alternatives for the crossing that would improve the resiliency of supply to West Kelowna, Summerland and Peachland.

Other than the communities mentioned above, there are few similar water crossings in FEI's distribution system where large numbers of customers remain at risk of extended supply outages because of crossing failures and a lack of redundant supply.

4. TRANSMISSION SYSTEM RESILIENCY

In the sections below, FEI discusses its approaches to addressing the three elements contributing to FEI's transmission system resiliency, namely balancing the need for: (1) diverse pipelines and supply; (2) ample on-system storage and (3) load management capabilities. For ease of reference, Figure E-2 from Section 2.3 is reproduced below.



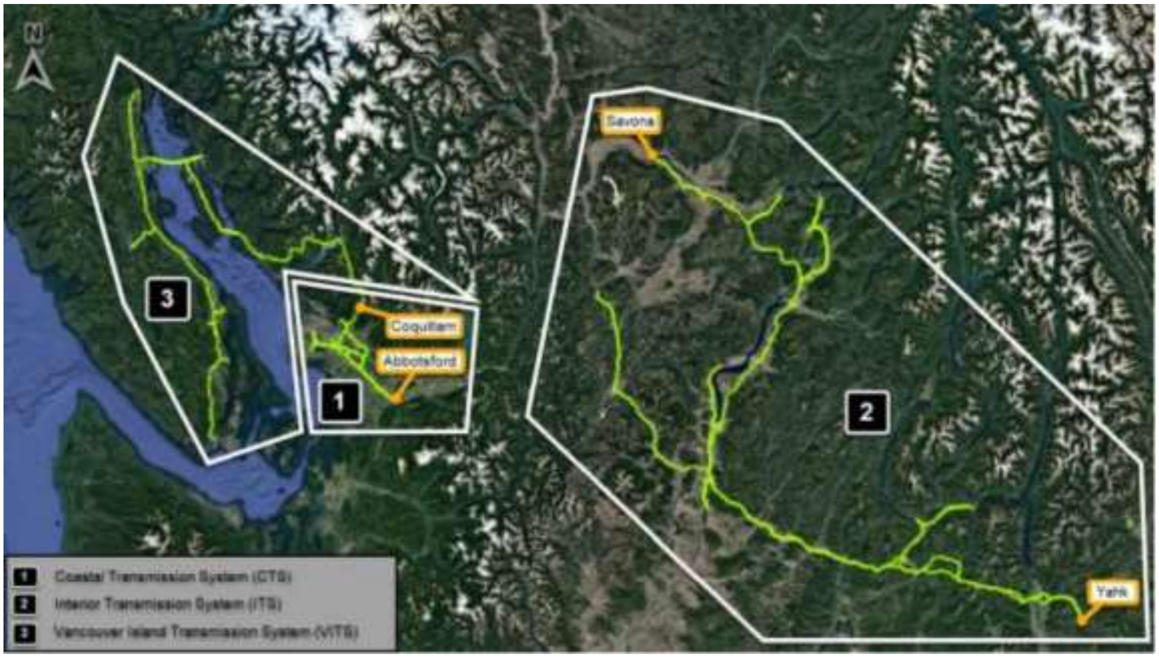
FEI then outlines the continued risk of supply disruption associated with its continued reliance on the T-South system and proposed medium and long-term resiliency enhancements.

4.1 FEI'S EXISTING PIPELINES AND ACCESS TO SUPPLY

FEI's transmission pipeline infrastructure is integral to its ability to deliver safe and reliable service to customers. In this section, FEI provides an overview of its existing transmission systems, explains the redundancy incorporated at the transmission level to date, and identifies the limitations of regional pipeline infrastructure in the province which directly impacts the gas system's overall resiliency.

Figure E-4 below shows a high-level layout of FEI's systems across the province and the Westcoast T-South system, from which FEI currently obtains the majority of its gas supply.

Figure E-4: FEI Transmission System Layout



FEI provides an overview of each of FEI's three major transmission systems below:

1. **Coastal Transmission System (CTS)**

   The CTS supplies gas to the Lower Mainland, Sunshine Coast and Vancouver Island. The CTS receives natural gas in Abbotsford and distributes it west. Construction of the CTS began in the 1950s and expansion continues today.

2. **Interior Transmission System (ITS)**

   The ITS supplies gas to the Okanagan, Kootenays, and portions of the Thompson. Natural gas is received by the ITS at two points: (1) from Savona and distributed east, and (2) from Yahk and distributed west. Construction of the ITS began in the 1950s and expansion continues today.

3. **Vancouver Island Transmission System (VITS)**

   The VITS supplies gas to the Sunshine Coast and Vancouver Island. Natural gas from the CTS is initially compressed at Coquitlam and sent to the Sunshine Coast and Vancouver Island. The VITS contains several marine crossings. Construction of the VITS began in the 1990s and expansion continues today.

Other communities in the province are served by transmission laterals supplied from other upstream pipelines, including TC Energy pipelines in the East Kootenay and Enbridge pipelines in the north and central interior.

4.1.1 FEI's Transmission System Incorporates Pipeline Redundancy

Before addressing access to upstream supply, FEI first observes that building system redundancy is a key means of improving resiliency. While redundancy may not increase reliability performance in any given year, it nonetheless enables the utility to withstand system failures and unforeseen events and prevent disruptions to gas supply when such events occur.

Redundancy can take the form of, for instance, redundant technology controlling a piece of infrastructure, excess capacity through larger sizing of a piece of infrastructure (e.g., a larger storage tank to supply more load if a pipeline fails), or duplicate infrastructure that can support loads in the event of one failing (e.g., two transmission lines or two pipelines to a source of supply).

FEI's transmission system has a degree of resiliency due to the redundancy incorporated into its design. This redundancy has been incorporated as the need arose for additional system capacity to supply customers during peak load periods. Below, FEI provides examples of redundancy incorporated into each of its three transmission systems:

Coastal Transmission System:

FEI has maintained or enhanced system resiliency on the CTS where it can be achieved cost-effectively.

First, while the CTS is configured to serve the northwest portion of the Lower Mainland from the south or the east (Fraser or Coquitlam Gate Stations respectively), the two pipelines do not provide full redundancy to the entire Lower Mainland. Further, natural gas flowing on both lines ultimately comes from the same source (the Westcoast T-South system). However, with the completion of the LMIPSU project, either of the CTS pipelines can provide supply to customers in the Vancouver, Burnaby, Coquitlam and North Shore areas in the event that flows on one of the branch lines is disrupted. In other words, the supply from either the Coquitlam or the Fraser Gate Station can independently support all downstream customers in all but the most extreme weather conditions. As described in Section 3.1.1.2 above, some of this added resiliency will be lost when the PGR project enters service and the existing Pattullo Bridge crossing pipeline is decommissioned in 2023.

FEI has also looped[9] various segments of the CTS to increase capacity.[10] While each of these projects was undertaken to increase the available capacity at peak times, a secondary benefit is that they also allow one of the parallel pipeline sections to be removed from service during light-load periods if required for maintenance, inspection, or repair.

[9] Looping refers to the construction and operation of two or more gas lines in parallel with each other, typically in the same right of way.

[10] For example, FEI added an NPS 42 pipeline to the CTS in parallel with existing NPS 18 and NPS 30 pipelines in 1977 and 1992, and looped existing NPS 20 and NPS 24 pipelines with an NPS 36 pipeline during the Coastal Transmission System Upgrade project in 2017.

Interior Transmission System:

Several portions of the ITS, across the south of the province, are looped by the Southern Crossing Pipeline (SCP). In particular, looped transmission laterals serving the communities of Cranbrook, Kimberley, Sparwood, and Salmon Arm provide additional redundancy. The proposed Okanagan Capacity Upgrade (OCU) project would provide redundant pipelines in the portions of the ITS between Penticton and Kelowna. From the end of the proposed OCU project to Savona there remains a single NPS 12 pipeline serving the Thompson Okanagan region. Increased resiliency and supply diversity within the high-population centres in this region of the ITS could be accomplished through either extensive pipeline looping and compression or through a centrally-located LNG supply that could provide short-term supply (like that proposed by the TLSE project), as discussed in Section 7.5.1.2 of the LTGRP. Further, Section 7.3.3.4 of the LTGRP provides a high level summary of the options to improve the resiliency of this portion of the ITS.

Vancouver Island Transmission System:

On the VITS, all pipeline submarine crossings in the system between the mainland and Texada Island and between Texada Island and Vancouver Island are twinned for redundancy. Moreover, as explained below, the Mount Hayes LNG facility at Ladysmith, BC provides a redundant means of supplying Vancouver Island customers if supply from the Lower Mainland is interrupted for any reason.

4.1.2 Limitations of Existing Regional Pipeline Infrastructure

As described below, there are a number of limitations in the resiliency of existing regional pipeline infrastructure upstream of FEI's system. Market and other constraints have also impeded the development of new infrastructure that would otherwise have enhanced resiliency, both for the Pacific Northwest region and for FEI's gas system.

4.1.2.1 Pipeline Interconnectivity

Compared to other regions in North America, the gas system in British Columbia has a relatively low amount of interconnectedness, decreasing the inherent resiliency of the system. In particular, the system is highly dependent on a single midstream pipeline for supply and has minimal on- and off-system storage.

The Westcoast T-South and the TC Energy (collectively, Nova Gas Transmission, Foothills BC and Gas Transmission Northwest) transmission systems serving FEI and the broader Pacific Northwest region are predominantly located in north-south corridors with limited interconnectivity between them, as shown in Figure E-5 below.

Figure E-5: Regional Gas Infrastructure

Pipeline	Daily Deliverability[1] (MMcf/day)
Westcoast T-South (Huntingdon Delivery Area)[2]	1800
Westcoast T-South (BC Interior)	224
FortisBC ITS (Oliver North)	140
FortisBC SCP (Oliver to Kingsvale)	105
FortisBC SCP (Yahk to Oliver)	245
TC FoothillsBC	2930
Northwest Pipeline Gorge	534

Market Area Storage	Daily Deliverability (MMcf/day)	Storage Capacity (Bcf)
Jackson Prairie (JPS)	1161	25
Mist	637	19

On System Storage	Daily Deliverability (MMcf/day)	Storage Capacity (Bcf)
Mt. Hayes LNG	150	1.5
Tilbury LNG	150	1.35

1. Daily deliverability is the maximum amount of gas that can flow on the pipeline or the maximum amount of gas that can be withdrawn out of storage. It is important to note that the daily deliverability out of the market area storage is assuming storage inventories are full. These resources do have withdrawal rates decline as working gas volumes decline.

2. Including 105 MMcf/day T-South Kingsvale to Huntingdon capacity.

The Westcoast T-South system consists of two looped gas transmission pipelines operating as a single system. The T-South system connects production fields in northeast BC with the Lower Mainland (Huntingdon) and Williams Northwest Pipeline (NWP) at Sumas, Washington. The T-South system flows north to south and runs approximately 916 km between Station 2 and Huntingdon. The two pipelines comprising the system are tied together by common headers and compressor stations and hence are operated as a single pipeline.

There is currently limited connectivity between the two north-south pipeline systems in BC (T-South and TC Energy), as illustrated in Figure E-5 above. FEI sources a small portion of supply from the TC Energy system in southeast BC, which is transported east to west through FEI's SCP to serve the various communities in the interior of BC. Approximately 105 MMcf/day of east to west connectivity from SCP can also be utilized to provide gas supply to customers in the Lower Mainland, via FEI's interconnection with the T-South system at Kingsvale. The SCP pipeline system has limited capacity at this time, and also relies on a 172 km segment of the T-South system (Kingsvale to Huntingdon) to deliver gas to the Lower Mainland. The FEI coastal demand centre makes up the vast majority of the FEI load and also precludes any system reinforcement other than from the northeast, east or south. This places a constraint on how much FEI is able to diversify its sourcing of gas supply away from northeast BC, so as to reduce its reliance on the T-North[11] and T-South systems.

4.1.2.2 High Cost of Development

The high costs associated with underwriting regional pipeline capacity is another reason why there has been limited new pipeline infrastructure in the region over the past several decades. To underwrite the cost of the new pipeline infrastructure generally requires broad regional support, backed by firm transportation contracts.

Historically, the regional market and regulatory model have not supported the construction of pipelines to add redundancy for reliability and/or resiliency. Rather, it has led to assets being constructed to meet the size and shape of the load in the region. The load profile in the region is significantly higher in the winter months than in the summer months, and therefore, has a low load factor. Shaping resources to match the load profile is generally the primary factor in regional gas infrastructure development given the high reliability of pipeline resources.

Furthermore, while the cost and regulatory requirements mean that regional cooperation is required for major pipeline infrastructure, it has historically been a challenge for regional shippers, such as utilities along the I-5 corridor, to agree on what the region requires to meet future load growth. This challenge, along with the difficulties in justifying the high cost of pipelines that are not utilized 365 days a year, has inhibited pipeline development in the region.

As a result of these challenges, the region has relied on lower cost smaller scale expansions, specifically, through storage assets such as off-system storage (Jackson Prairie and Mist) or on-system utility infrastructure (i.e., FEI's Mt. Hayes LNG Facility). However, regional gas demand has continued to grow since the last pipeline expansion (the SCP in 2000), and as discussed in Section 5.3 below, additional pipeline infrastructure may now be appropriate from a demand perspective, which could also benefit system resiliency.[12]

4.2 FEI'S EXISTING ON-SYSTEM STORAGE

On-system storage has unique value from a resiliency perspective and is one of three key elements of a resilient gas system. In this section, FEI describes the utility's existing on-system LNG infrastructure, which is comprised of the Tilbury and Mt. Hayes LNG facilities.

On-system storage provides a controllable supply resource with a high expectation of deliverability. This type of storage enables a utility to inject supply directly into the load centre to avoid a pressure collapse of the system. FEI's ability to draw on on-system resources in the event

[11] FEI contracts T-North Capacity to transport gas supply to and from the Aitken Creek storage facility. Aitken Creek is currently connected to the T-North section of the WEI pipeline system, which is supplied from several major gas processing plants.

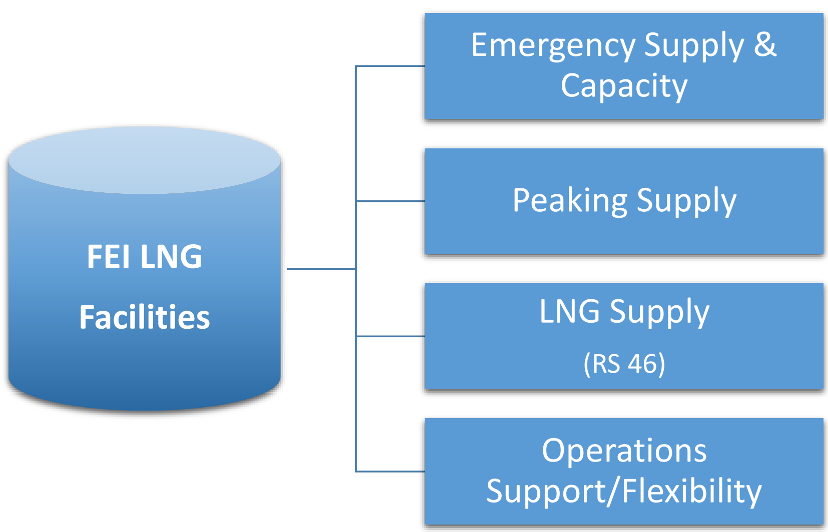
[12] Westcoast is currently constructing a small scale expansion on its T-South system (~100 MMcf/day of incremental capacity) and is planned to be placed in-service in 2021.

of a supply disruption does not depend on the physical or contractual availability of alternate pipeline capacity upstream of FEI's system. As such, on-system storage allows for additional response time until the flow of gas from pipelines can be partially or fully restored, or a new supply-demand balance can be achieved by shedding load.

Even once flows resume, pipeline capacity can remain constrained for long periods of time, and therefore, on-system storage remains important for managing typical peaking load events (e.g., cold weather). These events take on greater significance during the period that pipelines remain constrained.

As shown in Figure E-6 below, from a planning perspective, FEI's existing LNG facilities serve a number of beneficial purposes.

Figure E-6: Multiple Roles of FEI's LNG Facilities



These purposes are explained in further detail as follows:

- **Emergency Supply and Capacity** refers to the use of LNG to offset a supply shortfall and/or to provide additional capacity (via increasing pressure on the system) during a gas supply emergency;
- **Peaking Supply** refers to the use of LNG to provide supply during peak demand events due to cold weather. Similar to the above, LNG can provide additional capacity (by increasing pressure on the system) during a peaking event;
- **LNG Supply** refers to the use of LNG as a fuel source for transportation or remote energy use, such as FEI Rate Schedule (RS) 46 customers; and

- **Operations Support / Flexibility** refers to the use of LNG to support maintenance activities that may require specific flow conditions (i.e., in-line inspection) or temporary reductions in capacity.

FEI's on-system LNG inventory is managed on an integrated basis to provide these customer benefits. As part of its planning, FEI considers how much inventory may be needed for each function to ensure adequate resources are available to manage these events when they do occur.

4.2.1 Tilbury Base Plant

The Tilbury Base Plant was designed and built between 1969 and 1971 and has operated since commissioning with an excellent safety and reliability record. The facility was built to provide peaking supply, while also providing an important on-system capacity resource. The Tilbury Base Plant is strategically located providing on-system storage and gas supply support in the Lower Mainland load centre, and as such, it provides benefits related to security of supply, reliability and flexibility to serve loads within FEI's system. These are important benefits when mitigating temporary operational issues associated with FEI's pipeline infrastructure.

While the Tilbury Base Plant provides natural gas supply for short durations when demand during cold weather events exceeds contracted supply, it is not able to support the Lower Mainland demand in the event of a significant disruption in gas supply flowing to the Lower Mainland. The vapourization capacity at the Tilbury Base Plant (150 million cubic feet per day (MMcf/day)) is sufficient to serve 17 percent of the peak day requirements of FEI's RS 1 to 7 customers and RS 23 and 25 customers (i.e., firm rate schedule customers) in the Lower Mainland based on the 2019/2020 load forecast. As discussed in Section 5.2 below, the proposed TLSE Project would improve FEI's ability to withstand and manage its system through a significant supply emergency.

4.2.2 Mt. Hayes LNG Facility

The Mt. Hayes LNG facility also provides natural gas supply for short durations during cold weather events, but also provides a significant resiliency benefit to customers on Vancouver Island. This facility (which is much newer than the Tilbury Base Plant) is capable of serving the peak day load on Vancouver Island for approximately 10 days without relying on transmission support from the Lower Mainland. On low demand days on Vancouver Island, it is possible to physically flow gas from the Mt. Hayes LNG facility to the Lower Mainland by reverse flowing the VITS. However, this capability diminishes as Vancouver Island demand increases and is effectively zero during cold winter load periods. As such, the Mt. Hayes LNG facility could not also support the Lower Mainland to any significant extent.

4.3 *FEI'S EXISTING LOAD MANAGEMENT CAPABILITIES*

A key element that contributes to natural gas system resiliency is load management capabilities. Load management relates to the ability both to accurately assess the actual load across all parts of the gas system, and when necessary, to strategically reduce load on the gas system. Managing load helps to maintain the pressure on the system by restoring the balance of gas supply and demand in the event of a supply emergency. FEI currently has visibility of the overall load on the gas system; however, there is limited visibility regarding where the load is located within the system.

Similarly, controlled load shedding is partially within FEI's control today; however, FEI currently has no direct ability to remotely or automatically disconnect or otherwise curtail gas supply to customers. In the event of a sustained loss of gas supply, FEI is currently only able to respond by curtailing load in three ways: (1) directing interruptible customers to immediately disconnect from the system; (2) making public appeals for all customers to reduce their gas usage; and (3) shutting down major sections of the system with a single valve.

With FEI's current meter fleet, customers have to be manually disconnected from the system. Currently, the disconnection requires a field visit to each site which impedes FEI's ability to quickly implement load adjustments in emergency situations.

As discussed in Section 5.1 below, FEI has proposed investments in AMI in order to provide FEI with near real-time information about the total load on the overall system and detailed information about energy usage by individual customers. The utility would also be able to more accurately forecast the load on the system throughout the duration of the emergency to determine whether load shedding is required.

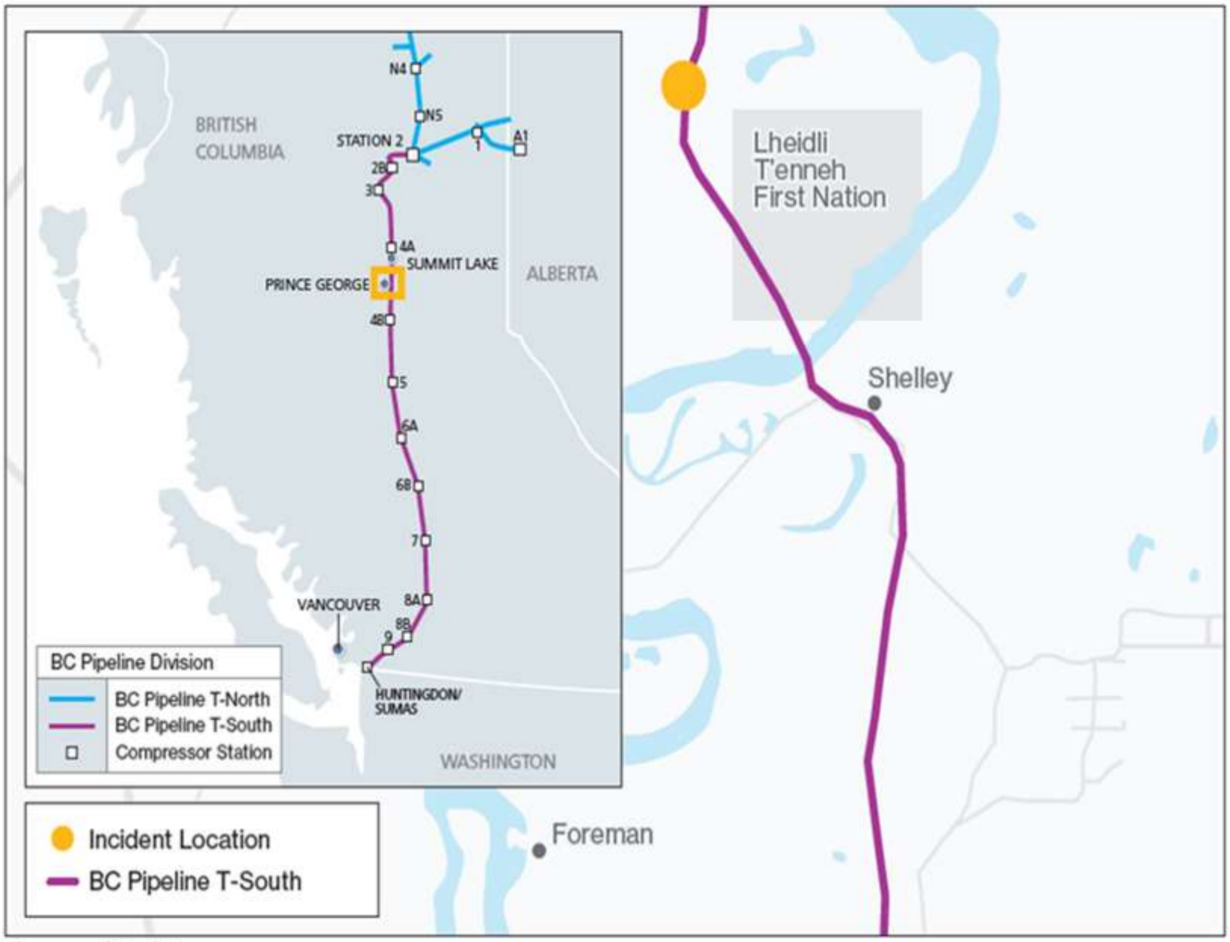
4.4 *RISK OF SUPPLY DISRUPTION DUE TO RELIANCE ON T-SOUTH SYSTEM*

FEI is dependent on the T-South system for approximately 85 percent of the gas entering its system. As discussed below, the pipeline rupture on the T-South system in 2018 highlighted the resiliency challenge posed by the extent of FEI's reliance on the T-South system – leaving FEI and its customers at risk of experiencing significant consequences resulting from a supply disruption.

4.4.1 2018 T-South Incident Underscored the Risks of Supply Interruption

On October 9, 2018, an NPS 36 natural gas pipeline forming part of the T-South system ruptured near Prince George, BC (the T-South Incident). The NPS 36 pipeline that ruptured shared the right-of-way with a second NPS 30 Westcoast pipeline. While only the NPS 36 pipeline had ruptured, the natural gas escaping from that pipeline had ignited and Westcoast shut down the adjacent NPS 30 pipeline as a precaution and monitored it to evaluate its condition. Figure E-7 below, shows the location of the gas pipeline rupture.

Figure E-7: Location of Rupture on the T-South Pipeline



Source: Enbridge

The T-South Incident underscored the value that additional resiliency in FEI's system would provide, as it resulted in a complete loss of gas supply from the two T-South pipelines. FEI's system was at risk of pressure collapse for a period of approximately 48 hours, and that outcome was narrowly avoided as a result of FEI's efforts and due to mild weather that had reduced heating load in the broader Pacific Northwest region, thereby allowing some gas to physically flow northwards across the border.[13]

The T-South Incident can be broken-down into three phases.

- **Phase 1:** This phase refers to the events that occurred in the 48 hours immediately following the rupture of the NPS 36 pipeline where gas supply on the T-South system was restricted to zero. In particular, on October 10, 2018, Westcoast issued a *force majeure* notice indicating that service was interrupted as a result of the rupture of the NPS 36

[13] As described later, there are normally physical constraints on the ability of gas to flow northwards during periods of higher demand in Washington and Oregon.

pipeline, and that flow was restricted to zero on all delivery points on the T-South system between Compressor Station 4B and Huntingdon.

- **Phase 2:** This phase refers to the period following the first phase where gas supply remained constrained, with the zero supply period in Phase 1 ending on October 11, 2018. Westcoast returned the NPS 30 pipeline to service, ramping the NPS 30 pipeline up to 80 percent of its 60 day high pressure prior to the incident, as permitted by the Canada Energy Regulator (CER)[14] order (restoring overall T-South system capacity to approximately 50 percent of firm capacity). Phase 2 concluded with the return to service of the ruptured NPS 36 pipeline on November 1, 2018, at a reduced capacity.
- **Phase 3:** The third phase refers to the 56 week period following the second phase, where the NPS 36 was returned to service. Capacity restrictions remained in place on the T-South system until Westcoast lifted its *force majeure* on December 2, 2019.[15] Given that the T-South to Huntingdon pipeline segment is normally fully utilized during the winter by customers along the I-5 corridor, the risk of a gas supply shortage persisted throughout the 2018/19 winter, not just for FEI and its customers, but for the region as a whole.

While FEI and the utilities along the I-5 corridor were able to manage through the T-South Incident and its aftermath, the incident resulted in higher gas supply costs for all market participants.

4.4.2 The Potential for Supply Interruption on the T-South System Remains

The T-South Incident highlighted that, although supply emergencies are rare, they do occur. The T-South Incident supported a re-examination of the resiliency of FEI's system, and the regional system as a whole. FEI's assessment demonstrated that:

- Additional regional pipeline infrastructure, if alternative pipeline routes can be developed, could add resiliency by reducing FEI's reliance on the T-South system;
- FEI should evaluate the potential to construct more on-system storage resources, which is a tool that can be used to prevent impacts to customers in the period immediately following a severe supply constraint or a "no-flow" event; and
- New tools to facilitate load shedding in a controlled and flexible fashion, a benefit associated with AMI, would complement on-system storage to mitigate the impacts of an outage on customers and society.

In the next section, FEI discusses the work it is currently undertaking to enhance overall system resiliency.

[14] At that time, the Canada Energy Regulator (CER) was referred to as the National Energy Board (NEB).

[15] During the Phase 3 period, the CER allowed Westcoast to increase the restricted operating pressure of the NPS 36 pipeline from 80 percent to 85 percent, and then to 88 percent of the previous 60 day high pressure by pipeline segment.

5. ENHANCING THE RESILIENCY OF THE TRANSMISSION SYSTEM CONTRIBUTES TO OVERALL SYSTEM RESILIENCY

FEI's portfolio of resiliency measures dovetails with the efficient supply portfolio outlined in its Annual Contracting Plans (ACPs), so as to avoid driving inefficient supply decisions that could be detrimental to ratepayers. FEI has effectively managed to the objectives of its ACPs in order to build an optimal gas supply portfolio.

However, and importantly, in addition to acquiring contractual rights to supply, resiliency requires backing by physical assets. This is a critically important concept. No amount of contracted supply from off-system sources, or offers of mutual aid from neighbouring utilities, will assist unless the physical infrastructure required to get the supply to the utility's own system is in place. FEI's resiliency needs are ultimately influenced by its physical location within the broader regional pipeline system, as well as customer load and composition.

In the preceding sections, FEI provided an overview of its existing resiliency solutions forming part of FEI's distribution and transmission systems and identified potential areas where resiliency-related risks remain. In this section, FEI provides the solutions it has identified to enhance the resiliency of the overall gas system. At a high-level, FEI has proposed the following enhancements:

- The adoption and implementation of automated meter reading processes, which addresses the need for better load management capabilities, through the AMI project.
- Expansion of FEI's on-system LNG storage, which ensures ample energy storage and provides immediate response capabilities to preserve the system during a critical supply emergency, through the TLSE project;
- The addition of new regional pipeline infrastructure, preferably constructed in a corridor different from the T-South system, in order to ensure supply is available during an event that involves a sustained loss of pipeline capacity, potentially through the RGSD project; and

From a resiliency portfolio perspective, on-system storage and new pipeline infrastructure are complementary assets to the supply portfolio as each separately addresses short-duration and long-duration supply issues in a cost effective manner;

Each of these proposed resiliency enhancing projects and approaches are discussed in further detail below.

5.1 *ADVANCED METERING INFRASTRUCTURE PROJECT*

On May 5, 2021, FEI filed a CPCN Application with the BCUC to implement an AMI network on its system. The purpose of this project is to deliver improved information about natural gas consumption and pipeline conditions to FEI and its customers. Importantly, the implementation of

AMI will also improve FEI's ability to manage load on its system in the event of an emergency – one of the three key elements of a resilient system. Following receipt of a BCUC decision to proceed with the project, FEI will begin AMI deployment in 2023 with final project completion anticipated in 2027.

The AMI project will involve the replacement of approximately one million existing residential and commercial customer meters with advanced meters, the associated infrastructure to support delivery of hourly metering information from the advanced meters at customer premises back to FEI. This would include the installation of communicating sensors on pipeline assets, some that would provide more complete indication of system pressure across FEI's distribution systems. Further, FEI will complete the installation of the approximately 700,000 remaining by-pass valves in order to avoid future interruption of gas service for meter-set maintenance activities at each premise and will replace gas regulators that are near end of life.

While the AMI project is primarily driven by the need to address the declining viability of manual meter reading, from a resiliency standpoint, the AMI system would significantly improve FEI's ability to manage system load during an extended loss of supply. In particular, AMI will provide FEI with more granular information regarding the demand on its system in the event of an extended loss of natural gas supply. Moreover, the remote shut-off valve in the AMI meter will enable FEI to strategically shut off gas to selected customers based on their gas usage and need, rather than solely based on their proximity to an isolated section of pipeline. These improvements will ultimately help FEI to keep the natural gas system pressurized, thereby reducing recovery time for customers that experience service interruption.

5.2 TILBURY LNG STORAGE EXPANSION PROJECT

On December 29, 2020, FEI filed a CPCN Application to add additional storage and vaporization capabilities at the existing Tilbury LNG facility, while also replacing FEI's 50-year old Tilbury Base Plant. This project is primarily a resiliency investment that will significantly improve FEI's ability to maintain continuity of service in the event of a disruption in the supply of natural gas to FEI's system, while also providing valuable ancillary benefits for system operations and customers.

The Tilbury facility will continue to serve supply requirements in the way it has done for the past 50 years, while also improve FEI's ability to withstand and manage its system through a significant supply emergency like phase 1 of the T-South Incident (discussed in Section 4.1.4 above). If approved by the BCUC, FEI plans to initiate the execution phase for the project in 2023, which would result in Project completion occurring in 2026.

As it stands, the Tilbury Base Plant provides peaking supply for FEI's core customers, as well as emergency supply to the system as a whole. However, it was designed in the late 1960s primarily as a winter peaking facility, and as such, its capability to provide emergency supply is limited.[16]

[16] In particular, the facility can only provide a fraction of the gas (approximately 17 percent) required to serve the peak demand of Firm Rate Schedule customers in the Lower Mainland.

Similarly, storage capacity at the Tilbury Base Plant is equivalent to less than one day of the Lower Mainland peak demand. In practical terms, this means that FEI would need to shed a significant portion of its load within the initial hours following an emergency event preventing natural gas from entering FEI's system during winter-time in order to mitigate the risk system collapse.

There are significant resiliency benefits that will come with increasing the storage and vapourization capacity at the Tilbury facility. In particular, the proposed project will allow FEI to withstand, and recover from, a 3-day "no-flow" event[17] on the T-South system, without having to shut down portions of FEI's distribution system or lose significant firm load.

5.3 REGIONAL GAS SUPPLY DIVERSITY (RGSD) SOLUTION

In this section, FEI discusses its consideration to augment the resiliency of the system by addressing the final element a resilient system – pipeline diversity – which necessarily involves a longer timeline (5+ years). Pipeline operators, including FEI, are exploring infrastructure options that will facilitate load growth opportunities and provide much needed gas supply resiliency to the region. Overall, any new pipeline infrastructure provides benefits to the region as a whole. However, certain projects will provide greater benefits for some shippers, depending on its proposed pipeline route.

The RGSD project would involve an expansion of the SCP, including constructing a new pipeline connecting the SCP (near Oliver, BC) to the Huntingdon/Sumas market and adding compressor stations along the SCP. At this time, this is the preferred option for FEI, as the project creates a flow path separate from the existing T-South system. Further, it would allow FEI to split the optimal amount of pipeline capacity between T-South and RGSD, thereby reducing FEI's current heavy dependence on the T-South system).

The RGSD project would also be able to mitigate the risk of a no-flow event during low demand (i.e., summer) periods, as well as help address the risks of a prolonged supply disruption similar to Phases 2 and 3 of the T-South Incident. Therefore, the project would diversity FEI's gas supply using a separate and distinct pipeline path, and supply sourcing from a different basin and market hub.

As discussed in the LTRGP, FEI believes that it is in the best interest of FEI and its customers to influence which regional pipeline infrastructure gets built, thus maximizing the value obtained from it. FEI is filing an application requesting approval of a deferral account to capture the costs of advancing the development or the RGSD project in Q2 2022. The application will demonstrate that there is a clear need for new pipeline infrastructure in the region and why FEI must continue to develop the RGSD project, while evaluating other potential pipeline expansion options, in order

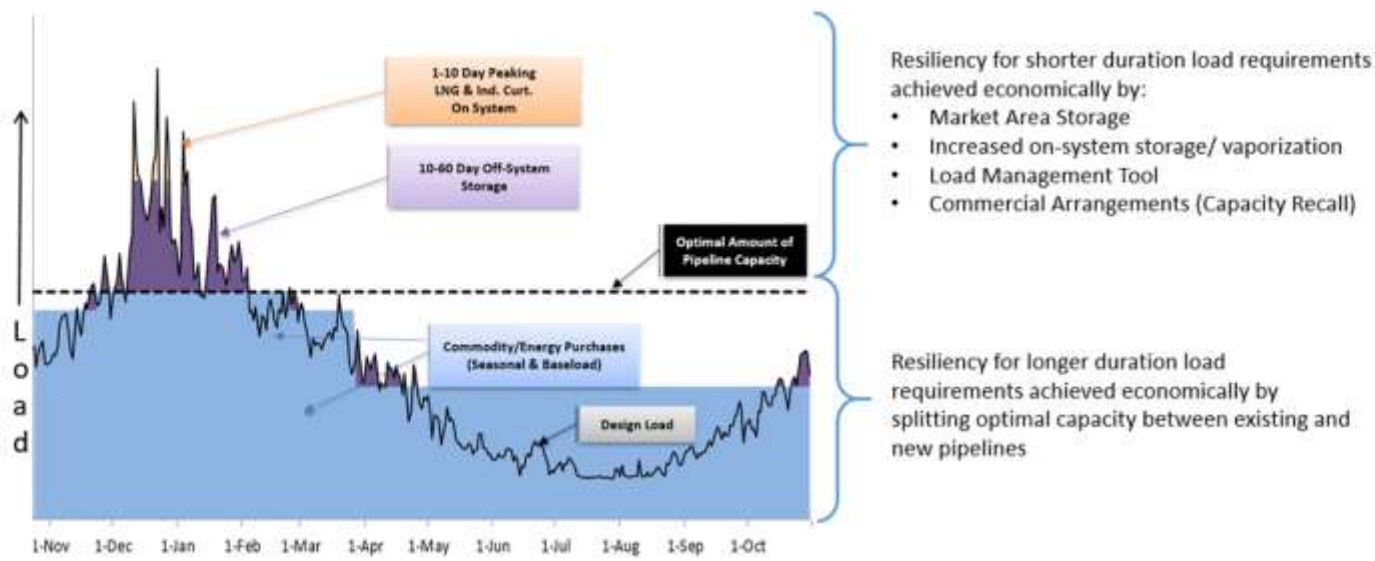
[17] FEI uses "no-flow event" to refer to an incident affecting regional pipeline infrastructure that results in the total interruption of gas flows on the pipeline. Similarly, the "no-flow" period is the period following the event that results in a total interruption of gas flows from that pipeline.

to address market conditions, reduce resiliency risks for FEI customers, and provide additional benefits.[18]

5.4 FEI'S PORTFOLIO APPROACH TO TRANSMISSION RESILIENCY

From a resiliency perspective, on-system storage and new pipeline infrastructure are complementary assets to the supply portfolio as each separately addresses short-duration and long-duration supply issues in a cost effective manner. Neither is a substitute for the other. For instance, the TLSE project will be the most cost-effective resource to respond immediately to withstand a short-term critical emergency that disrupts supply to FEI's Lower Mainland system, such as in phase 1 of the T-South Incident.[19] While FEI's ability to rely on the TLSE project in the event of a supply disruption does not depend on the physical or contractual availability of alternate pipeline capacity upstream of FEI's system, the TLSE project has limitations in addressing long-term capacity shortfalls or duration issues, as experienced during phases 2 and 3 of the T-South Incident. The RGSD project would help manage a long-duration supply disruption while also meeting the commercial needs of the region. Figure E-8 below illustrates how diverse pipeline capacity can be used efficiently, in combination with expanded peaking resources like on-system LNG storage, to build resiliency.

Figure E-8: Resiliency Measures Should Reflect Optimal ACP Supply Portfolio



If FEI proposed enhancing supply resiliency in the Lower Mainland with RGSD only, the pipeline would need to be sized to provide full replacement capacity for T-South if that system was not available for any reason. While building a new pipeline of this size may be technically possible, this would not be a cost-effective option for customers. It would come at a higher cost than FEI's

[18] FEI anticipates filing the RGSD development cost deferral account application in May 2022.
[19] Appendix E - Gas System Resiliency Plan.

portfolio approach to resiliency, given that FEI would need to hold excess total capacity on both pipelines (to ensure that full supply could be maintained in the event of an interruption on either the T-South or RGSD pipelines). This would result in FEI's customers paying demand charges for capacity on two pipelines with a significant portion going unused.

Moreover, the size of a pipeline expansion into the region would depend on potential interest from third-party shippers. Although the market requires additional pipeline capacity to satisfy growing gas demand, diversify market access especially during the winter, and provide much-needed gas supply resiliency to the region, at this time FEI does not believe there is enough support from third-party shippers to build a pipeline of that capacity (i.e., 800 MMcf per day[20]).

For the above reasons, the optimal solution is to balance the benefits and costs of additional and strategically located pipeline capacity with the benefits and costs of on-system storage located near the load centre. The optimal solution is therefore combining the benefits of the RGSD project with those of the TLSE project to cost-effectively provide broader resiliency benefits and improved flexibility to meet a range of potential supply disruptions and growing demand while also enabling the transition to renewable and low-carbon gas supplies.

[20] The TLSE Application determined 800 MMcf per day was required to meet FEI's Minimum Resiliency Planning Objective (MRPO). FEI's MRPO is a short-duration objective developed in consideration of FEI's operating experience, including its experience during the T-South Incident and the challenges that it experienced in maintaining service to customers during that time. The MRPO sets out FEI's objective to ensure that Lower Mainland system has the ability to withstand and recover from a three-day no-flow event on the T-South system without having to shut down portions of FEI's distribution system and thus avoid the loss of significant firm load.

6. CONCLUSION

In this appendix, FEI has discussed its overall approach to system resiliency, including how resiliency builds upon the foundations of system integrity and reliable infrastructure. It also described the three elements which contribute to system resiliency, namely: diverse pipelines and supply; load management capabilities; and ample on-system storage. As it stands, FEI is pursuing two major projects which will each contribute to increased system resiliency, the AMI project (which amongst other things will provide FEI with the ability to manage load at individual customer premises) and the TLSE project (which will add storage within the Lower Mainland region to allow the system to withstand a T-South no-flow event), and exploring one further project, the RGSD project (which would increase regional pipeline diversity). Finally, FEI intends to further develop its resiliency criteria for the distribution system, which it intends to include in a subsequent resource plan.

United Nations

UNITED NATIONS DECLARATION ON THE RIGHTS OF INDIGENOUS PEOPLES

United Nations

Resolution adopted by the General Assembly on 13 September 2007

[without reference to a Main Committee (A/61/L.67 and Add.1)]

61/295. United Nations Declaration on the Rights of Indigenous Peoples

The General Assembly,

Taking note of the recommendation of the Human Rights Council contained in its resolution 1/2 of 29 June 2006[1], by which the Council adopted the text of the United Nations Declaration on the Rights of Indigenous Peoples,

Recalling its resolution 61/178 of 20 December 2006, by which it decided to defer consideration of and action on the Declaration to allow time for further consultations thereon, and also decided to conclude its consideration before the end of the sixty-first session of the General Assembly,

1 See Official Records of the General Assembly, Sixty-first Session, Supplement No. 53 (A/61/53), part one, chap. II, sect. A.

Adopts the United Nations Declaration on the Rights of Indigenous Peoples as contained in the annex to the present resolution.

107th plenary meeting
13 September 2007

Annex

United Nations Declaration on the Rights of Indigenous Peoples

The General Assembly,

Guided by the purposes and principles of the Charter of the United Nations, and good faith in the fulfilment of the obligations assumed by States in accordance with the Charter,

Affirming that indigenous peoples are equal to all other peoples, while recognizing the right of all peoples to be different, to consider themselves different, and to be respected as such,

Affirming also that all peoples contribute to the diversity and richness of civilizations and cultures, which constitute the common heritage of humankind, *Affirming* further that all doctrines, policies and practices based on or advocating superiority of peoples or individuals on the basis of national origin or racial, religious, ethnic or cultural differences are racist, scientifically false, legally invalid, morally condemnable and socially unjust,

Reaffirming that indigenous peoples, in the exercise of their rights, should be free from discrimination of any kind,

Concerned that indigenous peoples have suffered from historic injustices as a result of, inter alia, their colonization and dispossession of their lands, territories and resources, thus preventing them from exercising, in particular, their right to development in accordance with their own needs and interests,

Recognizing the urgent need to respect and promote the inherent rights of indigenous peoples which derive from their political, economic and social structures and from their cultures, spiritual traditions, histories and philosophies, especially their rights to their lands, territories and resources,

Recognizing also the urgent need to respect and promote the rights of indigenous peoples affirmed in treaties, agreements and other constructive arrangements with States,

Welcoming the fact that indigenous peoples are organizing themselves for political, economic, social and cultural enhancement and in order to bring to an end all forms of discrimination and oppression wherever they occur,

Convinced that control by indigenous peoples over developments affecting them and their lands, territories and resources will enable them to maintain and strengthen their institutions, cultures and traditions, and to promote their development in accordance with their aspirations and needs,

Recognizing that respect for indigenous knowledge, cultures and traditional practices contributes to sustainable and equitable development and proper management of the environment,

Emphasizing the contribution of the demilitarization of the lands and territories of indigenous peoples to peace, economic and social progress and development, understanding and friendly relations among nations and peoples of the world, *Recognizing* in particular the right of indigenous families and communities to retain shared responsibility for the upbringing, training, education and well-being of their children, consistent with the rights of the child,

Considering that the rights affirmed in treaties, agreements and other constructive arrangements between States and indigenous peoples are, in some situations, matters of international concern, interest, responsibility and character,

Considering also that treaties, agreements and other constructive arrangements, and the relationship they represent, are the basis for a strengthened partnership between indigenous peoples and States,

Acknowledging that the Charter of the United Nations, the International Covenant on Economic, Social and Cultural Rights[2] and the International Covenant on Civil and Political Rights,[2] as well as the Vienna Declaration and Programme of Action,[3] affirm the fundamental importance of the right to self-determination of all peoples, by

2 See resolution 2200 A (XXI), annex.

3 A/CONF.157/24 (Part I), chap. III.

virtue of which they freely determine their political status and freely pursue their economic, social and cultural development,

Bearing in mind that nothing in this Declaration may be used to deny any peoples their right to self-determination, exercised in conformity with international law,

Convinced that the recognition of the rights of indigenous peoples in this Declaration will enhance harmonious and cooperative relations between the State and indigenous peoples, based on principles of justice, democracy, respect for human rights, non-discrimination and good faith,

Encouraging States to comply with and effectively implement all their obligations as they apply to indigenous peoples under international instruments, in particular those related to human rights, in consultation and cooperation with the peoples concerned,

Emphasizing that the United Nations has an important and continuing role to play in promoting and protecting the rights of indigenous peoples, *Believing* that this Declaration is a further important step forward for the recognition, promotion and protection of the rights and freedoms of indigenous peoples and in the development of relevant activities of the United Nations system in this field,

Recognizing and reaffirming that indigenous individuals are entitled without discrimination to all human rights recognized in international law, and that indigenous peoples possess collective rights which are indispensable for their existence, well-being and integral development as peoples,

Recognizing that the situation of indigenous peoples varies from region to region and from country to country and that the significance of national and regional particularities and various historical and cultural backgrounds should be taken into consideration,

Solemnly proclaims the following United Nations Declaration on the Rights of Indigenous Peoples as a standard of achievement to be pursued in a spirit of partnership and mutual respect:

Article 1

Indigenous peoples have the right to the full enjoyment, as a collective or as individuals, of all human rights and fundamental freedoms as recognized in the Charter of the United Nations, the Universal Declaration of Human Rights[4] and international human rights law.

Article 2

Indigenous peoples and individuals are free and equal to all other peoples and individuals and have the right to be free from any kind of discrimination, in the exercise of their rights, in particular that based on their indigenous origin or identity.

Article 3

Indigenous peoples have the right to self-determination. By virtue of that right they freely determine their political status and freely pursue their economic, social and cultural development.

Article 4

Indigenous peoples, in exercising their right to self-determination, have the right to autonomy or self-government in matters relating to their internal and local affairs, as well as ways and means for financing their autonomous functions.

---

4 Resolution 217 A (III).

Article 5

Indigenous peoples have the right to maintain and strengthen their distinct political, legal, economic, social and cultural institutions, while retaining their right to participate fully, if they so choose, in the political, economic, social and cultural life of the State.

Article 6

Every indigenous individual has the right to a nationality.

Article 7

1. Indigenous individuals have the rights to life, physical and mental integrity, liberty and security of person.

2. Indigenous peoples have the collective right to live in freedom, peace and security as distinct peoples and shall not be subjected to any act of genocide or any other act of violence, including forcibly removing children of the group to another group.

Article 8

1. Indigenous peoples and individuals have the right not to be subjected to forced assimilation or destruction of their culture.

2. States shall provide effective mechanisms for prevention of, and redress for:

   (a) Any action which has the aim or effect of depriving them of their integrity as distinct peoples, or of their cultural values or ethnic identities;

   (b) Any action which has the aim or effect of dispossessing them of their lands, territories or resources;

   (c) Any form of forced population transfer which has the aim or effect of violating or undermining any of their rights;

   (d) Any form of forced assimilation or integration;

   (e) Any form of propaganda designed to promote or incite racial or ethnic discrimination directed against them.

Article 9

Indigenous peoples and individuals have the right to belong to an indigenous community or nation, in accordance with the traditions and customs of the community or nation concerned. No discrimination of any kind may arise from the exercise of such a right.

Article 10

Indigenous peoples shall not be forcibly removed from their lands or territories. No relocation shall take place without the free, prior and informed consent of the indigenous peoples concerned and after agreement on just and fair compensation and, where possible, with the option of return.

Article 11

1. Indigenous peoples have the right to practise and revitalize their cultural traditions and customs. This includes the right to maintain, protect and develop the past, present and future manifestations of their cultures, such as archaeological and historical sites, artefacts, designs, ceremonies, technologies and visual and performing arts and literature.

2. States shall provide redress through effective mechanisms, which may include restitution, developed in conjunction with indigenous peoples, with respect to their cultural, intellectual, religious and spiritual property taken without their free, prior and informed consent or in violation of their laws, traditions and customs.

Article 12

1. Indigenous peoples have the right to manifest, practise, develop and teach their spiritual and religious traditions, customs and ceremonies; the right to maintain, protect, and have access in privacy to their religious and cultural sites; the right to the use and control of their ceremonial objects; and the right to the repatriation of their human remains.

2. States shall seek to enable the access and/or repatriation of ceremonial objects and human remains in their possession through fair, transparent and effective mechanisms developed in conjunction with indigenous peoples concerned.

Article 13

1. Indigenous peoples have the right to revitalize, use, develop and transmit to future genera-

tions their histories, languages, oral traditions, philosophies, writing systems and literatures, and to designate and retain their own names for communities, places and persons.

2. States shall take effective measures to ensure that this right is protected and also to ensure that indigenous peoples can understand and be understood in political, legal and administrative proceedings, where necessary through the provision of interpretation or by other appropriate means.

Article 14

1. Indigenous peoples have the right to establish and control their educational systems and institutions providing education in their own languages, in a manner appropriate to their cultural methods of teaching and learning.

2. Indigenous individuals, particularly children, have the right to all levels and forms of education of the State without discrimination.

3. States shall, in conjunction with indigenous peoples, take effective measures, in order for indigenous individuals, particularly children, including

those living outside their communities, to have access, when possible, to an education in their own culture and provided in their own language.

Article 15

1. Indigenous peoples have the right to the dignity and diversity of their cultures, traditions, histories and aspirations which shall be appropriately reflected in education and public information.

2. States shall take effective measures, in consultation and cooperation with the indigenous peoples concerned, to combat prejudice and eliminate discrimination and to promote tolerance, understanding and good relations among indigenous peoples and all other segments of society.

Article 16

1. Indigenous peoples have the right to establish their own media in their own languages and to have access to all forms of non-indigenous media without discrimination.

2. States shall take effective measures to ensure that State-owned media duly reflect indigenous

cultural diversity. States, without prejudice to ensuring full freedom of expression, should encourage privately owned media to adequately reflect indigenous cultural diversity.

Article 17

1. Indigenous individuals and peoples have the right to enjoy fully all rights established under applicable international and domestic labour law.

2. States shall in consultation and cooperation with indigenous peoples take specific measures to protect indigenous children from economic exploitation and from performing any work that is likely to be hazardous or to interfere with the child's education, or to be harmful to the child's health or physical, mental, spiritual, moral or social development, taking into account their special vulnerability and the importance of education for their empowerment.

3. Indigenous individuals have the right not to be subjected to any discriminatory conditions of labour and, inter alia, employment or salary.

Article 18

Indigenous peoples have the right to participate in decision-making in matters which would affect their rights, through representatives chosen by themselves in accordance with their own procedures, as well as to maintain and develop their own indigenous decision-making institutions.

Article 19

States shall consult and cooperate in good faith with the indigenous peoples concerned through their own representative institutions in order to obtain their free, prior and informed consent before adopting and implementing legislative or administrative measures that may affect them.

Article 20

1. Indigenous peoples have the right to maintain and develop their political, economic and social systems or institutions, to be secure in the enjoyment of their own means of subsistence and development, and to engage freely in all their traditional and other economic activities.

2. Indigenous peoples deprived of their means of subsistence and development are entitled to just and fair redress.

Article 21

1. Indigenous peoples have the right, without discrimination, to the improvement of their economic and social conditions, including, inter alia, in the areas of education, employment, vocational training and retraining, housing, sanitation, health and social security.

2. States shall take effective measures and, where appropriate, special measures to ensure continuing improvement of their economic and social conditions. Particular attention shall be paid to the rights and special needs of indigenous elders, women, youth, children and persons with disabilities.

Article 22

1. Particular attention shall be paid to the rights and special needs of indigenous elders, women, youth, children and persons with disabilities in the implementation of this Declaration.

2. States shall take measures, in conjunction with indigenous peoples, to ensure that indigenous women and children enjoy the full protection and guarantees against all forms of violence and discrimination.

Article 23

Indigenous peoples have the right to determine and develop priorities and strategies for exercising their right to development. In particular, indigenous peoples have the right to be actively involved in developing and determining health, housing and other economic and social programmes affecting them and, as far as possible, to administer such programmes through their own institutions.

Article 24

1. Indigenous peoples have the right to their traditional medicines and to maintain their health practices, including the conservation of their vital medicinal plants, animals and minerals. Indigenous individuals also have the right to access, without any discrimination, to all social and health services.

2. Indigenous individuals have an equal right to the enjoyment of the highest attainable standard of physical and mental health. States shall take the necessary steps with a view to achieving progressively the full realization of this right.

Article 25

Indigenous peoples have the right to maintain and strengthen their distinctive spiritual relationship with their traditionally owned or otherwise occupied and used lands, territories, waters and coastal seas and other resources and to uphold their responsibilities to future generations in this regard.

Article 26

1. Indigenous peoples have the right to the lands, territories and resources which they have traditionally owned, occupied or otherwise used or acquired.

2. Indigenous peoples have the right to own, use, develop and control the lands, territories and resources that they possess by reason of traditional ownership or other traditional occupation or use, as well as those which they have otherwise acquired.

3. States shall give legal recognition and protection to these lands, territories and resources. Such recognition shall be conducted with due respect to the customs, traditions and land tenure systems of the indigenous peoples concerned.

Article 27

States shall establish and implement, in conjunction with indigenous peoples concerned, a fair, independent, impartial, open and transparent process, giving due recognition to indigenous peoples' laws, traditions, customs and land tenure systems, to recognize and adjudicate the rights of indigenous peoples pertaining to their lands, territories and resources, including those which were traditionally owned or otherwise occupied or used. Indigenous peoples shall have the right to participate in this process.

Article 28

1. Indigenous peoples have the right to redress, by means that can include restitution or, when this is not possible, just, fair and equitable compensation, for the lands, territories and resources which they have traditionally owned or otherwise occupied or used, and which have been confiscated, taken, occupied, used or damaged without their free, prior and informed consent.

2. Unless otherwise freely agreed upon by the peoples concerned, compensation shall take

the form of lands, territories and resources equal in quality, size and legal status or of monetary compensation or other appropriate redress.

Article 29

1. Indigenous peoples have the right to the conservation and protection of the environment and the productive capacity of their lands or territories and resources. States shall establish and implement assistance programmes for indigenous peoples for such conservation and protection, without discrimination.

2. States shall take effective measures to ensure that no storage or disposal of hazardous materials shall take place in the lands or territories of indigenous peoples without their free, prior and informed consent.

3. States shall also take effective measures to ensure, as needed, that programmes for monitoring, maintaining and restoring the health of indigenous peoples, as developed and implemented by the peoples affected by such materials, are duly implemented.

Article 30

1. Military activities shall not take place in the lands or territories of indigenous peoples, unless justified by a relevant public interest or otherwise freely agreed with or requested by the indigenous peoples concerned.

2. States shall undertake effective consultations with the indigenous peoples concerned, through appropriate procedures and in particular through their representative institutions, prior to using their lands or territories for military activities.

Article 31

1. Indigenous peoples have the right to maintain, control, protect and develop their cultural heritage, traditional knowledge and traditional cultural expressions, as well as the manifestations of their sciences, technologies and cultures, including human and genetic resources, seeds, medicines, knowledge of the properties of fauna and flora, oral traditions, literatures, designs, sports and traditional games and visual and performing arts. They also have the

right to maintain, control, protect and develop their intellectual property over such cultural heritage, traditional knowledge, and traditional cultural expressions.

2. In conjunction with indigenous peoples, States shall take effective measures to recognize and protect the exercise of these rights.

Article 32

1. Indigenous peoples have the right to determine and develop priorities and strategies for the development or use of their lands or territories and other resources.

2. States shall consult and cooperate in good faith with the indigenous peoples concerned through their own representative institutions in order to obtain their free and informed consent prior to the approval of any project affecting their lands or territories and other resources, particularly in connection with the development, utilization or exploitation of mineral, water or other resources.

3. States shall provide effective mechanisms for just and fair redress for any such activities, and

appropriate measures shall be taken to mitigate adverse environmental, economic, social, cultural or spiritual impact.

Article 33

1. Indigenous peoples have the right to determine their own identity or membership in accordance with their customs and traditions. This does not impair the right of indigenous individuals to obtain citizenship of the States in which they live.

2. Indigenous peoples have the right to determine the structures and to select the membership of their institutions in accordance with their own procedures.

Article 34

Indigenous peoples have the right to promote, develop and maintain their institutional structures and their distinctive customs, spirituality, traditions, procedures, practices and, in the cases where they exist, juridical systems or customs, in accordance with international human rights standards.

Article 35

Indigenous peoples have the right to determine the responsibilities of individuals to their communities.

Article 36

1. Indigenous peoples, in particular those divided by international borders, have the right to maintain and develop contacts, relations and cooperation, including activities for spiritual, cultural, political, economic and social purposes, with their own members as well as other peoples across borders.

2. States, in consultation and cooperation with indigenous peoples, shall take effective measures to facilitate the exercise and ensure the implementation of this right.

Article 37

1. Indigenous peoples have the right to the recognition, observance and enforcement of treaties, agreements and other constructive arrangements concluded with States or their successors and to have States honour and re-

spect such treaties, agreements and other constructive arrangements.

2. Nothing in this Declaration may be interpreted as diminishing or eliminating the rights of indigenous peoples contained in treaties, agreements and other constructive arrangements.

Article 38

States in consultation and cooperation with indigenous peoples, shall take the appropriate measures, including legislative measures, to achieve the ends of this Declaration.

Article 39

Indigenous peoples have the right to have access to financial and technical assistance from States and through international cooperation, for the enjoyment of the rights contained in this Declaration.

Article 40

Indigenous peoples have the right to access to and prompt decision through just and fair procedures for the resolution of conflicts and disputes with States or other parties, as well as to effective remedies for all infringements of their individual and collective rights. Such a decision shall give due consideration to the customs, traditions, rules and legal systems of the indigenous peoples concerned and international human rights.

Article 41

The organs and specialized agencies of the United Nations system and other intergovernmental organizations shall contribute to the full realization of the provisions of this Declaration through the mobilization, inter alia, of financial cooperation and technical assistance. Ways and means of ensuring participation of indigenous peoples on issues affecting them shall be established.

Article 42

The United Nations, its bodies, including the Permanent Forum on Indigenous Issues, and specialized agencies, including at the country level, and States shall promote respect for and full application of the provisions of this Declaration and follow up the effectiveness of this Declaration.

Article 43

The rights recognized herein constitute the minimum standards for the survival, dignity and well-being of the indigenous peoples of the world.

Article 44

All the rights and freedoms recognized herein are equally guaranteed to male and female indigenous individuals.

Article 45

Nothing in this Declaration may be construed as diminishing or extinguishing the rights indigenous peoples have now or may acquire in the future.

Article 46

1. Nothing in this Declaration may be interpreted as implying for any State, people, group or person any right to engage in any activity or to perform any act contrary to the Charter of the United Nations or construed as authorizing or encouraging any action which would dismem-

ber or impair, totally or in part, the territorial integrity or political unity of sovereign and independent States.

2. In the exercise of the rights enunciated in the present Declaration, human rights and fundamental freedoms of all shall be respected. The exercise of the rights set forth in this Declaration shall be subject only to such limitations as are determined by law and in accordance with international human rights obligations. Any such limitations shall be non-discriminatory and strictly necessary solely for the purpose of securing due recognition and respect for the rights and freedoms of others and for meeting the just and most compelling requirements of a democratic society.

3. The provisions set forth in this Declaration shall be interpreted in accordance with the principles of justice, democracy, respect for human rights, equality, non-discrimination, good governance and good faith.

Footnote(s)

1 Low-income cut-offs, before tax (LICO-BT) - The Low-income cut-offs, before tax refers to an income threshold, defined using 1992 expenditure data, below which economic families or persons not in economic families would likely have devoted a larger share of their total income than average to the necessities of food, shelter and clothing. More specifically, the thresholds represented income levels at which these families or persons were expected to spend 20 percentage points or more of their total income than average on food, shelter and clothing. These thresholds have been adjusted to current dollars using the all-items Consumer Price Index (CPI).

The LICO-BT has 35 cut-offs varying by seven family sizes and five different sizes of area of residence to account for economies of scale and potential differences in cost of living in communities of different sizes. These thresholds are presented in Table 4.4 Low-income cut-offs, before tax (LICO-BT - 1992 base) for economic families and persons not in economic families, 2015, Dictionary, Census of Population, 2016.

When the total income of an economic family member or a person not in an economic family falls below the threshold applicable to the person, the person is considered to be in low income according to LICO-BT. Since the LICO-BT threshold and family income are unique within each economic family, low-income status based on LICO-BT can also be reported for economic families.

2 Low-income status - The income situation of the statistical unit in relation to a specific low-income line in a reference year. Statistical units with income that is below the low-income line are considered to be in low income.

For the 2016 Census, the reference period is the calendar year 2015 for all income variables.

3 The low-income concepts are not applied in the territories and in certain areas based on census subdivision type (such as Indian reserves). The existence of substantial in-kind transfers (such as subsidized housing and First Nations band housing) and sizeable barter economies or consumption from own production (such as product from hunting, farming or fishing) could make the interpretation of low-income statistics more difficult in these situations.

4 Prevalence of low income - The proportion or percentage of units whose income falls below a specified low-income line.

Data quality note(s) – British Columbia / Colombie-Britannique

- **Incomplete enumeration flag**

Excludes census data for one or more incompletely enumerated Indian reserves or Indian settlements.

- **Short-form data quality flag**
  Global non-response rate (GNR), short-form census questionnaire: 4.9%.
- **Short-form income data quality flag**
  Default. Data quality index showing a short-form income non-response rate lower than 10%.

Liberal

Cap and Cut Emissions from Oil and Gas

Greenhouse gas emissions from the oil and gas sector have risen 20% since 2005 and now makes up 26% of Canada's total emissions, making it the largest emitting sector in the country.

Climate change isn't just an environmental issue, it's a competitiveness issue for the oil and gas sector. The climate science is clear and global investors are clear, the oil and gas sector must accelerate its efforts to get on a path to net-zero emissions.

That is why a re-elected Liberal Government will put in place a decisive plan to ensure the oil and gas sector reaches net-zero emissions by 2050.

A re-elected Liberal government will:

- Make sure the oil and gas sector reduces emissions at a pace and scale needed to achieve net-zero by 2050, with 5-year targets to stay on track to achieving this shared goal. And driving down pollution starts with ensuring that pollution from the oil and gas sector doesn't go up from current levels.

- Set 2025 and 2030 milestones based on the advice of the Net-Zero Advisory Body to ensure reduction levels are ambitious and achievable and that the oil and gas sector makes a meaningful contribution to meeting the nation's 2030 climate goals.

Fortunately, Canada's largest oil and gas companies are already committed to achieving net-zero emissions by 2050. These actions will incentivize clean innovation and the adoption of clean technologies, including carbon capture, utilization, and storage (CCUS).

PAN-CANADIAN FRAMEWORK on Clean Growth and Climate Change

Canada's Plan to Address Climate Change and Grow the Economy

FOREWORD

The Pan-Canadian Framework on Clean Growth and Climate Change presented here is our collective plan to grow our economy while reducing emissions and building resilience to adapt to a changing climate. It will help us transition to a strong, diverse and competitive economy; foster job creation, with new technologies and exports; and provide a healthy environment for our children and grandchildren.

The Pan-Canadian Framework is both a commitment to the world that Canada will do its part on climate change, and a plan to meet the needs of Canadians. We have built on the momentum of the Paris Agreement by developing a concrete plan which, when implemented, will allow us to achieve Canada's international commitments.

When First Ministers met last March in Vancouver, they agreed to take ambitious action in support of meeting or exceeding Canada's 2030 target of a 30 percent reduction below 2005 levels of greenhouse gas (GHG) emissions. First Ministers issued the Vancouver Declaration on Clean Growth and Climate Change and agreed that a collaborative approach between provincial, territorial, and federal governments is important to reduce GHG emissions and to enable sustainable economic growth.

The Pan-Canadian Framework builds on the leadership shown and actions taken individually and collectively by the provinces and territories, including through the Declaration of the Premiers adopted at the Quebec Summit on Climate Change in 2015. To note, the province of Saskatchewan has decided not to adopt the Pan-Canadian Framework at this time. The federal government has committed to ensuring that the provinces and territories have the flexibility to design their own policies and programs to meet emission-reductions targets, supported by federal investments in infrastructure, specific emission-reduction opportunities and clean technologies. This flexibility enables governments to move forward and to collaborate on shared priorities while respecting each jurisdiction's needs and plans, including the need to ensure the continued competitiveness and viability of businesses.

In the Paris Agreement, Parties agreed that they should, when taking action to address climate change, recognize and respect the rights of Indigenous Peoples. As we implement this Framework, we will move forward respecting the rights of Indigenous Peoples, with robust, meaningful engagement drawing on their Traditional Knowledge. We will take into account the unique circumstances and opportunities of Indigenous Peoples and northern, remote, and vulnerable communities. We acknowledge and thank Indigenous Peoples across Canada for their climate leadership long before the Paris Agreement and for being active drivers of positive change.

Pricing carbon pollution is central to this Framework. Carbon pricing will encourage innovation because businesses and households will seek out new ways to increase efficiencies and to pollute less. We will complement carbon pricing with actions to build the foundation of our low-carbon and resilient economy.

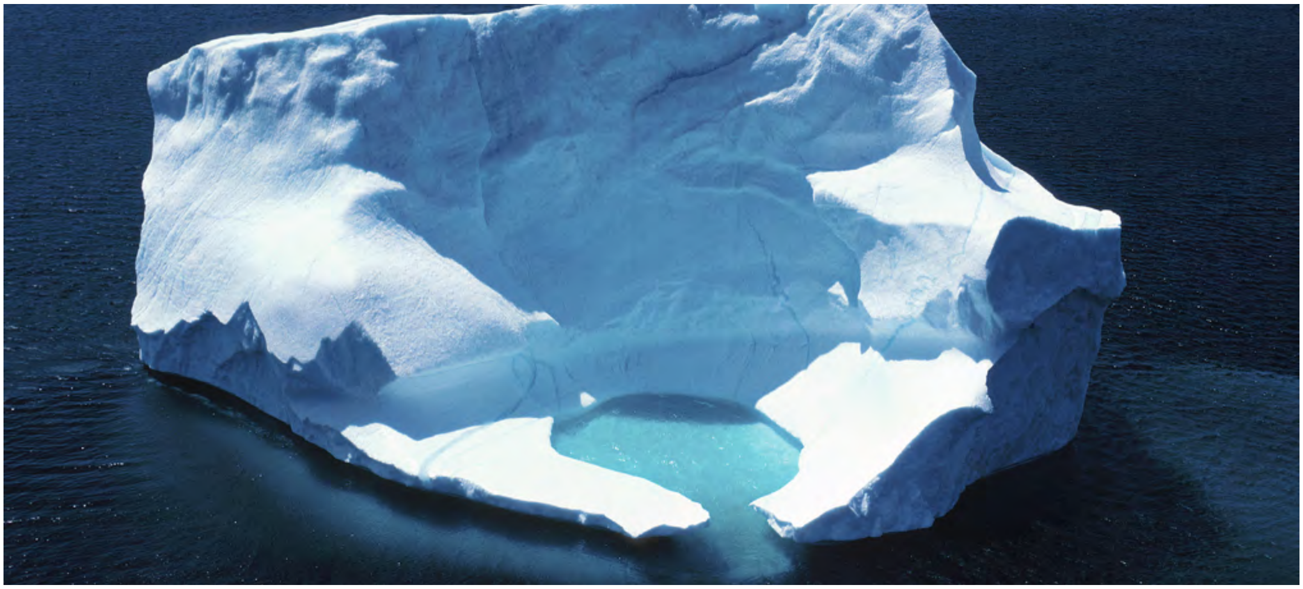
As Canada transitions to a low-carbon future, energy will play an integral role in meeting our collective commitment, given that energy production and use account for over 80 percent of Canada's GHG emissions. This means using clean energy to power our homes, workplaces, vehicles, and industries, and using energy more efficiently. It means convenient transportation systems that run on cleaner fuels, that move more people by public transit and zero-emission vehicles, and that have streamlined trade corridors. It means healthier and more comfortable homes that can generate as much power as they use. It means more resilient infrastructure and ecosystems that can better withstand climatic changes. It means land use and conservation measures that sequester carbon and foster adaptation to climate change. It means new jobs for Canadians across the country and opportunities for growth. It means leveraging technology and innovation to seize export and trade opportunities for Canada, which will allow us to become a leader in the global clean growth economy and will also help bring down the cost of low-emission technologies. It means healthier communities with cleaner air and healthy and diverse ecosystems across the country.

We will maintain a sustained focus on implementation of the Pan-Canadian Framework, consistent with the commitment under the Paris Agreement, to increase the level of ambition over time.

The Pan-Canadian Framework is a historic step in the transition to a clean growth and resilient economy. It is informed by what we have heard from Canadians. We will continue to grow our economy and create good jobs as we take ambitious action on climate change. We will work to ensure that the Pan-Canadian Framework opens new opportunities for Canadian businesses to not only maintain but also enhance their competitiveness. We will continue to engage Canadians to strengthen and deepen our action on clean growth and climate change. And we are committed to transparently assessing and reporting to Canadians on our progress.

Together, we have developed a Pan-Canadian Framework on Clean Growth and Climate Change. This is Canada's plan to address climate change and grow the clean economy.

TABLE OF CONTENTS



INTRODUCTION

In Canada and abroad, the impacts of climate change are becoming evident. Impacts such as coastal erosion; thawing permafrost; increases in heat waves, droughts and flooding; and risks to critical infrastructure and food security are already being felt in Canada. The science is clear that human activities are driving unprecedented changes in the Earth's climate, which pose significant risks to human health, security, and economic growth.

Taking strong action to address climate change is critical and urgent. The cost of inaction is greater than the cost of action: climate change could cost Canada $21-$43 billion per year by 2050, according to 2011 estimates from the National Round Table on the Environment and the Economy. Businesses and markets are increasingly considering climate risks. In recent years, severe weather events have cost Canadians billions of dollars, including in insured losses. Indigenous Peoples, northern and coastal regions and communities in Canada are particularly vulnerable and disproportionately affected. Geographic location, socio-economic challenges, and for Indigenous Peoples, the reliance on wild food sources, often converge with climate change to put pressure on these communities. Much has been done to begin addressing these challenges, including by Indigenous Peoples.

Acting on climate change will reduce risks and create new economic opportunities and good jobs for Canadians. There is already a global market for low-carbon goods and services worth over $5.8 trillion, which is projected to keep growing at a rate of 3 percent per year. Clean growth opportunities will benefit all sectors and regions. Canada will remain globally competitive through innovation, including through the development and promotion of innovative technologies with the potential to address climate change globally. This includes clean technology to enable the sustainable development of Canada's energy and resource sectors, including getting these resources to market, as Canada transitions to a low-carbon economy. Innovation can help further reduce emissions and the cost of taking action at home. Canadian technologies and solutions can also be exported abroad and deployed around the world, creating new markets and partners for Canadian businesses and supporting global action to reduce emissions.

The federal government will continue to work in close collaboration with other countries on climate solutions, including with partners across North America. A number of provinces and territories have already joined or are exploring entry into regional and international efforts to reduce GHG emissions.

Canadian municipalities will also continue to be important partners in developing and implementing climate solutions locally, as well as through international collaboration with other municipalities around the world.

The international community has agreed that tackling climate change is an urgent priority and also an historic opportunity to shift towards a global low-carbon economy. The adoption of the Paris Agreement in December 2015 was the culmination of years of negotiations under the United Nations Framework Convention on Climate Change. The Paris Agreement is a commitment to accelerate and intensify the actions and investments needed for a sustainable low-carbon future, to limit global average temperature rise to well below 2 °C above pre-industrial levels, and to pursue efforts to limit the increase to 1.5 °C. This will require taking action on long-lived GHGs such as carbon dioxide and short-lived climate pollutants such as methane, hydrofluorocarbons and black carbon.

As a first step towards implementing the commitments Canada made under the Paris Agreement, First Ministers released the Vancouver Declaration on Clean Growth and Climate Change on March 3, 2016.

1.1 How we developed the Framework

The development of the Pan-Canadian Framework was informed by input from Canadians across the country, who made it clear that they want to be part of the solution to climate change. Under the Vancouver Declaration, First Ministers asked four federal-provincial-territorial working groups to work with Indigenous Peoples; to consult with the public, businesses and civil society; and to present options to act on climate change and enable clean growth. The working groups heard solutions directly from Canadians, through an interactive website, in-person engagement sessions, and independent town halls.

Representatives of Indigenous Peoples contributed their knowledge and expectations for meaningful engagement in climate action and provided important considerations and recommendations either directly to working groups or to ministers, which helped shape this framework.

Ministers also reached out to Canadians, businesses, non-governmental organizations, and Indigenous Peoples to hear their priorities. In addition, ministerial tables were convened to provide their advice, including the Canadian Council of Ministers of the Environment, Ministers of Innovation, Ministers of Energy, and Ministers of Finance.

ENGAGING CANADIANS:
The Let's Talk Climate Action website was launched on April 22, 2016 to gather ideas and comments from Canadians about how Canada should address climate change. By the submission deadline of September 27, 2016, over 13,000 ideas and comments were received. In addition, consultations by governments and working groups on clean growth and climate change were held across Canada.

1.2 Pillars of the Framework

The Pan-Canadian Framework has four main pillars: pricing carbon pollution; complementary measures to further reduce emissions across the economy; measures to adapt to the impacts of climate change and build resilience; and actions to accelerate innovation, support clean technology, and create jobs. Together, these interrelated pillars form a comprehensive plan.

Pricing carbon pollution is an efficient way to reduce emissions, drive innovation, and encourage people and businesses to pollute less. However, relying on a carbon price alone to achieve Canada's international target would require a very high price.

Complementary climate actions can reduce emissions by addressing market barriers where pricing alone is insufficient or not timely enough to reduce emissions in the pre-2030 timeframe. For instance, tightening energy efficiency standards and codes for vehicles and buildings are common sense actions that reduce emissions, while also helping consumers save money by using less energy.

Canada is experiencing the impacts of climate change, so there is also a need to **adapt and build resilience**. This means making sure that our infrastructure and communities are adequately prepared for climate risks like floods, wildfires, droughts, and extreme weather events, including in particularly vulnerable regions like Indigenous, northern, coastal, and remote communities. This also means adapting to the impacts of changes in temperature, including thawing permafrost.

A low-carbon economy can and will be a strong and thriving economy. Taking action now, to position Canada as a global leader on clean technology innovation, will help ensure that Canada remains internationally competitive and will lead to the creation of new good jobs across the country. Investing in **clean technology, innovation, and jobs** will bring new and in-demand Canadian technologies to expanding global markets. These investments will help improve the efficiency and cost-effectiveness of mitigation and adaptation measures and will equip Canada's workforce with the knowledge and skills to succeed.

In implementing the Pan-Canadian Framework on Clean Growth and Climate Change, federal, provincial and territorial governments will review progress annually to assess the effectiveness of our collective actions and ensure continual improvement. First Ministers commit to **report regularly and transparently** to Canadians on progress towards GHG-reduction targets, on building climate resilience, and on growing a clean economy.

Our governments will continue to recognize, respect and safeguard the **rights of Indigenous Peoples** as we take actions under these pillars.

1.3 Elements of collaboration

The Pan-Canadian Framework reaffirms the principles outlined in the Vancouver Declaration, including

- recognizing the diversity of provincial and territorial economies and the need for fair and flexible approaches to ensure international competitiveness and a business environment that enables firms to capitalize on opportunities related to the transition to a low-carbon economy in each jurisdiction;
- recognizing that growing our economy and achieving our GHG-emissions targets will require an integrated, economy-wide approach that includes all sectors, creates jobs, and promotes innovation;
- recognizing that a collaborative approach between provincial, territorial, and federal governments is important to reduce GHG emissions and enable sustainable economic growth;
- recognizing that provinces and territories have been early leaders in the fight against climate change and have taken proactive steps, such as adopting carbon pricing mechanisms, placing caps on emissions, involvement in international partnerships with other states and regions, closing coal plants, carbon capture and storage projects, renewable energy production (including hydroelectric developments) and targets, and investments in energy efficiency;
- recognizing that the federal government has committed to ensuring that the provinces and territories have the flexibility to design their own policies to meet emission-reductions targets, including their own carbon pricing mechanisms, supported by federal investments in infrastructure, specific emission-reduction opportunities and clean technologies;
- recognizing the commitment of the federal government to work with provinces and territories to complement and support their actions without duplicating them, including by promoting innovation and enabling clean growth across all sectors;
- strengthening the collaboration between our governments and Indigenous Peoples on mitigation and adaptation actions, based on recognition of rights, respect, cooperation, and partnership;
- recognizing the importance of Traditional Knowledge in regard to understanding climate impacts and adaptation measures;

- recognizing that comprehensive adaptation efforts must complement ambitious mitigation measures to address unavoidable climate change impacts; and
- implementing a collaborative, science-based approach to inform Canada's future targets that will increase in stringency as required by the Paris Agreement.

Governments recognize the unique circumstances of the North, including disproportionate impacts from climate change and the associated challenges with food security, emerging economies and the high costs of living and of energy.

Federal, provincial, and territorial governments will work collaboratively to grow the economy, create good-paying and long-term jobs, and reduce GHG emissions in support of meeting or exceeding Canada's 2030 target. These actions will be supported by strong, complementary adaptation policies to build climate resilience. Indigenous Peoples will be important partners in developing real and meaningful outcomes that position them as drivers of climate action in the implementation of the Pan-Canadian Framework. All governments across Canada are committed to ambitious and sustained action on climate change, building on current actions and future opportunities.

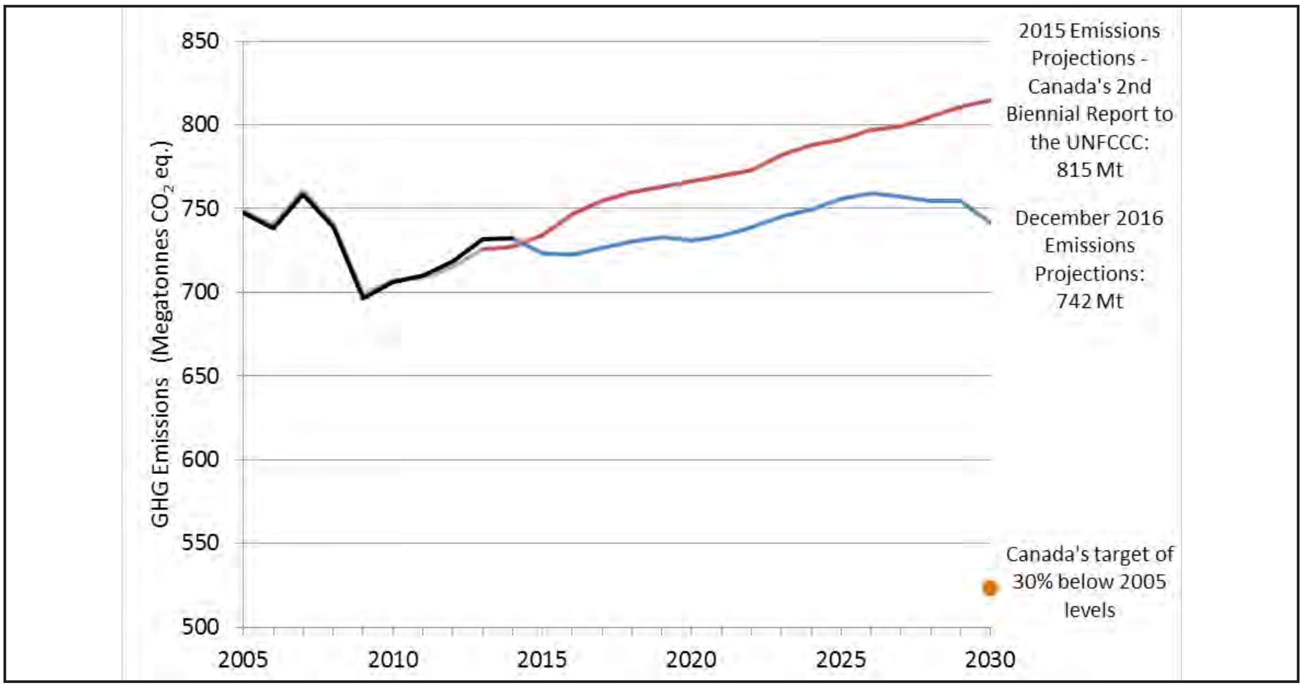
THE FEDERAL GOVERNMENT'S RENEWED RELATIONSHIP WITH INDIGENOUS PEOPLES:
The federal government also reiterates its commitment to renewed nation-to-nation, government-to-government, and Inuit-to-Crown relationships with First Nations, the Métis Nation and Inuit, based on the recognition of rights, respect, cooperation, and partnership, consistent with the Government of Canada's support for the United Nations Declaration on the Rights of Indigenous Peoples, including free, prior and informed consent.

1.4 Emissions trajectory to 2030

The graph below highlights that total Canadian GHG emissions are projected to be 742 megatonnes (Mt) in 2030 under the December 2016 emissions projections (Environment and Climate Change Canada)[1]. Canada's target is 523 Mt.

Projections from the December 2016 emissions projections include revised forecasts for GDP and oil and gas prices and production[2]. Also incorporated are new federal, provincial, and territorial government measures that have legislative or funding certainty as of November 1st, 2016 and were not included in the 2015 emissions projections. These include: federal measures for increasing energy efficiency of equipment in buildings; Ontario's commitment to join the Western Climate Initiative cap-and-trade system; Alberta's coal phase-out, carbon levy, and oil sands emissions cap; Quebec's regulations for new high-rise buildings; and, British Columbia's low carbon fuel standard.

Figure 1: Emissions Projections to 2030



1 Canada's 2016 greenhouse gas emissions projections to 2030 will be released by Environment and Climate Change Canada in December 2016.

2

	Scenarios		
December 2016 Assumptions	**Low**	**Reference**	**High**
Average Annual GDP Growth (2014-2030)	1.0%	1.7%	2.3%
2030 WTI Oil Price (2014 US$/bbl)	42	81	111
2030 Henry Hub Natural Gas Price (2014 US$/GJ)	2.89	3.72	4.62
2030 GHG Emissions (Mt C02eq.)	**697**	**742**	**790**

PRICING CARBON POLLUTION

Overview

Carbon pricing is broadly recognized as one of the most effective, transparent, and efficient policy approaches to reduce GHG emissions. Many Canadian provinces are already leading the way on pricing carbon pollution. British Columbia has a carbon tax, Alberta has a hybrid system that combines a carbon levy with a performance-based system for large industrial emitters, and Quebec and Ontario have cap-and-trade systems. With existing and planned provincial action, broad-based carbon pricing will apply in provinces with nearly 85 per cent of Canada's economy and population by 2017, covering a large part of our emissions.

The federal government outlined a benchmark for pricing carbon pollution by 2018 (see Annex I). The goal of this benchmark is to ensure that carbon pricing applies to a broad set of emission sources throughout Canada and with increasing stringency over time either through a rising price or declining caps. The benchmark outlines that jurisdictions can implement (i) an explicit price-based system (a carbon tax or a carbon levy and performance-based emissions system) or (ii) a cap-and-trade system. Some existing provincial systems already exceeded the benchmark. As affirmed in the Vancouver Declaration, provinces and territories continue to have the flexibility to design their own policies to meet emissions-reduction targets, including carbon pricing, adapted to each province and territory's specific circumstances.

> **"THERE IS A GROWING CONSENSUS AMONG BOTH GOVERNMENTS AND BUSINESSES ON THE FUNDAMENTAL ROLE OF CARBON PRICING IN THE TRANSITION TO A DECARBONIZED ECONOMY."**
>
> World Bank, State and Trends of Carbon Pricing 2015

The following **principles** guide the pan-Canadian approach to pricing carbon pollution, and they are broadly based on those proposed by the Working Group on Carbon Pricing Mechanisms:

- Carbon pricing should be a central component of the Pan-Canadian Framework.

- The approach should be flexible and recognize carbon pricing policies already implemented or in development by provinces and territories.
- Carbon pricing should be applied to a broad set of emission sources across the economy.
- Carbon pricing policies should be introduced in a timely manner to minimize investment into assets that could become stranded and maximize cumulative emission reductions.
- Carbon price increases should occur in a predictable and gradual way to limit economic impacts.
- Reporting on carbon pricing policies should be consistent, regular, transparent, and verifiable.
- Carbon pricing policies should minimize competitiveness impacts and carbon leakage, particularly for emissions-intensive, trade-exposed sectors.
- Carbon pricing policies should include revenue recycling to avoid a disproportionate burden on vulnerable groups and Indigenous Peoples.

NEW ACTIONS

1) Provincial and territorial actions on pricing carbon pollution are described in Annex II.

2) The federal government will work with the territories to find solutions that address their unique circumstances, including high costs of living and of energy, challenges with food security, and emerging economies. The federal government will also engage Indigenous Peoples to find solutions that address their unique circumstances, including high costs of living and of energy, challenges with food security, and emerging economies.

3) The overall approach will be reviewed by 2022 to confirm the path forward.

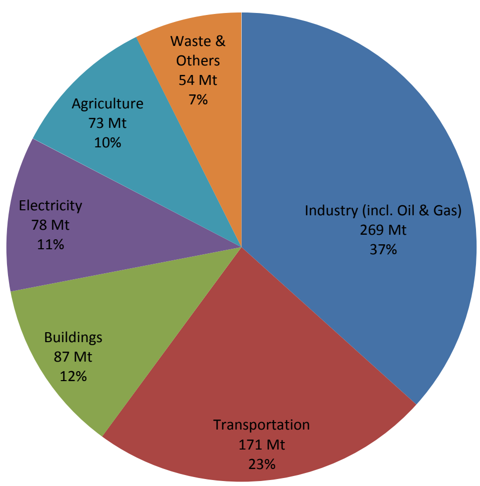
> **"CARBON PRICING IS THE MOST PRACTICAL AND COST-EFFECTIVE WAY TO LOWER GHG EMISSIONS WHILE ENCOURAGING LOW-CARBON INNOVATION."**
>
> Canada's Ecofiscal Commission

COMPLEMENTARY ACTIONS TO REDUCE EMISSIONS

Overview

To reduce emissions, meaningful action will need to be taken across all regions and sectors of the economy. Many of the things that Canadians do every day—like driving cars and heating homes—produce GHG emissions. Many activities that drive economic growth in the country, like extracting natural resources, industrial and manufacturing activities, and transporting goods to customers, also produce emissions. The policies that help drive down emissions can also help the economy to keep growing by cutting costs for Canadians, creating new markets for low-emission goods and services, and helping businesses use cleaner and more efficient technologies that give them a leg up on international competitors.

Emissions by sector in 2014 (megatonnes of CO_2 eq.)



Federal, provincial, and territorial governments will work together to make sure new actions build on and complement existing plans, policies, programs, and regulations and reflect lessons learned from past experience. New policies will be designed to focus on GHG-emission outcomes and will recognize flexibility for regional differences, including through outcomes-based regulatory equivalency agreements. Indigenous Peoples will be involved in defining and developing policies to support clean energy in their communities.

In developing policies, a number of factors will be considered, including:

- economic, environmental, and social impacts and benefits;
- how individual policies will work with carbon pricing;
- the need to consider and mitigate the impacts on emissions-intensive trade exposed sectors (e.g., resource sectors that are price takers on the global market), including the need to avoid carbon leakage;
- co-benefits such as improved health due to air pollutant reductions, and jobs and business growth;
- opportunities to realize near-term climate and health benefits through reducing emissions of short-lived climate pollutants; and,
- benefits for ecosystems and biodiversity.

FALLING COSTS OF RENEWABLE ENERGY:
Between 2010 and 2015, the costs for new utility-scale solar photovoltaic (PV) installations declined by two-thirds, while over the same period the cost of onshore wind fell by an estimated 30 percent on average (IEA, 2016)

Governments will be supporting the actions outlined in the Pan-Canadian Framework through policies and investments. Federal actions are described in Annex I, and provincial and territorial key actions and collaboration opportunities with the Government of Canada are described in Annex II.

3.1 Electricity

Canada already has one of the cleanest electricity systems in the world. About 80 percent of electricity production comes from non-emitting sources, more than any other G7 country. While electricity emissions are going down in large part due to the move away from coal-fired power toward cleaner sources, electricity generation is still Canada's fourth-largest source of GHG emissions.

Clean, non-emitting electricity systems will be the cornerstone of a modern, clean growth economy. Transformations to electricity systems will be supported by federal, provincial, and territorial governments, and, undertaken by utilities, private-sector players, and Indigenous Peoples.

The approach to electricity will include
(1) increasing the amount of electricity generated from renewable and low-emitting sources;
(2) connecting clean power with places that need it;
(3) modernizing electricity systems; and
(4) reducing reliance on diesel working with Indigenous Peoples and northern and remote communities.

Provinces and territories have already taken action on moving from traditional coal-fired generation to clean electricity. Ontario and Manitoba have already phased out their use of coal, Alberta has plans in place to phase out coal-fired electricity by 2030, Nova Scotia has created a regulatory framework to transition from coal to clean electricity generation, and Saskatchewan has a coal-fired generating unit with carbon capture technology, which captures 90 percent of emissions. New capacity will come from non-emitting sources—including hydro, wind, and solar—as well as natural gas. Energy efficiency and conservation will make added contributions to clean electricity systems.

ONTARIO'S COAL PHASE-OUT:
On April 15, 2014, **Ontario** became the first jurisdiction in North America to fully eliminate coal as a source of electricity generation. This action is the single largest GHG-reduction initiative in North America, eliminating more than 30 Mt of annual GHG emissions and equivalent to taking seven million vehicles off the road. On November 23, 2015, Ontario passed the *Ending Coal for Cleaner Air Act*, permanently banning coal-fired electricity generation in the province.

SASKATCHEWAN'S BOUNDARY DAM INTEGRATED CARBON CAPTURE AND STORAGE PROJECT:
is the world's first commercial-scale, coal-fired carbon capture and storage electricity project, and it is able to capture and sequester up to 90 percent of its GHG emissions.

WIND POWER:
Wind capacity in Canada grew 20 times between 2005 and 2015, and there is strong potential for further growth. For example, 4 wind farms in **Prince Edward Island** now generate almost 25 percent of the province's electricity requirements.

THE CANADIAN ENERGY STRATEGY:
Provinces and territories are already taking a cooperative approach toward sustainable energy development through the Canadian Energy Strategy, which was released by premiers in July 2015. As agreed under the Vancouver Declaration and building on the Quebec Summit on Climate Change in 2015, federal, provincial, and territorial energy ministers are collaborating on specific actions through the Canadian Energy Strategy, to contribute to the Pan-Canadian Framework on Clean Growth and Climate Change. Actions include energy conservation and efficiency, clean energy technology and innovation, and deployment of energy to people and global markets.

ALBERTA'S COAL PHASE-OUT:
Alberta's commitments to end emissions from coal-fired electricity and replace it with 30 percent renewable energy by 2030 are expected to achieve cumulative emission reductions of 67 Mt between now and 2030, and emissions in 2030 will be at least 14 Mt below what is forecast under the status quo. This reduction is the equivalent of taking 2.8 million cars off the road. This move will improve air quality and the health of Albertans and other Canadians. It will also ensure reliability, encourage private investment, and provide price stability for all Albertans.

Connecting clean power across Canada through stronger transmission-line interconnections will help reduce emissions and support the move away from coal. Many provinces already trade electricity across their borders, and there is potential to increase these flows, consistent with market rules and fair competition among electricity producers.

Modernizing electricity systems will involve expanding energy storage, updating infrastructure, and deploying smart-grid technologies to improve the reliability and stability of electric grids and to allow more renewable power to be added. As a leader in the development and deployment of innovative energy-storage solutions and smart-grid technology, Canadian clean technology producers stand to benefit from increased investments in our electricity systems.

Many Indigenous Peoples, as well as northern and remote communities in Canada rely on diesel fuel to produce electricity and heat. Opportunities exist for clean electricity infrastructure, distributed energy systems, renewable energy microgrids, as well as grid connections and hybrid systems, which will enhance wellbeing, create local economic opportunities, and contribute to better air quality and a cleaner environment overall. Investing in clean energy solutions will advance the priorities of Indigenous Peoples, as well as northern and remote communities to transition away from diesel.

COLVILLE LAKE SOLAR PROJECT – Colville Lake, Northwest Territories is located north of the Arctic Circle, and it is served with a winter road that is open just a couple of months each year. To reduce diesel use in this remote, off-grid community, a solar/diesel/battery hybrid electricity system has been installed. This system has allowed the diesel generators to be shut down for extended periods in the summer. This innovative energy solution has reduced diesel use and related emissions by 20-25 percent per year.

Taking these actions will have a number of benefits beyond reducing GHG emissions. Phasing out coal and reducing the use of diesel will reduce harmful air pollutants, which have significant implications for human health and associated health-care costs. Designing and building clean-power technologies and transmission lines represents major economic opportunities for Canada. Increasing the amount of clean and renewable electricity sold to the United States could also bring new revenue to utilities and provinces, respecting open-access rules under the authority of the U.S. Federal Energy Regulatory Commission.

THE CANADA INFRASTRUCTURE BANK: The federal government is creating the Canada Infrastructure Bank, which will work with provinces, territories, and municipalities to further the reach of government funding directed to infrastructure, including clean electricity systems.

COMMUNITY-BASED ENERGY GENERATION: In May 2015, **New Brunswick** introduced legislation to allow local entities to develop renewable-energy sourced electricity generation in their communities. This legislation will allow universities, non-profit organizations, cooperatives, First Nations, and municipalities to contribute to NB Power's renewable energy requirements.

NEW ACTIONS

1. Increasing renewable and non-emitting energy sources

Federal, provincial, and territorial governments will work together to accelerate the phase out of traditional coal units across Canada, by 2030, as recently announced by the federal government (see Annex I) and to build on provincial and territorial leadership.

The federal government has announced it will set performance standards for natural gas-fired electricity generation, in consultation with provinces, territories, and stakeholders (see Annex I).

Federal, provincial, and territorial governments will work together to facilitate, invest in, and increase the use of clean electricity across Canada, including through additional investments in research, development, and demonstration activities.

2. Connecting clean power with places that need it

Federal, provincial, and territorial governments will work together to help build new and enhanced transmission lines between and within provinces and territories.

3. Modernizing electricity systems

Federal, provincial, and territorial governments will work together to support the demonstration and deployment of smart-grid technologies that help electric systems make better use of renewable energy, facilitate the integration of energy storage for renewables, and help expand renewable power capacity.

4. Reducing reliance on diesel working with Indigenous Peoples and northern and remote communities

Governments are committed to accelerating and intensifying efforts to improve the energy efficiency of diesel generating units, demonstrate and install hybrid or renewable energy systems, and connect communities to electricity grids. This will be done in partnership with Indigenous Peoples and businesses. These actions will have significant benefits for communities, such as improving air quality and energy security, and creating the potential for locally owned and sourced power generation.

RAMEA WIND-HYDROGEN-DIESEL ENERGY PROJECT:
The off-grid community of Ramea in **Newfoundland and Labrador** hosts one of the first projects in the world to integrate generation from wind, hydrogen, and diesel in an isolated electricity system. Since 2010, the Ramea Wind-Hydrogen-Diesel Energy Project has successfully produced approximately 680 000 kilowatt hours of renewable energy.

3.2 Built environment

In Canada, using energy to heat and cool buildings accounted for about 12 percent of national GHG emissions in 2014 or 17 percent if emissions from generating the electricity used in buildings is also included. The emissions in this sector—created by burning fossil fuels and leaks in air conditioning systems—are projected to grow modestly by 2030 unless further action is taken.

In a low-carbon, clean growth economy, buildings and communities will be highly energy efficient, rely on clean electricity and renewable energy, and be smart and sustainable. Making the built environment more energy efficient reduces GHGs, helps make homes and buildings more comfortable and more affordable by lowering energy bills, and can promote innovation and clean job opportunities. Most building owners and architects estimate that retrofitting commercial and institutional buildings pays off in less than ten years, according to data from the Canada Green Building Council. Residential energy efficiency improvements helped Canadians save $12 billion in energy costs in 2013, an average savings of $869 per household.

The approach to the built environment will include (1) making new buildings more energy efficient; (2) retrofitting existing buildings, as well as fuel switching; (3) improving energy efficiency for appliances and equipment; and (4) supporting building codes and energy efficient housing in Indigenous communities.

Advances in clean technologies and building practices can make new buildings "net-zero energy", meaning they require so little energy they could potentially rely on their own renewable energy supplies for all of their energy needs. Through research and development, technology costs continue to fall, and government and industry efforts and investments will accelerate that trend. These advances, supported by a model "net-zero energy ready" building code, will enable all builders to adopt these practices and lower lifecycle costs for homeowners.

EFFICIENCY NOVA SCOTIA:
Canada's first energy efficiency utility—works with more than 100 local partners, and it has helped 225 000 program participants complete energy efficiency projects, saving Nova Scotians $110 million in 2016 alone. For example, the HomeWarming service is funded by the province of Nova Scotia as part of a long-term plan to upgrade all low-income homes in Nova Scotia, over the next 10 years.

At the same time, action is needed on existing buildings, since more than 75 percent of the building stock in 2030 will be composed of buildings already standing today. This can be supported by innovative policies like labelling a building's energy performance, establishing retrofit codes, and offering low-cost financing for retrofits.

Housing for Indigenous communities is particularly pressing. New housing will be built to high-efficiency standards and existing housing will be retrofitted. Indigenous Peoples have also identified the need to incorporate Traditional Knowledge and culture into building designs. Governments will partner with Indigenous Peoples in the design of relevant policies and programs.

Energy efficiency standards for equipment and appliances save consumers and businesses money on energy bills. An early market signal by the government, in the form of an intention to introduce standards by a specific year, can motivate the market to accelerate the uptake of the targeted technologies. Regulations can be supported by actions to educate consumers, to demonstrate benefits, and to overcome market barriers.

Construction in Canada is a $171 billion industry, and it employs well over a million people. New building codes will spur innovation and support Canadian businesses in developing more efficient building techniques and technologies. Investments in retrofits to improve energy efficiency have been shown to be strong job creators, providing direct local benefits, creating local jobs, and reducing energy bills.

NET-ZERO ENERGY BUILDINGS: Construction costs for net-zero energy buildings have dropped 40 percent in the past decade, and they are continuing to fall. The benefits of net-zero energy buildings are significant. Estimated operating costs for a net-zero energy ready house is 30 percent to 55 percent less than for a typical house, depending on region, fuel type and occupant behaviour. For example, on a -32 °C day, the Riverdale NetZero Project (a semi-detached duplex in Edmonton, Alberta) only needs 6500 W of power for heat—the same amount of heat produced by four toasters.

NEW ACTIONS

1. Making new buildings more energy efficient

Federal, provincial, and territorial governments will work to develop and adopt increasingly stringent model building codes, starting in 2020, with the goal that provinces and territories adopt a "net-zero energy ready" model building code by 2030. These building codes will take regional differences into account. Continued federal investment in research, development, and demonstration, and cooperation with industry will help to reduce technology costs over time.

2. Retrofitting existing buildings

Federal, provincial, and territorial governments will work to develop a model code for existing buildings by 2022, with the goal that provinces and territories adopt the code. This code will help guide energy efficiency improvements that can be made when renovating buildings.

Federal, provincial, and territorial governments will work together with the aim of requiring labelling of building energy use by as early as 2019. Labelling will provide consumers and businesses with transparent information on energy performance.

Provincial and territorial governments will work to sustain and, where possible, expand efforts to retrofit existing buildings by supporting energy efficiency improvements as well as fuel switching, where appropriate, and by accelerating the adoption of high-efficiency equipment while tailoring their programs to regional circumstances. The federal government could support efforts of provinces and territories through the Low Carbon Economy Fund and infrastructure initiatives.

3. Improving energy efficiency for appliances and equipment

The federal government will set new standards for heating equipment and other key technologies to the highest level of efficiency that is economically and technically achievable.

4. Supporting building codes and energy efficient housing in Indigenous communities

Governments will collaborate with Indigenous Peoples as they move towards more efficient building standards and incorporate energy efficiency into their building-renovation programs.

SOCIAL HOUSING RETROFITS:
To help fight climate change, Ontario invested $92 million in 2016 to retrofit social housing buildings to reduce GHG emissions by installing energy efficient boilers, insulating outer walls and mechanical systems, and installing more energy efficient windows and lighting. Ontario's Climate Change Action Plan builds on this initial investment by committing up to $500 million more for social housing retrofits over the next five years.

Aki Energy in **Manitoba** is a non-profit Aboriginal social enterprise that works with First Nations to start green businesses in their communities and to create local jobs and strong local economies. Aki Energy is committed to helping First Nations lower the utility bills to heat buildings, and it has installed over $3 million in cost-effective renewable energy technologies in partnership with Manitoba First Nations.

3.3 Transportation

The transportation sector accounted for about 23 percent of Canada's emissions in 2014, mostly from passenger vehicles and freight trucks. Transportation emissions are projected to decline slightly by 2030 if no further action is taken. Governments are already working to make all modes of transportation more efficient and convenient, but more action is needed.

Low-carbon transportation systems will use cleaner fuels, will have more zero-emission vehicles on the road, will provide convenient and affordable public transit, and will transport people and goods more efficiently.

The approach to transportation will include (1) setting and updating vehicle emissions standards and improving the efficiency of vehicles and transportation systems; (2) expanding the number of zero-emission vehicles on Canadian roads; (3) supporting the shift from higher to lower-emitting types of transportation, including through investing in infrastructure; and (4) using cleaner fuels.

Emissions standards for cars and trucks ensure new engines are more fuel efficient. Retrofitting freight trucks to reduce wind resistance can also cut emissions. And streamlining how goods are transported can improve the overall efficiency of transportation systems.

Zero-emission vehicle technologies include plug-in hybrids, electric vehicles, and hydrogen fuel-cell vehicles. Many of these are becoming increasingly affordable and viable, and governments can help accelerate these trends, including by investing in charging and fueling infrastructure.

ELECTRIFICATION OF TRANSPORTATION:
Québec has committed to take significant action on the electrification of transportation by 2020, including by increasing the number of electric and plug-in hybrid vehicles registered in Québec to 100 000; adding 5000 electric-vehicle jobs and generating $500 million in investments; reducing the amount of fuel used each year in Québec by 66 million liters; and cutting annual GHG emissions from the transportation sector by 150 000 tonnes.

Shifting from higher- to lower-emitting modes of transportation includes things like riding public transit or cycling instead of driving a car, and transporting goods by rail instead of trucks. Improving public transit infrastructure and optimizing freight corridors can help drive these shifts.

Using cleaner fuels such as advanced biofuels can reduce the lifecycle carbon intensities of all fuels across transportation systems, as well as in other sectors like industry and buildings.

Taking these actions will have additional environmental and economic benefits beyond reducing GHG emissions. Efficiency improvements can help Canadians and businesses save money by spending less on fuel and reducing the costs of transporting goods. New, cleaner fuels can create opportunities for resource sectors. Businesses that develop new fuel and vehicle technologies will create jobs, help the economy grow, and give those businesses a competitive edge.

NEW ACTIONS

1. Setting emissions standards and improving efficiency

The federal government will continue its work to implement increasingly stringent standards for emissions from light-duty vehicles, including fuel-efficient tire standards, and to update emissions standards for heavy-duty vehicles.

The federal government will work with provinces, territories, and industry to develop new requirements for heavy-duty trucks to install fuel-saving devices like aerodynamic add-ons.

The federal government will take a number of actions to improve efficiency and support fuel switching in the rail, aviation, marine, and off-road sectors.

2. Putting more zero-emission vehicles on the road

Federal, provincial, and territorial governments will work with industry and other stakeholders to develop a Canada-wide strategy for zero-emission vehicles by 2018.

Federal, provincial, and territorial governments will work together, including with private-sector partners, to accelerate demonstration and deployment of infrastructure to support zero-emission vehicles, such as electric-charging stations.

3. Shifting from higher- to lower-emitting modes and investing in infrastructure

Federal, provincial, and territorial governments will work together to enhance investments in public-transit upgrades and expansions.

Federal, provincial, and territorial governments will invest in building more efficient trade and transportation corridors including investments in transportation hubs and ports.

Federal, provincial, and territorial governments will consider opportunities with the private sector to support refueling stations for alternative fuels for light- and heavy-duty vehicles, including natural gas, electricity, and hydrogen.

4. Using cleaner fuels

The federal government, working with provincial and territorial governments, industry, and other stakeholders, will develop a clean fuel standard to reduce emissions from fuels used in transportation, buildings and industry.

This will take into account the unique circumstances of Indigenous Peoples and northern and remote communities.

3.4 Industry

Canada's industries are the backbone of the economy, but they are also a major source of GHG emissions. In 2014, industrial sectors accounted for about 37 percent of Canada's emissions, the majority of which came from the oil and gas sector. Industrial emissions are projected to grow between now and 2030 as demand grows for Canadian-produced goods, at home and abroad.

A low-carbon industrial sector will rely heavily on clean electricity and lower-carbon fuels, will make more efficient use of energy, and will seize opportunities unlocked by innovative technologies. The province of Alberta has legislated an absolute cap of 100 Mt a year on emissions from the oil sands sector. There are a number of near-term opportunities to reduce industrial emissions while maintaining the competitive position of Canadian firms.

The approach to the industrial sector will include three main areas of action: (1) regulations to reduce methane and hydrofluorocarbon (HFC) emissions; (2) improving industrial energy efficiency; and (3) investing in new technologies to reduce emissions. Together, these actions will help set the path for long-term clean growth and the transition to a low-carbon economy.

Methane and HFCs are potent GHGs, dozens to thousands of times more powerful than carbon dioxide. The oil and gas sector is the largest contributor to methane emissions in Canada. Building on provincial actions and targets, the federal government has committed to reduce methane emissions by 40-45 percent by 2025. Canada joined almost 200 other countries in signing the Kigali Amendment to the Montreal Protocol, which will push the global phase out of HFC emissions. Taking action on HFCs can prevent up to 0.5 °C of global warming due to the potency of these gases, while continuing to protect the ozone layer.

There is significant potential to improve energy efficiency in Canada's industrial sectors. Energy management systems such as ISO 50001, the Superior Energy Performance program (SEP), and the ENERGY STAR for Industry program are useful tools that help businesses track, analyze, and improve their energy efficiency.

Using today's low-emission technologies and switching to clean electricity and lower-carbon fuels are near-term actions industry can take to reduce emissions. Over the longer-term, more dramatic emission reductions will be possible by using new technologies to transform how some industries operate. Investing in promising new technologies is an important area for action. Innovation will help Canadian businesses access global markets and attract foreign investment.

LOWER-CARBON INDUSTRIAL ACTIVITY IN CANADA:
Quebec's aluminum smelters have reduced their emissions by 30 percent since 1990. The modernized world-class aluminum smelter in Kitimat, BC will boost production and reduce emissions by nearly 50 percent. As a result of these investments, Canada's aluminum industry is now the most carbon-efficient producer of aluminum in the world.

OIL SANDS INNOVATION:
COSIA (Canada's Oil Sands Innovation Alliance) is an alliance of 13 oil sands producers, representing 90 percent of production from the Canadian oil sands, who are working together to develop technologies that help reduce the environmental impact of the oil sands, including reducing GHG emissions. Member companies have shared 936 distinct environmental technologies, costing $1.33 billion, since coming together in 2012.

Taking these actions will benefit businesses. Strengthening energy performance is one of the most cost-effective ways for industry to reduce energy use, it generally has quick payback periods, and it will continually generate financial savings. Measures that help cut costs or develop new technologies can improve competitiveness and create jobs and export opportunities for the clean technology sector.

NEW ACTIONS

1. Reducing methane and HFC emissions

The federal government will work with provinces and territories to achieve the objective of reducing methane emissions from the oil and gas sector, including offshore activities, by 40-45 percent by 2025, including through equivalency agreements.

The federal government has introduced proposed regulations to phase down use of HFCs to support Canada's commitment to the Montreal Protocol amendment.

2. Improving industrial energy efficiency

Federal, provincial, and territorial governments will work together to help industries save energy and money, including by supporting them in adopting energy management systems.

3. Investing in technology

Federal, provincial, and territorial governments working with industry will continue to invest in research and development and to promote deployment of new technologies that help reduce emissions.

Federal, provincial, and territorial governments will also work with industry to identify demonstration projects for promising pre-commercial clean energy technologies required to reduce emissions from energy production and use in the Canadian economy, including in the oil and gas sector.

3.5 Forestry, agriculture, and waste

Emissions from agriculture (livestock and crop production) and extraction of forestry resources accounted for about 10 percent of Canada's emissions in 2014, and they are not projected to significantly change by 2030. Municipal waste accounts for a small portion (about 3 percent) of Canada's total GHGs, and these emissions are projected to decline, largely due to increases in landfill gas capture.

Agricultural soils and forests also absorb and store carbon. The emissions or removals from carbon sinks can fluctuate with natural disturbances (e.g. forest fires), but there are still a number of actions that can increase carbon storage and reduce emissions.

Forests, wetlands, and agricultural lands across Canada will play an important natural role in a low-carbon economy by absorbing and storing atmospheric carbon. Actions taken by jurisdictions and woodlot owners to accelerate reforestation, to continuously improve sustainable management practices, and to plant new forests where they do not currently exist will enhance stored carbon. Clean technology, such as lower-carbon bioenergy, and bioproducts that use feedstock from agriculture and forestry waste and dedicated crops to replace higher-carbon fuels can also reduce emissions. Continued innovation and clean technology in agriculture will build on past GHG reduction successes of decreasing emissions per unit of production. The municipal waste sector will also be a key source of cleaner fuels such as renewable natural gas from landfills.

The approach to these sectors will include (1) enhancing carbon storage in forests and agricultural lands; (2) supporting the increased use of wood for construction; (3) generating fuel from bioenergy and bioproducts; and, (4) advancing innovation.

Forests, wetlands, and agricultural lands can be enhanced as "carbon sinks" through actions such as planting more trees, improving forest carbon management practices, minimizing losses from fires and invasive species, restoring forests that have been affected by natural disturbances, and increasing adoption of land management practices like increasing perennial and permanent cover crops and zero-till farming. Protecting and restoring natural areas, including wetlands, can also benefit biodiversity and maintain or enhance carbon storage.

Increasing the use of wood for construction can reduce emissions as the carbon stored in that wood gets locked in for a long period of time. Increasing domestic demand for Canadian wood products will also support the vibrant forest industries across Canada, which have a long history of innovating to develop new products and more efficient and sustainable forest practices.

The **Cheakamus Community Forest** carbon offset project is located adjacent to the Resort Municipality of Whistler, within the traditional territories of the Squamish and Lil'wat Nations. The project retains more carbon in the forest by using ecosystem-based management practices that include increasing protected areas and using lower-impact harvesting techniques.

The forestry, agriculture, and waste sectors also provide biomass for bioproducts that can be used in place of fossil fuels in other sectors. For example, waste products from forestry, agriculture, and landfills can be converted into energy sources such as renewable natural gas. Dedicated crops can be grown as feedstocks for products like bioplastics. Expanding renewable fuel industries represents an opportunity to create new jobs and economic growth across Canada.

BIOMASS-FIRED DISTRICT HEATING:

Prince Edward Island is home to Canada's longest running, biomass-fired district heating system. Operating since the 1980's, the system has expanded to serve over 125 buildings in the downtown core of Charlottetown, including the University of Prince Edward Island and the Queen Elizabeth Hospital, and cleanly burns 66 000 tons of waste materials annually.

Innovative solutions, including clean technologies, are required to reduce emissions from agriculture. Promising new technologies are being developed to reduce emissions from livestock and crop production, including from the use of precision farming and "smart" fertilizers, which time the release to match plant needs, and from feed innovations that reduce methane production in cattle. Actions pertaining to the agriculture sector will be developed collaboratively through Canada's Next Agriculture Policy Framework.

These actions in the forestry, agriculture, and waste sectors, and supporting clean technology businesses, can help to create jobs and build more sustainable communities.

NEW ACTIONS

1. Increasing stored carbon

Federal, provincial, and territorial governments will work together to protect and enhance carbon sinks, including in forests, wetlands, and agricultural lands (e.g. through land-use and conservation measures).

2. Increasing the use of wood for construction

Federal, provincial, and territorial governments will collaborate to encourage the increased use of wood products in construction, including through updated building codes.

3. Generating bioenergy and bioproducts

Federal, provincial, and territorial governments will work together to identify opportunities to produce renewable fuels and bioproducts, for example, generating renewable fuel from waste.

4. Advancing innovation

Federal, provincial, and territorial governments will work together to enhance innovation to advance GHG efficient management practices in forestry and agriculture.

3.6 Government leadership

Governments are directly responsible for a relatively small share of Canada's emissions (about 0.6 percent), but they have an opportunity to lead by example. A number of provinces are already demonstrating leadership, including through carbon neutral policies.

CARBON NEUTRAL GOVERNMENT:
British Columbia's public sector has successfully achieved carbon neutrality each year since 2010. Over the past 6 years, schools, post-secondary institutions, government offices, Crown corporations, and hospitals have reduced a total of 4.3 million tonnes of emissions through improvements to their operations and investments of $51.4 million in offset projects. British Columbia was the first—and continues to be the only—carbon neutral jurisdiction on the continent.

In a low-carbon, clean growth economy, federal, provincial, and territorial governments will be leaders in sustainable, low-emission practices that support the goals of clean growth and address climate change.

Municipalities are also essential partners. How cities develop and operate has an important impact on energy use and therefore GHG emissions.

LEADERSHIP BY CITIES:
The City of Whitehorse's Sustainability Plan outlines 12 community-wide goals in areas such as transportation, buildings, waste, GHG reductions, and resilient, accessible food systems, with associated targets for 2020, 2030, and 2050. For example, Whitehorse has set a target that new buildings will be 30 percent more efficient than the National Energy Code of Canada for Buildings, the National Building Codes, or achievable comparable EnerGuide ratings, while city-owned buildings will be 50 percent more efficient than the National Energy Code.

The public sector can play an important role by setting ambitious emissions reduction targets and by demonstrating the effectiveness of policies to reduce emissions (e.g. from vehicle fleets and buildings).

The approach to government leadership will include (1) setting ambitious targets; (2) cutting emissions from government buildings and fleets; and (3) scaling up clean procurement.

Governments control a significant share of assets like fleets and buildings. By setting targets and implementing policies to make buildings more efficient and to reduce emissions from vehicle fleets, the public sector can help to demonstrate the business case for ambitious action. Governments are also major purchasers and providers of goods and services, and they can help to build demand for low-carbon goods and services through procurement policies. They can also provide a testing ground for new and emerging technologies, creating new opportunities for Canadian firms developing clean technology products, services, and processes.

NEW ACTIONS

1. Setting ambitious targets

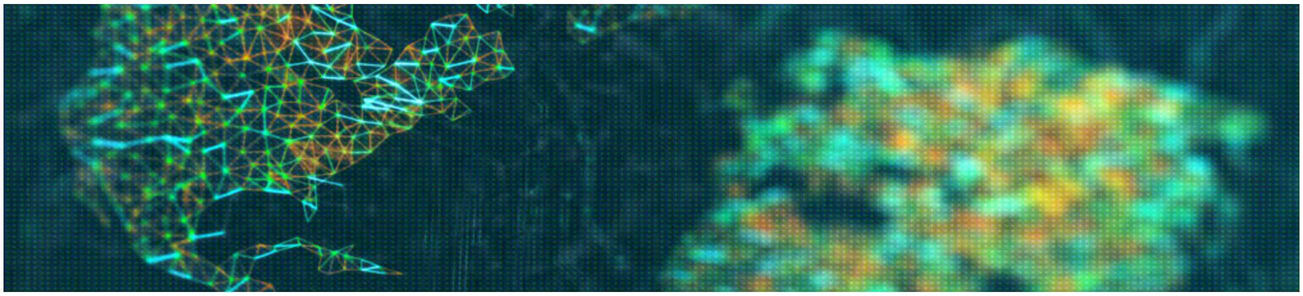
Federal, provincial, and territorial governments will demonstrate leadership through commitments to ambitious targets to reduce emissions from government operations. The federal government is committed to reduce its own GHG emissions to 40 percent below 2005 levels, by 2030 or sooner.

2. Cutting emissions from government buildings and fleets

Federal, provincial, and territorial government will scale up efforts to transition to highly efficient buildings and zero-emission vehicle fleets. The federal government has set a goal of using 100 percent clean power by 2025.

3. Scaling up clean procurement

Federal, provincial, and territorial governments will work together to modernize procurement practices, adopt clean energy and technologies, and prioritize opportunities to help Canadian businesses grow, demonstrate new technologies, and create jobs.



3.7 International leadership

Governments will work with their international partners, including developing countries, to help reduce emissions around the world. The federal government is investing $2.65 billion in climate finance to help developing countries transition to low-carbon economies and build climate resilience.

The priority is to first focus on reduction in emissions within Canada, but part of Canada's approach to climate change could also involve acquiring allowances for emissions reductions in other parts of the world, as a complement to domestic emissions reduction efforts. As recognized under the Paris Agreement (article 6), countries may choose to use emissions reductions that take place outside of their own borders, known as "internationally transferred mitigation outcomes", to meet their targets. Emissions reductions that take place outside of Canada may have lower costs and contribute to investment in sustainable development abroad. Quebec and California already participate in international emissions trading under their linked cap-and-trade system, which Ontario will soon join.

The approach to international leadership will include (1) delivering on Canada's international climate finance commitments; (2) acquiring internationally transferred mitigation outcomes; and (3) engaging in trade and climate policy.

Federal, provincial, and territorial governments will also explore mechanisms and opportunities for provinces and territories to collaborate in international fora, joint missions, and discussions on climate change and energy.

The federal government will continue to engage with and support Indigenous Peoples' action on international climate change issues, including through the United Nations Framework Convention on Climate Change, to formulate a platform for Indigenous Peoples, as agreed to in the Paris decision.

NEW ACTIONS

1. Delivering on Canada's international climate-finance commitments

The federal government will deliver on its historic commitment of $2.65 billion by 2020 to help the poorest and most vulnerable countries mitigate and adapt to the adverse effects of climate change.

2. Acquiring internationally transferred mitigation outcomes

The federal government, in cooperation with provincial and territorial governments and relevant partners, will continue to explore which types of tools related to the acquisition of internationally transferred mitigation outcomes may be beneficial to Canada and will advance a robust approach to the implementation of article 6 of the Paris Agreement. A first priority is ensuring any cross-border transfer of mitigation outcomes is based on rigorous accounting rules, informed by experts, which result in real reductions.

The federal government will work with Ontario, Quebec, and other interested provinces and territories, as well as with international partners, to ensure that allowances acquired through international-emissions trading are counted towards Canada's international target.

3. Engaging in trade and climate policy

The federal government, in cooperation with provincial and territorial governments, will work with its international partners to ensure that trade rules support climate policy.

ADAPTATION AND CLIMATE RESILIENCE

Overview

The impacts of climate change are already being felt across Canada. These changes are being magnified in Canada's Arctic, where average temperature has increased at a rate of nearly three times the global average. They pose significant risks to communities, health and well-being, the economy, and the natural environment, especially in Canada's northern and coastal regions and for Indigenous Peoples. Indigenous Peoples are among the most vulnerable to climate change due to their remote locations and reliance on wild foods. The changes already being experienced are both dramatic and permanent, with significant social, cultural, ecological, and economic implications.

Taking action to adapt to current and future climate impacts will help protect Canadians from climate change risks, build resilience, reduce costs, and ensure that society thrives in a changing climate.

INUIT AND CLIMATE IMPACTS:
Inuit and Inuit Nunangat, the homeland of Inuit in Canada, are experiencing significant climate change impacts, as highlighted in Inuit Tapiriit Kanatami's recent report on Inuit Priorities for Canada's Climate Strategy. More than 70 per cent of Canada's coastline is located in the Arctic and it is defined by ice. Average sea ice thickness is decreasing and sea ice cover is now dominated by younger, thinner ice. Some models are projecting that summer sea ice cover could be almost completely lost before 2050. These changes are already impacting access to wild foods and contributing to hazards and risks on ice.

Developing adaptation expertise and technology can further contribute to clean growth by creating jobs and spurring innovation. Adaptation is a long-term challenge, and it requires ongoing commitment to action, leadership across all governments, strong governance to assess and sustain progress, adequate funding, and meaningful engagement with, and continued leadership by, Indigenous Peoples. Federal investments (see Annex I) will support key adaptation measures.

Federal, provincial, and territorial governments have identified new actions to build resilience to climate change across Canada in the following areas:

1. Translating scientific information and Traditional Knowledge into action
2. Building climate resilience through infrastructure
3. Protecting and improving human health and well-being
4. Supporting particularly vulnerable regions
5. Reducing climate-related hazards and disaster risks

4.1 Translating scientific information and Traditional Knowledge into action

Canadians need authoritative science and information to understand current and expected changes. This includes changing conditions (e.g., rainfall, temperature, and sea ice) and the impacts of climate change across Canada. Long-term monitoring and local observations are also key. Data, tools, and information need to be widely accessible, equitable, and relevant to different types of decision-makers in different settings.

Translating knowledge into action takes leadership, skilled people, and resources. The Government of Canada's Adaptation Platform supports collaboration among governments, industry, and professional organizations on adaptation priorities. Building regional expertise and capacity for adaptation will improve risk management; support land-use planning; help safeguard investments; and strengthen emergency planning, response, and recovery. Decision-making by all governments will be guided by consideration of scientific and Traditional Knowledge.

INFORMATION AND TOOLS FOR ADAPTATION DECISIONS:
Decision-makers in five Quebec coastal municipalities collaborated with researchers, notably from the Université du Quebec à Rimouski and from Ouranos, a regional climate and adaptation consortium, to explore solutions to repeated damage of coastal infrastructure. Projections of future erosion, studies of sea ice and coastal vulnerability due to climate change, and cost-benefit analyses provided the foundation for the municipalities to make decisions on an adaptation solution.

The approach to information, knowledge, and capacity building will include (1) providing authoritative climate information and (2) building regional adaptation capacity and expertise.

Ensuring Canadians across all regions and sectors have the capacity to make informed decisions and to act on them provides the foundation for advancing adaptation in Canada. Indigenous-led community-based initiatives that combine science and Traditional Knowledge can help guide decision making. Including this information in regional and national impacts and adaptation assessments can further advance understanding of climate change across the country.

NEW ACTIONS

1. Providing authoritative climate information

The federal government will establish a Canadian centre for climate services, to improve access to authoritative, foundational climate science and information. This centre will work with provincial and territorial governments, Indigenous Peoples and other partners to support adaptation decision making across the country.

2. Building regional adaptation capacity and expertise

Governments will work with regional partners, including with Indigenous Peoples through community-based initiatives, to build regional capacity, develop adaptation expertise, respectfully incorporate Traditional Knowledge, and mobilize action. Canada's Adaptation Platform and regional consortia and centres support the sharing of expertise and information among governments, Indigenous Peoples and communities, businesses, and professional organizations and support action on joint priorities.

4.2 Building climate resilience through infrastructure

Climate change is already impacting infrastructure, particularly in vulnerable northern and coastal regions, as well as Indigenous Peoples. Climate-related infrastructure failures can threaten health and safety, interrupt essential services, disrupt economic activity, and incur high costs for recovery and replacement.

The approach to building climate resilience through infrastructure will include (1) investing in infrastructure that strengthens resilience and (2) developing climate-resilient codes and standards.

Traditional built infrastructure (e.g. roads, dykes, seawalls, bridges, and measures to address permafrost thaw) can address specific vulnerabilities. Additionally, living natural infrastructure (e.g. constructed/managed wetlands and urban forests) can build the resilience of communities and ecosystems and deliver additional benefits, such as carbon storage and health benefits.

Considering climate change in long-lived infrastructure investments, including retrofits and upgrades, and investing in traditional and natural adaptation solutions can build resilience, reduce disaster risks, and save costs over the long term.

ADAPTATION INFRASTRUCTURE:
The Red River Floodway was originally constructed in 1968 at a total cost of $63 million. It was recently expanded in 2014, at a cost of $627 million. Since 1968, the Floodway has prevented over $40 billion (in 2011 dollars) in flood-related damages for the City of Winnipeg.

NEW ACTIONS

1. Investing in infrastructure to build climate resilience

Federal, provincial, and territorial governments will partner to invest in infrastructure projects that strengthen climate resilience.

2. Developing climate-resilient codes and standards

Federal, provincial, and territorial governments will work collaboratively to integrate climate resilience into building design guides and codes. The development of revised national building codes for residential, institutional, commercial, and industrial facilities and guidance for the design and rehabilitation of climate-resilient public infrastructure by 2020 will be supported by federal investments.

4.3 Protecting and improving human health and well-being

Climate change is increasingly affecting the health and well-being of Canadians (e.g. extreme heat, air pollution, allergens, diseases carried by ticks and insects, and food security). Indigenous Peoples and northern and remote communities in particular are experiencing unique and growing risks to health and vitality.

The approach to protecting and improving human health and well-being will include (1) taking action to address climate change related health risks and (2) supporting healthy Indigenous communities.

Adaptation actions with an inclusive view of well-being (e.g. social and cultural determinants of health and mental health) will keep Canadians healthy and reduce pressures on the health system.

NEW ACTIONS

1. Addressing climate change-related health risks

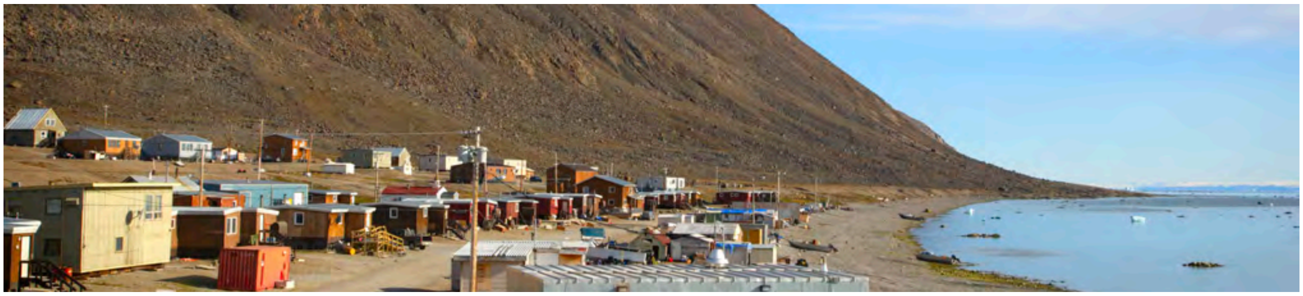
Governments will collaborate to prevent illness resulting from extreme heat events and to reduce the risks associated with climate-driven infectious diseases, such as Lyme disease. Federal adaptation investments will support actions including surveillance and monitoring, risk assessments, modelling, laboratory diagnostics, as well as health-professional education and public awareness activities. Efforts will also continue to advance the science and understanding of health risks and best practices to adapt.

2. Supporting healthy Indigenous communities

The federal government will increase support for First Nations and Inuit communities to undertake climate-change and health adaptation projects that protect public health.

The federal government will also work with the Métis Nation on addressing the health effects of climate change.

FOOD SECURITY AND SUSTAINABILITY – PLANNING FOR CLIMATE CHANGE IMPACTS IN ARVIAT, NUNAVUT:
With the goal of promoting and providing access to healthy foods, a community-based project in Arviat, **Nunavut** involved researchers and community youth to monitor and collect data on optimal growing conditions in the community greenhouse and to build capacity for its ongoing operation.



4.4 Supporting particularly vulnerable regions

The Indigenous Peoples of Canada, along with coastal and northern regions are particularly vulnerable and disproportionately affected by the impacts of climate change. Unlike rebuilding after an extreme event like a flood or a fire, once permafrost has thawed, coastlines have eroded, or socio-cultural sites and assets have disappeared, they are lost forever.

The approach to supporting vulnerable regions will include (1) investing in resilient infrastructure to protect vulnerable regions; (2) building climate resilience in the North; (3) supporting community-based monitoring in Indigenous communities; and (4) supporting adaptation in coastal areas.

Action taken to support adaptation in vulnerable regions can help communities, traditional ways of life, and economic sectors endure and thrive in a changing climate. The knowledge, expertise, technologies, and lessons from adaptation actions in vulnerable northern and coastal regions can benefit other vulnerable regions and sectors.

COLLABORATING TO ADDRESS CLIMATE IMPACTS IN THE NORTH:
Nunavut, the Northwest Territories, and Yukon hosted the Pan-Territorial Permafrost Workshop in 2013, which brought together front-line decision makers and permafrost researchers from each territory to share knowledge, form connections, and look at possibilities for adaptation in the future.

NEW ACTIONS

1. Investing in resilient infrastructure to protect vulnerable regions

Federal, provincial, and territorial governments will work together to ensure infrastructure investments help build resilience with Indigenous Peoples as well as in vulnerable coastal and northern regions.

2. Building climate resilience in the North

Federal, territorial, and northern governments and Indigenous Peoples will continue working together to develop and implement a Northern Adaptation Strategy to strengthen northern capacity for climate change adaptation. Federal investments to build resilience in the North and northern Indigenous Peoples will support this work.

3. Supporting community-based monitoring by Indigenous Peoples

The federal government will provide support for Indigenous communities to monitor climate change in their communities and to connect Traditional

Knowledge and science to build a better understanding of impacts and inform adaptation actions.

4. Supporting adaptation in coastal regions

Federal, provincial, and territorial governments will support adaptation efforts in vulnerable coastal and marine areas and Arctic ecosystems. Activities will include science, research, and monitoring to identify climate change impacts and vulnerabilities; the development of adaptation tools for coastal regions; and the improvement of ocean forecasting. This knowledge will help inform adaptation decisions related to fisheries and oceans management and coastal infrastructure. Federal adaptation investments will help advance this work.

SUPPORTING VULNERABLE COASTAL COMMUNITIES:
Through the Atlantic Climate Adaptation Solutions Project, **Newfoundland and Labrador, Nova Scotia, Prince Edward Island,** and **New Brunswick** partner together and with Indigenous communities, regional non-profits, and industry to develop practical tools and resources to help vulnerable coastal communities consider climate change in planning, engineering practices, and water and resource management. Examples include land-use planning tools, best practices, and risk assessments.

4.5 Reducing climate-related hazards and disaster risks

Climate change is impacting the intensity and frequency of events such as floods, wildfires, drought, extreme heat, high winds, and winter road failures. Recognizing this reality, Federal-Provincial-Territorial Ministers Responsible for Emergency Management are updating emergency management in Canada including work to mitigate disasters, review the Disaster Financial Assistance Arrangements, develop build-back better strategies, and collaborate on public alerting. Additionally, the Canadian Council of Forest Ministers is working on the establishment of the Canadian Wildland Fire Strategy, with climate change highlighted as a key challenge.

The approach to reducing climate-related hazards and disaster risks will include (1) investing in infrastructure to reduce disaster risks; (2) advancing efforts to protect against floods; and (3) supporting adaptation for Indigenous Peoples.

Disaster risk-reduction efforts and adaptation measures can reduce the negative impacts of these events, some of which have a disproportionate impact on Indigenous Peoples.

NEW ACTIONS

1. Investing in infrastructure to reduce disaster risks

Federal, provincial, and territorial governments will partner to invest in traditional and natural infrastructure that reduces disaster risks and protects Canadian communities from climate-related hazards such as flooding and wildfires.

2. Advancing efforts to protect against floods

Federal, provincial, and territorial governments will work together through the National Disaster Mitigation Program to develop and modernize flood maps and assess and address flood risks.

3. Supporting adaptation in Indigenous Communities

Governments will work in partnership with Indigenous communities to address climate change impacts, including repeated and severe climate impacts related to flooding, forest fires, and failures of winter roads. The federal government will provide support to Indigenous communities for adaptation.

FLOOD AND DROUGHT PROTECTIONS THROUGH WETLANDS RESTORATION:

Alberta's Watershed Resiliency and Restoration Program provided a grant to Ducks Unlimited to restore approximately 558 hectares of wetlands in the South Saskatchewan River basin for the purposes of water storage for flood and drought protection. Using historical imagery and LiDAR data to identify drained wetlands, project leads then work with and compensate landowners to restore wetlands on private land.

CLEAN TECHNOLOGY, INNOVATION, AND JOBS

Overview

Global demand for clean technologies is significant and increasing. Fostering and encouraging investment in clean technology solutions can facilitate economic growth, long-term job creation, and environmental responsibility and sustainability. Taking action on climate change will help to capture new and emerging economic opportunities, including for Indigenous Peoples and northern and remote communities. The window of opportunity exists for Canada to create the conditions for new clean technology investment and exports and seize growing global markets for clean technology goods, services, and processes.

To effectively compete in the global marketplace and capitalize on current and future economic opportunities, Canada needs a step change in clean technology development, commercialization, and adoption across all industrial sectors. Clarity of purpose, investment, and strong coordination that leverages pan-Canadian regional and provincial/territorial strengths are essential to seizing the economic growth and job-creation opportunities of clean technology. International research, development, and demonstration collaboration is also essential. Governments, Indigenous Peoples, industry, and other stakeholders all have a role to play and must be engaged.

5.1 Building early-stage innovation

To become a leader in the development and deployment of clean technologies, Canada needs a strong flow of innovative ideas.

Government investments in clean technology research, development, and demonstration will create the largest benefit where coordinated and focused in areas that will most effectively help Canada to meet its climate change goals, create economic opportunities, and expand global-market opportunities. Efforts to coordinate and focus investment must go beyond governments and involve the collaboration of industry, stakeholders, academia, and Indigenous Peoples in the innovation process. Canada must leverage its domestic strengths, which vary by region. Developing international partnerships will create new economic opportunities, build areas of shared expertise, and foster stronger bilateral relations.

Sustainable Development Technology Canada (SDTC) provides funding support to companies across Canada to develop, demonstrate, and deploy innovative new clean technologies. SDTC has also launched joint funding opportunities in collaboration with Emissions Reduction Alberta and Alberta Innovates and partners with the Ontario Centres of Excellence to enhance Ontario's Greenhouse Gas Innovation Initiative. SDTC estimates its projects have reduced annual emissions by 6.3 Mt of CO_2e, generated $1.4 billion in annual revenue and, in 2015, supported more than 9200 direct and indirect jobs.

Through its participation in Mission Innovation, the federal government has committed to double its investments in clean energy research and technology development over five years, while encouraging greater levels of private sector investment in transformative clean energy technologies. On November 14, 2016, Canada and 21 other Mission Innovation partners launched seven Innovation Challenges aimed at catalyzing global research efforts in areas that could provide significant benefits in reducing GHG emissions, increasing energy security, and creating new opportunities for clean economic growth.

NEW ACTIONS

1. Supporting early-stage technology development

Governments will support new approaches to early-stage technology development, including breakthrough technologies, to advance research in areas that have the potential to substantially reduce GHG emissions and other pollutants. Innovative partnerships with the private sector will make an important contribution to this effort.

2. Mission-oriented research and development

Governments will encourage new "mission-oriented" research approaches to focus RD&D facilities, programs, and supports on clean technology and environmental performance issues.

5.2 Accelerating commercialization and growth

Given Canada's small domestic market, Canadian firms must look to highly competitive international markets to achieve scale. Succeeding in the globally competitive clean technology marketplace requires globally competitive talent, access to the capital and resources needed to demonstrate the commercial viability of products, and strong international networks that facilitate the cross-border flow of clean technology goods and services.

Canadian clean technology producers and researchers are currently confronted by a myriad of programs and services, at the federal, provincial, and territorial level. Streamlining and integrating access to support programs and services is a priority for businesses and essential to building commercial capacity in this area.

Compared with other technology areas, clean technologies face unique challenges and often take longer to get to market, making access to "patient capital" important to successful commercialization. While federal and provincial governments already have a range of supports in place, key needs exist in terms of accessing venture capital as well as working capital and support for first, large-scale commercial projects or deployments.

20/20 Catalysts Program is a mentorship program that matches Indigenous and non-Indigenous project mentors with Indigenous mentees to promote knowledge sharing that will enable Indigenous communities to drive change towards clean technology business and economic development.

Further development of clean technologies could create new opportunities in Canada's resource sectors, increase the productivity and competitiveness of Canadian businesses, and create new employment opportunities, while also improving environmental performance. Canada will need to be able to access the skills and expertise of talented workers from around the world to enable Canadian businesses to succeed in the global marketplace. It will also be important to ensure a commitment to skills and training to provide Canadian workers with a just and fair transition to opportunities in Canada's clean growth economy.

Indigenous Peoples are leaders of change in the transition to a low-carbon economy. Indigenous governments, organizations, and businesses can play a key role in developing pathways for the adoption and adaptation of clean technology solutions for Indigenous Peoples.

Building stronger businesses and commercial capacity in all of Canada's regions is essential to taking advantage of new market opportunities. Support for new technology start-ups, through incubators and accelerators, is important to this effort. A strong, focused Canadian clean technology export strategy is needed to position Canada in growing and emerging global markets.

MaRS Cleantech works closely with entrepreneurs and investors to create solutions in energy, water, agri-tech, advanced materials and manufacturing, and smart cities. Industry looks to MaRS Cleantech to assist with company growth and to remove complex technology-adoption barriers. MaRS supports high-impact businesses by connecting innovators with potential partners, customers, investors, talent, and capital. MaRS strives to build globally competitive companies and to drive clean technology innovation.

NEW ACTIONS

1. Access to government programs

Federal, provincial, and territorial governments will work together to create a coordinated "no-wrong door" approach to supporting Canadian clean technology businesses, ensuring full and effective access to the suite of government programs and services available to support their commercial success.

2. Increasing support to advance and commercialize innovative technologies

Governments will collaborate to enable access to capital for clean technology businesses to bring their products and services to market, including at the commercial-scale demonstration and deployment stages. This will include support for clean technology businesses in the natural resource sectors to improve both competitiveness and environmental performance.

3. Strengthening support for skills development and business leadership

Governments will work together to strengthen skills development and business-leadership capacity in support of the transition to a low-carbon economy.

VENTURE CAPITAL:
BDC Capital is launching a new $135 million venture capital fund to support Canadian energy and clean technology start-up businesses with global potential. The Industrial, Clean and Energy Technology (ICE) Venture Fund II will invest in 15 to 20 new high-impact Canadian start-up firms that demonstrate efficiency and strong scalability and will support the transition to a low-carbon economy. Fund II is a follow-on to BDC Capital's highly successful ICE Venture Fund I, which was launched in 2011 with investments of $287 million now under management.

4. Expedite immigration of highly qualified personnel

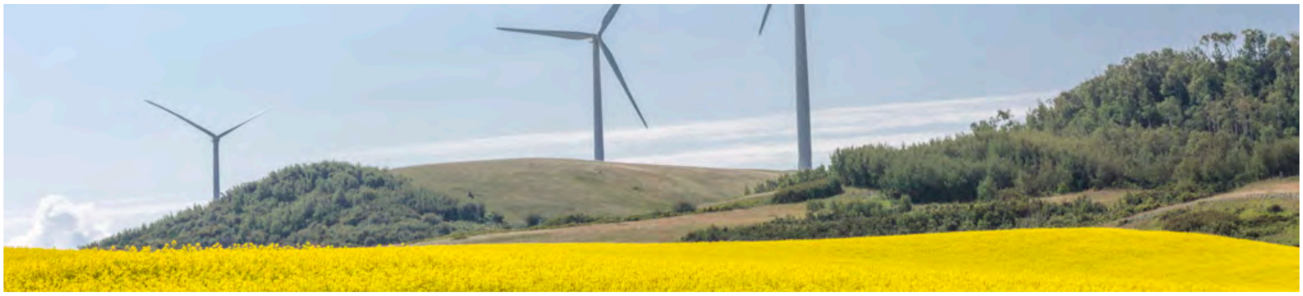
Governments will work together to enable expedited processing of visas and work permits for global talent, in particular for high-growth Canadian businesses such as those in the clean technology sector. This will attract top international talent and expand Canada's clean growth capacity.

5. Promoting exports of clean technology goods and services

Federal, provincial, and territorial governments will work collaboratively to strengthen clean technology export potential. This will include targeted export missions and the development of better market intelligence, addressing barriers to markets, support for export financing and marketing, and leveraging Canada's Trade Commissioner services.

6. Standards-setting

Governments will work together to exert a strong leadership role in international standards-setting processes for new clean technologies and to ensure that Canada's clean-technology capacity shapes future international standards.



5.3 Fostering adoption

The adoption of clean technology can create economic opportunities and improve environmental outcomes. Canada's performance on clean technology adoption by industry has significant room for improvement. Even amongst Canadian businesses that regularly adopt advanced technologies, clean technologies are the least likely to be adopted.

SmartICE (Sea-ice Monitoring And Real-Time Information for Coastal Environments) is a partnership with community, academic, government, and industry participation. It is developing an integrated system to provide near-real-time information about coastal sea-ice travel and shipping, improving safety and the ability to adapt to changing climate conditions. The pilot program is preparing to expand across the Arctic through a northern social enterprise.

Pricing carbon pollution will send a market signal that can drive innovation among Canadian businesses and, in return, will make them more competitive, including by opening up access to new markets and reducing costs of deploying clean technologies.

There is significant potential for Canadian governments to "lead by example" as early adopters of clean technology serving an essential role as a first or "reference customer" for Canadian clean technology goods, services, and processes. Having a "first sale" in Canada would boost businesses' chances of securing sales abroad. Beyond direct federal, provincial, and territorial government operations, other bodies, such as municipalities and publicly regulated utilities, could become significant markets for and adopters of clean technology.

Done effectively, the adoption of clean technology could be a mechanism for improving environmental circumstances and creating economic opportunity for Indigenous Peoples and northern and remote communities. Effective engagement and partnership with Indigenous Peoples is essential to this effort.

Encouraging dialogue between regulators and industry could improve certainty in clean technology development and allow for more effective and responsible regulation.

NEW ACTIONS

1. Leading by example

Federal, provincial, and territorial governments will develop action plans for greening government operations and encourage utilities and municipalities and other public sector entities to adopt clean technologies to lead by example.

2. Supporting Indigenous Peoples and northern and remote communities to adopt and adapt clean technologies

Federal, provincial, and territorial governments will support Indigenous Peoples and northern and remote communities in adopting and adapting clean technologies, and ensuring business models support community ownership and operation of clean technology solutions.

3. Consumer and industry adoption

Federal, provincial, and territorial governments will work together to promote and encourage effective working relationships between regulators and industry, providing for early dialogue and effective guidance, which can assist in bringing new clean technologies to market quickly and responsibly.

Governments will also support visible and effective certification programs to ensure consumer and business confidence and support green procurement.

5.4 Strengthening collaboration and metrics for success

An effective approach to clean technology development, commercialization, and adoption in Canada requires coherent, collaborative, and focused approaches. This is true within individual governments and between Canadian jurisdictions. A collaborative approach between governments should take into account regional strategies and jurisdictional responsibilities.

Regular and ongoing discussions between federal, provincial, and territorial governments regarding clean technology and clean growth would help eliminate duplication of efforts and identify gaps in support for clean technology development. Engaging Indigenous Peoples, industry, and stakeholders as a routine component of this process would be important.

There is inadequate data on Canada's clean technology capacity and potential. Building better data, and clear metrics for tracing the impact of government activities, would properly focus these activities and ensure that they achieve intended, meaningful results.

NEW ACTIONS

1. Enhance alignment between federal, provincial, and territorial actions

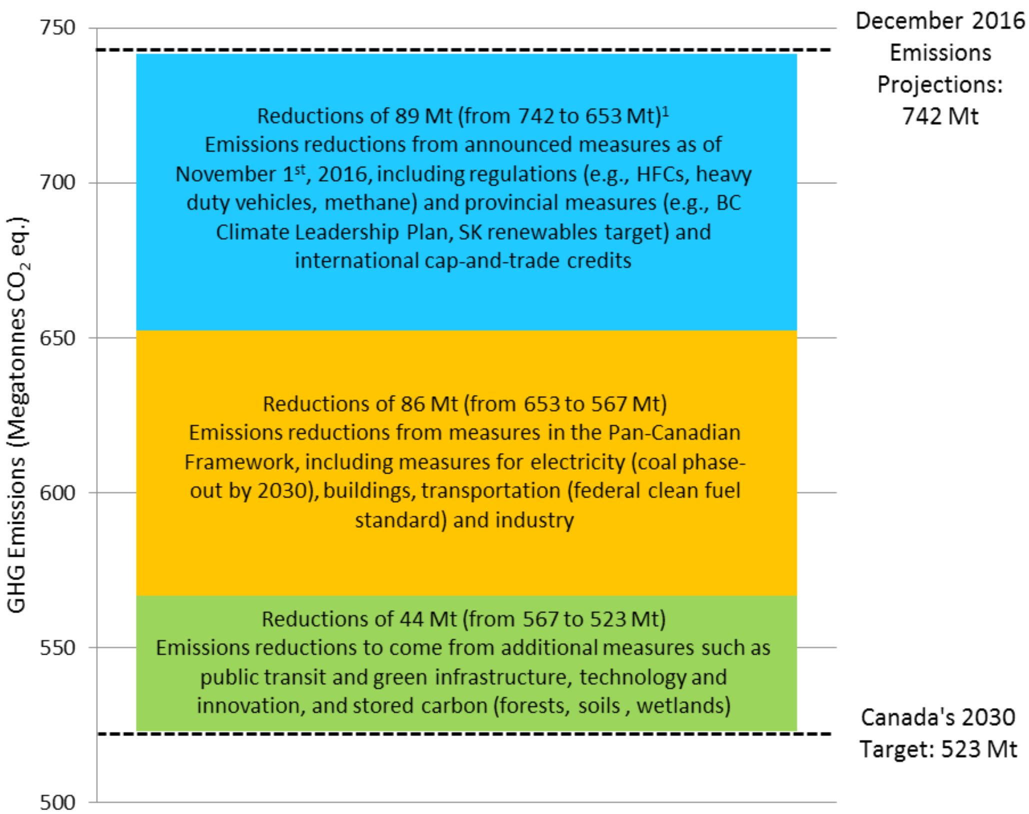
Governments will work together to improve policy and program coordination and sharing of data and best practices, which can sustain intergovernmental momentum and action on clean technology and clean growth. Continued partnership and engagement of Indigenous Peoples, industry, and stakeholders is essential to this effort.

Governments will work together to target and better align clean technology RD&D investments and activities in Canada, including opportunities for co-funding clean technology projects.

2. Establishing a clean technology data strategy

The federal government, working with the provinces and territories, will support the collection and regular publication of comprehensive data on clean technology in Canada to inform future government decision making, to improve knowledge in the private sector and stakeholder community, and to foster innovation.

PATHWAY TO MEETING CANADA'S 2030 TARGET



Note: Reductions from carbon pricing are built into the different elements depending on whether they are implemented, announced, or included in the Pan-Canadian Framework. The path forward on pricing will be determined by the review to be completed by early 2022.

[1] Estimates assume purchase of carbon credits from California by regulated entities under Quebec and Ontario's cap-and-trade system that are or will be linked through the Western Climate Initiative.

REPORTING AND OVERSIGHT

Overview

To help achieve the goals and actions laid out in this Pan-Canadian Framework, the programs and policies put in place will be monitored, results will be measured including impacts on GHG emissions, and actions and performance will be reported on publicly in a way that is transparent and accountable to Canadians. This public reporting will be complemented by ongoing public outreach, including with youth, inviting their contributions to Canada's action on clean growth and climate change. The effectiveness of actions will also be assessed with a view to ensuring continual improvement so as to increase ambition over time, in accordance with the Paris Agreement.

NEW ACTIONS

Measurement and reporting on emissions – Federal, provincial, and territorial governments will continue to collaborate on efforts to track and report GHG emissions in a consistent way across the country, to track progress on the Pan-Canadian Framework, and to support international reporting obligations. This will involve further technical work on measurement to improve emissions inventories and projections, and aligning these where possible. Federal, provincial, and territorial governments will work together through the Canadian Council of Ministers of the Environment (CCME) to examine options for the reporting of emissions and inventories to ensure consistency across provinces and territories, to support Canada's reporting to the UNFCCC, and for a pan-Canadian offset protocol framework and verified carbon credits that can be traded domestically and internationally.

Reporting on implementation – Federal, provincial, and territorial governments will work together to support the coordinated implementation of the Pan-Canadian Framework, engaging with relevant ministerial tables including ministers of environment, energy and mines, transportation, forestry, agriculture, innovation, infrastructure, emergency management, and finance, and with meaningful involvement of Indigenous Peoples. This will include a process to take regular stock of progress achieved, to report to Canadians and, to inform Canada's future national commitments in accordance with the Paris Agreement.

Analysis and advice – Federal, provincial, and territorial governments will engage with external experts to provide informed advice to First Ministers and decision makers; assess the effectiveness of measures, including through the use of modeling; and identify best practices. This will help ensure that actions identified in the Pan-Canadian Framework are open to external, independent review, and are transparent and informed by science and evidence.

Review - Federal, provincial, and territorial governments will work together to establish the approach to the review of carbon pricing, including expert assessment of stringency and effectiveness that compares carbon pricing systems across Canada, which will be completed by early 2022 to provide certainty on the path forward. An interim report will be completed in 2020 which will be reviewed and assessed by First Ministers. As an early deliverable, the review will assess approaches and best practices to address the competitiveness of emissions-intensive trade-exposed sectors.

Federal, provincial, and territorial governments will continue to engage and partner with Indigenous Peoples as actions are implemented and progress is tracked.

LOOKING AHEAD

This Plan provides a foundation for working together to grow the economy, reduce emissions, and strengthen resilience. Ongoing, collaborative action is needed to generate transformational change and to ensure that all Canadians benefit from the transition to a low-carbon economy. First Ministers are tasking their officials to develop an agenda for federal, provincial, and territorial Ministers to implement this Plan. Annual reports to First Ministers will enable governments to take stock of progress and give direction to sustain and enhance efforts.

ANNEX I: FEDERAL INVESTMENTS AND MEASURES TO SUPPORT THE TRANSITION TO A LOW-CARBON ECONOMY

FEDERAL INVESTMENTS

The federal government will help catalyze the transition to a clean growth economy through significant new investments to complement provincial and territorial actions and investments, including investments in infrastructure, the Low-Carbon Economy Fund, and clean technology funding.

- Budget 2016 outlined a number of new federal investments that will support a transition to a low-carbon economy. Some of these investments include
  - » $62.5 million to support the deployment of infrastructure for alternative transportation fuels, including charging infrastructure for electric vehicles and natural gas and hydrogen refueling stations as well as demonstration of next generation recharging technologies;
  - » $50 million over two years to invest in technologies that will reduce GHG emissions from the oil and gas sector;
  - » $82.5 million over two years to support research, development, and demonstration of clean energy technologies with the greatest potential to reduce GHG emissions;
  - » $100 million per year from the Regional Development Agencies to support clean technology, representing a doubling of thei existing annual aggregate support;
  - » $50 million over four years to Sustainable Development Technology Canada (SDTC) for the SD Tech Fund. These resources will enable SDTC to announce new clean technology projects in 2016 that support the development and demonstration of new technologies that address climate change, air quality, clean water, and clean soil;

THE FEDERAL GOVERNMENT HAS COLLABORATED WITH THE FEDERATION OF CANADIAN MUNICIPALITIES ON THE GREEN MUNICIPAL FUND (GMF) SINCE 2000.

- Budget 2016 provided an additional $125 million over two years including for projects that reduce GHG emissions.
- Recently announced projects under the GMF include a $31.5 million investment for 20 new sustainable municipal projects, such as Canada's first net-zero municipal library and Halifax's ground-breaking Solar City project.

» $40 million over five years to integrate climate resilience into building design guides and codes. The funding will support revised national building codes by 2020 for residential, institutional, commercial, and industrial facilities;
» $129.5 million to implement programming focused on building the science base to inform decision making, protecting the health and well-being of Canadians, building resilience in the North and Indigenous communities, and enhancing competitiveness in key economic sectors; and
» $10.7 million over two years to implement renewable energy projects in off-grid Indigenous and northern communities that rely on diesel and other fossil fuels to generate heat and power.

- Building on the infrastructure investments outlined in Budget 2016, the federal government has announced an additional $81 billion over 11 years for investments in public transit, social infrastructure, transportation that supports trade, Canada's rural and northern communities, smart cities, and green infrastructure.
- Green infrastructure funding will support projects that reduce GHG emissions, enable greater climate change adaptation and resilience, and ensure that more communities can provide clean air and safe drinking water for their citizens. Specific projects could include interprovincial transmission lines that reduce reliance on coal, the development of new low-carbon/renewable power projects, and the expansion of smart grids to make more efficient use of existing power supplies.
- The federal government is proposing the creation of the Canada Infrastructure Bank that will work with provinces, territories, and municipalities to further the reach of government funding directed to infrastructure. The Canada Infrastructure Bank will be responsible for investing at least $35 billion on a cash basis from the federal government into large infrastructure projects that contribute to economic growth through direct investments, loans, loan guarantees, and equity investments.
- Funding under the $2 billion Low Carbon Economy Fund will begin in 2017. This Fund will support new provincial and territorial actions to reduce emissions between now and 2030. Projects will focus on concrete measures that generate new, incremental reductions, while considering cost-effectiveness.
- The Government has also committed more than $1 billion, over four years, to support clean technology including in the forestry, fisheries, mining, energy and agriculture sectors.

FEDERAL CARBON PRICING BENCHMARK

The federal government outlined a benchmark for carbon pricing that reflects the principles proposed by the Working Group on Carbon Pricing Mechanisms and the Vancouver Declaration. Its goal is to ensure that carbon pricing applies to a broad set of emission sources throughout Canada with increasing stringency over time to reduce GHG emissions at lowest cost to business and consumers and to support innovation and clean growth.

The benchmark includes the following elements:

1. Timely introduction.

All jurisdictions will have carbon pricing by 2018.

2. Common scope.

Pricing will be based on GHG emissions and applied to a common and broad set of sources to ensure effectiveness and minimize interprovincial competitiveness impacts. At a minimum, carbon pricing should apply to substantively the same sources as British Columbia's carbon tax.

3. Two systems.

Jurisdictions can implement (i) an explicit price-based system (a carbon tax like British Columbia's or a carbon levy and performance-based emissions system like in Alberta) or (ii) a cap-and-trade system (e.g. Ontario and Quebec).

4. Legislated increases in stringency, based on modelling, to contribute to our national target and provide market certainty.

For jurisdictions with an explicit price-based system, the carbon price should start at a minimum of $10 per tonne in 2018 and rise by $10 per year to $50 per tonne in 2022.

Provinces with cap-and-trade need (i) a 2030 emissions-reduction target equal to or greater than Canada's 30 percent reduction target and (ii) declining (more stringent) annual caps to at least 2022 that correspond, at a minimum, to the projected emissions reductions resulting from the carbon price that year in price-based systems.

5. Revenues remain in the jurisdiction of origin.

Each jurisdiction can use carbon-pricing revenues according to their needs, including to address impacts on vulnerable populations and sectors and to support climate change and clean growth goals.

6. Federal backstop.

The federal government will introduce an explicit price-based carbon pricing system that will apply in jurisdictions that do not meet the benchmark. The federal system will be consistent with the principles and will return revenues to the jurisdiction of origin.

7. Five-year review.

The overall approach will be reviewed by early 2022 to confirm the path forward, including continued increases in stringency. The review will account for progress and for the actions of other countries in response to carbon pricing, as well as recognition of permits or credits imported from other countries.

8. Reporting.

Jurisdictions should provide regular, transparent, and verifiable reports on the outcomes and impacts of carbon pricing policies.

The federal government will work with the territories to address their unique circumstances, including high costs of living, challenges with food security, and emerging economies.

OTHER RECENT FEDERAL MEASURES

The federal government has also recently announced new federal measures, including

- During the North American Leaders Summit in June 2016, the federal government made joint commitments with the United States and Mexico to
  - » phase out fossil fuel subsidies by 2025. The commitment was reaffirmed by G-20 countries in September 2016.
  - » reduce methane emissions from the oil and gas sector by 40 to 45 percent below 2012 levels by 2025.
- On October 15, 2016, Canada signed onto the Kigali Amendment to the Montreal Protocol and committed to propose new regulations to significantly reduce HFC consumption and prohibit the manufacture and import into Canada of certain products containing HFCs. These proposed regulations were published on November 26, 2016. This is additional to measures already introduced to increase the recovery, recycling, and destruction of HFCs in refrigeration and air conditioning equipment and to established regulatory provisions for an HFC reporting system.
- On November 17, 2016, Canada released its Mid-Century Long-Term Low-Greenhouse Gas Development Strategy. The mid-century strategy describes various pathways for innovative and creative solutions. Canada's mid-century strategy is not a blueprint for action nor is it policy prescriptive. It is based on modelling of different scenarios and looks beyond 2030 to start a conversation on the ways we can reduce emissions for a cleaner, more sustainable future by 2050. As a result, it will be a living document.
- On November 21, 2016, the federal government announced that it would be amending its existing coal-fired electricity regulations to accelerate the phase out of traditional coal-fired electricity by 2030. The federal government also announced that, to support the transition away from coal towards cleaner sources of generation, performance standards for natural gas-fired electricity are also being developed.
- On November 25, 2016, the federal government announced that it will consult with provinces and territories, Indigenous Peoples, industries, and non-governmental organizations to develop a clean fuel standard. It is expected that once developed, a clean fuel standard would promote the use of clean technology and lower carbon fuels, and promote alternatives such as electricity, biogas, and hydrogen.

ANNEX II: PROVINCIAL AND TERRITORIAL KEY ACTIONS AND COLLABORATION OPPORTUNITIES WITH THE GOVERNMENT OF CANADA

INTRODUCTION

The Paris Agreement and the Vancouver Declaration have set an ambitious course for low carbon growth and climate action in Canada. The Pan-Canadian Framework on Clean Growth and Climate Change will build on the leadership shown and actions taken by the provinces and territories as well as new policies announced by the federal government.

This annex outlines provincial and territorial accomplishments in reducing greenhouse gas emissions and accelerating clean growth, and presents steps that each jurisdiction has taken or is taking to implement carbon pricing.

The annex also outlines areas where the federal government and each provincial and territorial government will work together to implement the Pan-Canadian Framework in order to spur growth and jobs for Canadians, reduce our emissions and adapt to climate change.

Each province and territory is unique and is responding to the urgency of climate change and the opportunity offered by clean growth in its own way. Effective action will require close collaboration between governments. Each provincial and territorial government has identified multiple areas for potential partnerships with the federal government, adapted to their own priorities, circumstances and strengths. Governments are committed to working together on these priorities to support the implementation of the Pan-Canadian Framework. Governments will also engage the contributions of Indigenous Peoples in advancing shared goals.

This work will be supported by significant new federal investments to drive the transition to a clean growth economy, as outlined in Budget 2016 and the 2016 Fall Economic Statement, including public transit and Green Infrastructure, the Canada Infrastructure Bank, the Low-Carbon Economy Fund, and funding for clean technology and innovation. Federal investments are intended to supplement and accelerate investments by provinces and territories, and will follow applicable program criteria.

BRITISH COLUMBIA

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in British Columbia include:

British Columbia's Climate Leadership Plan

B.C. has proven that it is possible to reduce emissions while growing the economy and creating jobs and it's important that this balance be maintained. With this in mind, B.C. released its Climate Leadership Plan in the summer of 2016.

Building on the comprehensive foundation established in 2008, the plan lays out a series of targeted, sector-specific actions that will reduce emissions by 25 million tonnes (Mt) of carbon dioxide equivalent (CO_2e) and create 66,000 jobs. The plan will be further strengthened in the months and years ahead, as B.C. continues to work with First Nations, the federal government, communities, industry and others. B.C. is committed to reducing GHG emissions by 80% below 2007 levels by 2050. To read B.C.'s Climate Leadership Plan, visit: http://climate.gov.bc.ca/

Revenue-Neutral Carbon Tax

B.C. has the highest broad-based carbon tax in North America. The carbon tax sets a transparent and predictable price on carbon while returning all revenue to B.C. individuals and businesses. The price signal creates a real incentive to reduce emissions across the economy and is the backbone of B.C.'s approach to climate action.

Forestry

B.C.'s forests offer potential for storing carbon, so the Province is taking further action to rehabilitate up to 300,000 hectares of Mountain Pine Beetle and wildfire impacted forests over the first five years of the program; recover more wood fibre; and avoid emissions from burning slash.

Clean LNG

B.C. has an abundance of natural gas, which is a lower carbon fuel that will play a critical role in transitioning the world economy off of high carbon fuels such as coal. B.C. is developing the resource responsibly, and provincial legislation will make the emerging LNG sector the cleanest in the world. B.C. is also electrifying upstream development of natural gas and will require a 45% reduction in methane emissions by 2025.

100% Clean Electricity

Thanks to significant historical investments, B.C.'s electricity is already 98% clean or renewable and British Columbians have the third-lowest residential rates in North America. Going forward under the Climate Leadership Plan, 100% of the supply of electricity acquired by BC Hydro for the integrated grid must be from clean or renewable sources. The $8.3 billion Site C Clean Energy Project is a major part of B.C.'s clean energy future and will create enough electricity to power 450,000 homes.

Clean Transportation

B.C. is taking real action to reduce emissions from the transportation sector and help British Columbians make greener choices—initiatives include Zero Emissions Vehicles rebates and funding for more charging stations (which have helped BC become the Canadian leader in clean energy vehicle sales per capita); a scrap-it program; low carbon and renewable fuel standards; and historic investments in transit. B.C.'s actions in the transportation sector have already reduced annual emissions by an estimated 2.5 Mt and combined with the new actions, will reduce annual emissions by up to a further 3.4 Mt by 2050.

Adaptation

In 2010, the Province created a comprehensive strategy to address the changes we will see as a result of climate change. It is based on three key strategies: build a strong foundation of knowledge and tools; make adaptation a part of government business; and assess risks and implement priority adaptation actions in key climate sensitive sectors. The Province is now working with the federal government and other Canadian jurisdictions to further improve the management of the risks associated with a changing climate.

These actions provide a strong contribution to a comprehensive pan-Canadian framework.

ACTION ON PRICING CARBON POLLUTION

B.C.'s revenue-neutral carbon tax has been in place since 2008. It is set at $30/tonne and covers approximately 75% of the province's economy. All revenues generated will be returned to tax payers. B.C. will assess the interim study in 2020 and determine a path forward to meet climate change objectives.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

British Columbia and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Growing our forests; reducing our emissions

Forests present a unique opportunity to address climate change because trees absorb CO_2 when they grow. British Columbia, the Government of Canada and First Nations will work together to reduce GHG emissions through forestry activities, including reforestation, enhanced silviculture techniques, and the salvaging of unmerchantable trees for processing into dimensional lumber and bioenergy. The initiative is expected to reduce emissions by 12 Mt in 2050 and create 20,000 jobs.

Preparing for and adapting to climate change

British Columbia and the Government of Canada will support projects across the province to make infrastructure more resilient to a changing climate, and to help communities adapt to a changing climate. Flood mitigation will be an area of focus.

Reduce Emissions from Natural Gas Activities

British Columbia and the Government of Canada will work together to bring clean grid electricity to natural gas operations in northeast B.C. They will co-fund the construction of new transmission lines and other public electrification infrastructure that could serve up to 760 megawatts of upstream natural gas processing load and avoid up to 4 Mt of emissions per year.

Electricity Grid Interconnection

British Columbia and the Governments of Canada and Alberta will work together to restore the capability of the existing high-voltage electricity grid interconnection with Alberta. This project will improve access to clean electricity in Alberta and will result in lower GHG emissions and air pollution, and improved grid reliability in both provinces.

Clean Technology Innovation

British Columbia and the Government of Canada will work together to spur the development and commercialization of new technologies that will reduce emissions and create jobs for Canadians.

ALBERTA

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in Alberta include:

Climate Leadership Plan

The Climate Leadership Plan is a made-in-Alberta climate change strategy, specifically designed for Alberta's unique economy. While details of the final strategy are still being developed, the Alberta government has moved forward on a number of key areas.

Clean Electricity

Alberta will phase-out GHGs from coal-fired power plants and achieve 30% renewable energy by 2030.

Alberta will add 5,000 megawatts of renewable energy capacity by 2030 through the Renewable Electricity Program. To meet this target, investment in Alberta's electricity system will be solicited through a competitive and transparent bidding process, while ensuring projects come online in a way that does not impact grid reliability and is delivered at the lowest possible cost to consumers.

A new provincial agency, Energy Efficiency Alberta, has been created to promote and support energy efficiency and community energy systems for homes, businesses and communities.

Capping Oil Sands Emissions

A legislated maximum emissions limit of 100 Mt in any year, with provisions for cogeneration and new upgrading capacity, will help drive technological progress.

Reducing Methane Emissions

Alberta will reduce methane gas emissions from oil and gas operations by 45% by 2025.

Innovation and Technology

Alberta is investing in innovation and technology to reduce GHGs, encourage a more diversified economy and energy industry, and create new jobs, while improving opportunities to get the province's energy products to new markets. Alberta has created a task force that will make recommendations on a Climate Change Innovation and Technology Framework.

These actions provide a strong contribution to a comprehensive pan-Canadian framework.

ACTION ON PRICING CARBON POLLUTION

A carbon levy to be included in the price of all fuels that emit greenhouse gases when combusted, including transportation and heating fuels such as diesel, gasoline, natural gas and propane. The levy will be applied at a rate of $20/tonne on January 1, 2017 and will increase to $30/tonne one year later.

The Climate Leadership Plan is designed for Alberta's economy. The economic impact of carbon pricing is expected to be small, and every dollar will be reinvested back into the local economy. Reinvesting carbon revenue in our economy will diversify our energy industry by investing in large scale renewable energy, bioenergy initiatives, and transformative innovation and technology. Over the next 5 years:

$6.2 billion will help diversify our energy industry and create new jobs:

- $3.4 billion for large scale renewable energy, bioenergy and technology

- $2.2 billion for green infrastructure like transit
- $645 million for Energy Efficiency Alberta

$3.4 billion will help households, businesses and communities adjust to the carbon levy:

- $2.3 billion for carbon rebates to help low- and middle-income families
- $865 million to pay for a cut in the small business tax rate from 3% to 2%
- $195 million to assist coal communities, Indigenous communities and others with adjustment

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

Alberta and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Clean Electricity

Alberta and the federal government will to work together to advance renewable energy, coal to natural gas conversion, and potential hydroelectric projects, including pump storage projects. Alberta is committed to developing incentives for renewable generation in a manner that is compatible with Alberta's unique electricity market.

B.C. – Alberta Intertie

Alberta is working with British Columbia and the federal government to explore new and enhanced interties. The Alberta Electric System Operator is currently working with BC Hydro and industry on a key project, the restoration of the B.C.-Alberta 950 MW intertie to its full path rating (expected completion is in 2020). This restoration would allow imports of 1200 MW on the BC-AB intertie.

Innovation and Technology

Alberta is focused on the opportunity to leverage environmental policies and programs into new manufacturing, innovation, and clean technology businesses. Current opportunities include superclusters, advanced sensor technology for environmental applications including methane monitoring and reductions, and municipal waste diversion. Innovative solutions will result in meaningful GHG reductions across Canada and the export of solutions to promote a lower carbon world.

Disaster Mitigation / Infrastructure

Alberta is undertaking targeted work to address the hazards to which Albertans are vulnerable, including flood, wildfire, heat, drought, landslides, and wind.

While hazards and disaster risks have always been a concern, climate change is driving the need to adapt to more intense and frequent events. Federal support for wildfire mitigation infrastructure will reduce the risk of wildland fires. In addition, flood risk requires immediate mitigation infrastructure such as dykes and dams. Federal partnership on these initiatives will support risk management.

.

ONTARIO

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in Ontario include:

Permanent Closure of Coal-fired Electricity Generating Stations

On April 15, 2014, Ontario became the first jurisdiction in North America to fully eliminate coal as a source of electricity generation. This action is the single largest GHG reduction initiative in North America. On November 23, 2015, Ontario passed the *Ending Coal for Cleaner Air Act*, permanently banning coal-fired electricity generation in the province.

Ontario's Climate Change Strategy and Action Plan

On November 24, 2015, Ontario released its Climate Change Strategy setting the framework for the province to meet its long-term 2050 GHG emissions reduction target. The Strategy highlights five key objectives for transformation:

1. A prosperous low-carbon economy with world-leading innovation, science and technology
2. Government collaboration and leadership
3. A resource-efficient, high-productivity society
4. Reducing GHG emissions across sectors
5. Adapting and thriving in a changing climate

On June 8, 2016, Ontario released its Climate Change Action Plan to implement the strategy over the next five years and put Ontario on the path to achieve its longer term objectives. Policies and programs identified in the Action Plan include:

- Transforming how ultra-low and carbon-free energy technologies are deployed in our homes and workplaces, and how we move people and goods
- Halting rising building-related emissions, with a focus on helping homeowners and small businesses move to low- and zero-carbon energy
- Making available funding for industries and manufacturers proposing to transform their operations and move off carbon-based fuels and peak electricity
- Aligning Ontario's R&D and innovation funding to place a greater emphasis on climate change science and technologies, with a view to making the discoveries that could lead to breakthroughs in zero-carbon technology

Ontario has made measurable progress in reducing GHGs. According to Environment and Climate Change Canada's 2016 National Inventory Report, from 2005 to 2014, Ontario's emissions decreased by 41 Mt (-19%), over the same period, Canada-wide emissions fell by 15 Mt (-2%).

These actions provide a strong contribution to a comprehensive pan-Canadian framework.

ACTION ON PRICING CARBON POLLUTION

On May 18, 2016, Ontario passed its landmark *Climate Change Mitigation and Low-carbon Economy Act,* which creates a long term framework for climate action. The Act creates a robust framework for cap and trade program, ensures transparency and accountability on how any proceeds collected under the program are used and enshrines emission reduction targets in legislation.

Ontario's approach, including its cap and trade program and associated emissions reduction targets, will exceed the standards of the federal carbon pricing benchmark. Ontario's targets are:

- 15% below 1990 levels by 2020;
- 37% below 1990 levels by 2030; and
- 80% below 1990 levels by 2050.

Ontario is a founding member of the Western Climate Initiative (WCI), a not-for-profit organization established in 2008 to help member states and provinces execute their cap and trade programs. In 2017, Ontario will link its cap and trade system with those of WCI members Quebec and California to create the largest cap and trade system in North America.

Ontario will set a cap on total emissions from the covered sectors in 2017 based on the forecast emissions for large final emitters, electricity generation and transportation and heating fuels. Allowances will then be created in an amount equal to the cap and either sold or provided free-of-charge to Ontario emitters.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

Ontario and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Invest in Zero Emission Transportation and Infrastructure

Ontario is committed to increase uptake of zero emission passenger and commercial vehicles, both by providing purchasing incentives and by expanding the EV charging network across Ontario. In its 2016 budget, the federal government committed to support the deployment of alternative transportation fuel infrastructure, including electric charging stations. Ontario and the Government of Canada will work together to support the deployment of EV vehicles through enabling infrastructure.

Invest in Other Zero Emission Transportation

Ontario seeks a partnership with the Government of Canada to support enabling infrastructure that will increase the availability and use of lower carbon fuels, including LNG, increase the use of low carbon trucks and buses and increase the availability of LNG fueling infrastructure. Ontario is dedicating significant resources for these additional transportation initiatives. Expected emissions reductions in the transportation sector overall are 2.45 Mt in 2020.

Assist with Building Retrofits, Energy Audits and Technology Deployment

Ontario seeks a partnership with the Government of Canada as the province develops programs for fuel switching and energy efficiency, such as retrofits for existing residential buildings (including targeted initiatives for low-income households), and clean technologies for industries and small and medium enterprises. Partnership would increase investment in this area, allowing acceleration and scaling up of progress.

Ontario Climate Modelling Services Consortium

Ontario seeks a partnership with the Government of Canada to build regional capacity and support adaptation actions. Ontario plans to establish an Ontario Climate Modelling Services Consortium, which would act as a one window source of data to help the public and private sectors make evidence-based decisions.

The Consortium would operate at arm's length from government. Ontario would seek partnerships with other governments, non-governmental organizations and the private sector to ensure the organization's effectiveness and long term success. The Consortium would also be expected to develop service fee revenue streams to contribute to the organization's fiscal sustainability.

Electricity Transmission

Ontario, in collaboration with the Government of Canada, will work with its regional partners to advance opportunities to expand and upgrade electricity transmission infrastructure to support clean hydroelectric power to displace the production of electricity from fossil fuels.

Ontario will also collaborate with the Government of Canada to accelerate access to clean electricity in remote Indigenous communities. This will lessen dependence on expensive diesel fuel and reduce greenhouse gas emissions and air pollution.

QUÉBEC

KEY ACTIONS TO DATE

Some of the key measures taken to date by Québec, which has the lowest greenhouse gas emissions per capita between the provinces in Canada, include:

2013-2020 Action Plan on Climate Change (PACC 2013-2020)

PACC 2013-2020 will reduce GHG emissions by 20% below the 1990 level by 2020. Among its other measures, the action plan offers financial help to the different stakeholders of Québec society so they can reduce their energy consumption, improve their practices, innovate and adjust. The work surrounding the development of the actions of Québec after the 2020 period is underway, in particular to reduce GHG emissions of the province by 37.5 % below the 1990 level by 2030.

2016-2030 Energy Policy

The Energy Policy will favour a transition to a low carbon footprint economy, chiefly by improving energy efficiency by 15%, by reducing petroleum consumption by 40%, and by increasing the production of renewable energies by 25%. Québec is one of the world's main producers of renewable energy, which represents 99.8% of its total electricity production.

2013-2020 Governmental Climate Change Adjustment Strategy

The Strategy will mitigate the impact of climate change on the environment, the economy and the communities, and will strengthen the resiliency of Québec society. The government of Québec has, notably, invested in the Ouranos consortium in order to get a better understanding of the impact of climate change on its territory, and to better inform the decision-making process and the development of solutions.

2015-2020 Transport Electrification Plan

Québec targets 100,000 electric vehicles on the road in 2020 and one million in 2030. The zero-emission vehicle (ZEV) standard adopted in October 2016 will encourage automotive manufacturers to improve their offer of ZEV, and the investments in electrification will allow Québec to build up its available renewable energies, its expertise and its world-class know-how.

These measures represent a major contribution at the Pan-Canadian level.

ACTION ON PRICING CARBON POLLUTION

Pioneer in the use of cap-and-trade systems for greenhouse gas emissions allowances, Québec`s system has been linked to California's since 2014, and will soon be linked to that of Ontario. It represents the largest carbon market in North America, and is often referred to as an example of performance and rigour. Because it is based on hard caps to reduce GHG emissions, it is a robust and efficient tool to achieve the ambitious mitigation goals Québec has set for itself for 2020 and 2030.

Furthermore, auction revenues from its cap-and-trade system are entirely reinvested in measures that will spur the transition of Québec's economy to a more resilient and low-carbon one. This comprehensive approach, tailored to the needs and specificities of Québec, allows Québec to fulfill its leadership role in the fight against climate change in North America and internationally.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

The governments of Québec and Canada intend to collaborate in the following priority areas in order to fight climate change and allow clean economic growth:

Electric and Public Transport

Support the development of the offer and infrastructure of electric and public transport, by completing various projects such as the Metropolitan Electric Network (MEN), the implementation of bus rapid transit (BRT) systems between Montreal and Laval, the extension of the BRT in Gatineau, and the implementation of a BRT in Québec.

Energy Efficiency and Conversion

Speed up the reduction of GHG emissions in Northern communities, as well as on the Lower North Shore and Magdalen Islands, by replacing diesel with renewable energy sources for the electricity supply of their free-standing network.

Promote the implementation of energy performance and efficiency standards for new buildings, as well as for the renovation of existing buildings. Invest in the industrial sector to improve the energy performance of fixed production processes, by providing innovative technologies and reducing the use of gases with high warming potential such as hydrofluorocarbons, which Québec will continue to prioritize.

Recognition of the International Trade of Emission Rights

Contribute to the implementation of Articles 6 and 13 of the Paris Accord, to which the accounting and disclosure principles of the Western Climate Initiative (WCI) can contribute, as well as within a possible agreement between Canada and the United States regarding the accounting and attribution of "internationally transferred mitigation outcomes" as part of the contributions determined at national level (CDN).

Québec will also share with the government of Canada a detailed methodology, developed in collaboration with California and soon Ontario, in order to tabulate in its international reports the emission reductions achieved by Québec thanks to the carbon market.

Innovation and Adjustment to Climate Change

Promote innovation in green technology and GHG emission reduction, and collaborate on increasing the resiliency of the communities affected by climate change, by assessing the vulnerabilities and risks, adjusting land planning and use, and designing sustainable projects.

Québec will provide its expertise to the initiatives of the government of Canada, focusing in particular on joint financing of prevention and protection infrastructure against certain natural disasters linked to climate change.

NEW BRUNSWICK

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in New Brunswick include:

Transitioning to a Low-Carbon Economy: New Brunswick's Climate Change Action Plan

The Climate Change Action Plan outlines a bold vision for New Brunswick and sets renewed GHG reduction targets: 2030 target of 35% below 1990 levels; and 80% below 2001 levels by 2050. The plan also address other commitments, such as the Canadian Energy Strategy, released by the Council of the Federation in 2015, and contains a Climate Change Adaptation Strategy supported by actions to build resilience into New Brunswick communities, businesses, infrastructures and natural resources.

The Action Plan provides a clear path forward to reduce GHG emissions while promoting economic growth and enhancing current efforts to adapt to the effects of climate change.

Locally-owned Renewable Energy Projects that are Small Scale (LORESS)

In May 2015, the province introduced legislation to allow local entities to develop renewable energy sourced electricity generation in their communities. This will enable universities, non-profit organizations, co-operatives, First Nations and municipalities to contribute to NB Power's renewable energy requirements.

Shifting to renewables in electricity generation

Two fossil fuelled power plants were closed in recent years – one coal and one heavy oil. Also, 300 megawatts of wind energy was installed in the province and biomass fuel use in industry was expanded to displace oil. Solid waste landfills are capturing biogas and some are generating electricity.

These actions are allowing NB Power to achieve the regulated Renewable Portfolio Standard of 40% of in-province sales from renewable energy sources by 2020. This translates to approximately 75% non-emitting by 2020 including nuclear.

Adaptation

The province has developed a progressive Climate Change Adaptation Program including assembling future climate projections, and supporting climate impact vulnerability assessments in communities and for infrastructure. Adaptation projects also focus on solutions building and advanced planning to help reduce or avoid the costs of impacts such as more severe and frequent flooding, coastal erosion and storm events and disease and pest migration.

Several projects are carried out in collaboration with other Atlantic provinces, notably under the Regional Adaptation Collaborative (RAC), which involves federal support, as well as with the Gulf of Maine Council and US partners.

These actions provide a strong contribution to a comprehensive Pan-Canadian Framework.

ACTION ON PRICING CARBON POLLUTION

The province will implement a made-in-New Brunswick carbon pricing mechanism that addresses the requirements of the federal government for implementing a price on carbon emissions by 2018 and that at the same time recognizes New Brunswick's unique economic and social circumstances. The provincial government will take into consideration the impacts on low-income families, trade-exposed and energy-intensive industries, and consumers and businesses, when developing the specific mechanisms and implementation details, including how to reinvest proceeds.

Any carbon pricing policy will strive to maintain competitiveness and minimize carbon leakage (i.e., investments moving to other jurisdictions). Proceeds from carbon emissions pricing will be directed to a dedicated climate change fund.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

The Government of New Brunswick and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Enhanced Electricity Generation and Transmission System

New Brunswick will work with the other Atlantic provinces and the Government of Canada to advance opportunities for clean electricity generation, transmission, storage and demand management linkages across the region. This will: improve access to non-emitting electricity; support the phase-out of coal-fired electricity generation; improve grid reliability and energy security; and, consistent with fair market principles, help provinces access export markets for clean, non-emitting electricity.

This will contribute to both the Atlantic Growth Strategy and Canadian Energy Strategy and will build on existing regional coordination efforts, leading to an integrated regional electricity strategy.

Energy Efficiency

The Government of New Brunswick, in partnership with the Government of Canada, will seek to enhance energy efficiency programs by targeting GHG emission reduction opportunities across sectors and fuels.

Examples of possible targeted interventions include programs that help: trucking fleets add aerodynamic and other efficiency measures to existing equipment; small- to medium-size industry improve their compressed air systems, boilers and lighting; commercial and institutional facilities invest in heating, lighting and other retrofits; and families retrofitting their homes to reduce energy costs, with special treatment for low- and fixed-income families.

Industrial Emissions Reductions

The Government of New Brunswick and the Government of Canada will work to support industrial emission reduction initiatives through technology and energy efficiency improvements while maintaining productivity. For example, there are significant opportunities to reduce emissions resulting from industrial production in the Belledune area of New Brunswick.

NOVA SCOTIA

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in Nova Scotia include:

The Environmental Goals and Sustainable Prosperity Act (2007)

In 2007, Nova Scotia passed legislation outlining principles for sustainable economic growth, including a requirement to reduce GHG emissions in the province to 10% below 1990 levels by 2020. The development and implementation of the Nova Scotia Climate Action Plan led to early action on the electricity sector, the largest source of emissions in the province. As a result, Nova Scotia has not only achieved its target six years early, it has also already met the Canadian 2030 target of 30% below 2005 levels, and is on a track to continue reducing emissions.

Nova Scotia's Greenhouse Gas Emissions Regulations

Nova Scotia was the first province in Canada to place a hard cap on GHG emissions from the electricity sector. These regulations, created in 2009 and enhanced in 2013, required the utility to reduce GHG emissions by 25% by 2020, and 55% by 2030. This is a measured and flexible approach which will enable a transition from coal to clean energy in the province.

Nova Scotia's Renewable Energy Regulations

In addition to the hard cap on GHG emissions, Nova Scotia also has a renewable energy standard for the electricity sector. This standard established requirements for 25% of electricity to be sourced from renewable energy by 2015, and 40% by 2020.

Energy Efficiency

Nova Scotia has Canada's first energy efficiency utility, Efficiency Nova Scotia. This independent organization has achieved an annual reduction in electricity demand of over 1% since its creation. It also administers comprehensive energy efficiency programs for low income and First Nations Nova Scotians. These efforts reduce GHG emissions while supporting the growth of the low carbon economy.

Tidal Energy

The Bay of Fundy and Minas Basin are home to the highest tides in the world- every day, more water flows into this bay than the output from all the rivers in the world combined. Nova Scotia has been supporting the development of these tides as a source of clean, predictable and reliable energy for Nova Scotians and as a clean technology export. The Fundy Ocean Research Centre for Energy (FORCE) now has a grid connected 2MW tidal turbine with plans to install more in the coming years.

Waste Management

Nova Scotia is also making efforts to reduce GHG emissions by diverting organic waste from landfills, recycling and creating a circular economy. Progress on waste diversion is reflected in a 30% reduction in greenhouse emissions from the waste sector since 2002.

These actions are just a snapshot of what Nova Scotians are doing to reduce GHG emissions and provide a strong contribution to a comprehensive pan-Canadian framework.

ACTION ON PRICING CARBON POLLUTION

As part of the pan-Canadian benchmark for carbon pricing, Nova Scotia has committed to implement a cap and trade program in the province that builds on our early action in the electricity sector.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

The Government of Nova Scotia and the Government of Canada intend to collaborate in the following priority domains to address climate change and advance clean growth:

Energy Efficiency

Nova Scotia and the Government of Canada are committed to partnering to enhance the existing provincial energy efficiency programs for homes and businesses with the objective of reducing energy use and saving energy costs. This could include expanded energy efficiency programs, efforts to accelerate the electrification of homes and businesses through heat pumps and smart meters, district energy systems, as well as electric vehicle infrastructure.

Renewable Energy Generation, Transmission and Storage

Nova Scotia, in partnership with the Government of Canada, will work together to advance opportunities for renewable energy generated from sources such as wind, tidal and solar, as well as the enabling transmission and storage infrastructure to ensure growth beyond current technical limits. Research and development capacity will continue to be strengthened.

Planning and Implementing Adaptation Infrastructure

Nova Scotia and the Government of Canada will work together and invest in projects to make infrastructure more resilient to a changing climate, and to help communities increase their capacity to adapt to a changing climate.

Regional Electricity Grid Connections

Nova Scotia will work with the other Atlantic provinces and the Government of Canada to advance opportunities for clean electricity generation, transmission, storage and demand management linkages across the region.

This will: improve access to non-emitting electricity; support the phase-out of coal-fired electricity generation; improve grid reliability and energy security; and, consistent with fair market principles, help provinces access export markets for clean, non-emitting electricity. This will contribute to both the Atlantic Growth Strategy and Canadian Energy Strategy and will build on existing regional coordination efforts, leading to an integrated regional electricity strategy.

PRINCE EDWARD ISLAND

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in Prince Edward Island include:

Climate Change Policy Framework

Prince Edward Island's primary areas of strategic focus for climate change fall into the themes of built environment, transportation, agriculture, conservation and adaptation. Prince Edward Island is in the process of developing new climate change strategies that will result in further actions and initiatives to reduce GHG emissions across the province, increase our resilience to a changing climate, and advance measures to strengthen and grow a prosperous green economy in the province.

Prince Edward Island does not have a legislated provincial emissions reduction target but does contribute to the regional target set by the Conference of the New England Governors and Eastern Canadian Premiers (NEG-ECP). The targets are 10% reductions from 1990 by 2020, 35% - 45% below 1990 levels by 2030, and 75-85% reduction from 2001 levels by 2050. PEI has realized a 9% reduction in GHG emissions since 2005.

PEI Wind Energy

Prince Edward Island is a world leader in producing clean electricity from wind. Prince Edward Island boasts the highest penetration of wind in Canada and 2nd highest in the world next to Denmark. The Government of Prince Edward Island has demonstrated a long-term commitment and investments of $119 million to wind energy.

The first commercial wind farm in Atlantic Canada was developed by the PEI Energy Corporation at North Cape in 2001. North Cape was expanded in 2003, doubling in size.

In January 2007, the PEI Energy Corporation commissioned its second wind farm at East Point. In 2014, the Island's newest wind farm was commissioned at Hermanville/ Clearspring. As a result, Prince Edward Island now has a total installed wind capacity of 78% of peak load, which supplies almost 25% of the province's total electricity requirements.

Biomass

Prince Edward Island is home to Canada's longest-running, biomass-fired district heating system. Operating since the 1980s, the system has expanded to serve over 125 buildings in the downtown core of Charlottetown, including the University of Prince Edward Island and the Queen Elizabeth Hospital. It has contributed to the establishment of a local waste-wood fuel-supply market. The system burns approximately 66,000 tons of waste materials annually.

Coastal Erosion

Prince Edward Island has partnered with the University of Prince Edward Island (UPEI) Climate Research Lab to study coastal vulnerability, including the award-winning Coastal Impacts Visualization Environment (CLIVE). CLIVE is an innovative 3D platform for visualizing the potential future impacts of coastal erosion and coastal flooding at local community scales, on PEI and elsewhere, using past data and Intergovernmental Panel on Climate Change models.

The province has also invested in UPEI in its development of an expansive, cutting-edge coastal erosion monitoring network. This research includes the use of drone and GIS technology to quantify and assess erosion volume of shoreline disappearance along Prince Edward Island's coastline.

Environmental Awareness in Agriculture

As a key industry for Prince Edward Island, agriculture is of particular consequence for climate change and green growth. In recent years, PEI farmers, watershed groups and the fertilizer industry have been implementing a 4R Nutrient Stewardship program to encourage the efficient use of fertilizer and help reduce related emissions.

Island farmers have been making advances in crop diversification, including testing potato varieties that require less fertilizer and adding nitrogen-fixing pulse crops which improve the environmental sustainability of annual cropping systems. The further use of robotics in dairy farming and food additives in livestock production is being employed to reduce methane emissions.

Prince Edward Island is also the first and only jurisdiction in Canada with a provincially-supported Alternative Land Use Services program. Currently, the program has converted almost 4,000 hectares of marginal land from annual crop production to perennial or permanent cover.

These actions provide a strong contribution to a comprehensive pan-Canadian framework and are helping facilitate the transition to a low-carbon economy.

ACTION ON PRICING CARBON POLLUTION

Prince Edward Island will introduce a made-in-PEI approach to carbon pricing which positively contributes to climate change action while benefitting Prince Edward Islanders and ensures optimal conditions for continued growth of the provincial economy. Prince Edward Island will focus on measures that will meaningfully decrease our GHG emissions and recognize the particular elements of our economy.

Our approach will ensure consistent and competitive alignment with efforts being made across the country, including mitigation and price initiatives in all provinces, especially those in our region. PEI is committed to an approach that will directly enhance provincial adaptation and mitigation efforts.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

Prince Edward Island and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Energy Efficiency

Prince Edward Island, in partnership with the Government of Canada, will pursue improved energy efficiency for all sectors in the province as outlined in the 2016 PEI Energy Strategy. The Strategy and forthcoming Climate Change Action Plan are key policy tools in reducing GHGs, driving economic growth and creating jobs locally and in the region.

Prince Edward Island is committed to engaging in incremental actions through solutions for the built environment, including businesses and homes, as well as in new building construction. It has been clearly illustrated by research in the region that investing in efficiency is one of the most effective means of delivering jobs and economic growth widely – across sectors and regions – while reducing emissions and providing savings to consumers.

With a predominantly rural population and some of the highest electricity rates in the country, particular consideration will be given to low-income Island families, and sectors that may find the transition to a lower-carbon environment challenging.

Clean Energy

Energy resilience and security and a move to greater electrification are key priorities for the province. Prince Edward Island, in partnership with the Government of Canada, will work to expand its world-class wind resource, invest in solar, and enable greater integration of renewable energy through storage. Prince Edward Island will work with the other Atlantic Provinces and the Government of Canada to advance opportunities for clean electricity generation, transmission, storage and demand management linkages across the region.

This will: improve access to non-emitting electricity; support the phase-out of coal-fired electricity generation; improve grid reliability and energy security; and, consistent with fair market principles, help provinces access export markets for clean, non-emitting electricity. This will contribute to both the Atlantic Growth Strategy and Canadian Energy Strategy and will build on existing regional coordination efforts leading to an integrated regional electricity strategy.

Adaptation

With its 1100 km of coastline, Prince Edward Island is uniquely vulnerable to climate impacts and is positioned to advance innovative solutions to make infrastructure more resilient to a changing climate.

Prince Edward Island and the Government of Canada will work together to act on findings from disaster risk reduction planning and coastal infrastructure assessment, and to improve decision-making capacity to adapt to climate change through planning, training and monitoring.

Research and Development

Prince Edward Island and the Government of Canada will work together to support research and development on promising practices and innovation in the areas of agriculture, marine industries, and smart grid and micro-grid/storage. Prince Edward Island provides an ideal demonstration site for development in these areas.

This research will advance better understanding of influences on emissions and opportunities for clean growth in key sectors of the Prince Edward Island economy.

Transportation

Prince Edward Island relies on exports for continued economic growth. The Prince Edward Island economy is heavily reliant on ground transportation for the movement of goods to markets across Canada and around the world, and the movement of people across the province. The province has no rail system, large container ports, or robust public transit. As the most rural province in Canada, mitigation in transportation is a difficult challenge.

Prince Edward Island and the Government of Canada will work together on methods to support an eventual move to greater electrification in transportation, including corresponding work with other jurisdictions in Canada. Proposed specific areas of work include installation of public charging infrastructure across the province and in collaboration regionally where possible.

NEWFOUNDLAND & LABRADOR

KEY ACTIONS TO DATE

Newfoundland and Labrador is making significant investments to increase the use of clean and renewable hydroelectric power in the province. The Muskrat Falls hydroelectric development, with capital costs of over $9 billion, will result in 98% of electricity consumed in the province coming from renewable sources by 2020.

Muskrat Falls will facilitate advancing by more than a decade the decommissioning of the largest thermal oil-fired electricity generation facility in the province, reducing greenhouse gas (GHG) emissions by about 1.2 Mt annually (equivalent to more than 10% of the province's total emissions in 2015), and assisting other jurisdictions to meet their GHG reduction targets.

To focus the province's efforts to tackle climate change, Newfoundland and Labrador has adopted GHG emission reduction targets of 10% below 1990 levels by 2020 and 75-85% below 2001 levels by 2050, and has endorsed, on a regional basis, the Conference of New England Governors and Eastern Canadian Premiers' reduction marker range of at least 35-45% below 1990 levels by 2030.

To make progress towards these targets Newfoundland and Labrador released a Climate Change Action Plan in 2011 identifying 75 actions to reduce GHG emissions and adapt to the adverse impacts of climate change. Building on this work, Newfoundland and Labrador passed the *Management of Greenhouse Gas Act* in June 2016, creating a legislative framework for reducing GHGs from large industry, and has completed public consultations to inform new provincial actions on climate change.

These actions provide a strong contribution to a comprehensive Pan-Canadian Framework.

ACTION ON PRICING CARBON POLLUTION

The Government of Newfoundland and Labrador and the Government of Canada continue to collaborate to ensure that Newfoundland and Labrador's climate change plan, including carbon pricing, is consistent with the goals in the Pan-Canadian Framework to reduce GHG emissions, improves resilience to climate impacts, and accelerates innovation and job creation.

This made-in-Newfoundland and Labrador plan will address the province's particular social, economic, and fiscal realities. This includes sensitivity to the particular circumstances facing Labrador communities, and the need to consider impacts on all remote and isolated communities, vulnerable populations, consumers and trade-exposed industries, as well as the need to take account of the province's reliance on marine transportation and the absence of lower carbon alternatives.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

Newfoundland and Labrador and the Government of Canada intend to explore collaboration in the following priority domains to address climate change and advance clean growth:

Renewable Energy

Newfoundland and Labrador and the Government of Canada intend to jointly explore opportunities to develop renewable energy, including such actions as enhancing hydroelectric capacity, increasing transmission infrastructure, and offsetting diesel use in small-scale off-grid electricity systems.

These efforts will also seek to maximize collaboration with other Atlantic provinces in the electricity sector, contributing to both the Atlantic Growth Strategy and Canadian Energy Strategy, and will build on existing regional coordination efforts, leading to an integrated regional electricity strategy.

Transportation

Newfoundland and Labrador and the Government of Canada intend to jointly explore opportunities to reduce GHG emissions in all parts of the transportation sector, including electric vehicles and associated infrastructure, on- and off-road freight and industrial transportation, marine vessels, and public transit.

Energy Efficiency

Newfoundland and Labrador and the Government of Canada intend to jointly explore opportunities to develop energy efficiency programming, improve energy codes, and support fuel switching in all sectors reliant on fossil fuels.

Adaptation

Newfoundland and Labrador and the Government of Canada intend to jointly explore opportunities to expand climate monitoring and adaptation product and information development, as well as best management practices.

Green Innovation

Newfoundland and Labrador and the Government of Canada intend to jointly explore opportunities in research and development in green technology, including fostering innovation networks and initiation of pilot projects.

YUKON

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in Yukon include:

Yukon Government Climate Change Action Plan

The Yukon government *Climate Change Action Plan* has four goals: reducing GHG emissions; addressing the impacts of climate change; leading Yukon action on climate change; and enhancing our knowledge and understanding of climate change.

KEY ACTIONS

Work to date in achieving *Climate Change Action Plan* goals includes:

Reducing GHG emissions (mitigation)

- Setting nine sector-specific targets in the areas of transportation, heating buildings, electricity, and industrial operations.
- Completing a study of Yukon's transportation sector, and launching a Ride Share program in partnership with the City of Whitehorse.
- Supporting Yukon homeowners with the Good Energy Residential Incentives Program, which provides incentives to purchase high efficiency wood stoves, boilers and pellet stoves.
- Carrying out detailed energy audits of seven high-consumption Yukon government buildings.
- A Yukon Biomass Strategy to guide the development of a biomass energy sector in the territory.

Addressing the impacts of climate change (adaptation)

- Completing ten adaptation projects in the areas of permafrost impacts to highways, buildings, hydrological responses, and agricultural capacity; flood risk mapping; forestry implications including the encroachment of mountain pine beetle in lodgepole pine forests; and bioclimate shifts.
- With the Pan-Territorial Adaptation Strategy, territorial governments are collaborating on practical adaptation measures for the north. Permafrost thaw has been a key focus.

Leading Yukon action on climate change

- Participating in international and national climate change efforts that impact Yukon, such as the United Nations Framework Convention on Climate Change Conference of the Parties (COP) meetings, including a developmental opportunity for a Yukon youth ambassador.
- Currently supporting the Yukon College to develop a climate change policy course to be offered by Yukon College.

Enhance our knowledge and understanding of climate change

- Supporting development of the Climate Change Indicators and Key Findings report, an important source of independent information that will guide action and research on climate change in Yukon.
- Provide ongoing funding for the Northern Climate Exchange at Yukon College.

These actions provide a strong contribution to a comprehensive pan-Canadian framework.

ACTION ON PRICING CARBON POLLUTION

The Government of Yukon recognizes the role of carbon pricing in the pan-Canadian Framework for Clean Growth and Climate Change.

Given Yukon's particular circumstances, the Government of Canada and the Government of Yukon will work together to assess the implications of carbon pricing in the territory for its economy, communities and people including energy costs, and to develop solutions together.

The Government of Yukon and the Government of Canada will also work together to assess the implications of carbon pricing in Canada on the cost of living in Yukon. This will be an important consideration for future policy development.

As outlined in the federal government's benchmark, 100% of the revenues from carbon pricing will be retained by Yukon. Yukon government will distribute these revenues back to individual Yukoners and businesses through a rebate.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

Yukon and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Advancing Renewable Energy

Yukon government and the Government of Canada will partner in advancing renewable energy projects in Yukon. This will improve the energy infrastructure in Yukon, including developing new renewable energy sources to provide clean energy for current and future electricity needs.

It will also support remote communities in diminishing their reliance on diesel for electricity and will support the expanded use of biomass as a cleaner option for heating in Yukon.

Energy Efficiency

Yukon government, in partnership with the Government of Canada, will support energy efficiency through the retrofitting of existing buildings. Sound investments in retrofits and new energy efficiency projects will be supported by expanding the capacity for collecting, analyzing, and reporting emissions data that will help identify the areas of greatest opportunity for reducing emissions.

Adaptation: Building Resilient Yukon Communities

Canada's Northern jurisdictions and the Government of Canada are working together to develop the Northern Adaptation Strategy. The Government of Canada will partner with Yukon to help build climate-resilient Yukon communities.

Research collaboration will build the knowledge necessary for evidence-based decision-making in community planning. Investments in infrastructure will address known risks such as infrastructure built on thawing permafrost.

Green Innovation and Technology

Yukon government and the Government of Canada will partner on new research and pilot projects that will explore promising areas for climate action in the north, such as seasonal energy storage, cleaner transportation options, and community-level renewable energy generation.

NORTHWEST TERRITORIES

KEY ACTIONS TO DATE

NWT Climate Change Strategic Framework

The Government of the Northwest Territories (GNWT) has committed to develop a climate change strategy that takes northern energy demands and the cost of living into account. It will reflect commitments to reduce greenhouse gas emissions, explore carbon pricing systems and how to develop local alternatives such as hydro, biomass, wind and solar.

NWT Energy Strategy

The GNWT is currently working on a new 10 year Energy Strategy. The Energy Strategy will focus on the affordability, reliability and environmental impacts of energy in the NWT and will promote energy efficiency, renewable and alternative energy in the electricity, heating and transportation sectors.

The GNWT continues to take the following territorial adaptation actions:

- Support adaptation decision-making with knowledge, information collection and sharing
- Build capacity to translate adaptation knowledge into action
- Build climate-resilience through investments in infrastructure
- Invest in land use planning, management plans and building adaptation capacity and expertise
- Support most vulnerable regions, conducting risk assessments and completing hazard mapping
- Reduce climate-related hazards and disaster by developing disaster risk management plans
- Adapt renewable energy options and solutions for cold regions

The GNWT continues to take the following territorial emissions mitigation actions:

- Work with our federal, provincial indigenous partners and others to find solutions to address diesel use in remote off-grid communities including to develop the NWT's hydroelectricity potential to reduce GHG emissions in the electricity sector.
- Implement policies to support the adoption of lower carbon and energy efficient technologies.
- Implement policies to support industry and large emitters in the adoption of lower carbon and energy efficient technologies.
- Continue biomass initiatives and work towards the development of a local forest and wood product industry and develop local wood pellet manufacturing as an alternate local fuel source.
- Addressing energy use and GHG emissions in government buildings and operations.

These actions provide a strong contribution to a comprehensive pan-Canadian framework.

ACTION ON PRICING CARBON POLLUTION

Through the Climate Change Strategic Framework, the GNWT is exploring potential impacts and opportunities that may arise from pursuing different carbon pricing systems in the territory.

The GNWT recognizes the role of carbon pricing in the pan-Canadian Framework for Clean Growth and Climate Change. Given the NWT's particular circumstances, the Government of Canada and the GNWT will work together to assess the implications of carbon pricing in the territory for its economy, communities and people including energy costs, and to develop solutions together.

The GNWT and the Government of Canada will also work together to assess the implications of carbon pricing in Canada on the cost of living in the NWT. This will be an important consideration for future policy development.

As outlined in the federal government's benchmark, 100% of the revenues from carbon pricing will be retained by the NWT.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

The NWT will work with the Government of Canada, in collaboration with regional partners, to advance opportunities for clean electricity generation, transmission, storage and demand management linkages across the region.

This will: improve access to non-emitting electricity; support the phase-out of coal-fired electricity generation; improve grid reliability and energy security; and, subject to fair market principles, help the region access export markets for clean, non-emitting electricity.

The NWT and the Government of Canada intend to collaborate in the following priority areas to address climate change and advance clean growth:

Taltson Hydro Expansion and Transmission Links

The proposed Taltson hydro expansion is a small scale run of river hydro project that could be developed with little environmental impact next to the existing power plant, on an already developed river, and combined with a transmission link to provide a green energy corridor to our southern neighbours.

The expansion of the Taltson hydro facility would help reduce Canada’s GHG emissions by 360,000 tonnes annually for 50-plus years.

The 60 MW expansion of the Taltson hydro facility could be built in partnership with NWT Indigenous governments, creating economic opportunities for Indigenous-owned businesses across the North. The NWT and Government of Canada will undertake technical and feasibility studies as a first step, including the NWT launching the environment assessment process.

Renewable Solutions for Off-Grid Diesel Communities

The Government of Canada and the GNWT will explore opportunities for reducing reliance on diesel in off-grid communities. For example, the Inuvik Wind Project could produce between 2 and 4 megawatts of wind energy for the Town of Inuvik. The project would reduce GHG emissions by 4,300 tonnes per year and eliminate the need for 1.3 million litres of diesel annually in the largest diesel community in the NWT, and help reduce the cost of living for residents.

For other off-grid diesel powered communities of the NWT, a suite of renewable solutions such as solar and wind in combination with energy storage systems and variable generators could reduce diesel use and emissions by 25 percent, an annual GHG elimination of nearly 3000 tonnes.

All-Weather Road Infrastructure for Adapting to Climate Impacts

The safety and reliability of winter roads is being impacted by climate change. Construction of the Mackenzie Valley Highway from Wrigley to Norman Wells would provide safe, secure, and reliable access into the Sahtu region, helping decrease the high cost of living in communities and support the development of resources in the region.

The Great Bear River is a priority as the seasonal ice crossing is increasingly vulnerable to impacts of climate change. Climate change is also limiting access to existing diamond mining operations in the Slave Geological Province.

Construction of an all-weather Slave Geological Province Access Corridor would reduce costs for industry exploration and development in a region that holds world-class deposits of natural resources and continues to be a major contributor to the Canadian and NWT economy.

NUNAVUT

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in Nunavut include:

Energy efficiency upgrades

The Nunavut Energy Retrofit Program was piloted in Iqaluit in 2007, and addressed all of the government of Nunavut's Iqaluit Government of Nunavut-owned buildings. The one-time project investment of $12.8 million has led to annual savings in excess of $1.6 million and 1,594 tonnes of GHG reductions.

In combination with the conversion of three of our facilities to residual heat, our GHG reduction is approximately 4,100 tonnes, which is roughly 20% of those buildings' total emissions.

Development of a Climate Change and Adaptation strategy

Upagiaqtavut was developed in 2011 and serves as a guiding document for the impacts of climate change in Nunavut (http://climatechangenunavut.ca/sites/default/files/3154-315_climate_english_reduced_size_1_0.pdf).

Climate change databank

The Government of Nunavut is developing and uses information technology to centralize and increase the access to climate change information, such as permafrost data and landscape hazards maps. The information is used to improve infrastructure planning and help mitigate the effects of climate change across Nunavut.

Climate Change Secretariat

The Government of Nunavut is establishing a Climate Change Secretariat (CCS), which will be the central point within the government to address both climate change adaptation and mitigation issues.

ACTION ON PRICING CARBON POLLUTION

The Government of Nunavut recognizes the role of carbon pricing in the pan-Canadian Framework for Clean Growth and Climate Change. Given Nunavut's particular circumstances, the Government of Canada and the Government of Nunavut will work together to assess the implications of carbon pricing in the territory for its economy, communities and people including energy costs, and to develop solutions together.

The Government of Nunavut and the Government of Canada will also work together to assess the implications of carbon pricing in Canada on the cost of living in Nunavut. This will be an important consideration for future policy development.

As outlined in the federal government's benchmark, 100% of the revenues from carbon pricing will be retained by Nunavut.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

Nunavut and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Nunavut and the Government of Canada will assess the economic and technical feasibility of electrification through hybrid power generation in Nunavut's communities. Hybrid power generation would significantly reduce emissions while at the same time ensure that Nunavut's isolated communities have reliable power.

Nunavut and the Government of Canada will work together to develop a retrofit program to increase the energy efficiency of public and private housing. Investment in safe and energy efficient housing is a key component of building strong resilient communities in the Arctic.

Government of Canada Gouvernement du Canada

What is the clean fuel standard?

On this page

Overview

Canadians and businesses use fuel every day – to produce and transport goods, and get from place to place. These fuels help power our economy, but their extraction and combustion also represent a significant source of pollution in Canada. In fact, the largest sources of greenhouse gas (GHG) emissions in Canada are from the extraction, processing and combustion of fossil fuels. The fossil fuels we use for transportation also have significant impacts on Canadians' health, creating harmful air pollution when they're extracted, refined and burned in car and truck engines.

As the world strives to achieve net-zero emissions by 2050, a major shift will occur to lower carbon and non-emitting fuels. Canada is in a powerful position to be the producer and consumer of these fuels that consumers are looking for now, and will increasingly be looking for in the future.

The Clean Fuel Regulations will drive investment and growth in Canada's clean fuel sector by increasing incentives for the development and adoption of clean fuels and technologies and processes. The goal of the Clean Fuel Standard is to significantly reduce pollution by making the fuels we use every day cleaner over time. The Clean Fuel Standard will require liquid fuel (gasoline and diesel) suppliers to gradually reduce the carbon intensity of the fuels they produce and sell for use in Canada over time, leading to a decrease of approximately 13% (below 2016 levels) in the carbon intensity of our liquid fuels used in Canada by 2030.

To speed up the transition to clean fuels, technologies and processes across Canada, the Government is supporting the development of a leading clean fuels sector in Canada through a series of significant investments and initiatives that complement the Clean Fuel Standard regulation.

These measures include the Government of Canada’s recent investment of $1.5B towards a Low-carbon and Zero-emissions Fuels Fund, which will increase support for domestic production of low-carbon fuels and their adoption, such as hydrogen and biofuels. These investments will also help implement early opportunities identified in the *Hydrogen Strategy for Canada*, which was announced by Natural Resources Canada on December 18 2020, by supporting the increased production of clean hydrogen.

This domestic growth will also position Canada to become a world-leading supplier of hydrogen and hydrogen technologies, generating economic opportunities through exports and direct foreign investment.

In addition, Canada's fall economic statement announced $150 million in additional funds to accelerate the deployment of infrastructure for zero-emission vehicles and the government’s intention to continue supporting electrification of public transit systems across Canada. These measures will work hand in hand with the CFS in supporting Canadians in their transition to a low-carbon future and in the uptake of ZEVs.

In the context of the continued increase to the carbon price and the new measures to support the production of hydrogen and biofuels, the scope of the Clean Fuel Standard has been narrowed to target only liquid fossil fuels, like gasoline and diesel, which are mainly used in the transportation sector. This is a progression in the design of the Clean Fuel Standard from its initial discussion in 2016, when it was proposed that the new measure will cover liquid, gaseous and solid fuels.

How fuels will become cleaner

The Clean Fuel Standard takes a lifecycle approach, meaning it takes into account the emissions associated with all stages of fuel production and use – from extraction through processing, distribution, and end-use.

The Clean Fuel Standard will require liquid fossil fuel primary suppliers (i.e., producers and importers) to reduce the carbon intensity of their liquid fossil fuels used in Canada from 2016 carbon intensity levels. In 2022 the carbon intensity reduction requirement will start at 2.4 gCO2e/MJ. It will gradually increase over time reaching 12 gCO2e/MJ in 2030. To achieve this, fuel producers will need to provide innovative solutions and new fuel options to consumers.

To drive innovation at the lowest cost, the Clean Fuel Standard establishes a credit market. Regulated parties (producers and importers of gasoline and diesel) must create or buy credits to come into compliance with the reduction requirements. Parties with an excess of credits can bank them for use in later years or sell them. The Clean Fuel Standard also provides opportunities for non-regulated parties to create credits.

The Clean Fuel Standard provides three ways to create credits:

1. Compliance category 1: undertaking projects that reduce the lifecycle carbon intensity of fossil fuels (e.g., carbon capture and storage, on-site renewable electricity, co-processing)
2. Compliance category 2: supplying customers with low carbon intensity fuels (e.g., ethanol, bio-diesel)
3. Compliance category 3: investing in advanced vehicle technologies (e.g., electric or hydrogen fuel cell vehicles)

Economic benefits of cleaner fuels

The Clean Fuel Standard will create economic opportunities for voluntary parties like biofuel producers and other lower carbon fuel producers to create and sell credits. In turn, this will create opportunities for feedstock providers like farmers and foresters supporting lower carbon fuel production.

The Clean Fuel Standard will also promote the uptake of advanced vehicle technologies, like electric vehicles. To allow for a wide range of participants to have access to this economic opportunity, any party can become a credit creator for residential electric vehicle charging. Revenues from credits associated with residential electric vehicle charging must be reinvested in vehicle charging infrastructure, rebates for consumers or electricity distribution infrastructure.

By promoting investments in low carbon fuels and technologies, the Clean Fuel Standard will:

- create well-paying jobs across the economy including in clean technology and in clean fuels like biofuels and hydrogen;

- grow Canada’s clean fuels industry at a time when the global market for clean fuels is rapidly expanding;
- create opportunities for companies producing renewable fuels and the farmers and foresters supplying their feedstock; and
- promote the accelerated use of zero-emission vehicles.

Key dates

The proposed regulations for the Clean Fuel Standard were published in *Canada Gazette*, Part I, on December 18. The draft regulations were available for a 75-day comment period.

Final regulations are targeted for publication in spring 2022.

Questions and answers

► Q1.) What is the Clean Fuel Standard?

► Q2.) How does it work?

► Q3.) What are the benefits of the Clean Fuel Standard?

► Q4.) Who has been consulted on this regulation?

► Q5.) Which other countries and jurisdictions currently have low carbon fuel policies, such as renewable fuel mandate or a clean fuel standards?

► Q6.) How much emissions will be reduced by the Clean Fuel Standard?

► Q7.) Will the removal of the CFS gaseous stream negatively impact the demand for low-carbon gaseous fuels, such as hydrogen and renewable natural gas?

► Q8.) How does removing the gaseous and solid fuels obligations affect gaseous and solid credit creation opportunities and incentives for uptake of low carbon gaseous and solid fuels?

More information

Learn more about the Clean Fuel Standard, including compliance options for industries and how the regulations will be implemented in the years ahead.

Government of Canada Gouvernement du Canada

A Healthy Environment and a Healthy Economy

From: Environment and Climate Change Canada

Backgrounder

As the Government of Canada continues to protect and support Canadians through the COVID-19 pandemic, it is also important that the country look to the future. Canadians want to see a growing middle class where no one is left behind. They want a future where their kids and grandkids have access to clean air and water. That future is within reach. Collectively, Canada needs to accelerate climate action to get there.

A Healthy Environment and a Healthy Economy is Canada's plan to build a better future. This plan builds on the Pan-Canadian Framework on Clean Growth and Climate Change. It continues down the path that Canadians, their governments, and businesses have been setting.

This plan is a cornerstone of the government's commitment in the 2020 Speech from the Throne to create over one million jobs, restoring employment to pre-pandemic levels. The plan includes 64 new measures and $15 billion in investments in addition to the Canada Infrastructure Bank's $6 billion for clean infrastructure announced this fall as part of its growth plan.

A Healthy Environment and a Healthy Economy will make life more affordable for households. It will make Canadian communities more livable. And it will, at every turn, focus on workers and their careers in a fair and just transition to a stronger and cleaner economy. The plan will do this through five pillars

Making the Places Canadians Live and Gather More Affordable by Cutting Energy Waste

Energy-efficient homes and buildings are more comfortable and cost less to power. This plan will make it easier for Canadians to improve the places in which they live and gather. This will cut pollution, make life more affordable and create thousands of good jobs and new careers in construction, technology, manufacturing and sales. To bring these benefits to communities, the government will:

- Invest $1.5 billion over three years for green and inclusive community buildings, and require that at least 10 percent of this funding be allocated to projects serving First Nations, Inuit and Métis communities.
- Provide $2.6 billion over seven years to help homeowners make their homes more energy efficient. This funding will provide grants of up to $5,000, up to one million free EnerGuide assessments, and support to recruit and train EnerGuide auditors.
- Work with the building materials sector and other stakeholders to develop a robust, low-emission building materials supply chain to ensure Canadian, locally-sourced products are available, including low-carbon cement, energy-efficient windows and insulation.

- Continue working with and building on successful provincial and territorial low-income retrofit programs to increase the number of low-income households that benefit from energy retrofits.
- Continue to work with provincial and territorial governments to develop a new model ’retrofit‘ code for existing buildings, by 2022, with the goal of collaborating with provinces and territories to have this code in place by 2025.
- Conduct Canada’s first-ever national infrastructure assessment, starting in 2021, to help identify needs and priorities in the built environment, and undertake long-term planning toward a net-zero emissions future.
- Invest $2 billion in financing commercial and large-scale building retrofits, which will be repaid by energy savings costs. This commitment is part of the CIB’s $10 billion Growth Plan.
- Develop a simple, low-cost loan program that integrates and builds on energy audits and grants to finance deeper home energy retrofits for homeowners.

Making Clean, Affordable Transportation and Power Available in Every Canadian Community

The government will expand the supply of clean electricity through investments in renewable and next-generation clean energy and technology, and encourage cleaner modes of transportation, such as low and zero-emission vehicles, transit and active transportation. This will make communities healthier, less congested and more vibrant.

To ensure Canadians have access to cleaner, more affordable transportation options, the government will:

- Invest an additional $287 million over two years to continue the Incentives for Zero-Emission Vehicles (iZEV) program until March 2022. The program provides a rebate of up to $5000 on a light-duty zero-emission vehicle.
- Invest an additional $150 million over three years in charging and refueling stations across Canada, as announced in the 2020 Fall Economic Statement.
- Work with partners in the year ahead on supply-side policy options to achieve additional reductions from Canada's light-duty vehicle fleet, including regulations and investments to accelerate and expand the consumer availability of ZEVs in Canada as demand grows.
- Build on historic investments in public transit in the Investing in Canada Infrastructure Program to develop next steps on public transit, including the government's plan to help electrify public transit systems, and provide permanent public transit funding.
- Engage the incoming United States Administration on approaches to increase the consumer availability of zero-emission vehicles in both countries, given the integrated nature of the North American auto sector.
- Work to align Canada's Light-Duty Vehicle regulations with the most stringent performance standards in North America post-2025, whether at the United States federal or state level.
- Develop a national active transportation strategy, and explore ways to deliver more active transportation options, such as walking trails, cycling paths and other forms of active mobility, which are a

complementary tool that can reduce reliance on cars and provide healthy transportation alternatives.

- Include the 100-percent tax write off for commercial light-duty, medium- and heavy-duty ZEVs.
- Implement Canada's Off-road Compression-Ignition (Mobile and Stationary) and Large Spark-Ignition Engine Emission Regulations to make new equipment and machines used by Canadians less polluting and more fuel-efficient.
- Further improve the efficiency of heavy-duty vehicles standards for post-2025 by aligning with the most stringent standards in North America—whether at the United States federal or state level.

And to make clean, affordable electricity options more available, the government will:

- Invest an additional $964 million over four years to advance smart renewable energy and grid modernization projects.
- Invest an additional $300 million over five years to advance the government's commitment to ensure rural, remote and Indigenous communities that currently rely on diesel have the opportunity to be powered by clean, reliable energy by 2030.
- Work with provinces and territories to connect parts of Canada that have abundant clean hydroelectricity with parts that are currently more dependent on fossil fuels for electricity generation—including by advancing strategic intertie projects, such as the Atlantic Loop and other regional initiatives. The Canada Infrastructure Bank has earmarked $2.5 billion as part of its $10 billion Growth Plan. The

government will invest an additional $25 million to support predevelopment work.

- Work with provinces, utilities and other partners to ensure that Canada’s electricity generation achieves net-zero emissions before 2050.

Continuing to Ensure Pollution Isn’t Free and Households Get More Money Back

Canada has proven that putting a price on carbon pollution and returning the proceeds back to households can meet our economic needs and our environmental goals at the same time. We cannot grow the economy we all want and need if it’s free to pollute. Moving forward, the government proposes to:

- Continue to put a price on pollution through to 2030, rising at $15 per tonne after 2022, while returning the proceeds back to households such that the majority receive more money back than they pay in provinces where the federal system applies.
- Move from carbon pollution pricing rebate payments being distributed on an annual basis to quarterly, starting as early as 2022.
- Explore the potential of border carbon adjustments, and work with like-minded economies—including the E.U. and Canada’s North American partners—to consider how this approach could fit into Canada’s broader strategy to meet climate targets while ensuring a fair environment for businesses.

- Review the standards used to assess provincial systems, also known as the federal "benchmark criteria", and engage with provinces and territories as well as with Indigenous Peoples on these proposals over the coming months.

In the context of the continued increase to the carbon price, the scope of the Clean Fuel Standard has been narrowed to cover only liquid fossil fuels. This is a progression in the design of the Clean Fuel Standard from its initial discussion in 2016, when it was proposed that the new measure would cover liquid, gaseous and solid fuels.

Building Canada's Clean Industrial Advantage

In the years ahead, Canada's industrial advantage and the jobs that will come from it will depend on the speed and success of decarbonisation efforts. In order to achieve the country's full potential, the government must assist Canadian companies as they seek to meet the demands of domestic and global consumers for low-carbon goods and services, and make investments that can drive Canada's low-carbon economy.

That is why the government will:

- Launch a Net-Zero Challenge for large emitters to support Canadian industries in developing and implementing plans to transition their facilities to net-zero emissions by 2050.
- Make investments to support decarbonization and drive the immediate creation of well-paying, resilient jobs, in complement to the Challenge. This would involve the Strategic Innovation Fund's Net-Zero

Accelerator Fund, through an investment of $3 billion over five years. The fund will rapidly expedite decarbonization projects with large emitters, scale-up clean technology and accelerate Canada's industrial transformation across all sectors.
- Use proceeds collected from the Output-Based Pricing System (OBPS) for industry to further support industrial projects to cut emissions and use cleaner technologies and processes.
- Invest $1.5 billion in a Low-carbon and Zero-emissions Fuels Fund to increase the production and use of low-carbon fuels (e.g., hydrogen, biocrude, renewable natural gas and diesel, cellulosic ethanol) in a manner that complements federal carbon pollution pricing, regulatory efforts and other federal programming.
- Introduce Canada's Hydrogen Strategy, which sets out a path for integrating low emitting hydrogen across the Canadian economy, before the end of the year.

The government will also:

- Propose to strengthen Canada's approach to reducing methane emissions from the oil and gas sector by establishing new targets and associated regulations for 2030 and 2035, based on international best practices. The design of the amended federal regulations to achieve additional reductions in 2030 and 2035 will be determined through consultations with provinces, territories, the oil and gas industry and civil society.
- Invest $165.7 million over seven years to support the agriculture sector in developing transformative clean technologies and help farmers adopt commercially available clean technology.

- Set a national emission reduction target of 30 percent below 2020 levels from fertilizers and work with fertilizer manufacturers, farmers, provinces and territories, to develop an approach to meet it.
- Continue to support Sustainable Development Technology Canada with an additional $750 million over five years. This would support startups and scale-up companies to enable pre-commercial clean technologies to successfully demonstrate feasibility as well as support early commercialization efforts.
- Leverage the Government of Canada’s purchasing power to support emerging clean technologies across Canada’s economic sectors, such as technologies to reduce emissions in federal buildings and reduce embodied carbon in construction materials. This would be part of the updated greening government strategy.
- Work with small businesses to get their feedback on all potential ways to further support them in taking action to reduce emissions, including through rebates, targeted investments, and other supports.
- Continue helping Canadian businesses navigate available federal resources and measures, understand their environmental outcomes, while exploring opportunities to integrate into supply chains of larger private and public purchasers, and expand their reach in Canadian and global markets.
- Develop new federal regulations to increase the number of landfills that collect and treat methane, and ensure that landfills already operating these systems make improvements to collect all they can.

Embracing the Power of Nature to Support Healthier Families and More Resilient Communities

Just as nature is under threat from climate change, it is also an ally in the fight against it. By planting two billion trees and better conserving and restoring our natural spaces, the government will cut pollution, clean the air we breathe, make communities more resilient and increase access to natural spaces. The government will also create thousands of jobs in areas such as tree planting, urban planning and tourism. The government will:

- Invest up to $3.16 billion over 10 years, to partner with provinces, territories, non government organizations, Indigenous communities, municipalities, private landowners, and others to plant two billion trees.
- Invest up to $631 million over 10 years to work with provinces, territories, conservation organizations, Indigenous communities, private landowners, and others to restore and enhance wetlands, peatlands, grasslands and agricultural lands to boost carbon sequestration.
- Provide $98.4 million over 10 years to establish a new Natural Climate Solutions for Agriculture Fund.
- Continue to support partnerships with Indigenous communities across the country through the establishment of new Indigenous Protected and Conserved Areas and Indigenous Guardians programs.

Additional Measures

The plan also commits to developing Canada's first-ever national adaptation strategy. It contains new measures to support Indigenous climate leadership. It will support a strong Canadian contribution toward international climate action. Every dollar spent in the post pandemic stimulus plan outlined in the Fall Economic Statement—amounting to three to four percent of GDP—will be assessed for its effectiveness in furthering the goals of this plan. The plan also commits to applying a climate lens to integrate climate considerations throughout government decision-making.

Next Steps

A Healthy Environment and a Healthy Economy builds on continuing work through the Pan Canadian Framework on Clean Growth and Climate Change. The Pan Canadian Framework has done more to cut pollution in a practical and affordable way than any other climate plan in Canada's history. Taken together with the Pan Canadian Framework, this means Canada will exceed its 2030 greenhouse-gas-reduction target—making it the first time ever this country has set a climate target and outlined a path to not only meet it but exceed it.

The plan will also establish the right building blocks to get to net zero by 2050 so that our kids and grandkids can grow up in a country with clean air and water.

Moving forward, the federal government will consult with provinces and territories, Indigenous partners, and Canadians in all socio-economic sectors to further elaborate a strong plan for a healthier environment and economy that we can implement together. By further working with provinces and territories, the government is confident Canada can achieve reductions within the range of 32 to 40 percent below 2005 levels in 2030. So let's keep working together to build a healthier environment and healthier economy.

Saving energy saves you money

Buildings, including our homes, account for 18% of Canada's greenhouse gas emissions. We want to help Canadians make where they live more energy-efficient. This means homes will be more comfortable and more affordable to maintain while also supporting our environmental objectives. The Canada Greener Homes Grant will help homeowners make their homes more energy-efficient, create new jobs across Canada for energy advisors, grow our domestic green supply chains, and fight climate change.

What's available through the initiative?

Up to 700,000 grants of up to $5,000 to help homeowners make energy efficient retrofits to their homes, such as better insulation

- **EnerGuide evaluations (worth up to $600) and expert advice** to homeowners so they can begin to plan their retrofits
- **Recruitment and training of EnerGuide energy advisors** to meet the increased demand; this will create new jobs across Canada.

Participants are eligible for up to $5,600 total under the initiative. Updates will be provided over the life of the initiative to keep homeowners informed. As part of our work, we are committed to ensuring Greener Homes reaches diverse Canadians including those living in remote and northern communities and those with limited internet access. We are working on building a diverse network of energy advisors to provide career opportunities to all Canadians and to meet the need of our communities.

Be wary of high-pressure sales tactics that claim to have EnerGuide or Natural Resources Canada (NRCan) backing

NRCan has not approved any third parties to reach out to homeowners in an unsolicited fashion to register or participate in the Canada Greener Homes Grant. The Government of Canada, NRCan and its family of brands (ENERGY STAR, EnerGuide) never solicit over the telephone, by email or go door-to-door asking to enter Canadians' homes to inspect, sell, or rent heating and cooling products. EnerGuide home energy evaluations are performed by licensed service organizations only at the request of homeowners.

Government of Canada Gouvernement du Canada

Strategic Assessment of Climate Change Revised, October 2020

The Strategic Assessment of Climate Change [PDF (Portable Document Format) - 663 KB (Kilobyte)]

On this page

Executive summary

In August 2019, the *Impact Assessment Act* (IAA) came into force. The IAA establishes a new process for considering environmental, health, social and economic effects of projects that will undergo a federal impact assessment. One of the factors to be considered in the impact assessment process of a designated project is the extent to which the effects of the designated project hinder or contribute to the Government of Canada's ability to meet its commitments in respect of climate change such as the Paris Agreement, Canada's 2030 target and the goal of Canada achieving net-zero emissions by 2050.

The strategic assessment of climate change will enable consistent, predictable, efficient and transparent consideration of climate change throughout federal impact assessments.

A draft strategic assessment of climate change was published in August 2019. This final version [1] considers comments received on the August 2019 version and reflects the Government's goal of net-zero emissions by 2050.

This strategic assessment of climate change:

- describes the greenhouse gas (GHG) and climate change information that project proponents need to submit at each phase of a federal impact assessment;
- requires proponents of projects with a lifetime beyond 2050 to provide a credible plan that describes how the project will achieve net-zero emissions by 2050; and
- explains how the Impact Assessment Agency of Canada (IAAC) or lifecycle regulators, with support from expert federal authorities, will review, comment on and complement the climate change information provided by proponents.

Environment and Climate Change Canada (ECCC) plans to review and update the strategic assessment of climate change every 5 years.

Glossary

Best Available Technologies / Best Environmental Practices (BAT/BEP)

the most effective technologies, techniques, or practices, including emerging technologies, that can be technically and economically feasible for reducing GHG emissions during the lifetime of the project.

Carbon leakage

the situation that may occur if economic activity moves to other countries with less stringent emissions constraints, which could lead to an increase in global emissions.

Carbon sink

the ability of a forest, ocean or other natural environment to absorb carbon dioxide from the atmosphere.

Climate change resilience

the ability of a system (built, natural, social or economic) to anticipate, withstand, recover, adapt to and transform in response to a climate-related hazard.

Downstream GHG emissions

the emissions that may occur after the project, including emissions resulting from the end use of products made by a project.

Lifecycle regulators

agencies that regulate a project from planning through to project abandonment. These agencies include the Canada Energy Regulator (CER), the Canadian Nuclear Safety Commission (CNSC) and the Offshore Petroleum Boards.

Net GHG emissions

see Section 3.

Offset credits

Represent GHG emission reductions or removals generated from activities that are additional to what would have occurred in the absence of the offset project (i.e., generated from activities that go beyond legal requirements and a business-as-usual standard). Each offset credit generated by an offset project represents one tonne of carbon dioxide equivalent (CO_2 eq) reduced or removed from the atmosphere.

Projects undergoing a federal impact assessment

projects under the IAA, as well as projects under review by lifecycle regulators.

Upstream GHG emissions

emissions from all stages of production, from the point of resource extraction or utilization to the project under review.

1. Introduction

1.1 Objective

The strategic assessment of climate change will enable consistent, predictable, efficient and transparent consideration of climate change throughout the impact assessment process. It describes the climate change-related information requirements throughout the federal impact assessment process, and requires proponents of projects with a lifetime beyond 2050 to provide a credible plan to achieve net-zero emissions by 2050. It also explains how the Impact Assessment Agency of Canada (IAAC) or lifecycle regulators, with support from expert federal authorities, will review, comment on and complement this information.

Environment and Climate Change Canada (ECCC) plans to review and update the strategic assessment of climate change every 5 years.

1.2 Application

The strategic assessment of climate change applies to designated projects under the *Impact Assessment Act* (IAA).

The principles and objectives underlying the strategic assessment of climate change will be built into guidance for the review of non-designated projects on federal lands and outside Canada under the IAA. Guidance for projects regulated by the Canada Energy Regulator (CER) will similarly consider the principles and objectives of the strategic assessment of climate change.

The strategic assessment of climate change may also apply to environmental reviews by other federal lifecycle regulators, and be used in regional assessments.

1.3 Using this document

The strategic assessment of climate change complements other policy and guidance documents that support the impact assessment process. It is assumed that readers of this document have a good understanding of the impact assessment process. [2]

This document is organized as follows:

Section 2: Context

Provides an overview of Canada's climate change commitments, of Canada's impact assessment system, and of the process for conducting the strategic assessment of climate change.

Section 3: Quantification of GHG Emissions from a Project

Provides guidance on how to quantify a project's GHG emissions, and identifies the conditions when an upstream GHG assessment is required.

Section 4: Climate Change in the Planning Phase

Outlines how the information related to GHG emissions and climate change provided in the Planning Phase will be used to develop the Tailored Impact Statement Guidelines.

Section 5: Climate Change in the Impact Statement Phase

Outlines the information that will be asked for all projects, when an upstream GHG assessment will be required, and when a credible plan to achieve net-zero emissions by 2050 will be required.

Section 6: Climate Change in the Impact Assessment Phase

Outlines how IAAC and relevant lifecycle regulators will analyze the information provided by proponents in the Impact Statement and complement it with input from expert federal authorities.

Section 7: Climate Change in Decision-Making and Conditions

Explains how the information related to GHG emissions and climate change will inform the decision on the project and conditions related to project approvals.

Section 8: Climate Change in the Post-Decision Phase

Explains how a follow-up program, if required, could be used to ensure the proponent is meeting any conditions related to GHG emissions and climate change.

Section 9: Contact information

Provides contact information for the strategic assessment of climate change.

2. Context

2.1 Canada's climate change commitments

The Paris Agreement is an international agreement to strengthen the global response to the threat of climate change, building on the United Nations Framework Convention on Climate Change. The Paris Agreement, which entered into force in November 2016, established a collective long-term goal to hold the increase in the global average temperature to well below 2 degrees Celsius above pre-industrial levels, and to pursue efforts to limit that increase to below 1.5 degrees. [3] The Paris Agreement also establishes a global goal of enhancing adaptive capacity, strengthening resilience and reducing vulnerability to climate change with a view to contributing to sustainable development and ensuring an adequate adaptation response in the context of the temperature goal. [4]

Since 2016, the Government of Canada has been working with provinces, territories, and Indigenous peoples, to implement the Pan-Canadian Framework on Clean Growth and Climate Change. This plan outlines over 50 concrete measures to reduce carbon pollution, help us adapt and become more resilient to the impacts of a changing climate, spur clean technology solutions, and create good jobs that contribute to a stronger economy.

In Fall 2019, the Government of Canada announced further commitments to strengthen existing, and introduce new, actions to exceed Canada's 2030 emission reduction target, and to develop a plan to set Canada on a path to achieve a prosperous net-zero emissions future by 2050.

The IAA establishes a process for considering the environmental, health, social and economic effects within federal jurisdiction of certain projects for determining whether those projects are in the public interest. [5] Among other factors, the IAA requires that this decision account for the extent to which the effects of the designated project hinder or contribute to the Government of Canada's ability to meet its commitments in respect of climate change.

Other features of the IAA include:

- A planning phase to allow for early engagement, increased efficiency, improve project design, and give project proponents certainty about the next steps, requirements and timelines in the process;
- Indigenous engagement and partnership throughout the process;
- Increased public participation opportunities within legislated, prescribed timelines;

- Legislated timelines, tailored impact assessment guidelines and rigorous timeline management to provide clarity and regulatory certainty;
- Strong follow-up, monitoring and enforcement; and
- Transparent decisions based on science and Indigenous knowledge.

IAAC leads assessments of designated projects under the IAA. Where projects link to lifecycle regulators – such as the CER and the Canadian Nuclear Safety Commission (CNSC), IAAC will work in collaboration with them to draw on their expert knowledge and ensure that safety, licensing requirements, international obligations and other relevant regulatory factors are considered as part of a single, integrated assessment.

2.2 Technical guides

ECCC plans to publish technical guides to provide additional details on specific elements of the strategic assessment of climate change in 2020-2021, such as:

- Quantification of net greenhouse gas (GHG) emissions, upstream GHG emissions, and carbon sinks;
- GHG mitigation measures, Best Available Technologies / Best Environmental Practices (BAT/BEP) and plans to achieve net-zero emissions by 2050; and
- Climate change resilience.

3. Quantification of GHG emissions

from a project

Proponents of projects undergoing a federal impact assessment will be required to provide an estimate of the project's GHG emissions and, in certain cases, an upstream GHG emission assessment. An estimate of downstream emissions is not required.

A consistent and coherent approach to quantifying a project's GHG emissions will ensure fairness during the impact assessment process and accurate emission intensity comparisons with comparable projects.

While the general approach to quantify GHG emissions is provided in this document, ECCC plans to publish a technical guide with additional detailed guidance on how to quantify a project's net and upstream GHG emissions.

The GHG emissions for new projects and replacement or expansion projects are assessed differently. For new projects, the GHG emissions should reflect the full design capacity of the project. For replacement or expansion projects, GHG emissions are assessed based on the additional capacity the project creates in comparison to the original design capacity.

3.1 Quantification of a project's net GHG emissions

3.1.1 Net GHG emissions calculation

The *Information and Management of Time Limits Regulations* [6] under the IAA set out the information that proponents are required to provide in their initial and detailed Project Descriptions, which includes an estimate of any GHG emissions associated with the project. This should be calculated as the net GHG emissions associated with the project and estimated based on the information available to proponents at each stage. An initial estimate would be provided in the initial Project Description, updated in the detailed Project Description, and further refined in the Impact Statement as more information becomes available. Equation 1 defines net GHG emissions.

Equation 1: Net GHG emissions

Net GHG emissions =

Direct GHG emissions

+ Acquired energy GHG emissions

- CO_2 captured and stored

- Avoided domestic GHG emissions

- Offset credits

In the Impact Statement, each term of equation 1 must be reported separately for each year of the project lifetime (i.e., for all phases of the project: construction, operation and decommissioning).

Project proponents must provide the methodologies, a description of the model if a model is used, data, emission factors and any assumption used to estimate a project's net GHG emissions.

Direct GHG emissions: GHG emissions generated by activities that are within the defined scope of the project. (Note: If transportation of products beyond the project is included in the scope of the project, then emissions generated by that transportation are to be included as direct GHG emissions.)

Examples of direct emissions include:

- Emissions from land use change (e.g., land clearing including deforestation, biomass decay, etc.);
- Emissions from mobile combustion (e.g., vehicle, machinery, etc.);
- Emissions from stationary combustion (e.g., boilers, burners, reciprocating engines, etc.);
- Emissions from industrial process (e.g., chemical, mineral and metal production, incineration, etc.); and
- Flaring, venting and fugitive emissions.

Acquired energy GHG emissions: GHG emissions associated with the generation of electricity, heat, steam or cooling, purchased or acquired from a third-party for the project. Examples of acquired energy GHG emissions include: emissions associated with the generation of purchased or acquired electricity from the grid, and of purchased or acquired steam, heat or cooling from an adjacent facility. Upstream GHG emissions, as defined in Section 3.2, are assessed separately and are not included in this definition.

CO_2 captured and stored: CO_2 emissions that are generated by the project and permanently stored in a storage project that meets the following criteria:

- the geological site into which the CO_2 is injected is a deep saline aquifer for the sole purpose of storage of CO_2, or a depleted oil reservoir for the purpose of enhanced oil recovery; and
- the quantity of CO_2 stored for the purposes of the project is captured, transported and stored in accordance with the federal, provincial, U.S., or state laws.

Avoided domestic GHG emissions: GHG emissions that are reduced or eliminated in Canada as a result of the project. The avoided GHG emissions only apply to the project's net GHG emissions (i.e., not to any upstream emissions calculations).

The following examples illustrate avoided domestic GHG emissions:

- In the case of an expansion project, the emissions reduction resulting from the replacement of existing equipment with more energy-efficient equipment on the project site.
- In the case of a new project, the emissions reduction resulting from the replacement of a high-emitting facility with a lower-emitting facility.
- In the case of any facility that generates and sells surplus energy, the amount of emissions saved from producing that energy from the previous, higher-emitting source.

Avoided domestic GHG emissions can also include GHG emissions removed as a result of mitigation measures seperate from the project and not reflected in the project's direct GHG emissions. This could include, for example, action taken at the corporate level in Canada, such as the use of diret air capture technology and afforestation, provided that action is not required by law, is not also counted as offset credits (see below), and can be assigned to the project.

Infrastructure Canada's Climate Lens General Guidance [8] provides general guidance on how to quantify avoided emissions. The proponent must select the appropriate "total net baseline scenario emissions" and the "total net baseline scenario removals", and provide the rationale for those scenarios. The scenarios must consider new measures (e.g., policies, regulations, plans and programs) applicable to the project put in place by provincial, territorial and federal governments, be realistic, conservative and take into account market conditions and feasibility.

In the quantification approach, the avoided domestic GHG emissions should represent reductions or removals that are real, additional, quantified, verifiable, unique, and permanent.

Avoided foreign emissions should not be quantified in the avoided domestic GHG emissions. Proponents will have the opportunity to discuss potential impacts of their project on global GHG emissions. Section 5.1.3 describes this consideration. Further details on quantification of avoided domestic GHG emissions will be included in the technical guide on GHG quantification.

Offset credits: Represent GHG emission reductions or removals generated from activities that are additional to what would have occurred in the absence of the offset project (i.e., generated from activities that go beyond legal requirements and a business-as-usual standard). Each offset credit generated by an offset project represents one tonne of carbon dioxide equivalent (CO_2 eq) reduced or removed from the atmosphere.

Offset credits must:

- Not have been retired / cancelled for any other purpose, including:
    - compliance with any regulatory requirement;
    - voluntary claims by the proponent (i.e., for purposes unrelated to the impact assessment); or
    - compliance or voluntary purposes by any other entity.

- Be sourced from a project that is registered in a Canadian regulatory offset program that aligns with the best practices outlined in the Canadian Council of Ministers of the Environment Pan-Canadian Offsets Framework. [9]
- Be issued on the basis of the GHG reductions and removals that have already occurred, instead of on the basis of expected reductions or removals.
- Be verified to a reasonable level of assurance by an accredited third-party verification body.
- Be sourced from project activities that are verifiable, quantifiable, additional to a business-as-usual scenario and a project baseline that incorporates legal or regulatory requirements.

In addition:

- Any offset credits used to compensate for project emissions should have been issued no more than 5 years before the year the emissions occured.
- With the exception of offsets that satisfy the next criterion, offset credits must be sourced from offset projects in Canada, and represent emission reductions of one or more of the greenhouse gases included in Canada's most recent version of the National Inventory Report.
- Foreign offset credits will only count if they fully comply with the rules for Internationally Transferred Mitigation Outcomes (ITMOs) established in Article 6 of the Paris Agreement, all applicable decisions adopted by the Conference of the Parties and any further criteria for international offsets to be developed by ECCC. For

example, international offset credits must represent real, quantified and additional mitigation outcomes, which have been authorized by the host country for use toward Canada’s national emissions targets under the Paris Agreement, and are subject to robust accounting to avoid double-counting.

- Proponents should provide an annual report with information on the offsets retired or cancelled for the previous year.

3.1.2 Emission intensity calculation

In addition to providing the project’s net GHG emissions, the proponent will provide the estimated GHG emission intensity using Equation 2.

Equation 2: Emission intensity calculation

$$\text{Emission intensity} = \frac{\text{Net GHG Emissions}}{\text{Units produced}}$$

The proponent must calculate the emission intensity estimate for each year of the operation phase of the project. The emission intensity and units produced must be reported separately for each year of the operation phase of the project.

The emission intensity will be used to compare the project to similar high-performing, energy-efficient project types in Canada and internationally in the Impact Statement. The emission intensity units will be specified in the Tailored Impact Statement Guidelines; the emission intensity estimate may not be possible nor relevant for some project types.

3.2 Assessing a project’s upstream GHG emissions

3.2.1 Overview

Upstream emissions are the domestic and non-domestic emissions from all stages of production, from the point of resource extraction or utilization, to the project under review.

In 2016, the Government of Canada published a draft methodology for estimating upstream GHG emissions in *Canada Gazette*, Part I. [10] An upstream GHG assessment has two parts:

- **Part A** is a quantitative estimate of upstream GHG emissions associated with the project based on the project's maximum throughput or capacity (new project) or additional throughput or capacity (replacement or expansion project). This requires information on the methodology, data, assumptions, and approach to estimating those upstream GHG emissions.
- **Part B** is a qualitative discussion about the incrementality of the upstream GHG emissions estimated in Part A. It provides the conditions under which the upstream emissions estimated in Part A could be expected to occur regardless of whether the project proceeds.

3.2.2 When an upstream GHG emissions assessment will be required

Proponents of projects likely to exceed the upstream GHG emissions threshold outlined in Table 1 will need to complete an upstream GHG assessment. The upstream GHG emissions threshold declines over time.

Table 1: Upstream GHG emissions thresholds for conducting an upstream GHG assessment

Publication year of Tailored Impact Statement Guidelines	Upstream GHG threshold (kt CO_2 eq/year)
2020-2029	500
2030-2039	300
2040-2049	200
2050 and beyond	100

The Tailored Impact Statement Guidelines will confirm if an upstream GHG assessment is required in the Impact Statement based on preliminary calculations conducted by IAAC with the support of expert federal authorities.

3.3 Discussion on the development of emissions estimates and uncertainty assessment

Project proponents should describe the uncertainty associated with their project's net and upstream GHG emissions estimates. This description can be qualitative, although quantitative estimations of uncertainty should also be included where available.

Two types of uncertainty should be considered: i) uncertainty related to data and ii) uncertainty related to methods and models.

The discussion of uncertainty related to data should identify any assumptions made in selecting the data, its applicability to the project, its representativeness, and its completeness. The discussion should explain how the data may be improved with more certainty on the project design and variables (type and volume of fuel used for example). A comparison of the data to comparable data sets may inform the uncertainty discussion. The discussion of uncertainty should also acknowledge that the uncertainty of GHG emissions estimates generally increases for years further out into the future.

The discussion on uncertainty of the methods and models, if applicable, should list the assumptions related to the method or model used and their rationale. The uncertainty could be represented using different methods and models, or by developing scenarios with varying data inputs to generate a range of reasonable emissions. There could be scenarios related to changes in project design and scenarios related to external considerations that may affect a project's GHG emissions over time. Examples include a qualitative discussion on how the economics surrounding the project could influence the project's emissions, such as the price of commodities, and how the emissions could change depending on the type of equipment, fuel or other source of energy used.

Finally, the discussion on uncertainty should describe how the uncertainty of the emissions estimates was reduced.

Further guidance on the development of the emissions estimates will be provided in the technical guide on quantifying GHG emissions for projects.

4. Climate change in the Planning Phase

Projects subject to the IAA will go through a Planning Phase in which potential impacts are discussed with the public and with Indigenous peoples at the outset of the impact assessment process. The information collected in the Planning Phase will inform the Tailored Impact Statement Guidelines, which will outline the scope and information related to climate change required in the Impact Statement.

Information related to the project's GHG emissions and climate change will be provided through three avenues during the Planning Phase:

1. **The initial and detailed Project Description**, which includes: the project type, its purpose and an estimate of its GHG emissions, which should be calculated as net GHG emissions.
2. **Engagement with Indigenous peoples, local communities, other jurisdictions, the public, and federal authorities**. Following engagement on the initial Project Description, IAAC (or relevant body) will prepare a Summary of Issues. This will outline the issues it considers relevant to the assessment, informed by the input from Indigenous peoples, stakeholders, other jurisdictions and the public during early engagement on the project and the expertise of federal departments.
3. **Additional information provided by the proponent** during the Planning Phase, such as the proponent's response to the Summary of Issues, and any other information provided by the proponent at its discretion.

4.1 Initial and detailed project description

The *Information and Management of Time Limits Regulations* [11] under the IAA set out the information that proponents must provide in their initial and detailed Project Descriptions. On GHG emissions and climate change, proponents are required to provide an estimate of the project's GHG emissions, and are encouraged to provide information on GHG mitigation measures to be considered in the Impact Statement.

4.1.1 GHG emissions estimates

The *Information and Management of Time Limits Regulations* require project proponents to provide an estimate of any GHG emissions associated with the project. To fulfill this requirement, the following information should be provided in initial and detailed Project Descriptions:

- estimate of the maximum annual net GHG emissions for each phase of the project, including a breakdown of each term of Equation 1; and
- the methodology, data, emission factors and assumptions used.

4.1.2 Carbon sinks

The *Information and Management of Time Limits Regulations* require project proponents to provide a description of the physical and biological environment of the project's location. Project proponents should provide the following information to help IAAC, or the relevant lifecycle regulators, with the support of expert federal authorities, understand the potential impacts on carbon sinks:

- a description of the activities that would result in an impact on carbon sinks; and
- land areas expected to be impacted by the project, by ecosystem type (forests, cropland, grassland, wetlands, built-up land) over the course of the project lifetime, including any areas of restored or reclaimed ecosystems.

4.1.3 Alternative means of carrying out the project

The *Information and Management of Time Limits Regulations* require project proponents to list (for the initial Project Description) or describe (for the detailed Project Description) the potential alternative means of carrying out the project that are technically and economically feasible, including through the use of best available technologies.

When evaluating alternative means of carrying out the project, project proponents should discuss the potential impacts of the alternatives on GHG emissions and how GHG emissions were considered as a criterion in the alternatives selection.

Project proponents are also encouraged to provide information on the measures being considered to reduce the project’s GHG emissions on an ongoing basis. These measures could include technologies and practices to reduce the project’s GHG emissions.

For projects with a lifetime beyond 2050, proponents are encouraged to provide an overview of the measures being considered to ensure projects are net-zero emissions by 2050.

4.2 Tailored Impact Statement Guidelines

The scope of information related to GHG emissions and climate change in the Impact Statement will be tailored to the project in the Tailored Impact Statement Guidelines published by IAAC at the end of the Planning Phase.

All projects undergoing a federal impact assessment will be required to provide information with respect to GHG emissions, impact of the project on carbon sinks, impact of the project on federal emissions reduction efforts and on global GHG emissions, GHG mitigation measures, and climate change resilience.

Proponents of projects with **upstream GHG emissions likely greater than or equal to the threshold** outlined in Table 1 (refer to Section 3.2.2) will also be asked to provide an upstream GHG assessment (refer to Section 5.2).

Proponents of projects with **lifetime beyond 2050 will be asked to provide a credible plan** for the project to achieve net-zero emissions by 2050 (refer to Section 5.3).

Other information that may arise in the Planning Phase, either provided by the proponent in the initial or detailed Project Description, or from engagement on the Summary of Issues prepared by IAAC or relevant body, may be considered in determining the scope and type of information that will be requested in the Impact Statement. For example, a description of any potential benefits of the project with respect to GHG emissions and climate change provided by the proponent in the Project Description could be considered in tailoring the scope and type of information that will be asked for in the Impact Statement.

5. Climate change information in the Impact Statement Phase

Following the publication of the Tailored Impact Statement Guidelines for the project, the proponent will prepare an Impact Statement that adheres to the Tailored Impact Statement Guidelines. Information provided in the Impact Statement will be reviewed by IAAC, or relevant lifecycle regulators, with the support of expert federal authorities in the Impact Assessment Phase, as outlined in Section 6.

5.1 Information to be provided for all projects

All project proponents will be asked to provide information on GHG emissions, impact of the project on carbon sinks, impact of the project on federal emissions reduction efforts and on global GHG emissions, mitigation measures and climate change resilience.

5.1.1 GHG emissions

Project proponents must provide:

- A description of each of the project's main sources of GHG emissions and their estimated annual GHG emissions over the lifetime of the project;
- Net GHG emissions by year for each phase of the project based on the project's maximum throughput or capacity (new project) or additional throughput or capacity (replacement or expansion project) (refer to Section 3.1.1);
- Each term of Equation 1 (direct GHG emissions, acquired energy GHG emissions, CO_2 captured and stored, avoided domestic GHG

emissions and offset credits, if applicable), per year for each phase of the project (refer to Section 3.1.1);

- Emission intensity for each year of the operation phase of the project (refer to Section 3.1.2);
- The quantity and a description of the ”units produced” used in Equation 2 for each year of the operation phase of the project (refer to Section 3.1.2);
- Methodology, data, emission factors and assumptions used to quantify each element of the net GHG emissions (refer to Section 3.1.1);
- A discussion on the development of emissions estimates and uncertainty assessment (refer to Section 3.3); and
- A description of large sources of GHG emissions that may be the consequence of accidents or malfunctions.

5.1.2 Impact of the project on carbon sinks

The calculation of a project’s net GHG emissions accounts for emissions related to land-use change. Proponents must also provide a qualitative description of the project’s positive or negative impact on carbon sinks. This is because some projects may improve or reduce the ability of an ecosystem, land area or ocean to absorb carbon dioxide from the atmosphere. An impact on a carbon sink implies the interruption or alteration of a natural continual process that removes carbon from the atmosphere.

This information must include:

- Description of project activities in relation to significant landscape features such as topography, hydrology and regionally dominant ecosystems.
- Land areas directly impacted by the project, by ecosystem type (forests, cropland, grassland, wetlands, built-up land) over the course of the project lifetime; this includes the areas of restored or reclaimed ecosystem(s).
- Initial carbon stocks in living biomass, dead biomass and soils (by ecosystem type) on land directly impacted by the project over the course of the project lifetime.
- Fate of carbon stocks on directly impacted land, by ecosystem type: immediate emissions, delayed emissions (timeframe), storage (e.g., in wood products).
- Anticipated land cover on the impacted land areas after the project is in place.

ECCC is developing an approach to estimate losses or gains to carbon sinks. ECCC will provide that approach in the technical guide on GHG Quantification. Once the methodology is published in the technical guide, proponents will be required to provide a quantitative and qualitative description of the project's positive or negative impacts on carbon sinks. Estimating quantitative impacts of a project on carbon sinks amounts to estimating the reduction (or increase) in the quantity of carbon that an area would have accumulated without the project, over the project lifetime.

5.1.3 Impact of the project on federal emissions reduction efforts and on global GHG emissions

Proponents must provide in their Impact Statement:

- An explanation of how the project may impact **Canada's efforts to reduce GHG emissions**, if applicable. For some projects, there will be nothing to add in this section. For some, however, the Impact Statement may be able to explain how the project would result in GHG emission reductions in Canada (e.g., by replacing higher-emitting activities).
- A discussion on how the project could **impact global GHG emissions**, if applicable. This could include, for example:
  - If there is a risk of carbon leakage if the project is not built in Canada, the Impact Statement could include an explanation of the likelihood and possible magnitude of carbon leakage if the project is not approved.
  - If the project may displace emissions internationally, the Impact Statement could describe how the project is likely to result in global emission reductions. For example, a project that enables the displacement of high-emitting energy abroad with lower-emitting energy produced in Canada could be considered as having a positive impact.

5.1.4 GHG mitigation measures

In the Impact Statement, proponents must describe the mitigation measures they will take to minimize GHG emissions throughout all phases of the project. Emphasis should be placed on minimizing absolute emissions as early as possible in the project lifespan. Proponents will be asked to conduct a BAT/BEP Determination for their project, including an assessment of emerging technologies. The

BAT/BEP Determination will play an important role in the Impact Assessment Phase as it may inform the enforceable conditions imposed on the project if it is approved.

For all projects proceeding to the Impact Assessment Phase, the proponent will be asked to provide in the Impact Statement:

- A BAT/BEP Determination to identify ways to minimize the project's GHG emissions (refer to Section 5.1.4.1).
- A description of any additional mitigation measures (such as direct air capture technology and afforestation) that will be taken to mitigate remaining GHG emissions, if applicable.
- A description of any offset credits that have been or will be obtained to mitigate remaining GHG emissions, if applicable. Proponents may also provide information on their intent to acquire or generate international offset credits. Offset credits must comply with the criteria in Section 3.1.1, and will be considered as the last option in terms of GHG mitigation measures.
- A description of measures taken to mitigate the project's impact on carbon sinks, including measures to restore disturbed carbon sinks, if applicable.
- Subject to the public availability of information, a comparison of the project's projected GHG emission intensity to the emission intensity of similar high-performing, energy-efficient project types in Canada and internationally. If applicable, the comparison should explain why the emission intensity of the project is different.
- A list of the federal, provincial or territorial GHG legislation, policies or regulations that will apply to the project.

5.1.4.1 Best Available Technologies / Best Environmental Practices Determination

BAT/BEP are defined as the most effective technologies, techniques, or practices, including emerging technologies, that can be technically and economically feasible for reducing GHG emissions during the lifetime of the project.

This assessment is to be conducted to confirm that the project's design will minimize GHG emissions, in line with the boundaries of the project undergoing the federal impact assessment. Setting the scope of the analysis at the project level, instead of the equipment level, gives project proponents flexibility to optimize the project's overall design while demonstrating the use of BAT/BEP.

The BAT/BEP Determination process is outlined in Table 2.

Table 2: BAT/BEP Determination

Process step	Information requirement
Listing	Proponent establishes a list of all technologies and practices, including emerging technologies, based on the identified sources of emissions for the project during its lifetime.
Technical Feasibility Assessment	Proponent eliminates options determined to not be technically feasible, providing rationale. Proponent describes the timing and circumstances in which the eliminated options could become technically feasible.

Process step	Information requirement
GHG Reduction Potential Assessment	Proponent ranks remaining options based on GHG reduction potential.
Economic Feasibility Assessment and Additional Considerations	Proponent eliminates options determined to not be economically feasible, providing rationale. Proponent describes the timing and circumstances in which the eliminated options could become economically feasible. Proponent outlines additional environmental, social, or other considerations, providing rationale.
Selection of BAT/BEP	Proponent describes the technologies and practices to be used in the Project, and provides a justification for selecting any technology or practice that is not a BAT/BEP. Proponent provides information on how the options eliminated because of technical and economical unfeasibility could be phased in during the project lifetime, including how they could be considered during periods of project maintenance and facility upgrades.
Review	IAAC or the relevant lifecycle regulator, with support from expert federal authorities, reviews the BAT/BEP Determination and requests additional information if required.

The conclusion of the BAT/BEP Determination will be provided in the Impact Statement, and will include:

- The technologies that will be used to mitigate the project's GHG emissions. These could include, for example, the use of low-emitting technologies, the use of low-carbon or renewable fuel, electrification, or carbon capture and storage.
- The practices that will be taken to mitigate the project's GHG emissions, such as anti-idling practices for mobile equipment, leak detection and repair systems, continuous monitoring systems, or fleet optimization.
- The additional technologies and practices that could be considered during periods of project maintenance and facility upgrades to further reduce the project's GHG emissions through the lifetime of the project, as well as the planning process, timing and circumstances for that consideration.

ECCC plans to publish a technical guide to help project proponents conduct their BAT/BEP determination by providing additional information on technical, economic, social and environmental considerations.

5.1.5 Climate change resilience

A commitment in the Paris Agreement, climate change resilience aims to strengthen the global response to climate change. Adaptation and resilience is also a pillar of the Pan-Canadian Framework on Clean Growth and Climate Change, which recognizes that the impacts of climate change are already being felt across Canada. Climate change may alter the likelihood or magnitude of sudden weather events such as extreme precipitation that can contribute to flooding, as well as contribute to longer-term changes such as sea level rise, permafrost thaw and changes to migration patterns. Changes related to warming are already evident in many parts of Canada, and are projected to continue in the future with further warming. If not properly considered, such changes may cause issues such as equipment failures that can threaten the environment, human health and safety, interrupt essential services, disrupt economic activity, and require high costs for recovery and replacement.

All proponents will be required via the Tailored Impact Statement Guidelines, to provide information in the Impact Statement on how the project is resilient to and at risk from both the current and future impacts of a changing climate. This information will include descriptions of:

- the scope and timescale of the climate change resilience assessment and of the methods used to identify, evaluate and manage the climate risks that could affect the project itself and thereby the surrounding environment; and
- the project's vulnerabilities to climate change both in mean conditions and extremes over the full project lifetime from project construction to decommissioning. This could include the impacts of extreme weather events on project infrastructure, impacts to water quality and availability, etc.

ECCC plans to publish a technical guide to provide further instructions and details on the level of information for the climate change resilience assessment.

The resilience assessment should consider multiple scenarios, and should discuss the assumptions and data sources used and the confidence or uncertainty in the results. Where in-house models or forecasts are developed to support a specific assessment, the modeling methodology, assumptions, statistical certainty and data sources should be provided.

In general, given the inherent uncertainty and ongoing research in projecting future climate and associated impacts, proponents should look to global climate model projections of future climate, models of potential impacts and expert advice to inform how their project is resilient to climate change.

Proponents are encouraged to draw from reports such as the current national assessment, Canada in a Changing Climate: Advancing our Knowledge for Action, which was launched in 2017. [12] This series of reports outlines the state of knowledge pertaining to changes in Canada's climate, the impacts of these changes, and how we are adapting to reduce risk. The first report in this series is Canada's Changing Climate Report. [13]

Infrastructure Canada's Climate Lens - General Guidance [14] provides general information on conducting climate change resilience assessments, including guidance for assessing climate impacts and risks to a project, as well as a variety of resources to assist proponents in undertaking such analysis.

Information about how to access and use historical and future climate data can be obtained from the Canadian Centre for Climate Services (CCCS), established by the Government of Canada so that Canadians have the information and support they need to understand and reduce the risks from climate change.

5.2 Upstream GHG emissions assessment

Proponents of projects with upstream GHG emissions likely greater than or equal to the thresholds outlined in Table 1 (refer to Section 3.2.2) will be required in the Tailored Impact Statement Guidelines to provide an upstream GHG assessment and related uncertainty assessment (refer to Section 3.3).

5.3 Plan to achieve net-zero emissions by 2050

Proponents of projects with a lifetime beyond 2050 will be required to provide a credible plan that describes how the project will achieve net-zero emissions by 2050. The plan will complement and be informed by the GHG mitigation measures planned by the proponent (refer to Section 5.1.4).

The plan should demonstrate how the net GHG emission equation in Section 3.1.1 (Equation 1) will equal 0 kt CO_2 eq / year by 2050 and thereafter for the remainder of the lifetime of the project. The plan to achieve net-zero emissions does not apply to upstream GHG emissions, even if an upstream GHG emissions assessment was conducted.

A net-zero plan does not need to describe every technology or practice the project will implement over time to acheive net-zero emissions. Proponents can describe the process they will follow in order to make the decisions and investments needed to achieve net-zero emissions by 2050. A net-zero plan should describe emissions reductions at specified intervals up to 2050 and seek to maximize absolute emissions reductions in the earlier years of a project's lifespan.

Proponents may also identify any supportive actions by the Government that they would need in order to be able to achieve net-zero emissions. This could include, for example, identifying the need for the construction of a grid intertie to enable access to clean electricity.

The project's plan should explain the impact of the actions the company will take to achieve net-zero emissions on Canada's net-zero goal. The project's credible plan to achieve net-zero emissions can refer to the corporate's net-zero emission plan.

Like all of the other information to be provided under an impact assessment, the content of the plan will be taken into account by the relevant decision-makers with respect to project approvals. The submission of a plan that does not specify how a project will achieve net-zero emissions by 2050 will not disqualify a project from proceeding through the impact assessment process. Where it is not feasible to specify how later-year reductions will be achieved, if the project is approved, the Minister of Environment and Climate Change may require a proponent to update plans to specify how additional emissions reduction will be achieved (refer to Section 7) as a condition in the Decision Statement.

ECCC plans to publish a technical guide to provide further guidance and details on developing a credible plan to achieve net-zero emissions by 2050.

6. Climate change in the Impact Assessment Phase

IAAC or the lifecycle regulator, with the support of expert federal authorities, will review, comment on and complement, as needed, the GHG and climate change-related information provided by project proponents in their Impact Statements. This may include consideration of the methodologies, data, emission factors and assumptions used by the proponent, as well as comments received by the public and Indigenous peoples on the Impact Statement.

IAAC or the lifecycle regulator, with the support of expert federal authorities, will review, comment on and complement, as needed, the information about federal, provincial or territorial climate policies and measures that will apply to the project. This will not involve an assessment or commentary on the adequacy of these policies and measures, but will ensure that IAAC or the lifecycle regulator has complete information about all applicable policies and measures and their implication for the project.

In reviewing the project, IAAC or the lifecycle regulator, with the support of expert federal authorities, will consider mitigation measures that are in use in similar high-performing, energy-efficient project types, and will compare the project's emission intensity with similar projects in Canada and internationally. For projects with a lifetime beyond 2050, IAAC or the lifecycle regulator will review the proponent's plan to achieve net-zero emissions by 2050 and will also consider the supportive government actions identified by the proponent in order for the project to be able to achieve net-zero emissions.

Finally, IAAC or the lifecycle regulator, with the support of expert federal authorities, will provide supplemental analysis on the project's (net and upstream) GHG emissions in the context of Canada's emissions targets and forecasts, including Canada's commitments under the Paris Agreement, the goal for Canada to achieve net-zero emissions by 2050, Canada's 2030 emissions targets and Canada's Mid-Century Long-Term Low-Greenhouse Gas Development Strategy. This may include considering, for example, whether the project's emissions are built into the sector projections in ECCC's national forecast in Canada's National Communications and Biennial Reports submitted to the United Nations Framework Convention on Climate Change.

IAAC or the lifecycle regulator, with the support of expert federal authorities, will also review, comment on and complement, as needed, the proponent's climate change resilience assessment.

The review and analysis of the Impact Statement by IAAC or the lifecycle regulator, with the support of expert federal authorities, will be made available to the public and decision-makers.

7. Climate change in decision-making and conditions

Under the IAA, the Minister or Governor in Council [15] must decide whether the project is in the public interest.

The IAA also requires that the Minister or Governor in Council consider, among other factors, the extent to which the effects of the project hinder or contribute to the Government of Canada's ability to meet its environmental obligations and its commitments in respect of climate change. The information provided by project proponents pursuant to the guidance in this strategic assessment of climate change, together with the analysis of that information by IAAC or the lifecycle regulator, will ensure that assessment decisions account for a project's likely climate change-related effects. Decision-makers will be provided with analysis, including but not limited to, the project's GHG emissions in the context of Canada's emissions targets and forecasts, such as Canada's commitments under the Paris Agreement, Canada's 2030 emissions targets, Canada's Mid-Century Long-Term Low-Greenhouse Gas Development Strategy, and Canada's goal for achieving net-zero emissions by 2050.

The Minister will issue a decision statement on whether the project is in the public interest. If the project is in the public interest and allowed to proceed, the decision statement will contain **enforceable conditions**, as well as the rationale for the decision. The GHG emissions-related conditions would only be applicable to a project's net GHG emissions, not to upstream activities even if an upstream GHG assessment was conducted. The GHG emissions-related **enforceable conditions** may refer to **mitigation measures and other requirements** to reduce or control a project's GHG emissions. These conditions may also include a reporting program in which the proponent would demonstrate progress towards implementing these mitigation measures and the plan for reaching net-zero emissions by 2050 for projects with a lifetime beyond 2050.

8. Climate change in the post-decision phase

If a decision is made that the project can proceed, the proponent must comply with any conditions in the Minister's decision statement. **These may include conditions** related to **GHG mitigation measures** and **follow-up program requirements**, including requirements to report progress in implementing these GHG mitigation measures and in implementing the plan for reaching net-zero emissions by 2050 for projects with a lifetime beyond 2050.

Proponents will submit information to IAAC to demonstrate they are in compliance with the conditions in the decision statement. IAAC will review the information, and may conduct on-site visits.

9. Contact information

Annex II – Developing the strategic assessment of climate change

On July 19, 2018, ECCC published a discussion paper to seek views on the objectives and scope of the strategic assessment of climate change. [16] Comments received informed the development of the Terms of Reference and the draft strategic assessment of climate change.

On March 11, 2019, ECCC published Terms of Reference that outlined the scope, process and timelines for conducting the strategic assessment of climate change [17].

The strategic assessment of climate change has been developed under the authority of the *Department of the Environment Act*, adhering as closely as possible to the provisions in the IAA, including the obligations to:

- Take into account any scientific information and Indigenous knowledge provided;
- Make the information used available to the public; and
- Ensure the public is provided with an opportunity to participate meaningfully.

The Terms of Reference outlined the scope of the strategic assessment of climate change, and stated that it would provide guidance for:

1. Quantifying a project's GHG emissions, including the approach to estimating direct and upstream GHG emissions, and how avoided emissions, GHG offsets and carbon sinks could be factored into estimates of GHG emissions;
2. Considering climate change in the Planning Phase of a project review; and
3. Considering climate change in the Impact Assessment Phase of a project review.

ECCC engaged provinces, territories, industry stakeholders, environmental non-government organizations, and Indigenous peoples in developing the draft strategic assessment of climate change. ECCC has:

- convened three Provincial/Territorial working group meetings to provide information and seek feedback on the approach to the strategic assessment of climate change;
- held a multi-stakeholder meeting and compiled the results of this engagement to inform the approach; and
- invited Indigenous peoples that provided comment on the discussion paper to individual meetings.

The draft strategic assessment of climate change was published on August 8, 2019. In August 2019, ECCC organized webinars to present the document to stakeholders, respond to questions and receive feedback. Comments received in response to the draft strategic assessment of climate change were considered in the development of the strategic assessment of climate change.

Minister Wilkinson deemed the strategic assessment of climate change, published in July 2020, a strategic assessment conducted under section 95 of the *Impact Assessment Act*.

In October 2020, a revised version of the SACC was published to provide further clarity on how the net-zero plans and offset credits will be considered in the impact assessment process.

Footnotes

1 The final SACC was originally published on July 16th 2020. This revised version provides further clarity on how the net-zero plans and offset credits will be considered in the impact assessment process.

2 For more information on the impact assessment process, please consult the Impact Assessment Agency of Canada (IAAC) website.

DISCUSSION PAPER ON STRATEGIC ASSESSMENT OF CLIMATE CHANGE

A NEW IMPACT ASSESSMENT SYSTEM

Terms of Reference for Conducting a Strategic Assessment of Climate Change

1. Context

The Government is undertaking a Strategic Assessment of Climate Change to provide guidance on how Canada's climate change commitments should be considered in impact assessments.

This strategic assessment will provide guidance relevant to environmental assessments under the *Canadian Environmental Assessment Act*, 2012. It will also provide guidance for impact assessments under the proposed *Impact Assessment Act* if it becomes law.

The Strategic Assessment of Climate Change will be developed under the authority of the *Department of the Environment Act*, but will adhere as closely as possible to the provisions in the proposed *Impact Assessment Act*, including the obligations to:

- take into account any scientific information and Indigenous knowledge provided;
- make the information used available to the public; and
- ensure the public is provided with an opportunity to participate meaningfully.

Under the proposed *Impact Assessment Act*, the impact assessment must take into account the extent to which the project's effects will hinder or contribute to Canada's ability to meet its climate change commitments and the environment's potential impact on the project, including as a result of climate change.

The Strategic Assessment of Climate Change will be an evergreen document that can be updated over time to reflect relevant changes in climate change policy and targets.

2. Objectives

The Strategic Assessment of Climate Change will provide guidance to proponents, stakeholders, Indigenous Peoples and decision-makers on how climate change policies and commitments should be considered in impact assessments. Central to this work is engagement with provinces and territories.

3. Approach to Conducting the Strategic Assessment of Climate Change

In conducting the Strategic Assessment of Climate Change, ECCC will:

- Convene a Provincial/Territorial working group to provide information, advice, and feedback in the development of the Strategic Assessment of Climate Change (further details on the working group in section 5);
- Arrange for multi-stakeholder input and compile the results of engagement to inform the approach and assessment;
- Provide an opportunity for the public to comment on a draft Strategic Assessment of Climate Change; and
- Publish a final Strategic Assessment of Climate Change.

4. Content of the Strategic Assessment of Climate Change

The Strategic Assessment of Climate Change will include, at a minimum, the following guidance:

1) Quantification of a project's GHG emissions

The Strategic Assessment of Climate Change will provide an approach to quantifying the GHG emissions of proposed projects. This will include clarifying:

- the approach to estimate direct and upstream GHG emissions;
- that downstream emissions will not be assessed; and

- how avoided emissions, GHG offsets, and carbon sinks could be factored into estimates of GHG emissions.

2) Consideration of climate change in the planning phase of a project review

Under the proposed *Impact Assessment Act*, a planning phase would be used to confirm whether an impact assessment of a project is required, the type of assessment (i.e. Agency-led review or Panel review) and the factors to be considered in the assessment. The Government is developing *Information Requirements and Time Management Regulations* for the proposed *Impact Assessment Act* to set out the requirements of an initial project description at the planning phase. The Strategic Assessment of Climate Change will provide additional guidance on the information that could be used to support the consideration of climate change at the planning stage. This guidance could include:

- an explanation of how applicable federal, provincial or territorial GHG laws, regulations and policies will be considered;
- the roles of best available technology and best environmental practices economically feasible to mitigate emissions; and
- significance of the level of emissions.

3) Consideration of climate change in the impact assessment phase of a project review

For projects that proceed to an assessment whether under existing environmental assessment regimes or under the proposed *Impact Assessment Act*, the Strategic Assessment of Climate Change will provide guidance on the information needed to assess the GHG emissions of the project as well as other climate change considerations. This guidance could include:

- how to consider applicable federal, provincial, or territorial GHG laws, regulations and policies, and international climate commitments;
- when upstream GHG emissions will be assessed; and
- how to account for the use of best available technology and best environmental practices and innovation.

Over time, ECCC may supplement the Strategic Assessment of Climate Change with additional guidance documents to provide further details on key elements of the Strategic Assessment of Climate Change, such as guidance on methodologies for estimating project GHG emissions.

5. Engagement

5.1 Working Group

ECCC will convene a Provincial/Territorial Working Group to provide information, advice and feedback to ECCC during the development of the Strategic Assessment of Climate Change. The Provincial/Territorial Working Group will be open to all provincial and territorial governments.

ECCC will send invitations to provincial and territorial members of the Canadian Council of Ministries of the Environment.

ECCC will request that each province and territory assign one official to the group, and that those officials represent departments or agencies with responsibility for climate change and environmental assessments.

5.2 Working Group Meetings

The Provincial/Territorial Working Group will meet at least three times during the course of the Strategic Assessment of Climate Change. Members will be able to attend in person or remotely. ECCC's Director General of the Energy and Transportation Directorate and ECCC's Director General of the Fisheries Act and Impact Assessment Team will co-chair the Working Group meetings. Working Group members will be given reasonable notice of meetings, and be provided with the necessary background materials ahead of time.

The first meeting will be an introductory session on the Strategic Assessment of Climate Change to:

- provide an overview of comments received as a result of the Strategic Assessment of Climate Change Discussion Paper;
- provide an overview on how climate change features in the proposed *Impact Assessment Act*;
- discuss working group planning: schedules, expectations, and work plans; and
- seek initial views and guidance on:
    - the approach to quantifying the GHG emissions of a project; and
    - considering climate change in planning and impact assessment.

Working Group members will be provided one week for comments on the materials presented and discussed during the Working Group Meetings.

5.3 Indigenous Engagement

Recognizing the unique experiences of Indigenous Peoples with respect to climate change, ECCC will seek their views and input. This engagement will be flexible and goal-oriented, and will seek to avoid duplicating other Indigenous engagement initiatives related to the proposed *Impact Assessment Act*.

6. Timelines

The intent is to complete the Strategic Assessment of Climate Change by summer 2019.

Category	Timelines
Launching the Strategic Assessment of Climate Change with the Publication of the terms of reference	February 2019
First Working Group Meeting	February 2019
Second Working Group Meeting	March 2019
Third Working Group Meeting	Late March 2019
Indigenous Engagement through Regular Information Sessions	February to May 2019
Publication of the draft Strategic Assessment of Climate Change followed by a 30-day public comment period	Late April – Late May 2019
Publication of the final Strategic Assessment of Climate Change	Summer 2019

DECLARATION ON THE RIGHTS OF INDIGENOUS PEOPLES ACT ACTION PLAN

2022-2027

BRITISH COLUMBIA

Copies of this report are available from:

Reconciliation Transformation and Strategies Division
BC Ministry of Indigenous Relations and Reconciliation
Email: declaration@gov.bc.ca

and electronically (in a .pdf file) from:
http://declaration.gov.bc.ca

Cover design:

Cover photo: The photo was taken by Melody Charlie, a First Nations photographer. Melody is based out of Yuuthluithaht (Ucluelet) B.C. Her photography reflects the love and respect she holds for her culture and ways of life, always focussing on the strengths and resilience of her people.

Front and back cover art: The feather and drum art presented on the cover was developed by Andy Everson. Andy is an accomplished artist from the K'omoks First Nation on Vancouver Island. He draws upon his roots amongst the Kwakwaka'wakw, Salish and Tlingit peoples to create artwork that reflects the convergence of ancient traditions with modern society.

The four feathers represent the diversity of the Indigenous Peoples of British Columbia, while the drum symbolizes the heartbeat of ceremonies. The feathers are arranged in four directions to represent the people of the North Coast (North), Interior (East), Salish (South) and those who are disenfranchised or have relocated to western Canada (West).

BRITISH COLUMBIA

JOINT MESSAGE FROM THE PREMIER OF BC AND THE MINISTER OF INDIGENOUS RELATIONS AND RECONCILIATION

On November 26, 2019, with the unanimous passage of the *Declaration on the Rights of Indigenous Peoples Act* in the B.C. legislature, we committed to upholding the human rights of Indigenous Peoples. Under this legislation, we have begun with a five-year action plan in consultation and cooperation with Indigenous Peoples to advance this vital work. We are pleased to present the first *Declaration on the Rights of Indigenous Peoples Act* action plan.

This has been challenging work in challenging times. Over the past two years while we worked together on this plan, we faced incredible adversities. We have been grappling with a global pandemic, a toxic drug supply crisis, and our communities were ravaged by wildfires, floods and heat waves. Through all of these challenges, Indigenous Peoples have carried a disproportionate burden. This burden was made even heavier by the devastating findings of unmarked graves at former residential school sites. These experiences have been stark reminders of the continued effects of colonialism and systemic racism. They also reinforce with absolute certainty the importance of the work to be carried out through this action plan to implement and uphold the human rights of Indigenous Peoples.

Even in the face of these overwhelming challenges, Indigenous Peoples throughout the province continued to work with us on this action plan, determined to create a better future for all generations to come. We are grateful for the time, energy, leadership, and expertise they contributed to finalizing this action plan.

We are also grateful for the dedication of the many public servants who contributed to this work, and who will work in partnership with Indigenous Peoples to carry out these actions to advance our shared long-term vision of reconciliation. We acknowledge the support for this action plan from local governments, business and industry, the non-profit sector, scholars, and many others who share our commitment to reconciliation.

Our government is committed to pursuing the goals and achieving the outcomes articulated in this action plan. It includes 89 actions that represent contributions by each and every ministry. Together, we will work to advance reconciliation in tangible and measurable ways in communities across the province.

This work requires real and meaningful systemic change. We see the commitment to that change across the board – from the Province, Indigenous Peoples, allies, and supporters, and it gives us great hope that the outcomes of this plan are not only possible, but achievable. We have much work ahead of us, and together we will create a better future for everyone.

John J. Horgan

Murray Rankin

Murray Rankin, QC
Minister of Indigenous
Relations and Reconciliation

CONTENTS

INTRODUCTION

The *Declaration on the Rights of Indigenous Peoples Act* (Declaration Act)[1] was unanimously passed by the British Columbia Legislative Assembly in November 2019. This made B.C. the first jurisdiction in Canada to adopt the United Nations Declaration on the Rights of Indigenous Peoples (UN Declaration).[2] The Declaration Act was developed jointly with Indigenous leaders and legal staff and was introduced through historic ceremony.

The Declaration Act established the UN Declaration as the Province's framework for reconciliation, as called for by the Truth and Reconciliation Commission.[3] Section 4 of the Declaration Act requires development and implementation of an action plan, in consultation and cooperation with Indigenous Peoples,[a] to achieve the objectives of the UN Declaration. The UN Declaration is a "universal framework of minimum standards for the survival, dignity and well-being of the Indigenous [P]eoples of the world and it elaborates on existing human rights standards and fundamental freedoms as they apply to the specific situation of Indigenous [P]eoples."[4] The provincial government is committed to upholding these human rights in its institutions, laws, policies and practices to advance reconciliation and address the legacy and harms of colonialism on Indigenous Peoples. The Province reaffirms its intent to achieve government-to-government relationships based on respect, recognition and exercise of Aboriginal title and rights and reconciliation of Aboriginal and Crown titles and jurisdiction.

The *Declaration on the Rights of Indigenous Peoples Act* contributes to the implementation of the UN Declaration in B.C. by:

- requiring the Province, in consultation and cooperation with Indigenous Peoples to take all measures necessary to ensure the laws of B.C. are consistent with the UN Declaration (section 3);
- requiring the development and implementation of an action plan, in consultation and cooperation with Indigenous Peoples, to achieve the objectives of the UN Declaration (section 4);
- requiring the Province to report annually on progress made toward alignment of laws and achievement of the goals in the action plan (section 5); and
- enabling agreements with Indigenous governing bodies, including joint or consent-based decision-making agreements that reflect free, prior and informed consent (sections 6 and 7).

This action plan outlines significant actions the Province will undertake in consultation and cooperation with Indigenous Peoples over the next five years. The Province will continue to demonstrate commitment and ensure accountability to implement the UN Declaration and the Declaration Act Action Plan through collaborative annual reporting.

a Consistent with section 35 of the *Constitution Act, 1982* and section 1 of the Declaration Act, the term "Indigenous Peoples" includes First Nations, *Métis* and Inuit Peoples in Canada.

The Province conducted initial engagement to develop the draft action plan with Indigenous Peoples between July 2020 and February 2021.[b,5] The Province conducted broader engagement on the draft action plan to seek input from Indigenous Peoples to inform the final action plan between June and September 2021. Engagement focused on Indigenous Peoples in B.C.; however, local governments and non-Indigenous people, organizations, business and industry leaders also participated.[c] Engagement feedback was carefully reviewed, considered and utilized to finalize this action plan.

Colonization and the associated attempted genocide of Indigenous Peoples fractured the self-determined lives, cultures and well-being of Indigenous Peoples across Canada. The Declaration Act is both an acknowledgment of these histories and a commitment by the Government of B.C. to respect and uphold the human rights of Indigenous Peoples. If history is a teacher, meeting this collective responsibility will require a different approach from that previously taken. This action plan has been built through discussion with Indigenous Peoples in B.C. It describes initial actions for the Province to take in consultation and cooperation with Indigenous Peoples over the next five years. Through the action plan, the Province is committed to changing the trajectory of history through coherent, concrete and cooperative action.

b For further details on the development of the draft action plan, see the *Declaration on the Rights of Indigenous Peoples Act 2020/21 Annual Report*.

c Further details and reflection on the draft action plan engagement process will be included in the forthcoming annual report for 2021-2022.

PURPOSE

This action plan provides a province-wide, whole-of-government approach to achieve the objectives of the UN Declaration over time. The Province acknowledges the widespread socio-economic and health inequities for Indigenous Peoples in B.C. and across Canada. This includes the overrepresentation of Indigenous people in the justice and child welfare systems, lower rates of education, and higher instances of poverty, unemployment and homelessness. The goals and outcomes of this action plan focus on addressing the inequities experienced by Indigenous Peoples by achieving the highest attainable standard for health and well-being.

DISTINCTIONS-BASED APPROACH:

The Province is committed to a distinctions-based approach. This requires that the Province's dealings with First Nations, Métis and Inuit Peoples be conducted in a manner that acknowledges the specific rights, interests, priorities and concerns of each, while respecting and acknowledging these distinct Peoples with unique cultures, histories, rights, laws, and governments. Section 35 of the *Constitution Act, 1982*, recognizes and affirms the rights of Aboriginal Peoples of Canada, while all Indigenous Peoples have human rights that are expressed in the UN Declaration. However, not all rights are uniform or the same among or between all Indigenous Peoples. In many cases, a distinctions-based approach may require that the Province's relationship and engagement with First Nations, Métis and Inuit Peoples include different approaches or actions and result in different outcomes.

These actions are intended to support changes in understandings, behaviours and systems to shift the status quo, address Indigenous-specific racism and establish new foundations of government that respect and uphold the human rights of Indigenous Peoples. The actions identified advance a distinctions-based approach that recognizes First Nations, Métis and Inuit as the Indigenous Peoples of Canada.

The action plan is meant to help everyone who lives in British Columbia understand the importance of reconciliation and how it will help the province achieve its greatest social, cultural and economic potential.

The actions identified in the plan build on priorities brought forward through decades of advocacy and leadership by Indigenous Peoples. These include existing priorities identified in current agreements between the Province and Indigenous organizations.

The 2018 *Implementing the Commitment Document - Concrete Actions: Transforming Laws, Policies, Processes and Structures*[6] is one existing document between the First Nations Leadership Council[d] and

d The First Nations Leadership Council is comprised of the political executives of the BC Assembly of First Nations, First Nations Summit, and the Union of BC Indian Chiefs.

the Province that sets out priorities with First Nations, including with respect to policy and legislative changes that reflect the recognition and implementation of title and rights.

The October 27, 2021 Letter of Intent[7] between Métis Nation British Columbia (MNBC) and the Province is another document that commits to strengthening relationships. This Letter of Intent proposes a new whole-of-government approach to Métis relations as a partnership between MNBC and British Columbia that respects Métis self-determination.

The 2022 government-to-government Shared Priorities Framework between each of the eight modern treaty nations and the Province commits to concrete actions to ensure timely, effective and fully resourced implementation of modern treaties.

Each action listed in this plan will be implemented in consultation and cooperation with Indigenous Peoples, reflecting our commitment to work in partnership and collaboration. The plan outlines actions that will be undertaken between 2022 and 2027. Progress will be reviewed on an annual basis and publicly reported in the Declaration Act annual reports.

It is important to note that the action plan does not include all provincial initiatives to advance reconciliation in B.C. Further, while closely linked to work under section 3 of the Declaration Act to ensure laws are consistent with the UN Declaration, the action plan is a separate and distinct obligation. Actions proposed in this plan do not replace, limit, change or stop existing initiatives or related commitments. These efforts will continue alongside the development and implementation of the action plan.

ANTI-RACISM:

The government of British Columbia recognizes the need to address Indigenous-specific racism in this province and within our systems, practices, and policies. First Nations, Métis and Inuit Peoples have experienced ongoing, systemic and race-based discrimination that has maintained unequal treatment and normalized the false notion that Indigenous Peoples are 'less than' their non-racialized counterparts.

Anti-racism is fundamental to achieving the objectives of the UN Declaration. Therefore, anti-racism is foundational to the goals, objectives and actions laid out in this plan. Key to the implementation of the Declaration Act are actions that identify, challenge, prevent, eliminate and change the values, structures, policies, programs, practices and behaviours that perpetuate racism. This will require understanding and targeting the root causes of systemic discrimination, our colonial and racist foundations, and committing to take action to create conditions of greater inclusion, equality and justice.[e,8]

e Indigenous-specific racism and anti-racism in this action plan are defined as per the 2020 *In Plain Sight* Report.

MODERN TREATIES IN BRITISH COLUMBIA:

The Province's relationship with the eight Nations with whom it has signed modern treaties is distinct and unique. These treaties, to which the Government of Canada is also a signatory, set out constitutionally protected rights and obligations of the parties and contain the actions and language necessary to carry out those rights and obligations. The rights and obligations contained in modern treaties have been established, a distinction that has significant and important implications for the work the Province does with modern treaty nations.

The Province recognizes that, consistent with the distinctions-based approach, all Indigenous Nations can choose whether they wish to enter the treaty making process.

The Province's work with modern treaty nations to fully implement these treaties occurs both with individual nations and collectively through the Alliance of British Columbia Modern Treaty Nations (the Alliance). The Alliance was formed to collaborate and advance areas of shared interest relating to the implementation of modern treaties in B.C.

As part of the continued work under the action plan, the Province has entered into a government-to-government Shared Priorities Framework with modern treaty nations with the goal of renewing its commitment to timely, effective and fully resourced implementation of modern treaties. The framework will address three broad outcomes:

- Comprehensive organizational and policy changes in the public service to ensure timely, effective, fully resourced whole-of-government approach to treaty implementation;
- Appropriate fiscal arrangements to fulfill treaty rights and obligations; and
- Meaningful involvement of modern treaty nations in legislative and policy initiatives.

Progress made to achieve these outcomes will be included in future annual Declaration Act annual reports.

SHARED UNDERSTANDINGS

This action plan and its implementation are informed by the following understandings:

Comprehensive The articles of the UN Declaration are interrelated and interdependent, intended to be read together and understood as an indivisible whole.

Distinctions-based The Province of British Columbia recognizes First Nations, Métis and Inuit as the Indigenous Peoples of Canada with rights recognized and affirmed in section 35(1) of the *Constitution Act, 1982*. The Province also recognizes that First Nations, Métis and Inuit are distinct, rights-bearing communities, and is committed to a distinctions-based approach to its relationship with each.

Diverse The action plan reflects the principle of diversity amongst Indigenous Peoples as stated in section 1(2) of the Declaration Act, which includes meeting the standard in article 37(2) that nothing in the UN Declaration "may be interpreted as diminishing or eliminating the rights of [I]ndigenous [P]eoples contained in treaties, agreements and other constructive arrangements."[9]

Legally Plural The action plan is grounded in the affirmation, consistent with the UN Declaration, that upholding the human rights of Indigenous Peoples includes recognizing that within Canada there are multiple legal orders, including Indigenous laws and legal orders with distinct roles, responsibilities and authorities.

Principled The goals, outcomes and actions in the action plan, and the process of implementing them will be consistent with "the minimum standards for the survival, dignity and well-being"[10] of Indigenous Peoples in the UN Declaration.

Cooperative The action plan has been developed and will be implemented in consultation and cooperation with Indigenous Peoples.

Enabling The action plan must enable and support government-to-government relationships between Indigenous Peoples and the Province based on recognition and implementation of the rights of Indigenous Peoples.

Impactful The implementation of the action plan must make tangible improvements to Indigenous Peoples' social, physical, cultural and economic well-being.

Transparent Progress under the action plan will be reviewed and publicly reported on annually.

2022-2027 ACTIONS

The actions are organized by the following four themes:

1. **Self-determination and inherent right of self-government**
2. **Title and rights of Indigenous Peoples**
3. **Ending Indigenous-specific racism and discrimination**
4. **Social, cultural and economic well-being**

Each theme includes a ***Goal***, with ***Outcomes*** and ***Actions.***

The **goals** and **outcomes** are drawn from the UN Declaration. They describe what the Province is striving for with this action plan and set the vision for achieving the objectives of the UN Declaration.

The **actions** articulate the specific commitments and steps that the Province will take between 2022 and 2027 to achieve those goals and outcomes.

Each action identifies the ministry or ministries responsible for leading its implementation. As this action plan takes a cross-government approach, other ministries may be involved in the work, even if they are not listed within an action.

INTERPRETIVE GUIDANCE

The following *must* be applied when interpreting and implementing this action plan.

First, all actions identified in this action plan are to be implemented in consultation and cooperation with Indigenous Peoples in B.C., as described in the Declaration Act.

Second, a wide range of terminology is used in the goals, outcomes and actions referring to Indigenous peoples including: "Indigenous Peoples," "First Nations," "Indigenous Nations," and others. Effort has been made to use this terminology consistently and coherently using a distinctions-based approach; wherever possible, reference to First Nations, Métis and Inuit Peoples are made intentionally to reflect these distinctions. There are currently some variances in use for several reasons; for example, out of respect for the diversity of preferences among Indigenous Peoples, or to reflect and remain consistent with terminology used in existing commitments, agreements and other constructive arrangements. A distinctions-based approach must be applied in the interpretation and implementation of the action plan. Some of the actions referencing Indigenous Peoples may, through implementation, come to be more aptly focused on First Nations and/or Métis people.

Lastly, progress on implementing this action plan will be provided through the Declaration Act annual reports. In those reports, the Province must make reference to First Nations, Métis and Inuit Peoples intentionally to uphold a distinctions-based approach.

THEME

1 Self-Determination and Inherent Right of Self-Government

THEME 1. Self-Determination and Inherent Right of Self-Government

GOAL

Indigenous Peoples exercise and have full enjoyment of their rights to self-determination and self-government, including developing, maintaining and implementing their own institutions, laws, governing bodies, and political, economic and social structures related to Indigenous communities.

OUTCOMES

A British Columbia where:

- Indigenous Peoples are fully supported in their work of freely determining and implementing their systems and institutions of government, through their internal processes of nation-rebuilding.
- Through their governments, Indigenous Peoples are recognized and engaged through formalized and predictable relationships with the Province, and exercise their jurisdictions and laws.
- Indigenous Peoples exercise self-determination and self-government.
- Through their governments, Indigenous Peoples have open, respectful and productive working relationships with the Province that recognize legal pluralism and reflect cooperative federalism.
- Indigenous Peoples have the necessary legal space to strengthen the application of their Indigenous Laws and legal orders in various areas not adequately addressed through the Canadian legal system.
- The overall emergency management structure and regime in B.C. is revised, in collaboration with the Government of Canada and Indigenous Peoples, to enhance Indigenous Peoples' emergency management outcomes through a strong tripartite approach.

2022-2027 ACTIONS

The Province recognizes that the work of nation-rebuilding is the work of Indigenous Peoples, and is to be conducted in accordance with Indigenous legal processes, rights, cultures, languages, protocols, traditions and standards, and undertaken as part of expressing, building, strengthening and implementing freely chosen governance systems.

To advance this, the Province will take the following actions in consultation and cooperation with Indigenous Peoples from 2022 to 2027:

1.1 In partnership with the Government of Canada, establish a new institution designed and driven by First Nations to provide supports to First Nations in their work of nation- and governance-rebuilding and boundary resolution in accordance with First Nations laws, customs and traditions. *(Ministry of Indigenous Relations and Reconciliation)*

1.2 Shift from short-term transactional arrangements to the co-development of long-term agreements that recognize and support reconciliation, self-determination, decision-making and economic independence. *(Ministry of Indigenous Relations and Reconciliation)*

1.3 Utilize sections 6 and 7 of the Declaration Act to complete and implement government-to-government agreements that recognize Indigenous self-government and self-determination. *(Ministry of Indigenous Relations and Reconciliation)*

1.4 Co-develop with Indigenous Peoples a new distinctions-based fiscal relationship and framework that supports the operation of Indigenous governments, whether through modern treaties, self-government agreements or advancing the right to self-government through other mechanisms. This work will include collaboration with the Government of Canada. *(Ministry of Finance, Ministry of Indigenous Relations and Reconciliation)*

1.5 Co-develop and implement new distinctions-based policy frameworks for resource revenue-sharing and other fiscal mechanisms with Indigenous Peoples. *(Ministry of Finance, Ministry of Indigenous Relations and Reconciliation)*

1.6 Co-develop an approach to deliver on the BC Tripartite Education Agreement commitment, in which the Ministry of Education and Child Care and the First Nations Education Steering Committee will co-develop legislation that requires local education agreements (LEAs) with First Nations where a First Nation wants one, and that requires the application of the provincial LEA at the request of a First Nation. *(Ministry of Education and Child Care)*

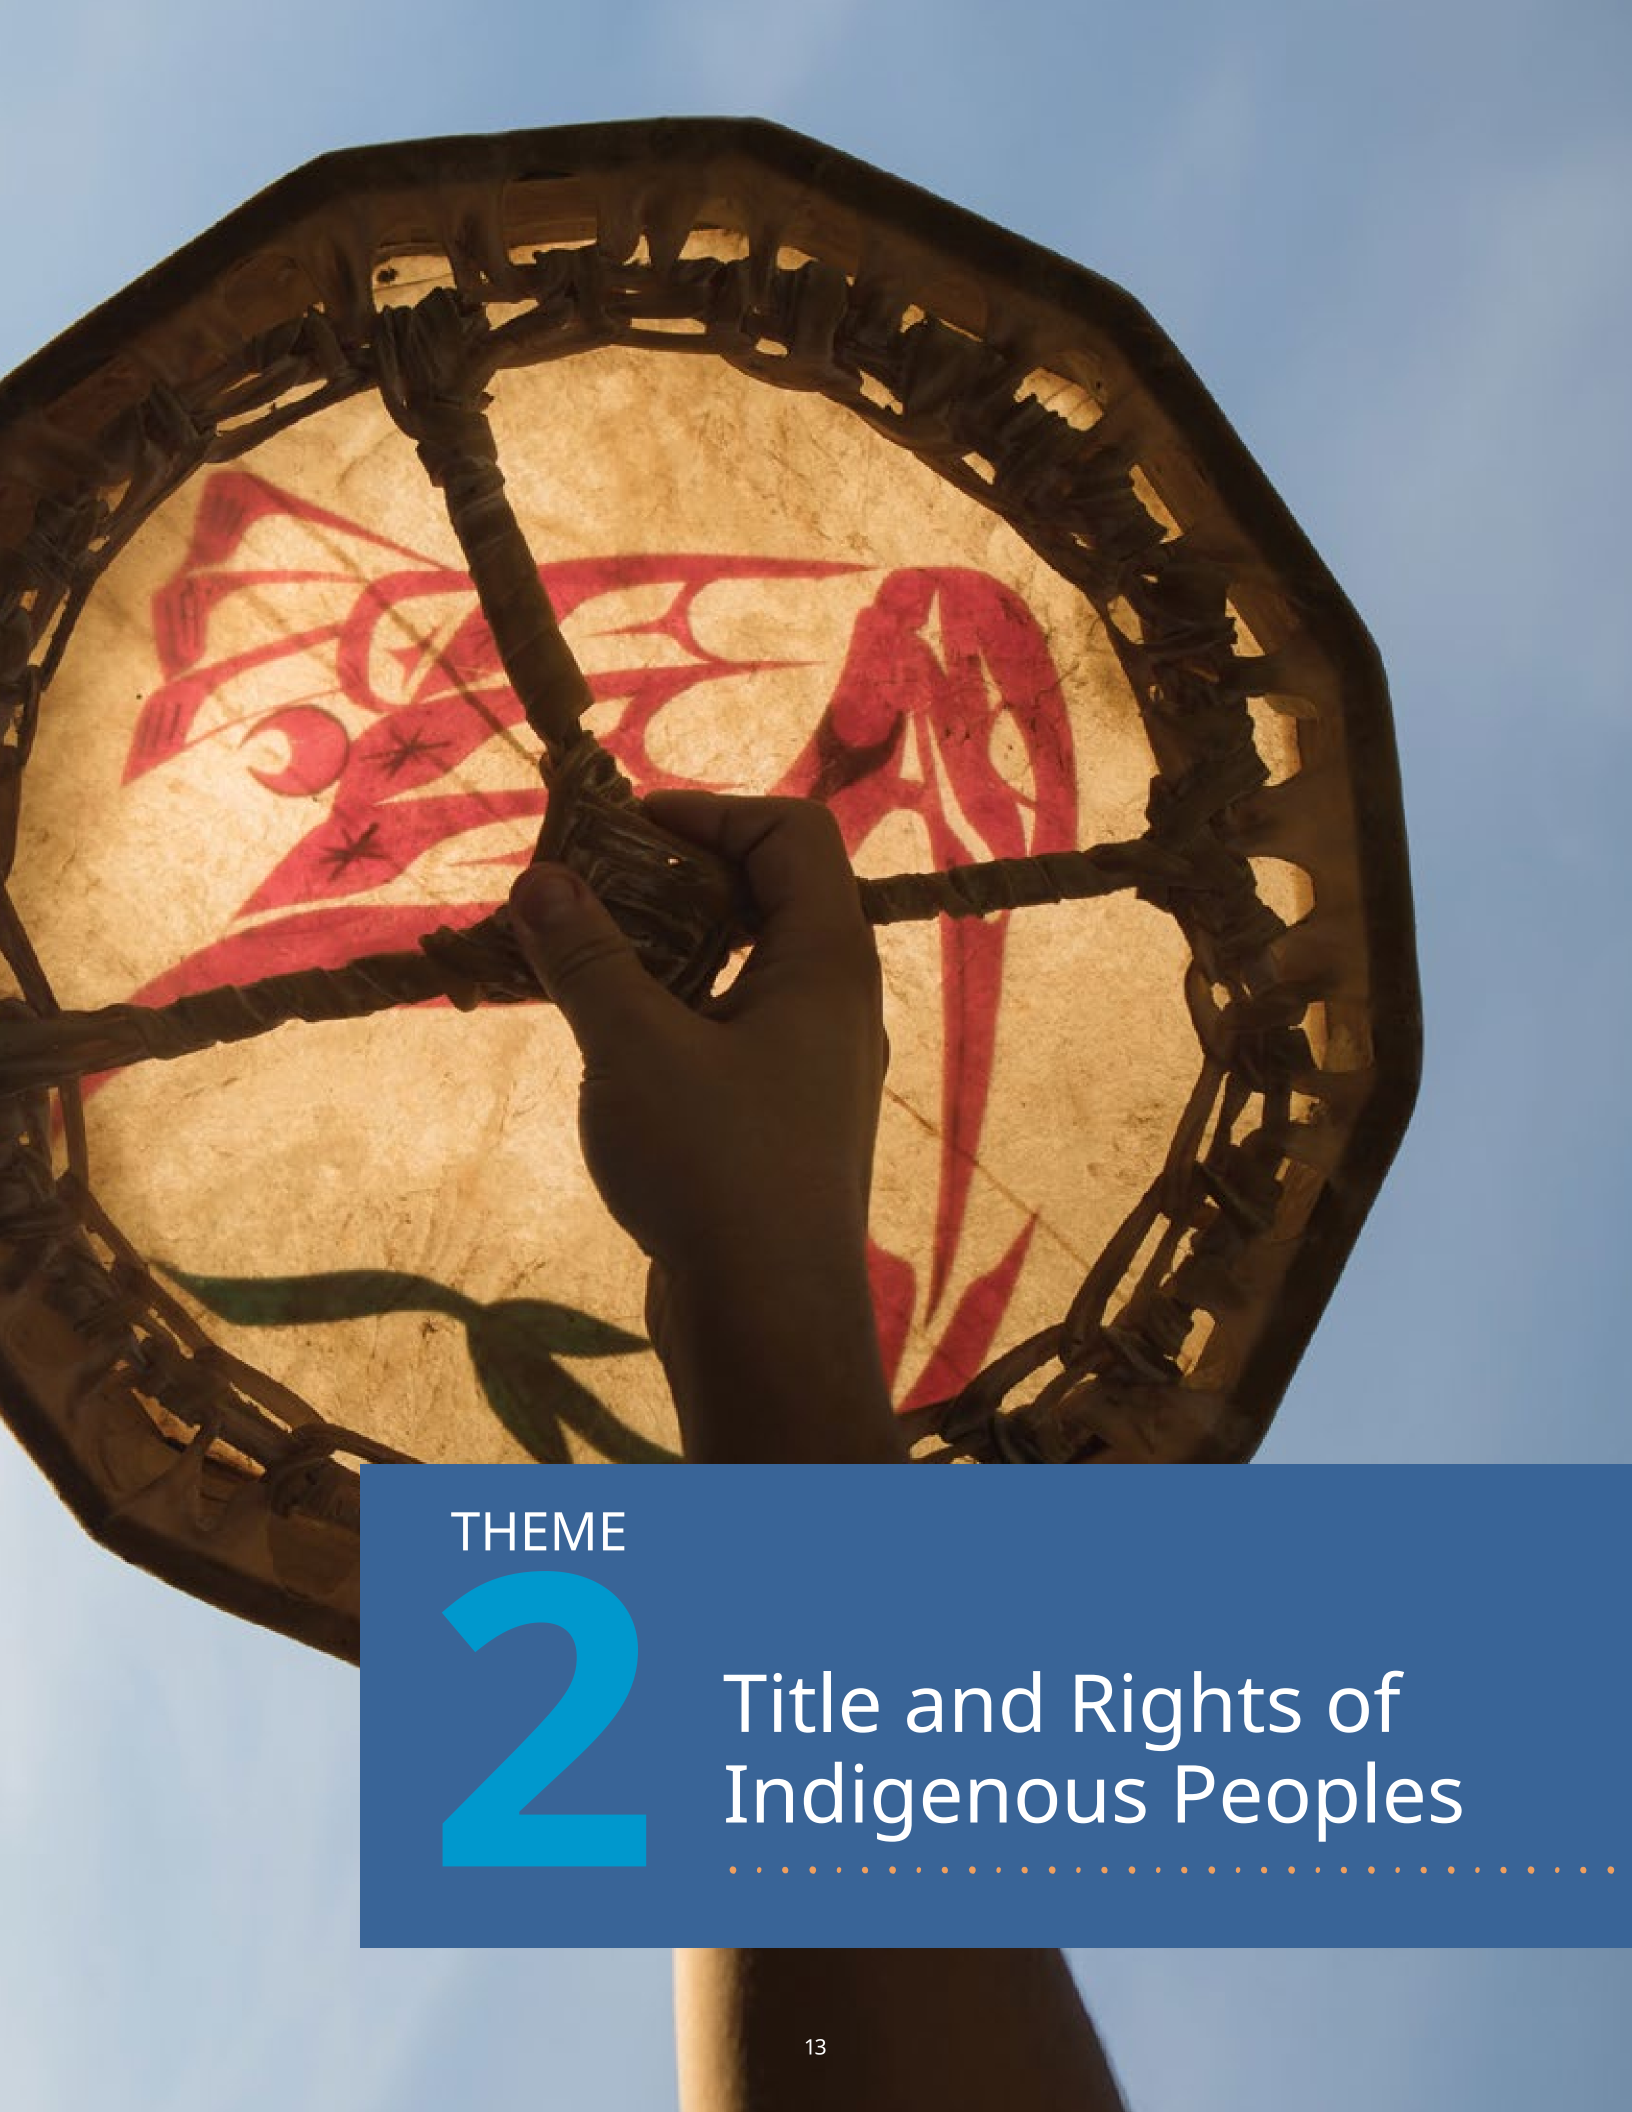
1.7 Update the Bilateral Protocol agreement between the BC Ministry of Education and Child Care and the First Nation Education Steering Committee for relevancy, effectiveness, and consistency with the UN Declaration to support First Nation students in the K-12 education system. *(Ministry of Education and Child Care)*

1.8 Recognize the integral role of Indigenous-led post-secondary institutes as a key pillar of B.C.'s post-secondary system through the provision of core funding, capacity funding and the development of legislation. This includes institutes mandated by First Nations, as well as a Métis post-secondary institute being developed by Métis Nation BC. *(Ministry of Advanced Education and Skills Training)*

1.9 Work with the Nicola Valley Institute of Technology, and the Urban Native Youth Association to co-develop an urban Indigenous centre that supports the childcare, housing and post-secondary needs of Indigenous learners, and strengthen the capacity of the Native Education College to provide culturally relevant post-secondary opportunities for urban Indigenous learners. *(Ministry of Advanced Education and Skills Training)*

1.10 Co-develop modernized emergency management legislation (replacing the *Emergency Program Act*) with First Nations. *(Emergency Management BC)*

1.11 Support inclusive regional governance by advancing First Nations participation in regional district boards. *(Ministry of Municipal Affairs)*



THEME

2 Title and Rights of Indigenous Peoples

THEME 2. Title and Rights of Indigenous Peoples

GOAL

Indigenous Peoples exercise and have full enjoyment of their inherent rights, including the rights of First Nations to own, use, develop and control lands and resources within their territories in B.C.

OUTCOMES

A British Columbia where:

- The distinctions-based rights of Indigenous Peoples are respected, upheld and exercised.
- The rights of Indigenous Peoples, including First Nations title, are exercised, recognized and respected, and cooperatively implemented including through treaties, government-to-government agreements and other constructive arrangements.
- The Province's laws, policies and practices recognize and respect the distinctions-based rights of Indigenous Peoples.
- Dispute-resolution and relationship-building with Indigenous Peoples are supported through cooperatively established institutions and processes that are fair, just and accessible, integrate Indigenous laws and protocols, and use the court system only as a last resort.
- First Nations benefit socially, culturally and economically from land and resources in their territories, including having access to multiple and diverse streams of revenue to finance their governments and deliver services to their citizens.
- Through their governments, Indigenous Peoples exercise their autonomy to set their own priorities, allocate fiscal resources and determine how to deliver programs and services to their citizens.
- Indigenous Peoples have meaningful and sufficient access to abundant and healthy traditional foods and have peaceful enjoyment of their harvesting rights.
- First Nations exercise their right to determine and develop priorities and strategies for the development, use and/or stewardship of their traditional territories and other resources.

2022-2027 ACTIONS

The Province recognizes the need to shift from patterns of litigation, and expensive and slow negotiations about title and rights, to cooperative implementation through effective government-to-government relationships.

To advance this, the Province will take the following actions in consultation and cooperation with Indigenous Peoples from 2022 to 2027:

2.1 Establish a Secretariat to guide and assist government to meet its obligation to ensure legislation is consistent with the UN Declaration on the Rights of Indigenous Peoples, and is developed in consultation and cooperation with Indigenous Peoples. *(Declaration Act Secretariat)*

2.2 Finalize the Draft Principles that Guide the Province of British Columbia's Relationship with Indigenous Peoples.[11] *(Ministry of Indigenous Relations and Reconciliation)*

2.3 Issue guidelines from the Attorney General of B.C. to the Ministry of Attorney General legal counsel regarding the conduct of civil litigation involving the rights of Indigenous Peoples. *(Ministry of Attorney General)*

2.4 Negotiate new joint decision-making and consent agreements under section 7 of the Declaration Act that include clear accountabilities, transparency and administrative fairness between the Province and Indigenous governing bodies. Seek all necessary legislative amendments to enable the implementation of any section 7 agreements. *(Ministry of Indigenous Relations and Reconciliation, Ministry of Land, Water and Resource Stewardship)*

2.5 Co-develop and employ mechanisms for ensuring the minimum standards of the UN Declaration are applied in the implementation of treaties, agreements under sections 6 and 7 of the Declaration Act and other constructive arrangements with First Nations. *(Ministry of Indigenous Relations and Reconciliation)*

2.6 Co-develop strategic-level policies, programs and initiatives to advance collaborative stewardship of the environment, land and resources, that address cumulative effects and respects Indigenous Knowledge. This will be achieved through collaborative stewardship forums, guardian programs, land use planning initiatives, and other innovative and evolving partnerships that support integrated land and resource management. *(Ministry of Land, Water and Resource Stewardship, Ministry of Indigenous Relations and Reconciliation, Ministry of Environment and Climate Change Strategy, Ministry of Forests, Ministry of Energy, Mines and Low Carbon Innovation, BC Oil and Gas Commission)*

2.7 Collaborate with First Nations to develop and implement strategies, plans and initiatives for sustainable water management, and to identify policy or legislative reforms supporting Indigenous water stewardship, including shared decision-making. Co-develop the Watershed Security Strategy with First Nations and initiate implementation of the Strategy at a local watershed scale. *(Ministry of Land, Water and Resource Stewardship)*

2.8 Collaborate with Indigenous partners on issues related to conservation and biodiversity in B.C., including the protection of species at risk. *(Ministry of Land, Water and Resource Stewardship)*

2.9 Develop new strategies to protect and revitalize wild salmon populations in B.C. with First Nations and the federal government, including the development and implementation of a cohesive B.C. Wild Pacific Salmon Strategy. *(Ministry of Land, Water and Resource Stewardship)*

2.10 Reform forest legislation, regulations and policy to reflect a shared strategic vision with First Nations that upholds the rights and objectives of the UN Declaration. *(Ministry of Forests)*

2.11 Integrate traditional practices and cultural uses of fire into wildfire prevention and land management practices and support the reintroduction of strategized burning. *(Ministry of Forests, Emergency Management BC)*

2.12 Collaboratively develop and implement CleanBC and the Climate Preparedness and Adaptation Strategy to support resilient communities and clean economic opportunities for Indigenous Peoples that benefit our shared climate and advance reconciliation. *(Ministry of Environment and Climate Change Strategy)*

2.13 Identify and advance reconciliation negotiations on historical road impacts and road accessibility with First Nations on reserve, treaty and title lands, including reporting-out on the completion and implementation of these negotiations collaboratively with First Nations partners. *(Ministry of Transportation and Infrastructure)*

2.14 Modernize the *Mineral Tenure Act* in consultation and cooperation with First Nations and First Nations organizations. *(Ministry of Energy, Mines and Low Carbon Innovation)*

THEME

3 Ending Indigenous-specific Racism and Discrimination

THEME 3. Ending Indigenous-specific Racism and Discrimination

GOAL

Indigenous Peoples fully express and exercise their distinct rights, and enjoy living in B.C. without interpersonal, systemic and institutional interference, oppression or other inequities associated with Indigenous-specific racism and discrimination, wherever they reside.

OUTCOMES

A British Columbia where:

- All citizens have a constructive and respectful understanding of the distinct history and unique rights of Indigenous Peoples in B.C.
- The overrepresentation of Indigenous Peoples in the justice system is eliminated.
- Indigenous Peoples feel safe accessing the health-care system, knowing that they will receive high quality care, be treated with respect and receive culturally safe and appropriate services.
- Indigenous women, girls, and 2SLGBTQQIA+[f] people enjoy full protection and guarantees against all forms of violence and discrimination.
- Indigenous Knowledge, laws and legal orders are affirmed and recognized as part of decision-making.
- Indigenous learners feel welcomed, respected, and comfortable learning and being Indigenous in schools and other educational institutions.

2022-2027 ACTIONS

The Province recognizes that systemic racism and discrimination against Indigenous Peoples exists throughout British Columbia and that fundamental changes to systems, behaviours, attitudes and beliefs are needed.

To advance this, the Province will take the following actions in consultation and cooperation with Indigenous Peoples between 2022 and 2027:

3.1 Develop essential training in partnership with Indigenous organizations, and deliver to the B.C. public service, public institutions and corporations that aims to build foundational understanding and competence about the history and rights of Indigenous Peoples, treaty process, rights and title, the UN Declaration, the B.C. Declaration Act, the dynamics of proper respectful relations, Indigenous-specific racism, and meaningful reconciliation. *(Public Service Agency, Ministry of Finance – Crown Agencies and Board Resourcing Office)*

3.2 Establish an operational approach to set and achieve targets for equitable recruitment and retention of Indigenous Peoples across the public sector, including at senior levels. *(Public Service Agency, Public Sector Employers' Council Secretariat)*

f 2SLGBTQQIA+ refers to two-spirit, lesbian, gay, bisexual, transgender, queer, questioning, intersex, asexual and other sexually and gender diverse people.

3.3 Conduct an external review of Indigenous-specific racism and discrimination in the provincial public education system, and create a strategy, including resources and supports, to address findings. *(Ministry of Education and Child Care)*

3.4 Implement a mandatory course or bundle of credits related to First Peoples as part of graduation requirements in B.C. and co-create culturally relevant provincial resources with Indigenous people for use by all educators across the K-12 education system. *(Ministry of Education and Child Care)*

3.5 Provide resources to Indigenous organizations to improve public understanding of Indigenous histories, rights, cultures, languages and the negative impacts of Indigenous-specific racism. *(Ministry of Tourism, Arts, Culture and Sport)*

3.6 Introduce anti-racism legislation that addresses Indigenous-specific racism. *(Ministry of Attorney General)*

3.7 Implement recommendations made in the *In Plain Sight: Addressing Indigenous-specific racism and discrimination in B.C. health care*[12] report, striving to establish a health care system in B.C. that is culturally safe and free of Indigenous-specific racism. *(Ministry of Health)*

3.8 Develop and implement community-driven activities to end violence against Indigenous women, girls and 2SLGBTQQIA+ people, beginning with the foundational activities in *A Path Forward: Priorities and Early Strategies for B.C.*[13] and steps towards achieving the mandate commitment to develop a gender-based violence action plan. *(Ministry of Public Safety and Solicitor General, Ministry of Attorney General, Ministry of Finance - Gender Equity Office)*

3.9 Identify and implement multi-modal transportation solutions that provide support and enable the development of sustainable, safe, reliable and affordable transportation options for First Nations communities. *(Ministry of Transportation and Infrastructure)*

3.10 Implement improvements to public safety oversight bodies and complaints processes, such as enhanced investments in the B.C. Human Rights Tribunal and new models for including Indigenous laws in complaints resolution. *(Ministry of Attorney General, Ministry of Public Safety and Solicitor General)*

3.11 Develop and implement comprehensive policing reforms to address systemic biases and racism. This will include: updating the *Police Act*, BC Provincial Policing Standards[14] and mandatory training requirements; enhancing independent oversight; clarifying the roles and responsibilities of police officers in the context of complex social issues such as mental health, addiction and homelessness; and contributing to the modernization of the federal First Nations Policing Program. *(Ministry of Public Safety and Solicitor General, Ministry of Attorney General, Ministry of Mental Health and Addictions)*

3.12 Prioritize implementation of the First Nations Justice Strategy to reduce the substantial overrepresentation of Indigenous Peoples involved in and impacted by the justice system. This includes affirming First Nations self-determination and enabling the restoration of traditional justice systems and culturally relevant institutions. *(Ministry of Attorney General, Ministry of Public Safety and Solicitor General)*

3.13 Prioritize endorsement and implementation of the Métis Justice Strategy to reduce the substantial overrepresentation of Métis Peoples in and impacted by the justice system. This includes affirming Métis self-determination, and enabling the restoration of traditional justice systems and culturally relevant institutions. *(Ministry of Attorney General, Ministry of Public Safety and Solicitor General)*

3.14 Advance the collection and use of disaggregated demographic data, guided by a distinctions-based approach to Indigenous data sovereignty and self-determination, including supporting the establishment of a First Nations-governed and mandated regional data governance centre in alignment with the First Nations Data Governance Strategy. *(Ministry of Citizens' Services)*

3.15 Adopt an inclusive digital font that allows for Indigenous languages to be included in communication, signage, services and official records. *(Ministry of Citizens' Services)*

THEME

4 Social, Cultural and Economic Well-being

THEME 4. Social, Cultural and Economic Well-being

GOAL

Indigenous Peoples in B.C. fully enjoy and exercise their distinct rights to maintain, control, develop, protect and transmit their cultural heritage, traditional knowledge, languages, food systems, sciences and technologies. They are supported by initiatives that promote connection, development, access and improvement, as well as full participation in all aspects of B.C.'s economy. This includes particular focus on ensuring the rights of Indigenous women, youth, Elders, children, persons with disabilities and 2SLGBTQQIA+ people are upheld.

OUTCOMES

A British Columbia where:

- Indigenous Peoples, communities and nations in B.C. are thriving and prospering as full participants in the social, cultural and economic landscape of the province.
- Indigenous Peoples design, control and set the standards and policies for the services that support and facilitate the well-being of Indigenous citizens.
- Indigenous Peoples care for their own children and youth in their communities, and exercise jurisdiction over their own child and family services through systems and practices they determine for themselves, with family preservation prioritized and children and youth kept within their families and communities.
- Indigenous children in need of protection are cared for by their community, and where they cannot be cared for by their community, they are connected to their communities and cultures.
- Health, social and education systems apply an intersectional lens to meet the needs and honour the worldviews, cultures, lived experiences, knowledge and histories of Indigenous Peoples.
- Indigenous languages are living, used, taught and visible throughout their respective territories, including in the provincial public education system.
- Indigenous food systems are recognized and supported in their foundational and interconnected role in providing for cultural, social, environmental and economic well-being.
- Indigenous learners lead graduation rates, are supported to pursue their own excellence, and can access relevant and responsive post-secondary education and skills training.
- Government functions in such a way that distinct Indigenous cultures and identities are understood, upheld and respected, including how Indigenous Peoples access and interact with all provincial government services.
- Respect for Indigenous cultures is tangibly demonstrated through Indigenous maintenance, control, protection and development of their cultural heritage resources, intellectual property, art, spiritual traditions, knowledge systems, economic systems, food systems and spiritual and sacred sites.

- Indigenous Peoples are thriving in their role as stewards and managers of their cultural heritage and receive funding and support to develop community-based cultural heritage plans and programming that will assist with: documenting oral histories and cultural traditions; managing cultural heritage sites, objects and systems; and supporting the intergenerational transmission of cultural knowledge; and showcasing and commemorating Indigenous cultural heritage.
- First Nations create archives for historical community records, mapping services and place-naming.
- Governance of the economy respects, acknowledges and upholds Indigenous rights and interests and First Nations title, is co-led with Indigenous Peoples, and ensures that all First Nations have economic opportunities and benefit from the lands and resources in their territories.
- Indigenous Peoples freely determine their economic development goals, priorities and strategies, and exercise their right to maintain and develop their economic systems and institutions to support self-governance, along with traditional and other economic activities.
- The Province and Indigenous Peoples collaborate and participate in ongoing, meaningful, and enduring dialogue to achieve a more inclusive, innovative, and sustainable economy for the benefit of present and future generations that reflects Indigenous values, interests, goals and worldviews.
- The Province and Indigenous Peoples collaborate through meaningful dialogue to create more inclusive, sustainable and low carbon economies for the benefit of present and future generations and a just climate transition.
- Indigenous peoples with disabilities are supported in accessing culturally relevant care and services.

2022-2027 ACTIONS

The Province recognizes that social and economic disparities exist in British Columbia with particular impacts on Indigenous Peoples, and that addressing these disparities while supporting the cultural distinctiveness of Indigenous Peoples is fundamental to upholding human rights.

To advance this, the Province will take the following actions in consultation and cooperation with Indigenous Peoples from 2022 to 2027:

Social

4.1 Identify and undertake concrete measures to increase the literacy and numeracy achievement levels of Indigenous students at all levels of the K-12 education system, including the early years. *(Ministry of Education and Child Care)*

4.2 Develop and implement an effective recruitment and retention strategy to increase the number of Indigenous teachers in the K-12 public education system. *(Ministry of Education and Child Care, Ministry of Advanced Education and Skills Training)*

4.3 Co-develop and implement a framework for the involvement of Indigenous Education Councils in school district financial planning and reporting. *(Ministry of Education and Child Care)*

4.4 Identify, develop and implement mechanisms and approaches to enable boards of education to better support Indigenous students, including increasing and ensuring equitable access to education and safe environments. *(Ministry of Education and Child Care)*

4.5 Co-develop a policy framework for Indigenous post-secondary education and skills training that includes:

- supporting post-secondary institutions to be more culturally relevant and responsive to the needs of First Nations, Métis and Inuit learners and communities;
- expanding the Aboriginal Service Plan program to all 25 public post-secondary institutions;
- ensuring that Indigenous learners have access to student housing that is safe, inclusive, and enables them to thrive personally, academically, and culturally;
- developing mechanisms for First Nations, Métis and Inuit learners and communities to play an integral role in public post-secondary institutions' decision-making; and
- identifying legislative amendments needed to ensure all public post-secondary institution boards include at least one Indigenous person.

(Ministry of Advanced Education and Skills Training)

4.6 Promote culturally relevant sport, physical activity and recreation initiatives and opportunities that increase Indigenous engagement, participation and excellence in both traditional and mainstream sports for individuals in both urban and rural or remote areas. *(Ministry of Tourism, Arts, Culture and Sport)*

4.7 Demonstrate a new and more flexible funding model and partnership approach that supports First Nations to plan, design and deliver mental health and wellness services across a full continuum of care and to address the social determinants of health and wellness. *(Ministry of Health, Ministry of Mental Health and Addictions)*

4.8 In alignment with the tripartite health plans and agreements, continue to strengthen and evolve the First Nation health governance structure in B.C. to ensure First Nations are supported to participate as full and equal partners in decision-making and service delivery at local, regional and provincial levels, and engage First Nations and the Government of Canada on the need for legislation as envisioned in the tripartite health plans and agreements. *(Ministry of Health, Ministry of Mental Health and Addictions)*

4.9 As a part of the implementation of the *Accessible British Columbia Act*, support the identification, prevention and removal of barriers for Indigenous persons with disabilities. This includes ensuring that the development of accessibility standards considers the rights recognized and affirmed by the UN Declaration. *(Ministry of Social Development and Poverty Reduction)*

4.10 Prioritize the implementation of Primary Care Networks, the First Nations-led Primary Health Care Initiative, and other primary care priorities, embedding Indigenous perspectives and priorities into models of care to increase Indigenous Peoples' access to primary care and other health services, and to improve cultural safety and quality of care. *(Ministry of Health)*

4.11 Increase the availability, accessibility and the continuum of Indigenous-led and community-based social services and supports that are trauma-informed, culturally safe and relevant, and address a range of holistic wellness needs for those who are in crisis, at-risk or have experienced violence, trauma and/or significant loss. *(Ministry of Public Safety and Solicitor General, Ministry of Health, Ministry of Mental Health and Addictions)*

4.12 Address the disproportionate impacts of the overdose public health emergency on Indigenous Peoples by:

- applying to the Government of Canada to decriminalize simple possession of small amounts of illicit drugs for personal use, and continuing campaigns and other measures to help end the stigma and shame associated with addiction;
- expanding prescribed safer supply and other harm reduction measures; and
- ensuring accessibility of recovery beds, and evidence-based, culturally relevant and safe services to meet the needs of Indigenous Peoples, including youth.

(Ministry of Mental Health and Addictions, Ministry of Public Safety and Solicitor General, Ministry of Attorney General)

4.13 Increase the availability and accessibility of culturally safe substance use services, including through the renovation and construction of Indigenous-run treatment centres and the integration of land-based and traditional approaches to healing. *(Ministry of Health, Ministry of Mental Health and Addictions)*

4.14 Increase the availability and accessibility of resources to Indigenous partners in COVID-19 pandemic health and wellness planning and response, including the implementation of the Rural, Remote, First Nations and Indigenous COVID-19 Framework[15] to ensure access for all Indigenous Peoples to immediate and culturally safe and relevant care closer to home. *(Ministry of Health, Ministry of Mental Health and Addictions)*

4.15 Incorporate Indigenous experiences and knowledge of poverty and well-being into ongoing poverty reduction efforts and the 2024 Poverty Reduction Strategy. The strategy will recognize the ongoing impacts of colonialism and include Indigenous-identified actions and progress measures. *(Ministry of Social Development and Poverty Reduction)*

4.16 Co-develop a B.C.-specific fiscal framework, in partnership with First Nations, Métis and Inuit, and in consultation with key Indigenous organizations, to support and move forward with jurisdiction over child and family services. *(Ministry of Children and Family Development)*

4.17 In collaboration with B.C. First Nations and Métis Peoples, and Inuit, continue implementing changes to substantially reduce the number of Indigenous children and youth in care through increased prevention and family support services at all stages of contact with the child welfare system. *(Ministry of Children and Family Development)*

4.18 As committed to in the First Nations Children and Youth in Care Protocol, co-develop and implement measures to support improved education outcomes of current and former First Nation children and youth in care, including meaningful data collection to inform policy planning and service delivery. *(Ministry of Education and Child Care, Ministry of Children and Family Development, Ministry of Advanced Education and Skills Training)*

4.19 As part of a commitment to an inclusive, universal childcare system, work in collaboration with B.C. First Nations, Métis, and Inuit Peoples to implement a distinctions-based approach to support and move forward jurisdiction over child care for First Nations, Métis and Inuit Peoples who want and need it in B.C. *(Ministry of Education and Child Care)*

4.20 Advance a collaborative, whole-of-government approach in the partnership between the Métis Nation of British Columbia and the Province of B.C., respecting Métis self-determination and working to establish more flexibility and sustainability in funding. *(Ministry of Indigenous Relations and Reconciliation)*

4.21 Bring together key Indigenous urban leaders to create a provincial urban Indigenous advisory table to develop and implement a five-year plan to address the priorities of urban Indigenous Peoples, including a focus on Elders, youth, children, women, men, 2SLGBTQQIA+ and persons with disabilities. *(Ministry of Indigenous Relations and Reconciliation, Ministry of Social Development and Poverty Reduction)*

4.22 Ministers and executives across the provincial government social sector will meet annually with urban Indigenous service organization leaders, such as the provincial urban Indigenous advisory table (see Action 4.21), to discuss successes, innovations, and challenges of supporting the social, cultural and economic needs of urban Indigenous Peoples. (*Ministry of Indigenous Relations and Reconciliation*)

4.23 Undertake a cross-government review of provincial supports and services for Indigenous Peoples in urban settings and develop a plan with clear timelines that will provide greater collaboration and coordination to meet needs. *(Ministry of Indigenous Relations and Reconciliation)*

4.24 Expand support to Aboriginal Friendship Centres and other urban Indigenous organizations that serve the needs of urban Indigenous people in B.C. while also acknowledging that Aboriginal Friendship Centres and other urban Indigenous organizations play a vital role for those that wish to connect to their cultures and traditions. *(Ministry of Indigenous Relations and Reconciliation)*

4.25 Work with Indigenous Peoples to build more on- and off-reserve housing and pursue new federal contributions. *(Ministry of Attorney General, Ministry of Indigenous Relations and Reconciliation)*

4.26 Strengthen the health and wellness partnership between Métis Nation British Columbia, the Ministry of Health and the Ministry of Mental Health and Addictions, and support opportunities to identify and work to address shared Métis health and wellness priorities. *(Ministry of Health, Ministry of Mental Health and Addictions)*

Cultural Heritage

4.27 Review the principles and processes that guide the naming of municipalities and regional districts, and evolve practices to foster reconciliation in local processes. *(Ministry of Municipal Affairs)*

4.28 Draft a report with recommendations for how BC Parks can better reflect Indigenous Peoples' histories and cultures in provincial parks and protected areas. *(Ministry of Environment and Climate Change Strategy)*

4.29 Establish an Indigenous-led working group to develop a strategy for the revitalization of Indigenous languages in B.C., including potential legislative supports. *(Ministry of Indigenous Relations and Reconciliation, Ministry of Education and Child Care, Ministry of Advanced Education and Skills Training)*

4.30 Support Indigenous language revitalization through sustainable funding. *(Ministry of Indigenous Relations and Reconciliation, Ministry of Advanced Education and Skills Training)*

4.31 Develop full-course offerings in First Nation languages and implement the educational Calls to Action from the Truth and Reconciliation Commission in the K-12 education system. *(Ministry of Education and Child Care)*

4.32 Co-develop a K-12 First Nations Language Policy and associated implementation plan for the public education system with the First Nations Education Steering Committee, including ensuring that the language and culture of the local First Nation(s) on whose territory(ies) a board of education operates schools are the ones primarily reflected in any First Nations language and culture programs and services of the board. *(Ministry of Education and Child Care)*

4.33 Co-develop a policy framework to support repatriation initiatives. *(Ministry of Tourism, Arts, Culture and Sport)*

4.34 Reset the relationship between the Royal BC Museum and Indigenous Peoples in B.C. by ensuring that Indigenous voices are prioritized and inform the development of narratives, exhibitions and learning programs. *(Ministry of Tourism, Arts, Culture and Sport)*

4.35 Work with First Nations to reform the *Heritage Conservation Act* to align with the UN Declaration, including shared decision-making and the protection of First Nations cultural, spiritual, and heritage sites and objects. *(Ministry of Forests, Ministry of Tourism, Arts, Culture and Sport)*

Economic

4.36 Ensure every First Nations community in B.C. has high-speed internet services. *(Ministry of Citizens' Services)*

4.37 Provide funding to assist Indigenous tourism businesses that have been financially impacted by the COVID-19 pandemic, in order to further support recovery of the Indigenous tourism sector in B.C. *(Ministry of Tourism, Arts, Culture and Sport)*

4.38 Provide investments to Indigenous Tourism B.C. to support Indigenous tourism, Indigenous job creation, preservation of Indigenous languages, celebration of Indigenous cultures and the stewardship of territories, and to tell the stories of Indigenous Peoples in B.C. in their own words. *(Ministry of Tourism, Arts, Culture and Sport)*

4.39 Work with the Province's Economic Trusts and First Nation partners to develop a mechanism that ensures inclusion of First Nations at a regional decision-making level. *(Ministry of Jobs, Economic Recovery and Innovation)*

4.40 Ensure Indigenous collaboration in the development and implementation of the BC Economic Plan, including a technology and innovation roadmap. *(Ministry of Jobs, Economic Recovery and Innovation)*

4.41 Work with First Nations, Métis chartered communities and urban Indigenous organizations to provide funding for self-determined, community-led programs for Indigenous Peoples to upgrade skills, obtain credentials, secure employment, and develop and support community economies. *(Ministry of Advanced Education and Skills Training, Ministry of Social Development and Poverty Reduction)*

4.42 Co-develop economic metrics to help evaluate progress as reconciliation is advanced. The baseline data will begin to address the persistent gap in Indigenous-specific economic metrics and through this co-designed effort, build a comprehensive set of data to measure Indigenous economic well-being and track progress over time. *(Ministry of Jobs, Economic Recovery and Innovation, Ministry of Indigenous Relations and Reconciliation)*

4.43 Co-develop recommendations on strategic policies and initiatives for clean and sustainable energy. This includes identifying and supporting First Nations-led clean energy opportunities related to CleanBC, the Comprehensive Review of BC Hydro, and the BC Utilities Commission Inquiry on the Regulation of Indigenous Utilities. *(Ministry of Energy, Mines and Low Carbon Innovation)*

4.44 Review, evaluate and improve B.C.'s Indigenous Youth Internship Program. *(Public Service Agency)*

4.45 Prioritize and increase the number of technology sector training opportunities for Indigenous Peoples and other groups currently under-represented in B.C.'s technology sector. *(Ministry of Jobs, Economic Recovery and Innovation)*

4.46 Improve economic supports for Indigenous workers and employers by increasing access for Indigenous clients to the Ministry of Labour's services and programs, including employment standards, workers' compensation and workplace safety. *(Ministry of Labour)*

4.47 Advance a collaborative approach to cannabis-related governance and jurisdiction between First Nations and the Province that reflects common objectives to protect youth, prioritize public health and safety, strengthen First Nations governance capacity and secure economic benefits for First Nations. *(Ministry of Public Safety and Solicitor General)*

4.48 Work with the B.C. Indigenous Advisory Council on Agriculture and Food and other Indigenous partners to identify opportunities to strengthen Indigenous food systems and increase Indigenous participation in the agriculture and food sector. *(Ministry of Agriculture and Food)*

4.49 Review existing provincial mandates to enhance treaty and self-governing Nations' fiscal capacity to deliver services to their citizens. *(Ministry of Indigenous Relations and Reconciliation)*

ACCOUNTABILITY AND IMPLEMENTATION

The Province's development of the action plan was undertaken in consultation and cooperation with Indigenous Peoples in B.C. and centred around the shared understandings outlined on page 6. The process to implement the action plan will be approached in the same way: comprehensive, distinctions-based, diverse, legally plural, principled, cooperative, enabling, impactful and transparent.

Ministries across government will continue to work in consultation and cooperation with Indigenous Peoples across the province to implement actions identified in this plan, reflecting our mutual commitment to work together in partnership. Identified ministries are accountable for their actions as well as ensuring effective monitoring and reporting on progress. As the action plan is province-wide in scope, it requires an all-of-government approach with coordination across ministries to support implementation.

The Province will work with Indigenous Peoples to identify suitable tools, indicators and measures for monitoring, assessing and reporting progress on implementation of the Declaration Act. Progress under the action plan will be reviewed on an annual basis and publicly reported in an annual report that will be prepared consultation and cooperation with Indigenous Peoples, and submitted to the B.C. Legislature by June 30 each year. The action plan will be comprehensively updated within five years.

Introduction

Current Policies Scenario: A new name for the Reference Scenario

In EF2021, we have renamed one of the core scenarios of the Canada's Energy Future series. The "Current Policies Scenario" shares the same premise as the "Reference Case" or "Reference Energy System Scenario" in past versions of the report. We changed the name to "Current Policies" to increase clarity and be more explicit about the assumptions of the scenario: that it models only energy and climate policies that are currently in place. This change also clarifies that the scenario is not meant to be a most-likely or base-case scenario. EF scenarios provide alternative views on how the energy system could evolve in Canada given different inputs and assumptions.

Canada's Energy Future 2021: Energy Supply and Demand Projections to 2050 (EF2021) is the latest long-term energy outlook from the Canada Energy Regulator (CER). The *Canada's Energy Future* series explores how possible energy futures might unfold for Canadians over the long term. We use economic and energy models to make these projections. The CER bases our projections on assumptions about future trends in technology, energy and climate policies, energy markets, human behaviour, and the structure of the economy.

EF2021 includes two core scenarios: The Evolving Policies Scenario and the Current Policies Scenario. The central difference between these scenarios is the level of future climate action, both globally and domestically. In both scenarios we provide projections for all energy commodities and all provinces and territories.

EF2021 also includes six additional electricity scenarios that explore what Canada's electricity system might look like in a net-zero[1] world. These scenarios focus only on how Canada will meet given electricity demands under different conditions, and do not include projections for other energy commodities. Electricity is an important contributor to achieving net-zero emissions, so these projections are an important step in modeling related to a net-zero energy system in the *Canada's Energy Future* series.

The analysis and projections for EF2021 are based on several important assumptions, outlined for the core scenarios in the "Scenarios and Assumptions" section of the report. The "Results" section provides an overview of our core scenario projections for various parts of the Canadian energy system to 2050, focusing on the Evolving Policies Scenario. The "Towards Net-Zero" section explores what Canada's electricity system could look like in a net-zero world, including assumptions and projections. Finally, the "Access and Explore Energy Futures Data" section provides links to access data, tools, and interactive data visualizations that offer further insight into EF2021.

1 Net-zero GHG emissions refers to the concept of balancing human-caused GHG emissions with removals from the atmosphere. See the text box "What is "Net-Zero"?" in the Towards Net-Zero section for more information.

Executive Summary

Overview and Background

The *Canada's Energy Future* series explores how possible energy futures might unfold for Canadians over the long term. *Canada's Energy Future 2021: Energy Supply and Demand Projections to 2050* (EF2021) is our latest long-term energy outlook. The outlook covers all energy commodities and all Canadian provinces and territories, and makes projections using economic and energy models. We also make assumptions about technology, energy and climate policies, energy markets, human behaviour, and the economy.

In the long term, global and Canadian ambition to reduce greenhouse gas (GHG) emissions will be a critical factor in how energy systems evolve. EF2021 considers two main scenarios, where energy supply and demand projections differ based on the level of future action[2] to reduce GHG emissions. EF2021 also includes six additional scenarios that explore what Canada's electricity system might look like in a net-zero world. The two main scenarios include projections for all energy commodities, whereas the six electricity scenarios focus only on how Canada will meet given electricity demands under different conditions.

[2] "Action" in this context is led by increasing policies, while also considering behavioural decisions by consumers and firms.

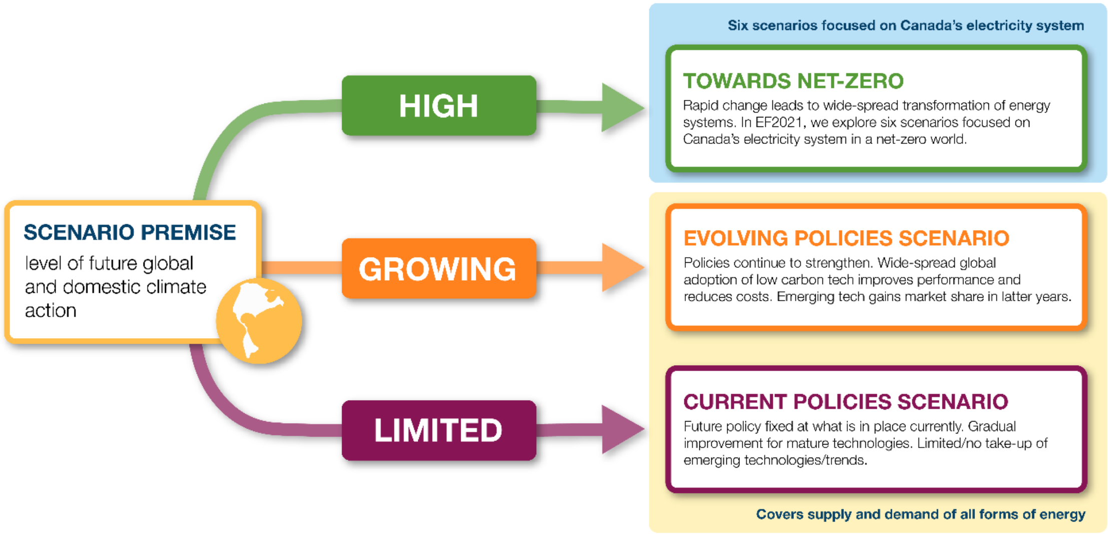
The first main scenario in EF2021 is the Evolving Policies Scenario. The premise of this scenario is that action to reduce GHG emissions from our energy system continues to increase at a pace similar to recent history, in both Canada and the world. Relative to a scenario with less action to reduce GHG emissions, this projection implies less global demand for fossil fuels, and greater use of low-carbon technologies. The second main scenario is the Current Policies Scenario, which assumes limited action to reduce GHGs beyond policies in place today.

These scenarios do not explicitly model climate goals or targets. Instead, we make assumptions based on the scenario premises and rely on the Energy Futures Modelling Framework to make long-term projections of energy supply and demand in Canada. Together, these scenarios provide insights into what the energy system might look like if action to reduce GHG emissions continues to grow at the pace it has in recent years, or if it were to stop at current levels.

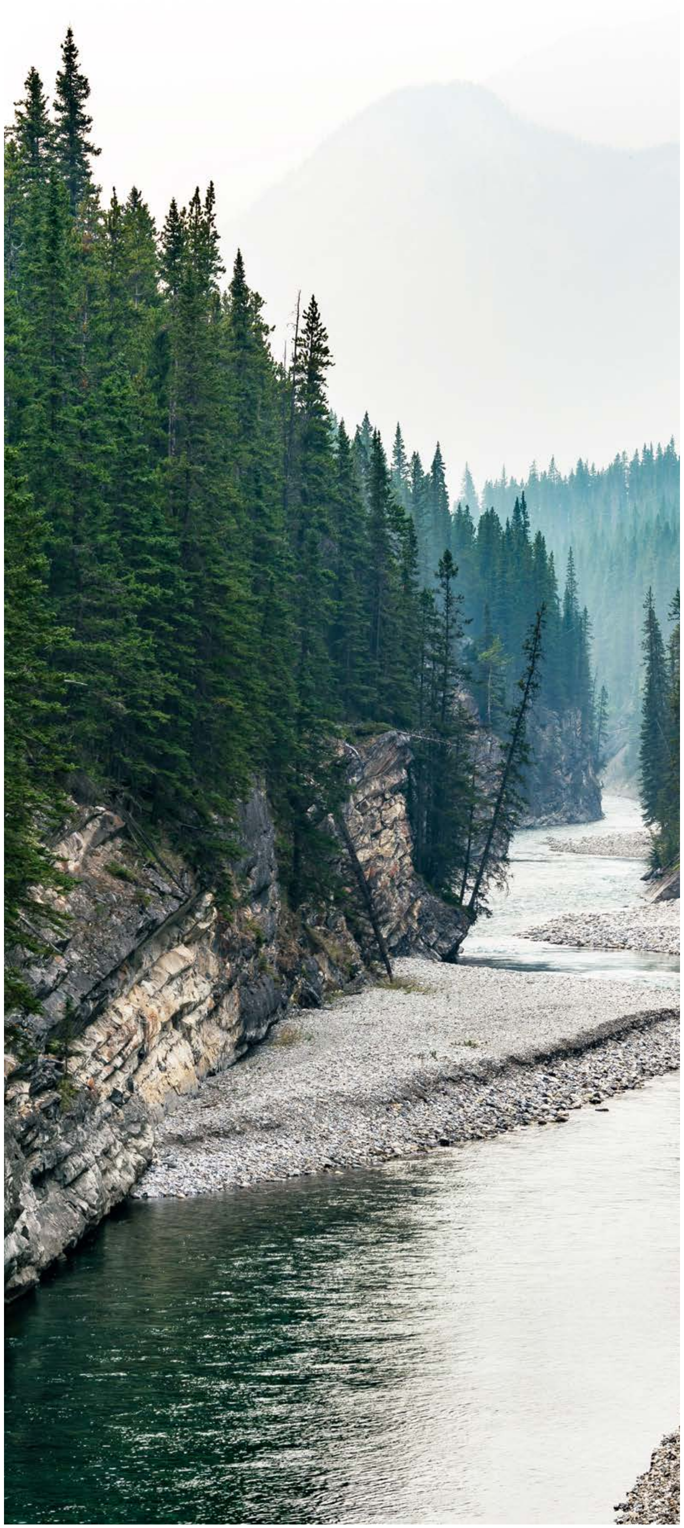
Canada has committed to reducing its GHG emissions by 40 to 45% below 2005 levels by 2030 and achieving net-zero GHG emissions by 2050. Reducing emissions to these levels will likely require more change than we model in the Evolving or Current Policies scenarios. Therefore, EF2021 introduces six new scenarios that explore a net-zero future. Specifically, these scenarios explore what Canada's electricity system might look like in a net-zero world under different assumptions about future technologies, climate policies, and electricity use. Electricity is expected to be an important contributor to achieving net-zero emissions, so these projections are an important step in modeling related to a net-zero energy system in the *Canada's Energy Future* series.

Figure ES.1 provides a conceptual illustration of the two main scenarios included in EF2021, as well as the net-zero scenarios focused on electricity.

Figure ES.1:
Conceptual Illustration of EF2021 Scenarios



This Executive Summary highlights the key findings of EF2021. The "Scenarios and Assumptions" section outlines the specific assumptions used in the Evolving and Current Policies scenarios. The "Results" section provides an overview of the projections for the various parts of the Canadian energy system under our two main scenarios, with a focus on the Evolving Policies Scenario. The "Towards Net-Zero" section includes the first major net-zero modeling exercise of the *Canada's Energy Future* series: six scenarios that examine the effect of different factors (e.g. technology, policies, level of electrification, infrastructure) on Canada's electricity system in a net-zero world. Finally, the "Access and Explore Energy Futures Data" section provides links to access data, tools, and interactive data visualizations for further exploration of EF2021.



Key Findings

1. In the Evolving Policies Scenario, combustion of fossil fuels whose emissions are not captured falls 62% from 2021 to 2050, while use of low and non-emitting energy sources increases. While this implies a significant reduction in GHG emissions by 2050, achieving net-zero will likely require more change than is included in this scenario.

In the Evolving Policies Scenario, Canadians reduce their energy consumption and adopt lower carbon sources (Figure ES.2). Total primary energy use falls 21% from 2021 to 2050 as energy efficiency improves. Low and non-emitting sources–including renewables, nuclear, and fossil fuels with carbon-capture and storage (CCS)–grow to make up the strong majority of energy use. Unabated fossil fuel combustion (fossil fuel combustion without CCS) falls 19% from current levels by 2030, 45% by 2040, and 62% by 2050 (Figure ES.3).

Policy assumptions in the Evolving Policies Scenario are based on strengthening or expanding existing global and domestic policies at a pace consistent with recent trends. The Evolving Policies Scenario projections show significant changes in Canada's energy system and imply large reductions in GHG emissions. However, given the remaining unabated fossil fuel demands in 2050, the Evolving Policies Scenario also signals the need for greater long-term change in order to reach Canada's target of net-zero emissions by 2050. In addition to policy, many other factors we discuss in EF2021–such as global energy markets, technology, and consumer behaviour and preferences–will also influence future Canadian energy and emission trends.

Figure ES.2:
Total Canadian Energy Use, Evolving Policies Scenario

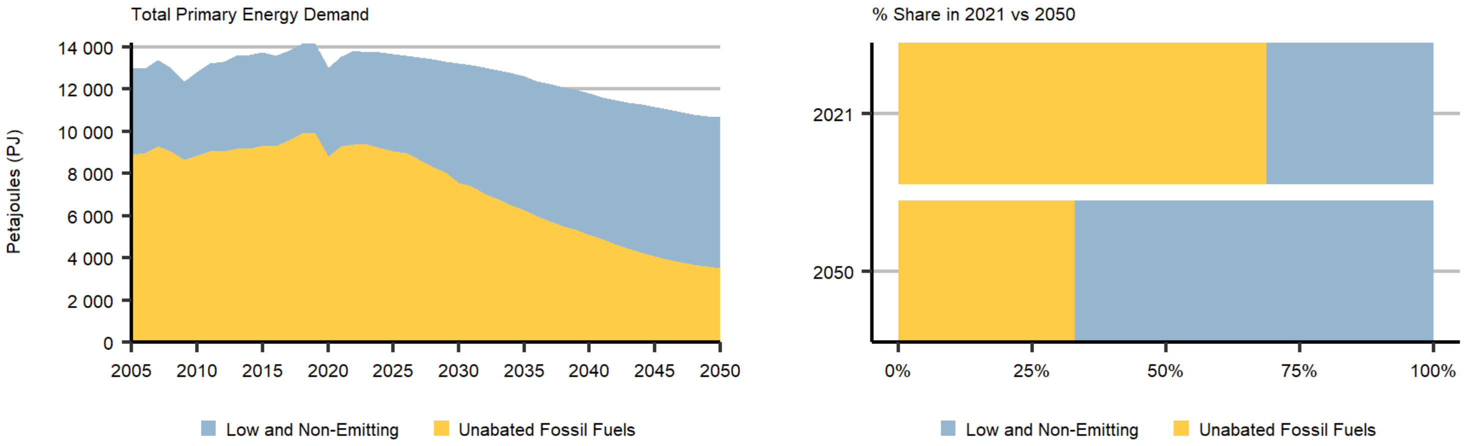


Figure ES.3:
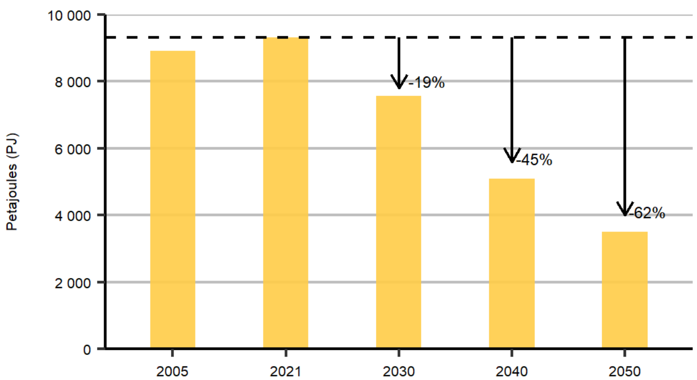
Total Canadian Energy Use, Evolving Policies Scenario



2. Canadians use more electricity, from increasingly low-carbon sources. Despite total energy use declining, electricity demand grows 44% from 2021 to 2050 in the Evolving Policies Scenario, much of it from new areas such as electric vehicles and hydrogen production. Canada's electricity system also gets greener, going from 82% low and non-emitting in 2021 to 95% in 2050.

Compared to the past two decades when electricity use grew very slowly, electricity demand grows quickly over the projection period in the Evolving Policies Scenario. This increase is driven by increased electrification of the energy system. Total electricity demand increases by 44% from 2021 to 2050, or by about 245 terawatt hours (TWh) (Figure ES.4). Half of this increase is driven by increased electrification in the industrial, residential, and commercial sectors. The other half comes from electric vehicles in transportation and the production of hydrogen. In particular, by 2050, electric vehicles dominate Canada's vehicle mix and increase electricity demand by 70 TWh. This results from the Evolving Policies Scenario assuming nearly all new passenger vehicles sold in 2035 are battery or plug-in hybrid electric vehicles.

As demand grows, Canadian electricity generation increases. Wind and solar generation provide much of this additional electricity over the projection period, given their low cost. Natural gas generation is increasingly equipped with CCS. Low and non-emitting electricity generation make up 82% of total generation in 2021, rising to 88% by 2030, 94% by 2040, and 95% by 2050.

Figure ES.4:
Electricity Demand by Sector, Evolving Policies Scenario

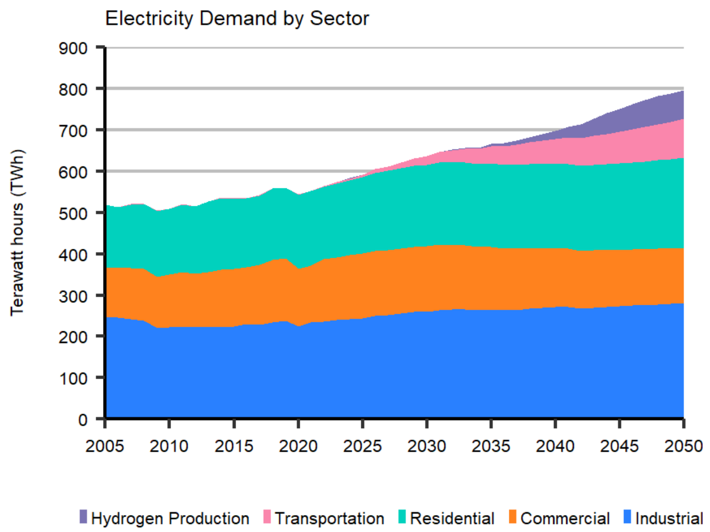


Figure ES.5:
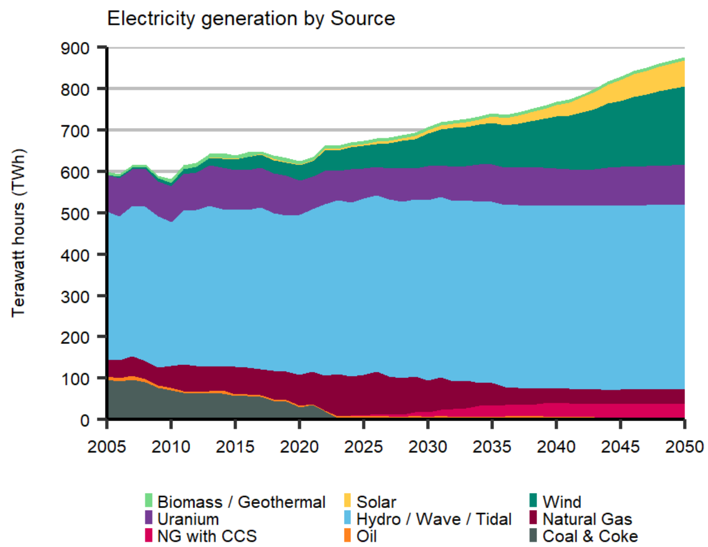
Electricity Generation by Source, Evolving Policies Scenario

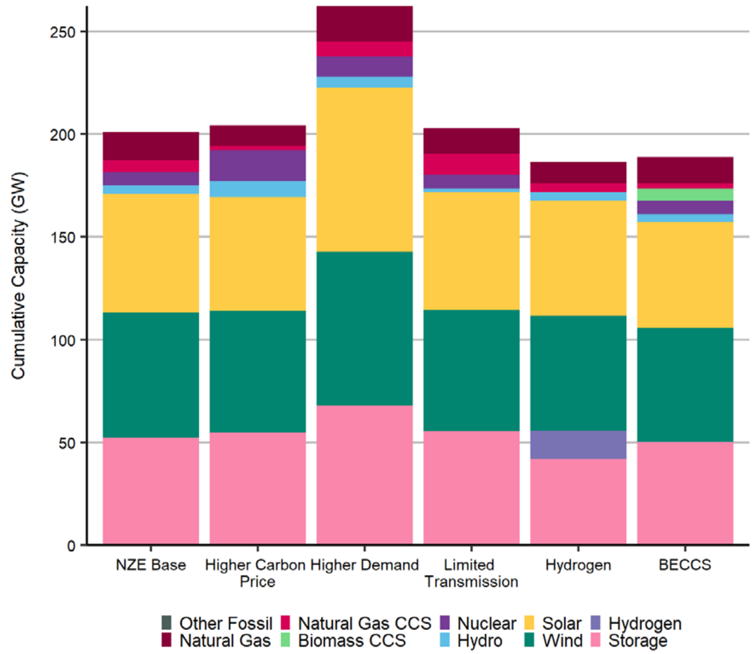


3. Wind, solar, and battery storage dominate electric capacity additions in all six net-zero electricity scenarios, making up between 82-85% of added capacity. With rising levels of wind and solar, all scenarios require flexible generation sources to balance supply and demand. There are large differences in the types and capacities of flexible generation sources adopted among scenarios.

The net-zero electricity scenarios each have a unique set of assumptions that examine many factors including technology, policies, level of electrification, and infrastructure. Figure ES.6 shows the net capacity additions for all six scenarios from 2019 to 2050. Consistent across all scenarios are large additions of wind and solar capacity, ranging from 100 gigawatts (GW) to 150 GW. These technologies are increasingly adopted due to their assumed low future costs in all scenarios. With large amounts of wind and solar capacity, power systems require additional flexible generating resources to balance supply and demand (given the variability of wind and sun conditions). Across the net-zero scenarios, the flexible generating resources are a combination of battery storage, natural gas-fired generation (with and without CCS), small modular nuclear reactors, hydropower, hydrogen-fired generation, biomass-fired generation with CCS, and transmission between provinces. The relative share of these flexible resources varies significantly across the scenarios, though the role of storage in balancing the grid increases dramatically in all scenarios.

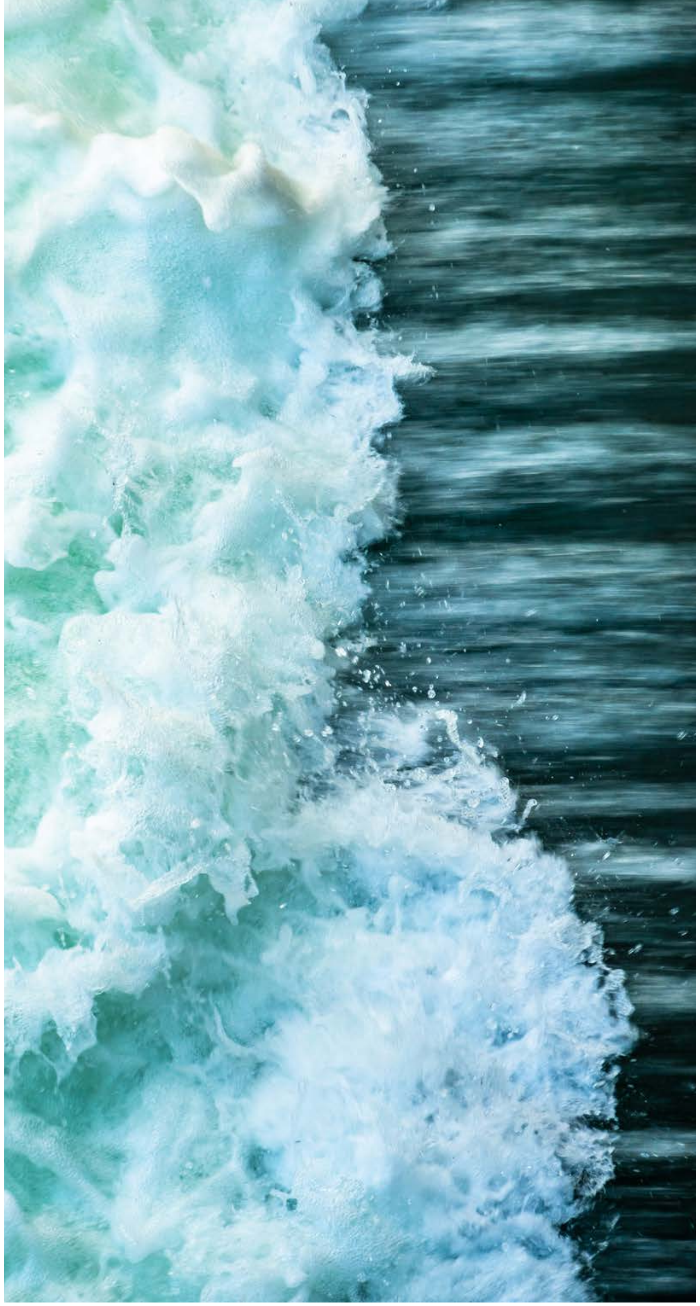
Figure ES.6:

Cumulative Capacity Additions to 2050, All Net-Zero Electricity Scenarios



Electricity Emissions in a Net-Zero World

In these scenarios, the emissions from the electricity sector drops dramatically, but a very small amount of emissions remains from natural gas-fired plants in five of the six scenarios. We allow these emissions because the value of these facilities in terms of electricity system reliability and stability is high. This allowance reflects that, in the context of a broader net-zero world, the use of carbon removal options could potentially provide more cost-effective options than reducing those last few emissions from the electricity system in 2050.



4. The net-zero electricity scenarios suggest that Canadian power systems will continue to be very distinct across the country, even in a low-carbon future. In each net-zero electricity scenario, the ten provinces meet their electricity demands in diverse ways, with widely varying mixes of hydro, nuclear, fossil fuel with CCS, wind, solar, hydrogen, and biomass with CCS.

Figure ES.7 shows the generation mix for each province in the main net-zero electricity scenario. In British Columbia (B.C.), Manitoba, Quebec, and Newfoundland and Labrador, electricity generation continues to be primarily hydropower. Nuclear power remains limited to Ontario and New Brunswick and represents about 41% and 24%, respectively, of those provinces' electricity supply in 2050.

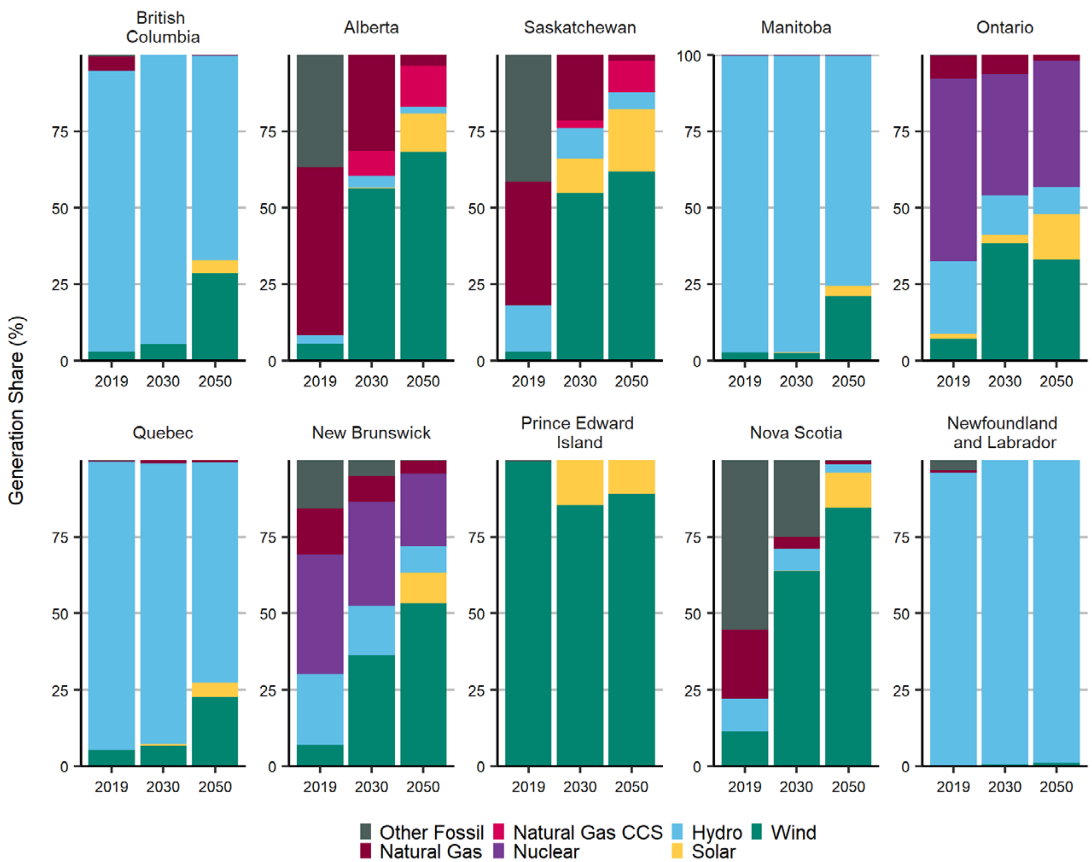
Natural gas-fired electricity generation remains a relatively important share, about 15%, of the electricity supply of Alberta and Saskatchewan in the main net-zero electricity scenario. However, by 2050, the vast majority of this generation utilizes CCS technology. In many other provinces, although the generation share is small, natural gas units nonetheless provide flexible capacity required to maintain system reliability.

Transmission between provinces is a key factor that enables the electricity system to reach net-zero. For example, in the Base net-zero electricity scenario, increased transmission occurs in western Canada, where hydroelectric generation from B.C. and Manitoba helps Alberta and Saskatchewan decarbonize.

While we continue to see diversity between the various provincial electricity systems in each net-zero electricity scenario, results vary somewhat between cases. In a scenario where transmission expansions are limited, Alberta and Saskatchewan use more generation from natural gas with CCS. By contrast, in the Higher Carbon Price scenario, natural gas with CCS is lower in these provinces as small modular reactors make inroads in western Canada. Meanwhile, in the Hydrogen scenario there is a 26% reduction of all types of natural gas-fired generation relative to the main net-zero electricity scenario in 2050, and the flexible nature of hydrogen-fired generation means battery storage falls by 32%. In the Bioenergy with CCS (BECCS) scenario, the availability of biomass CCS units for electricity generation partially displaces all other generation technologies in Alberta and Saskatchewan. Due to the carbon removal capability of biomass CCS, the electricity system in Canada becomes a net negative emissions economic sector in the BECCS scenario.

Figure ES.7:

Electricity Generation Share by Technology, Main Net-Zero Electricity Scenario



5. In the Evolving Policies Scenario, crude oil production grows much more slowly than in the past decade, rising 16% to a peak of 5.8 MMb/d in 2032. Afterwards, production declines slowly to 2050. As crude oil available for export from western Canada increases over the next decade , it comes close to filling the level of total export capacity that would be provided by existing pipeline capacity, planned pipeline expansions, and structural rail.

Canadian crude oil production recovered to pre-pandemic levels by late 2020, after steep reductions in the spring of 2020. In both scenarios, production increases in the near term, but long-term trends differ significantly based on scenario assumptions, such as future price levels and domestic climate policy.

In the Evolving Policies Scenario, Canadian production growth slows over the next decade, peaking at 5.8 million barrels per day (MMb/d) in 2032, up from 5.0 MMb/d in 2021 (Figure ES.8). After 2032, production declines steadily, reaching 4.8 MMb/d in 2050. In the Evolving Policies Scenario, the assumed Brent crude oil price gradually falls from an annual average of US$68 per barrel in 2021 to US$40 per barrel in 2050 (2020 dollars, adjusted for inflation).

Canadian crude oil production levels are resilient through to 2050 despite the Evolving Policies Scenario's relatively low prices and steadily more ambitious climate policies. This largely stems from the nature of the oil sands facilities, which are long-lived and have low operating costs once built. Throughout the projection period, the vast majority of oil sands production is from facilities that are producing today (Figure ES.9).

Future global climate policy, and how it affects global crude oil markets, will be important for Canadian production. The Current Policies Scenario assumes higher global oil prices than the Evolving Policies Scenario, premised on there being higher global oil demand. The Brent crude oil price stays at US$70 per barrel through much of the projection period and Canadian production increases more rapidly, plateauing in 2040 at 6.7 MMb/d. Conversely, some recent global net-zero scenarios, such as the International Energy Agency's Net Zero Emissions by 2050 scenario in World Energy Outlook 2021, show rapidly declining global oil demand, which could lead to significantly lower Canadian production levels compared to the Evolving Policies Scenario.

Figure ES.8:
Crude Oil Production, Evolving and Current Policies Scenarios

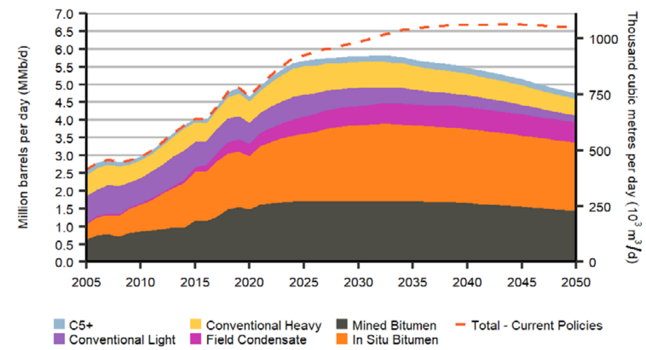


Figure ES.9:
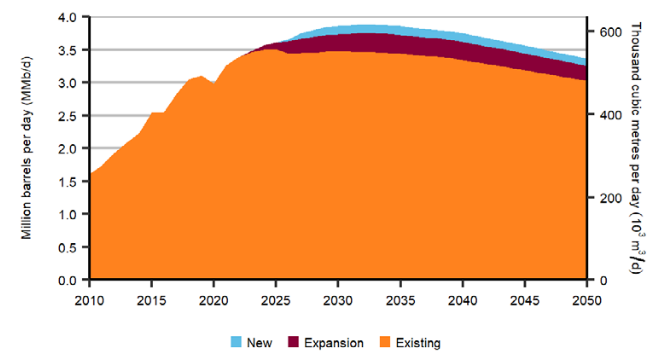
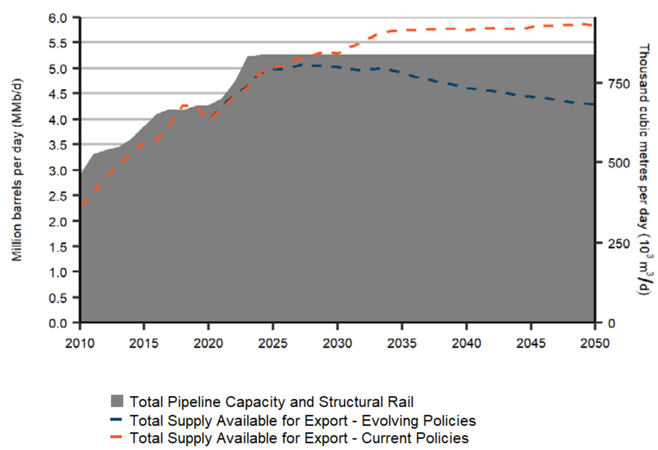
Oil sands Production from Currently Producing Facilities, Expanded, and New Facilities, Evolving Policies Scenario



A key issue for Canadian oil pricing and production trends over the last number of years was the availability of crude oil export pipeline and rail capacity. In the Evolving Policies Scenario, crude oil available for export from western Canada comes very close to, but stays slightly below the illustrative total export capacity provided by existing plus planned pipeline capacity and structural rail, as shown in Figure ES.10. EF2021 does not assess whether additional pipeline capacity would be required to avoid constraining Canadian crude oil production below levels projected in the Evolving Policies Scenario. In the Current Policies Scenario, however, production would clearly be constrained below projected levels without additional pipeline capacity, as supply significantly exceeds the illustrative total export capacity through much of the projection period. Our crude oil supply projections are not adjusted to reflect potential pipeline constraints in either scenario.

Figure ES.10:
Illustrative Export Capacity from Pipelines and Structural Rail, vs. Total Crude Oil Supply Available from the Western Canadian Sedimentary Basin (WCSB), Evolving and Current Policies Scenarios



Crude Oil Pipelines in Canada's Energy Future

The *Canada's Energy Future* series makes projections of energy production and use in Canada. To develop these projections, we need to make assumptions about crude oil markets. Figure ES.10 is an illustrative comparison of our crude oil supply projections with the level of total export capacity that would be provided if planned pipeline expansions go ahead, existing pipelines otherwise experience no increases or decreases in capacity, and a consistent level of structural rail exports continues.

Making this comparison provides insight into whether pipeline constraints might impact crude oil production in our scenarios. However, we do not adjust our crude oil production projections based on potential constraints. EF2021 does not explore the complexities of how pipeline infrastructure interacts with energy supply and demand outcomes. Instead, EF2021 assumes that western Canadian crude oil prices will consistently track prices in international markets. In reality, this is not always the case. For example, if the pipeline system is very full–where export volumes are above or only slightly below total pipeline capacity–crude prices in western Canada can fall well below prices in international markets.

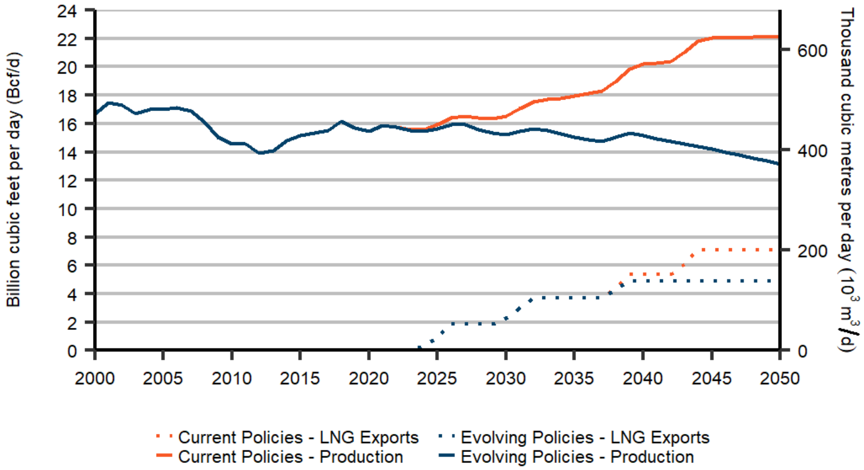
Sufficient spare pipeline capacity is generally required for western Canadian prices to consistently track prices in international markets. Spare capacity provides oil producers and others in the marketplace with flexibility to access higher value markets, and avoid the impacts of maintenance, unforeseen outages, and higher cost rail. This flexibility would remain even with excess capacity and long-term underutilization of pipelines, though this could result in higher pipeline tolls, which could lead to some consistent incremental discounting of western Canadian crude prices. Analysis of these considerations is beyond the scope of EF2021. We caution readers from drawing definitive conclusions from the illustrative comparison shown Figure ES.10.

6. Investment in natural gas production is spurred by assumed liquefied natural gas (LNG) exports in both scenarios. In the Evolving Policies Scenario, nearly 40% of Canadian natural gas production is liquefied and exported to global markets by 2050. Despite considerable LNG-related production growth, natural gas production remains relatively stable through much of the projection period before declining gradually to reach 13.1 Bcf/d by 2050, 17% lower than current levels.

In the Evolving Policies Scenario, natural gas production remains near current levels of approximately 15.5 billion cubic feet per day (Bcf/d) through much of the next two decades. We assume that LNG exports grow over that period, starting with 1.8 Bcf/d by 2026 and reaching 4.9 Bcf/d by 2039 in the Evolving Policies Scenario. The additional investment in production to feed these LNG exports sustains overall production levels. Without LNG, production would otherwise decline given the assumed natural gas prices and the costs associated with assumed domestic climate policies. After 2040, with LNG exports assumed to stay flat, total production begins to decline, falling to 13.1 Bcf/d by 2050. Assumed Henry Hub natural gas prices in the Evolving Policies Scenario steadily increase from US$3.00 per Million British Thermal Units (MMBtu) in 2021 to US$3.64/MMBtu by 2050 (2020 dollars, adjusted for inflation).

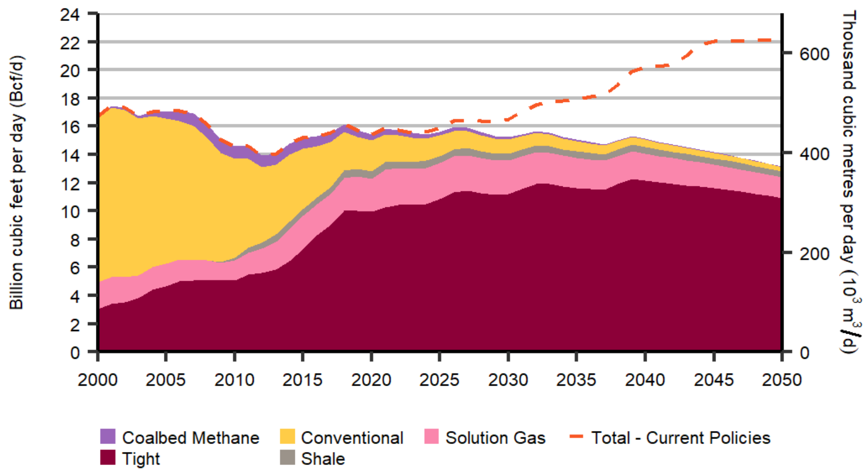
In the Current Policies Scenario, natural gas production is significantly higher. To reflect higher global and North American demand for natural gas due to the scenario's lower climate action, we assume LNG exports increase to 7.1 Bcf/d by 2044 and the Henry Hub price reaches $4.40/MMBtu by 2050 (2020 dollars, adjusted for inflation). These two drivers, combined with less stringent domestic climate policies relative to the Evolving Policies Scenario, lead to natural gas production increasing steadily throughout the projection, reaching 22.2 Bcf/d in 2050, a 40% increase from 2021 production levels.

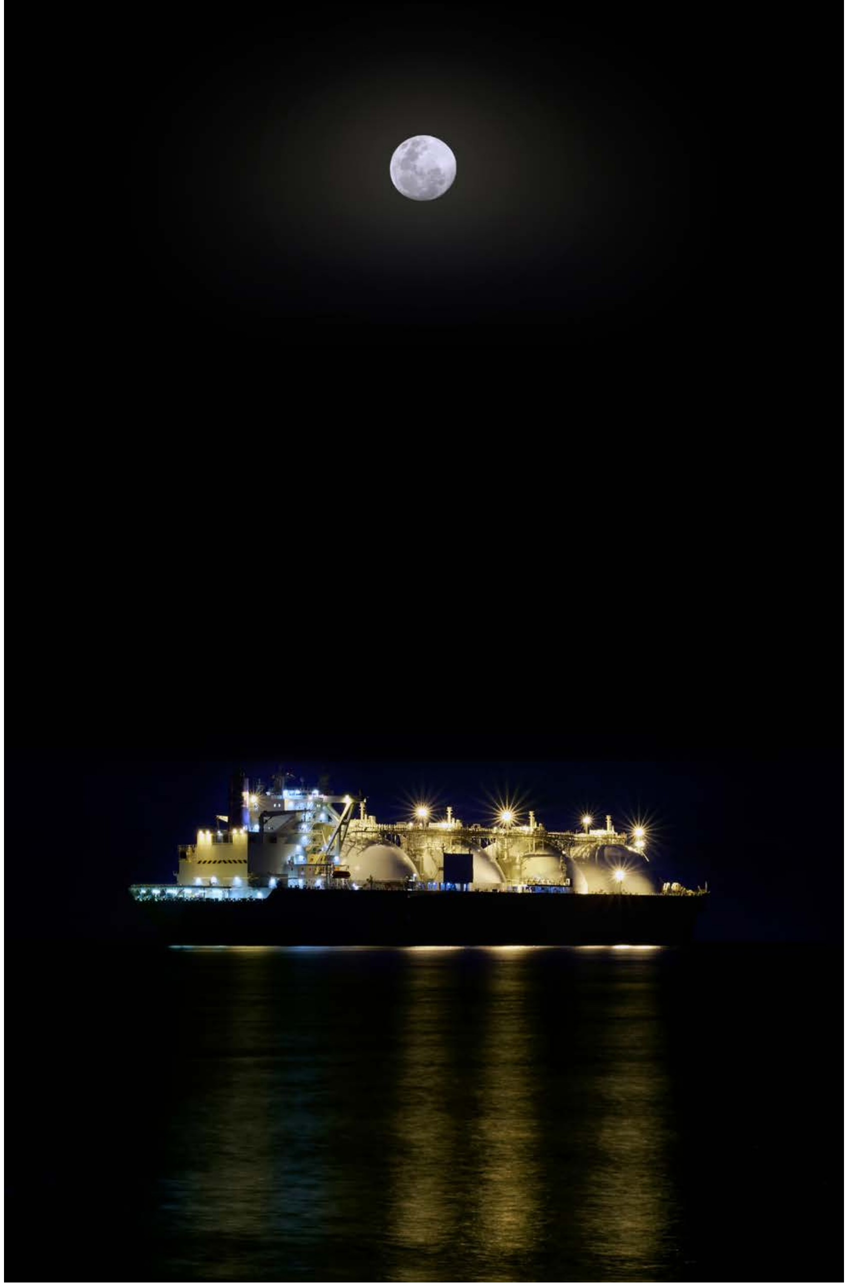
Figure ES.11:
Total Natural Gas Production and LNG Export Assumptions, Evolving and Current Policies Scenarios

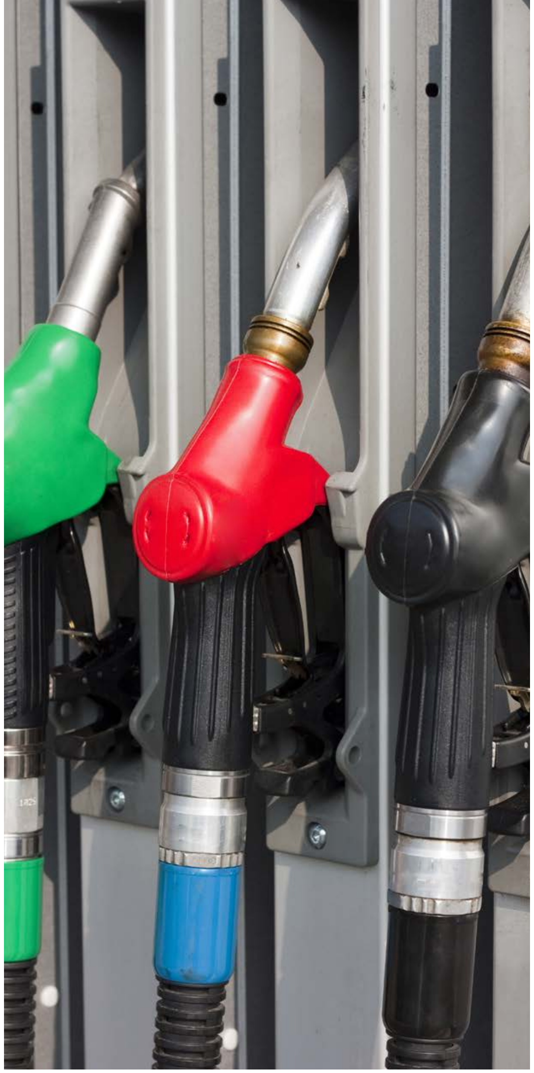


In both scenarios, natural gas production from the Montney Formation, which straddles the Alberta-B.C. boundary and is rich in higher value natural gas liquids (NGLs), grows significantly. In many other regions, production is stable or declines throughout the projection. Much of the production growth related to LNG exports occurs in B.C. and production in B.C. surpasses that of Alberta by 2028.

Figure ES.12:
Natural Gas Production, Evolving and Current Policies Scenarios







7. As Canada's energy system decarbonizes in the Evolving Policies Scenario, we use less fossil fuels. Coal becomes a negligible part of the energy mix. Use of oil-derived fuels declines, especially gasoline and diesel for transportation. After briefly rising in the near term, total natural gas use declines, and our consumption of natural gas is increasingly tied to the future of CCS. Natural gas with CCS for industrial uses, power generation, and hydrogen production are key demand growth areas.

In the Evolving Policies Scenario, total Canadian fossil fuel use declines over 40% from 2021 to 2050. However, projections differ across the various fossil fuels. Canadian demand for natural gas has seen relatively strong growth over the last decade, driven by increased use in the oil sands and power generation as coal was phased out. In the Evolving Policies Scenario, gas demand grows over the next two years, as Alberta electricity producers aim to no longer use coal for electricity generation by 2023. Over the longer term, although natural gas remains an important part of Canada's energy mix, total demand declines from around 13 Bcf/d in 2021 to 8.5 Bcf/d in 2050. Factors that reduce natural gas demand include: increasing use of renewables in power generation, renewable natural gas and hydrogen blended into gas streams, energy efficiency improvements, and declining crude oil and natural gas production (which itself requires natural gas). These declines are partially offset by applying CCS technology when using natural gas in industry, the power sector and to produce low-carbon hydrogen.

Coal consumption declines significantly over the projection, driven by its phase-out from electricity generation. Coal drops to less than 1% of Canada's energy mix by 2035, compared to 5% in 2019. Use of refined petroleum products (RPPs) and NGLs gradually falls throughout most of the projection period, driven by declines in gasoline and diesel fuel demand. In the earlier years, this fall is driven by fuel efficiency improvements and increased blending of biofuels, and in the long term by increased use of electric and hydrogen vehicles in transportation. Demand for RPPs used for non-combustion purposes (petrochemical feedstocks, asphalt, lubricants, etc.), as well as for aviation fuel, is relatively steady throughout the projection.

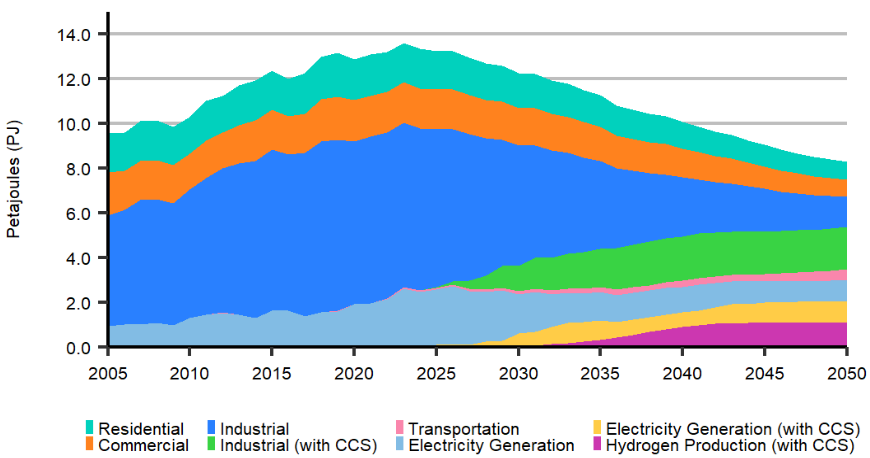
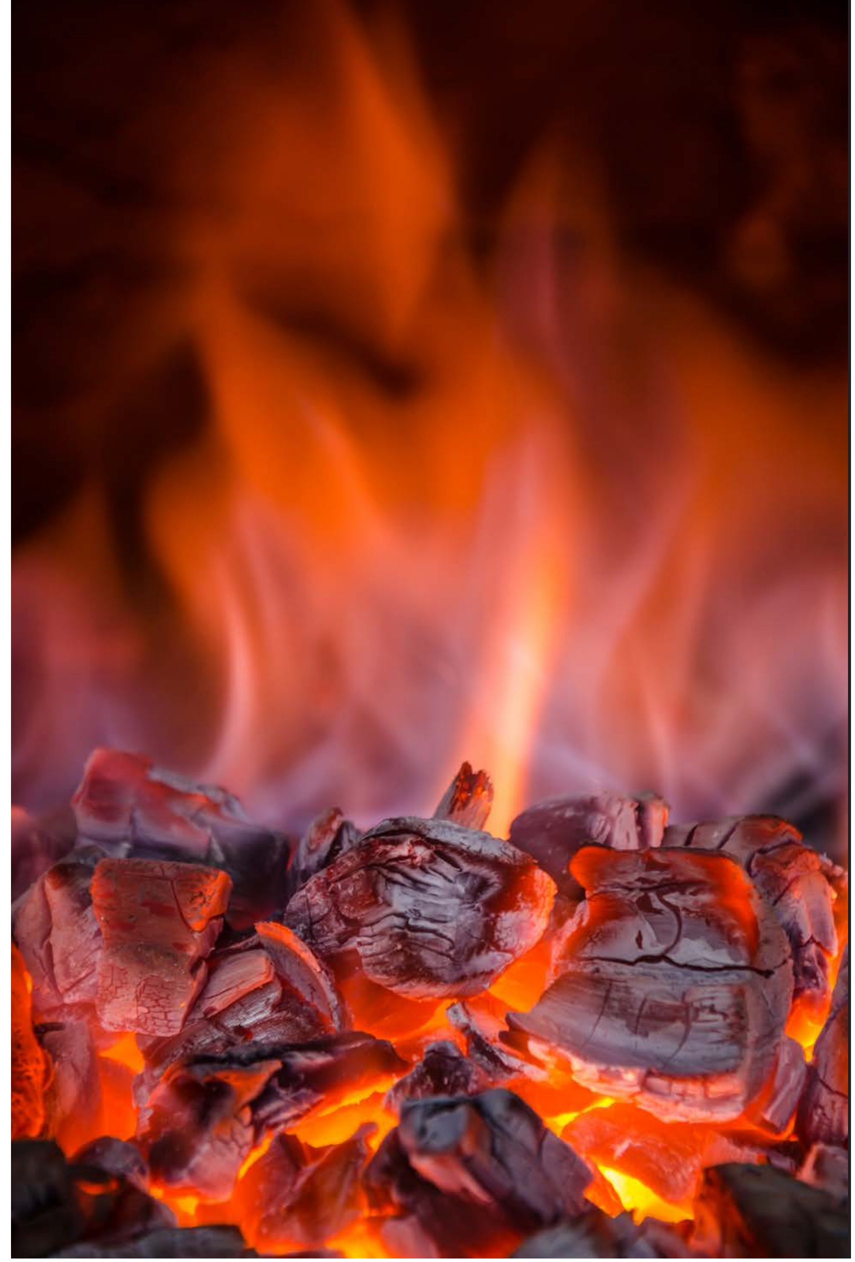
Natural Gas Demand by Sector, Evolving Policies Scenario





Scenarios and Assumptions

This chapter describes the two core scenarios in EF2021, the Evolving Policies Scenario and the Current Policies Scenario, and the assumptions that underpin those scenarios. The six scenarios, and underpinning assumptions, that explore what achieving net-zero means for Canada's electricity system are described in the "Towards Net-Zero" section of this report. However, Figure A.1 illustrates the key differences between the two core scenarios and the group of six additional net-zero scenarios that explore the electricity system.

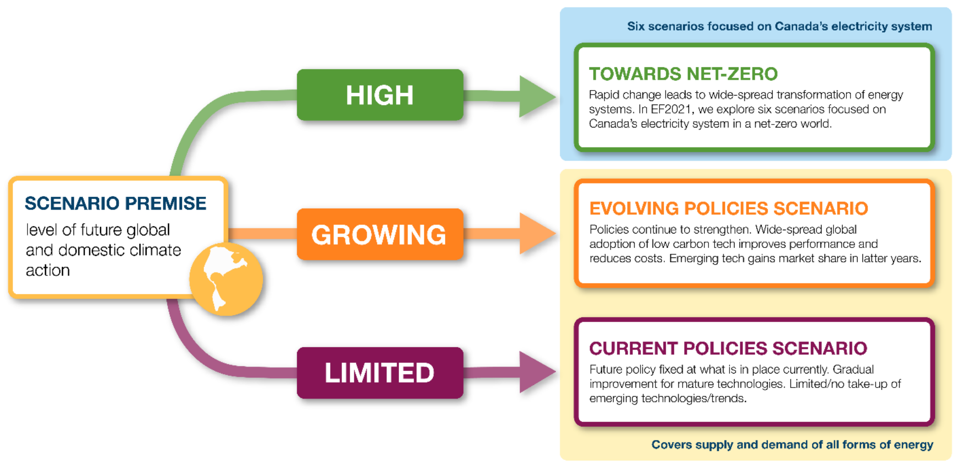
Scenario Premise

EF2021 includes two core scenarios: the Evolving Policies Scenario and the Current Policies Scenario. The central premise to these scenarios is based on the level of future climate action, both globally and domestically. The Evolving and Current Policies scenarios provide projections for all energy commodities and all Canadian provinces and territories.

The primary scenario in EF2021 is the Evolving Policies Scenario. The core premise of the scenario is that action to reduce the GHG intensity of our energy system continues to increase at a pace similar to recent history, in both Canada and the world. Relative to a scenario with less action to reduce GHG emissions, this evolution implies less global demand for fossil fuels, and greater adoption of low-carbon technologies. In contrast, the core premise of the Current Policies Scenario is that there is generally no additional action to reduce GHGs beyond those policies in place today, implying relatively higher global demand for fossil fuels and less adoption of low-carbon technologies. Consistent with these implications, the Evolving Policies Scenario assumes lower international prices for fossil fuels and a higher pace of technological change over the projection period, compared to the Current Policies Scenario.

The Evolving and Current Policies scenarios do not explicitly model climate goals or targets. Given its static policy framework, the Current Policies Scenario is extremely unlikely to lead to the significant GHG reductions needed to meet Canada's Paris commitments. In the Evolving Policies Scenario, significant GHG emission reductions will be realized, but ambitious goals such as net-zero by 2050 are unlikely to be met.

Figure A.1:
Conceptual Illustration of EF2021 Scenarios



The Energy Futures Analytical Process

The analysis in EF2021 follows a three-step process

1. Define the premises of the Scenarios: We develop the scenarios in the *Canada's Energy Future* series to explore key uncertainties for the future of the energy system. In EF2021, the primary premise which differentiates the scenarios is the level of global and domestic climate action. We then consider the implications of that premise on factors such as global fossil fuel demand and technology development. These implications are discussed further in this section, under the heading "Scenario Premise."

2. Make explicit assumptions on key inputs: We then make explicit assumptions about key factors which will influence the Canadian energy system. These assumptions are intended to be consistent with the scenario premises defined in Step 1. Key inputs include specific domestic climate policies such as carbon prices, international crude oil and natural gas benchmark prices, and technology cost and performance trends. These are detailed in this section under the heading "Key Assumptions."

3. Develop projections: Given these input assumptions, we develop projections to 2050 using the Energy Futures Modeling System. Results from these projections are included in the following chapters. Additional information about the energy modeling system is included in Appendix 2: Overview of the Energy Futures Modeling System.

Table A.1:
Explaining the Scenarios and Relationship Between the Assumptions

KEY DIFFERENCES BETWEEN SCENARIOS	EVOLVING POLICIES	CURRENT POLICIES
SCENARIO PREMISE	**PREMISE**: Continually increasing global and Canadian action to reduce GHG emissions. The pace of increase in future action continues the historical trend.	**PREMISE**: Global and Canadian action to reduce GHG emissions generally stops at current levels.
INTERNATIONAL CRUDE OIL MARKETS	**GENERAL IMPLICATION**: Due to increasing policy action, global crude oil demand is lower than the Current Policies Scenario.	**GENERAL IMPLICATION**: Less policy action leads to higher global crude oil demand compared to the Evolving Policies Scenario.
	EXPLICIT ASSUMPTION INCLUDED IN EF MODELING: Lower demand implies lower crude oil prices compared to the Current Policies Scenario. Brent crude oil trends gradually downward, reaching $40/bbl 2020USD in 2050.	**EXPLICIT ASSUMPTION INCLUDED IN EF MODELING**: Stronger demand implies stronger crude oil prices compared to the Evolving Policies Scenario. Brent crude oil averages $70/bbl 2020USD through most of the projection period.
INTERNATIONAL NATURAL GAS MARKETS	**GENERAL IMPLICATION**: Due to increasing policy action, global natural gas demand is lower than the Current Policies Scenario.	**GENERAL IMPLICATION**: Less policy action leads to higher global natural gas demand compared to the Evolving Policies Scenario.
	EXPLICIT ASSUMPTION INCLUDED IN EF MODELING: Henry Hub natural gas prices rise from $3.00/MMbtu 2020 USD in 2021, but at a slower pace than the Current Policies Scenario, reaching $3.64/mmbtu 2020USD in 2050. Canadian liquefied natural gas (LNG) exports increase to 4.9 bcf/d by 2050.	**EXPLICIT ASSUMPTION INCLUDED IN EF MODELING**: Henry Hub natural gas prices rise faster and higher than in the Evolving Policies Scenario, to $4.40/mmbtu 2020USD in 2050. Canadian LNG exports increase to 7.1 bcf/d by 2050.
LOW-CARBON TECHNOLOGIES	**GENERAL IMPLICATION**: Increasing policy action drives increasing global adoption of low-carbon technologies, which leads to cost and efficiency improvements as technology advances.	**GENERAL IMPLICATION**: Limited policy action provides a weaker incentive for global technology adoption. Cost declines and performance of low-carbon technologies are weaker compared to the Evolving Policies Scenario
	EXPLICIT ASSUMPTION INCLUDED IN EF MODELING: Costs for technologies with a growing market share, such as wind and solar power, fall faster compared to the Current Policies Scenario. Emerging technologies are included on a larger scale. Performance of both technology categories improves as compared to the Current Policies Scenario.	**EXPLICIT ASSUMPTION INCLUDED IN EF MODELING**: Costs continue to improve for technologies where there is a clear trend, such as wind and solar power, but at a slower rate than the Evolving Policies Scenario. Limited inclusion of emerging technologies.
DOMESTIC CLIMATE POLICIES	**GENERAL IMPLICATION**: Policy action continues to increase at the pace of the historical trend.	**GENERAL IMPLICATION**: Policy action is fixed to what is currently in place.
	EXPLICIT ASSUMPTION INCLUDED IN EF MODELING: A hypothetical suite of future policy changes is assumed. This includes an increase in carbon pricing beyond 2030, tightening of standards for large emitters, a national ZEV mandate, and an increasingly strict emissions intensity mandate for fuels beyond 2030.	**EXPLICIT ASSUMPTION INCLUDED IN EF MODELING**: Only policies that are law or near-law are included.

Table A.1 summarizes the implications of the core premise of the scenarios across some key areas. It describes how the premise of the Evolving and Current Policies scenarios affects each area, first in a general sense (rows labelled "General Implication") and then how these translate into explicit assumptions, such as prices or technology costs, included in the EF models (rows labelled "Explicit Assumption Included in EF Modeling"). Many of these areas, such as international markets and technology development, are international in nature. Since EF2021 analysis is focused on Canada, the explicit assumptions, such as market prices and technology cost trends, are developed via a review of global scenario analysis produced by institutions, academia, industry, private forecasters, and other relevant energy analysis.[3]

[3] Key resources that informed the Evolving and Current Policies scenario assumptions include: ECCC Healthy Economy, Healthy Environment (2021), various federal, provincial and territory policy documents, IEA World Energy Outlook (2020) and Net-Zero by 2050 (2021), EIA Annual Energy Outlook (2021) and Short Term Energy Outlook (various 2021), BP Outlook (2020), Shell Scenarios (2021), National Renewable Energy Laboratory Annual Technology Baseline (2021), price forecasts from GLJ and Sproule, and scenario analytics services from IHSMarkit, S&P Global, and WoodMackenzie.

EF2021 is a Baseline for Discussion

It is important to note that the projections presented in EF2021 are a baseline for discussing Canada's energy future today and do not represent the CER's predictions of what will take place in the future. EF2021 projections are based on assumptions which allow for analysis of possible outcomes. Any assumptions made about current or future energy infrastructure, market developments, or climate policies, are hypothetical and have no bearing on any regulatory proceeding that is, or will be, before the CER.

Over the projection period, it is likely that developments beyond normal expectations, such as geopolitical events or technological breakthroughs, will occur. Also, new information will become available, and trends, policies, and technologies will continue to evolve. This report is not an official, or definitive, impact analysis of any specific policy initiative, nor does it aim to show how specific goals, such as Canada's climate targets, will be achieved.

Key Assumptions

Domestic Climate Policy

The Evolving Policies Scenario begins with domestic climate policies currently in place. It then builds on the current policy framework with a hypothetical suite of future policy developments. These policies are chosen to reflect increasing ambition to reduce GHG emissions, and generally align with the broad trends of historical progress. Alternatively, the Current Policies Scenario only includes policies that are currently in place. This section outlines specific policies included, and additional policy detail is available in Appendix 1: Domestic Climate Policy Assumptions.

Existing policies:

The Current Policies Scenario includes only policies that currently exist. In the Evolving Policies Scenario, existing policies provide a baseline that is built upon over the projection.

In order to determine whether to include a policy in the analysis, the following criteria were applied:

- The policy was publicly announced prior to 1 August 2021.
- Sufficient details exist to model the policy.[4]
- Goals and targets, including Canada's international climate targets, are not explicitly modelled. Rather, policies that are announced, and in place, to address those targets are included in the modelling and analysis.

Relative to Canada's Energy Future 2020 (EF2020), key changes in the Evolving and Current Policies scenarios include the increased carbon pricing included in the Federal Strengthened Climate Plan. The Clean Fuel Standard for liquid fuels has also been included in the Current Policies Scenario, following the publishing of the draft regulations in December 2020.

[4] For example, in July 2021, the Federal government announced a forthcoming mandate for all passenger vehicle sales to be zero-emissions by 2035, but at the time of analysis there was not sufficient detail to include this mandate in the Current Policies Scenario.

Future policies:

The Evolving Policies Scenario adds a hypothetical suite of future policy developments to existing policies. These policy assumptions take into account several considerations:

- Announced policies that are currently in the development stage are included to the extent possible. Generally, their inclusion requires simplifying assumptions as final regulations are not available.
- Some policies that are being increasingly enacted by various jurisdictions are broadened to other jurisdictions later in the projection period.
- Existing policies that can be strengthened over time, are strengthened. For example, following the carbon price increases to 2030 that are set out in current policy, we include a hypothetical carbon price that continues to rise from 2031 to 2050, as well as a hypothetical tightening of the benchmarks for large emitters subject to the output-based pricing system.

Table A.2 describes specific policy initiatives. Figure A.2 compares the federal backstop carbon price to the increasing cost of carbon pollution in the Evolving Policies Scenario.

Table A.2:
Overview of Domestic Policy Assumptions

Key Differences Between Scenarios

Key Existing Policy Assumptions:
The base for policy assumptions in the Evolving Policies Scenario, while the Current Policies Scenario only includes these existing policies.

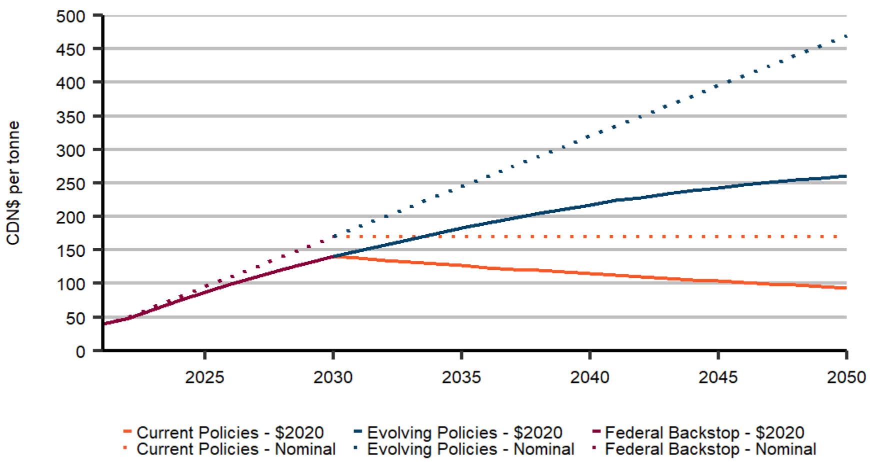
Policy	Description
Carbon Pricing	Current provincial and territorial systems, as well as the Federal Carbon Pricing Backstop.
Coal Phase-Out	Traditional coal-fired generation is phased out of electricity generation by 2030.
Clean Fuel Regulation	Liquid fuels only, where standard strengthens to 2030.
Energy Efficiency	Currently in place regulations including appliance standards, building codes, and vehicle standards.
Electric Vehicles	Provincial policies and initiatives including those in British Columbia (B.C.) and Quebec, as well as Federal rebates and infrastructure program.[5]
Renewable Energy	Current requirements for renewable electricity, and blending of ethanol, biodiesel, and renewable natural gas.

Key Future Policy Assumptions:
Hypothetical increases in policy stringency only included in the Evolving Policies Scenario

Hypothetical Policy Change	Description
Carbon pricing	Carbon prices continue to rise beyond existing announcements. For the federal pricing system, prices continue to increase after 2030 at $15 per tonne of carbon dioxide equivalent (CO_2e) per year, in nominal terms, as shown in Figure A.2. In systems for large emitters, such as the federal output-based pricing system, benchmarks are tightened by 2% annually from 2022 to 2050.
Low Carbon/Clean Fuel Regulations	The Federal Clean Fuel Regulation emission intensity improvement trend (2022-2030) for liquid fuels is extrapolated through the remainder of the projection period. A federal renewable natural gas blending requirement is introduced in 2030, rising to 10% by 2040.
Zero-Emission Vehicles	A federal zero-emission vehicle (ZEV) mandate is introduced in 2025, rising to 100% of new passenger vehicle sales by 2035 in the provinces. Remote communities and the territories are assumed to be exempt.
Energy Efficiency	Gradually stronger energy efficiency regulations across the economy, including net-zero-ready building codes, improving appliance standards, and increasing light-duty vehicle efficiency standards.
Support for clean energy technology and infrastructure	Policy continues to support new technology development as well as key infrastructure developments including electric transmission, carbon capture and storage (CCS), hydrogen production, and electric vehicle charging infrastructure.

[5] In June 2020 the Federal government announced a goal for 100% of car and passenger truck sales to be zero-emission by 2035 in Canada.
At the time of analysis, policy measures to achieve this target were still under development, and this goal is not included in the Current Policies Scenario.

Figure A.2:
Current Federal Backstop Carbon Pricing Schedule[6] (2020 to 2030), and Evolving and Current Policy Scenario Economy-wide Carbon Pricing Assumptions (2030 to 2050)



[6] For illustration purposes: In the EF2021 analysis, carbon prices are modeled based on individual provincial and territorial systems, many of which differ from the federal backstop system. The Federal Backstop price includes the announced increase to $170/tonne by 2030 in nominal terms. For the remainder of the Current Policies Scenario projection, this is held constant, and the price in inflation-adjusted terms declines by the rate of inflation.

Evolving Policies Scenario: Key Changes between EF2020 and EF2021

The Evolving Policies Scenario was introduced as the new primary scenario of the *Canada's Energy Future* series in EF2020. In the time since EF2020 analysis was completed, there have been some significant changes in global and domestic trends that have led to revisions in Evolving Policies Scenario assumptions between EF2020 and EF2021. Key changes include:

Significantly stronger domestic climate policy, including Canada's Strengthened Climate Plan carbon price path. Several new domestic policy initiatives have been introduced, including a higher federal carbon pricing backstop to 2030, draft regulations for the federal clean fuel regulation, and several provincial and territorial policies and plans.

Higher crude oil and natural gas prices in the near term, but lower prices in the longer term. Prices have trended higher than those in EF2020 in the near term, through the combined effect of pandemic recovery, vaccine rollout, and global crude oil production cuts. Over the longer term, EF2021 crude oil and natural gas prices are lower than EF2020, in light of several new international policy and GHG reduction target announcements.

Increased momentum for emerging technologies. Since EF2020's release, Canada has released hydrogen and small modular reactor (SMR) roadmaps. Automakers have announced more models of electric vehicles (EVs). Several major carbon-capture and storage (CCS) and hydrogen projects have also been announced.[7]

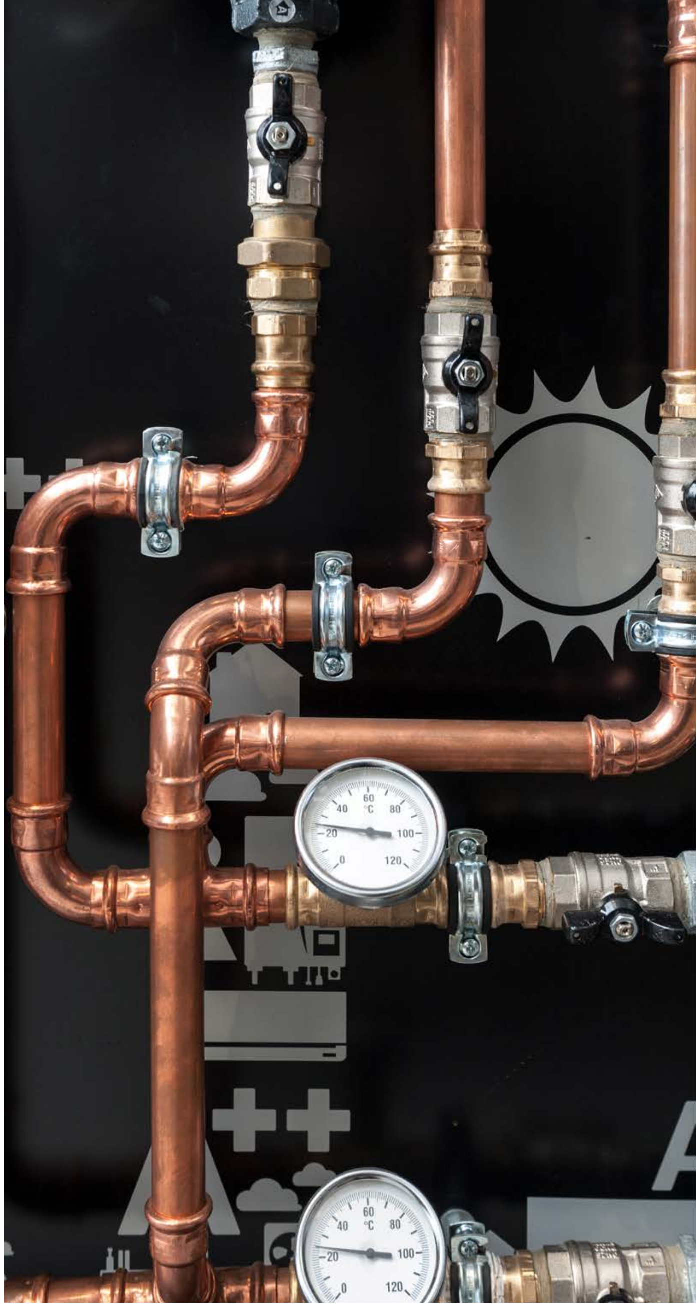
[7] These include the Hydro-Québec green hydrogen electrolyzer project, the Air Products Net-Zero Hydrogen Energy Complex, the Pembina and TC Energy Alberta Carbon Grid, Pieridae Caroline Carbon Capture Power Complex, Nauticol Energy and Enhance Energy's Blue Methanol facility, and the Shell Polaris CCS project.

Technology

Technological changes can have large impacts on energy systems. There is a strong link between policies and the pace of technological development. Policy frameworks are key drivers of technological innovation and greater use of GHG-reducing technologies. Over the past decade, technological advancements have provided access to unconventional fossil fuel resources and dramatically reduced the cost of technologies like wind, solar, and batteries. The Evolving Policies Scenario assumes substantial technological progress, including adoption of many promising technologies currently in the early stages of commercialization. The Current Policies Scenario assumes slower technological progress compared to the Evolving Policies Scenario, including incremental efficiency improvements and cost reductions for well-established technologies. Table A.3 provides an overview for key technology assumptions in the Evolving and Current Policies Scenarios.

Table A.3:
Technology Assumptions, Evolving and Current Policies Scenarios

Technology	Evolving Policies Scenario	Current Policies Scenario
Wind and Solar Electricity	Costs fall and performance improves. See table A.4 for details.	Costs continue to fall, but at a slower rate than the Evolving Policies Scenario. See table A.4 for details.
Electric Vehicles	Battery costs fall from 2020US$ 170/kilowatt (kW) in 2021 to $ 45/kW in 2050 (reduction of 74%).	Battery costs fall to 2020US$ 100/kW by 2050 (reduction of 40%).
Hydrogen	Cost of low-carbon hydrogen falls throughout the projection period. Electrolysis hydrogen falls from $2020 US$ 6-10 currently to $1.5-6 by 2050. Natural gas with CCS derived hydrogen falls from $2020 US$ 1.6-2 currently to $1.5-1.7 by 2050.	Currently announced projects included, costs remain near current levels.
Renewable Natural Gas	Costs an average 2020US$ 15/GJ throughout the projection, with a maximum demand of 500 petajoules (PJ).	Only current projects and in-place blending policies (B.C. and Quebec) are included.
Solvent-Assisted Oil Sands Extraction	All new oil sands facilities added post 2025 include solvent-assisted extraction. Adoption in existing facilities begins in the latter half of the projection period.	Limited adoption of solvent-assisted technology.
Small Modular Nuclear Reactors (SMRs)	Cost falls from 2020US$ 7000/kW in 2030 to 6000/kW in 2040, 5000/kW in 2050.	Not included.



Critical Minerals and the Energy Transition

A continued global transition toward low-emission energy systems will involve the deployment of many existing and emerging technologies, such as wind turbines, solar panels, and batteries. These technologies require input materials, and global scenario analysis (such as International Energy Agency's (IEA's) *Net Zero by 2050* and *The Role of Critical Minerals in Clean Energy Transitions*, and MIT Energy Initiative's *Insights into Future Mobility*) are increasingly focused on the inputs necessary to produce these technologies. The cost and availability of minerals that are needed to manufacture low-carbon technologies are key uncertainties for energy systems.

Increasing demand for these critical minerals (such as lithium, cobalt, nickel, and copper) could put upward pressure on their prices. In turn, increasing raw material prices could limit cost reductions for wind, solar, and batteries. If costs of these technologies are higher than assumed in the EF2021 scenarios (see Table A.4), there could be lower adoption than projected, and/or higher energy system costs.

Conversely, sustained demand for critical minerals can encourage investment in new sources of supply or increased recycling, potentially keeping price increases at bay or even driving down prices over time.[8] Technology development could offset potential increases in input material costs through changes in design (such as changing lithium-ion battery chemistry to use less cobalt, and/or use of different technologies, such as moving towards a solid-state battery and away from the nickel-manganese-cobalt technology used today), or production improvement.[9]

Although the outlook for the global critical minerals market is uncertain, it is clear that mining critical minerals for low-carbon technologies will have major economic impacts. The IEA's Net Zero Energy scenario estimates that the global value of select critical minerals will grow substantially over the next two decades, reaching today's level for coal market value (about $400 billion 2019USD) by 2040. In the Canadian context, the Canadian Institute for Climate Choices' *Canada's Net Zero Future* study finds that increased mining and manufacturing activity could be an important contributor to Canada's economic growth as Canada and the world decarbonize.

---

8 For example, exploration for rare earth metals substantially increased in the early 2010s, driven by the prospect of increased demand (Eggert, R. G. (2011). Minerals go critical. Nature Chemistry, 3, 688-691.). For a discussion of critical minerals exploration dynamics see Humphreys, D. (2014). The mining industry and the supply of critical minerals. In British Geological Survey, Critical Metals Handbook (pp. 20-40). John Wiley & Sons, Ltd. doi:10.1002/9781118755341.

9 See Victoria et al., Solar photovoltaics is ready to power a sustainable future, Joule (2021), for a discussion on how production efficiencies have reduced material needs for Solar PV, and reduced risk exposure to input materials.

Crude Oil and Natural Gas Markets

International crude oil and natural gas prices are a key driver of the Canadian energy system and are determined by supply and demand factors beyond Canada's borders. Canadian crude oil and natural gas benchmark prices (such as western Canada Select (WCS) for heavy crude oil and Nova Inventory Transfer (NIT) for natural gas) are driven by international trends, but are also driven by local factors, such as local crude quality and adequacy of pipeline capacity. In recent years, the availability of pipeline capacity within and leaving western Canada has been a key issue that has affected both Canadian markets and production levels.

Figure A.3 shows the EF2021 crude oil assumptions for Brent, the primary global benchmark price for crude oil, for the Evolving and Current Policies scenarios. Global crude oil prices fell in 2020 due to the COVID-19 pandemic. In the second half of 2021, prices have increased to 2019 levels and above. In the longer term, prices in the Evolving and Current Policies scenarios diverge based on their different premises. In the Evolving Policies Scenario increased global action on climate change, which implies reduced demand for crude oil relative to the Current Policies Scenario, puts downward pressure on prices and the Brent price declines to 2020US$40/barrel (bbl)[10] by the end of the projection period, from 2020US$68/bbl in 2021. In the Current Policies Scenario, crude oil prices stay at 2020US$70/bbl over the projection period. In both scenarios, West Texas Intermediate (WTI), a key North American crude benchmark, is 2020US$4.00 lower than Brent in the long term.

Both EF2021 scenarios assume that the Canadian heavy benchmark price is discounted to WTI consistent with the historical average. The WTI-WCS differential is 2020US$12.50/bbl for most of the projection. However, in reality, if future supply available for export approaches and/or exceeds the level of total capacity provided by pipelines and structural rail, this differential could increase significantly. We do not adjust the assumed differential for such dynamics. Figure R.14 in the "Results" section provides an illustration of how tight or constrained pipeline capacity could become in our two scenarios, based on existing pipeline capacity, planned pipeline expansions, and structural rail.

Figure A.4 shows the EF2021 natural gas price assumptions for the Evolving and Current Policies Scenarios. Over the projection period, Henry Hub, a key North American benchmark price, increases gradually reaching 2020 US$3.60/MMBtu by 2050 in the Evolving Policies Scenario, from $3.00/MMBtu in 2021. In the Current Policies Scenario, natural gas prices rise faster, reaching 2020 US$4.40/MMBtu by 2050. This is consistent with greater North American demand growth and LNG export volumes compared to the Evolving Policies Scenario. EF2021 assumes Henry Hub is 2020US$0.90/MMBtu higher than NIT for the majority of the projection. However, the NIT price discount could materially rise if there are periods where pipeline capacity becomes constrained for moving western Canadian natural gas to markets.

[10] This means $40 in USD currency, and adjusted for inflation in real terms with a base year 2020.

Figure A.3:
Brent Crude Oil Price Assumptions to 2050, Evolving and Current Policies Scenarios

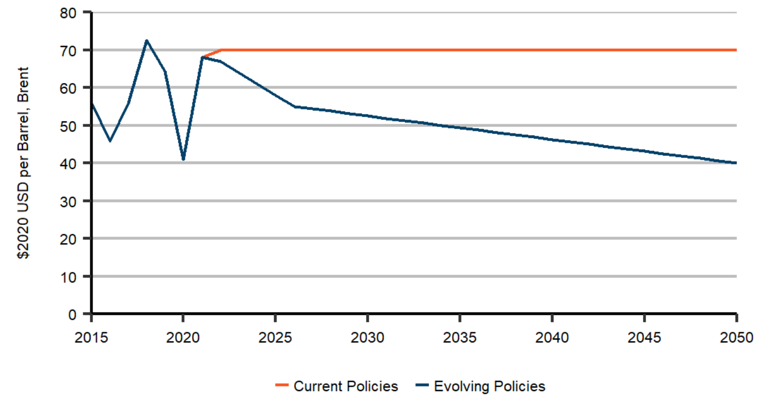


Figure A.4:
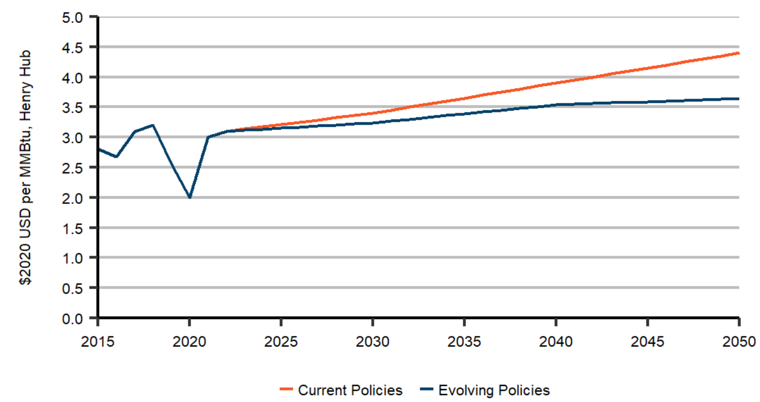
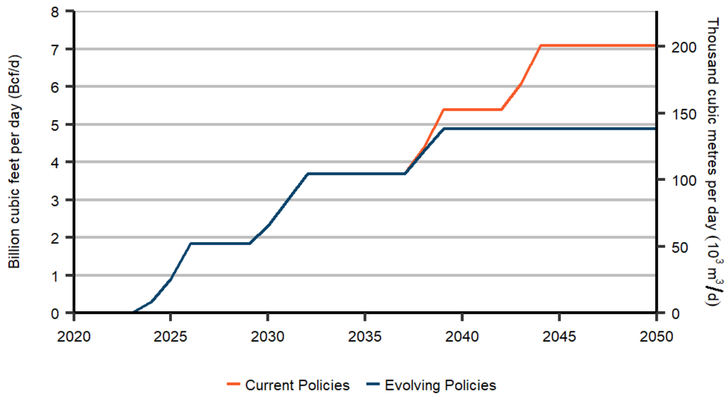
Henry Hub Natural Gas Price Assumptions to 2050, Evolving and Current Policies Scenarios



EF2021 assumes LNG export volumes from Canada as shown in Figure A.5. We assume all volumes originate from Canada's west coast. These volumes include Phase 1 of the LNG Canada project, which has a positive final investment decision and is currently under construction. We also include an assumption of additional volumes that are not specific to a particular project. The Current Policies Scenario assumes greater LNG exports than in the Evolving Policies Scenario, beginning in 2039. Future LNG development is uncertain and could be significantly different than implied by these assumptions. For both scenarios, we assume that 75% of the natural gas that will be liquefied will come from natural gas production dedicated to supplying LNG facilities. This means that this 75% comes from production that only exists because LNG export capacity exists and is above and beyond what would be produced based solely on our North American natural gas price assumptions.

Figure A.5:
Canadian LNG Export Volume Assumptions to 2050, Evolving and Current Policies Scenarios



Full benchmark price assumption data and LNG export assumption levels are available in the accompanying data files and appendices, described in the "Access and Explore Energy Futures Data" section.

Electricity

The analysis in EF2021 reflects current utility and system operator expectations of future electricity developments in their respective regions, especially for major planned projects. We also make assumptions on the cost to add new electricity generating capacity in the future. Table A.4 shows assumptions for natural gas, solar, and wind costs, including their capacity factors. Current schedules and plans from utilities, companies, and system operators are the primary basis for the timing and magnitude of other forms of generation added over the projection period (such as hydroelectric and nuclear refurbishments).

As discussed earlier in this section, costs for wind, solar, and other emerging technologies are lower in the Evolving Policies Scenario than the Current Policies Scenario. This assumes a stronger global shift towards these low-carbon technologies, and advancements and efficiencies that continue to lower their costs and improve their performance.

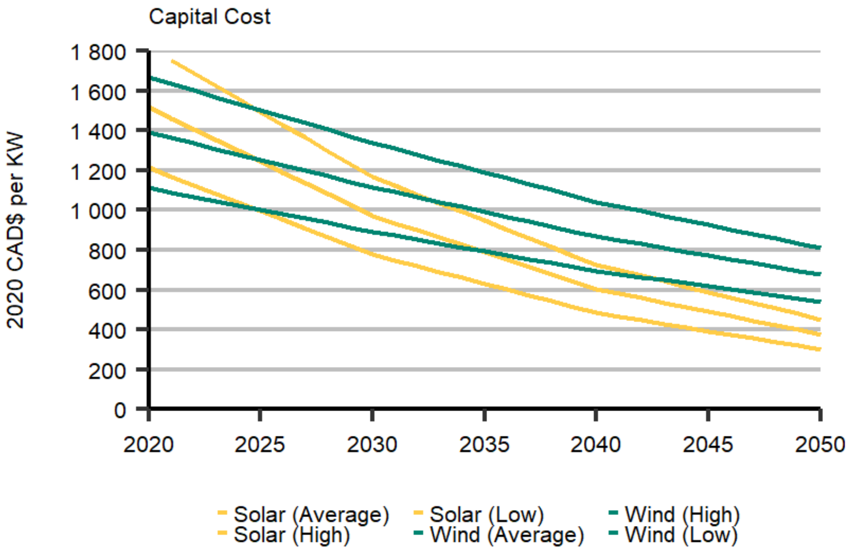
Table A.4:

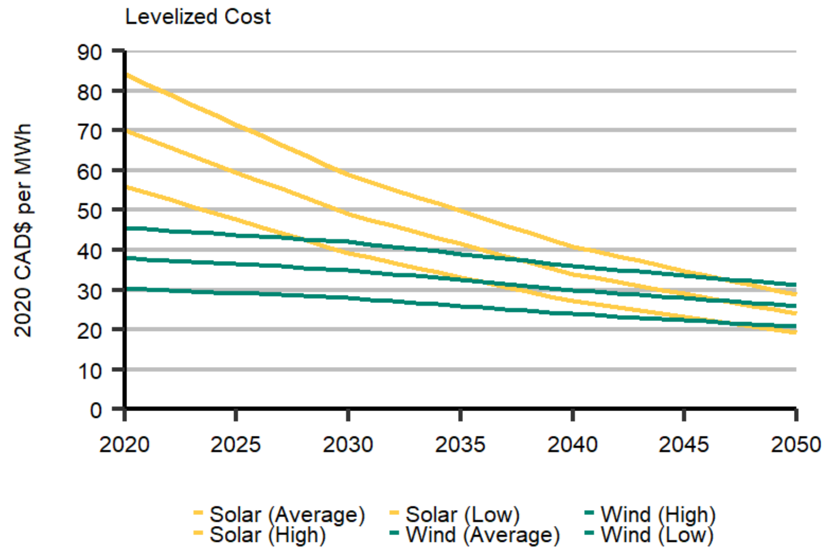
Electricity Cost Assumptions for Natural Gas, Onshore Wind, and Utility Scale Solar to 2050, Evolving and Current Policies Scenarios

	Capital Cost (2020CN $/ kilowatt(kW))	Fixed Operating and Maintenance Costs (2020CN$/kW)	Variable Operating and Maintenance Costs (2020CN$/ megawatt hour(MWh))	Capacity Factor (%)[11]
Gas Combined Cycle (2020-2050, both scenarios)	1 300-1 800	21	5	70
Gas Peaking (2020-2050, both scenarios)	950-1 400	18	5	20
Wind (2020)	1 389	25-60	0	30-45
Solar (2020)	1 516	20-27	0	10-20
Evolving Policies Scenario				
Wind (2030)	1 115	25-60	0	35-55
Wind (2040)	868	25-60	0	35-55
Wind (2050)	676	25-60	0	35-55
Solar (2030)	972	20-27	0	15-25
Solar (2040)	605	20-27	0	15-25
Solar (2050)	376	20-27	0	15-25
Current Policies Scenario				
Wind (2030)	1 226	25-60	0	30-45
Wind (2040)	1 184	25-60	0	30-45
Wind (2050)	1 117	25-60	0	30-45
Solar (2030)	1 066	20-27	0	10-20
Solar (2040)	772	20-27	0	10-20
Solar (2050)	561	20-27	0	10-20

[11] Capacity factors are the actual energy produced by a generator divided by the maximum possible generation over a given period. Capacity factors vary by region and technology, and on average improve throughout the projection period due to improved performance.

Figure A.6:
Wind and Solar Capital Costs and Levelized Cost[12] Assumptions to 2050, Evolving Policies Scenario





12 The range around the capital costs is +/- 20%, which reflects the variability across different estimates of current, and future, wind and solar costs. Costs and performance characteristics can vary across regions and time. The ranges around the levelized costs include the variation in capital costs shown in the figure, ranges in other costs and capacity factors shown in Table A.2, as well as higher and lower project financing costs.

Hydrogen

Hydrogen can be produced from organic compounds such as biomass, natural gas, or coal through various processes. It can also be produced from water via electrolysis. The two main forms of production in EF2021 are electrolysis and natural gas with CCS.

- **Natural gas with CCS:** Currently, the most common method for hydrogen production is steam methane reforming of natural gas. In this method, high-temperature steam reacts with methane to produce hydrogen and carbon dioxide (CO_2). Coupling this method with a CCS technology can produce hydrogen with relatively low CO_2 emissions. Going forward, autothermal reforming (ATR) could have a cost advantage compared to steam methane reforming and could allow for a higher rate of CO_2 capture. The recently announced Air Products project in Alberta is proposing to use an ATR technology for its facility. In our analysis we assume all natural gas with CCS hydrogen production has a capture rate greater than 90%. We also assume that because of proximity to sequestration capacity, hydrogen production from natural gas with CCS is only an option in B.C., Alberta, and Saskatchewan.

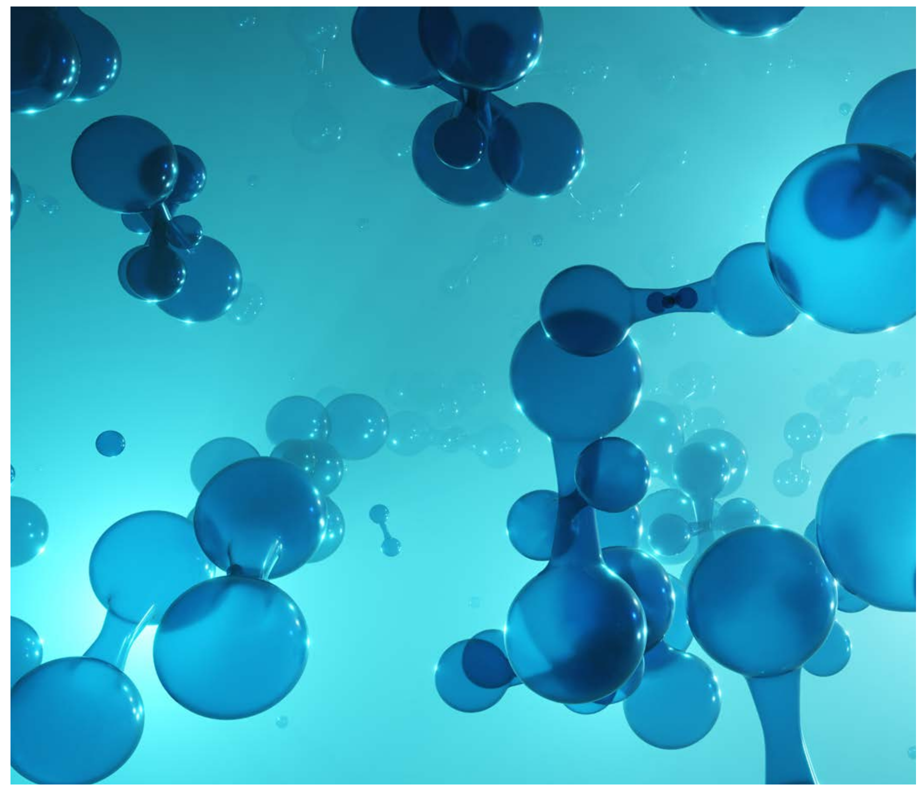
- **Electrolysis:** Electrolysis is a process whereby electricity is passed through water and splits water into its components: hydrogen and oxygen. Depending on the source of electricity, hydrogen produced through this process can have low- to zero-carbon emissions. EF2021 distinguishes between two categories of electrolysis based on how the electricity is supplied: a) grid electrolysis, which uses electricity from the provincial grid at a similar price to industrial users, and b) renewable electrolysis, which utilizes dedicated wind and solar resources.[13] Electrolysis is available in all provinces, and its adoption is based on relative costs.

Hydrogen production cost varies by region and resource availability. The cost of hydrogen production will depend on technology improvements and future electricity and natural gas prices. We assume costs significantly decline in the Evolving Policies Scenario (Table A.6), and remain near current levels in the Current Policies Scenario.

[13] Electricity price is the largest cost component of hydrogen production that uses the electrolysis method. Dedicated renewable electrolysis reduces this cost by producing electricity onsite with the hydrogen production.

Table A.6:
Hydrogen Technology Costs, Evolving Policies Scenario

Cost by Technology type (2020US$/kg)	2020	2030	2040	2050
Electrolysis – Grid	$6.00-8.00	$4.00-7.00	$4.00-$6.00	$4.00-6.00
Electrolysis – Dedicated renewables	$8.00-10.00	$4.00-6.00	$2.00-3.00	$1.50-2.00
Natural Gas with CCS	$1.60-2.00	$1.50-$1.80	$1.50-$1.80	$1.50-$1.70



Given falling costs, as well as other policies such as increasing carbon prices, hydrogen has the potential for adoption across Canada's energy system. The relative economics of hydrogen are a key driver of adoption in the various demand sectors. At the same time, each sector has some other important considerations and uncertainties.

- **Residential and Commercial:** There are physical limits on how much hydrogen can be blended into existing natural gas pipelines and used in conventional end-use devices.[14] To account for this uncertainty we assume maximum blending of hydrogen in the natural gas stream gradually increases throughout the projection period, as infrastructure and technology improves. Maximum blending increases to 3% by volume (1% by energy content) by 2030, 15% by volume (5% by energy content) by 2040, and 20% by volume (7% by energy content) by 2050.

- **Industrial:** Hydrogen demand is modeled on a sector-by-sector level, as industrial sectors have unique characteristics that could influence hydrogen adoption. Certain industries, such as iron and steel, have emerging technologies that are able to incorporate high concentrations of hydrogen as the main fuel. In some industries, such as cement production, it remains more uncertain if significant amounts of hydrogen will be consumable as a low carbon alternative fuel without significantly alerting the final industrial product.

- **Transportation:** As hydrogen costs fall, and carbon prices increase, hydrogen could offer substantial fuel cost savings compared to diesel in freight trucking. Adoption will be determined by other factors as well, such as the cost of hydrogen fuel cell trucks relative to conventional diesel trucks, as well as the development of hydrogen distribution and refuelling infrastructure. We assume fuel cell trucks become cost comparable to diesel trucks around 2035 to 2040, and infrastructure sees widespread deployment from 2035 to 2050 as hydrogen fuel cell trucks gain market share.

We assume that hydrogen is produced within each province to meet local demands, and there is no inter-provincial and international trade. This is an important assumption which affects the results, in that regions with lower cost options for producing low-carbon hydrogen–such as Alberta, with CCS access and announced projects, and Quebec, with relatively low grid electricity prices–are early adopters of the technology. This assumption follows recent hydrogen projects, which are intended for use at the facility where the hydrogen is produced, or in the nearby region. However, large-scale hydrogen trade has been proposed[15] and is still being analyzed. If significant trade between regions occurs, it could alter the production and consumption trends shown in our hydrogen results.

[14] Studies by the National Renewable Energy Laboratory and the Transition Accelerator have suggested that current end-use technologies and pipeline infrastructures could handle up to 15% blending by volume.

[15] For example, Alberta's 2021 Hydrogen Roadmap highlights hydrogen exports as a key pillar, potentially by 2030.

Results

This section presents results of the EF2021 projections. The primary focus is the Evolving Policies Scenario. These projections are not a prediction, but instead present possible future outcomes based on the assumptions described in the previous section. There are many factors and uncertainties that will influence future trends. Key uncertainties are discussed in each section.

For a description of the various ways to access the data supporting this discussion, including full data tables for both the Evolving and Current Policies scenarios, see the “Access and Explore Energy Futures Data” section.

Macroeconomics

The economy is a key driver of the energy system. Economic growth, industrial output, inflation, exchange rates, and population growth all influence energy supply and demand trends.

In the near term, the economy continues its gradual recovery from the COVID-19 pandemic. As shown in Figure R.1, total real gross domestic product (GDP) declined 5.3% in 2020 and grows by 5.7% in 2021.

The long-term projections for key economic variables are in Figure R.2. Economic growth (adjusted for inflation) averages 1.6% per year over the projection period in both the Evolving Policies Scenario, and the Current Policies Scenario, with the Current Policies Scenario slightly higher. Economic growth over the projection is generally slower than the 1990 to 2018 historical period for a variety of reasons, including an aging population and slower global economic growth.

KEY UNCERTAINTIES:

Macroeconomics

COVID-19 pandemic recovery: Recovery from COVID-19 is a key uncertainty for global, North American, and Canadian macroeconomic growth.

Global economic growth: Global economic growth affects many factors that are important for Canada's economy, including commodity prices, and demand for Canadian energy and non-energy exports.

Figure R.1:
GDP Growth Rebounds Following a Steep Decline in 2020

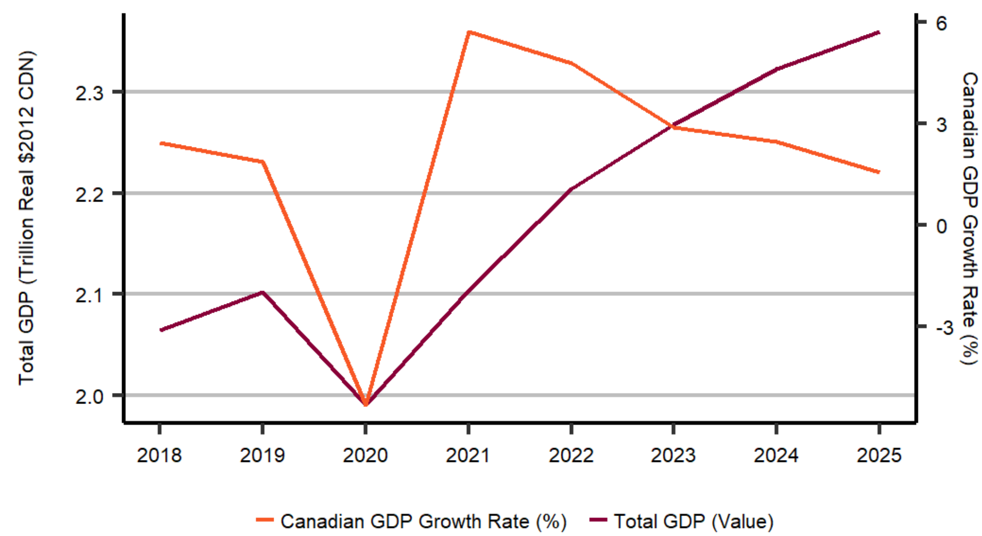


Figure R.2:
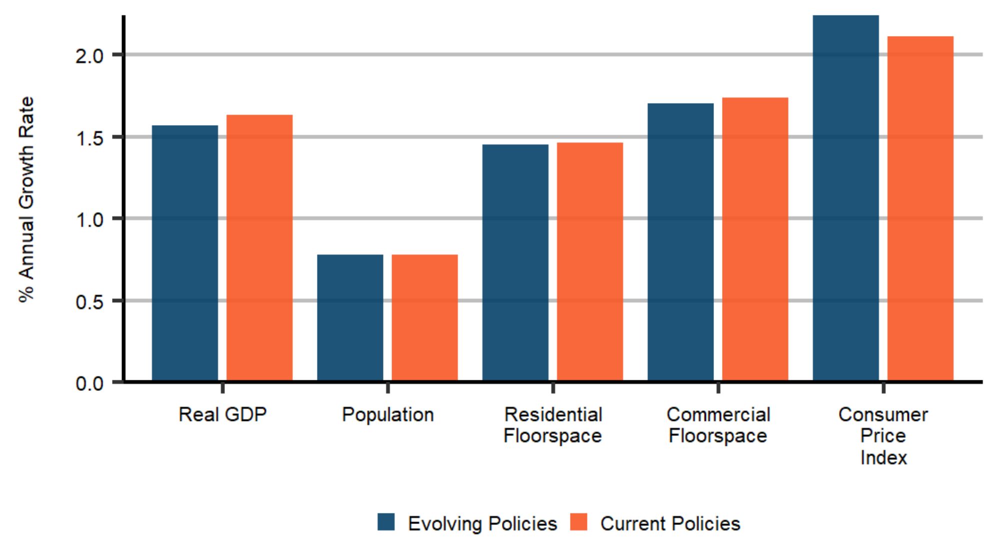
Economic Indicators, Evolving and Current Policies Scenarios (2019 to 2050)



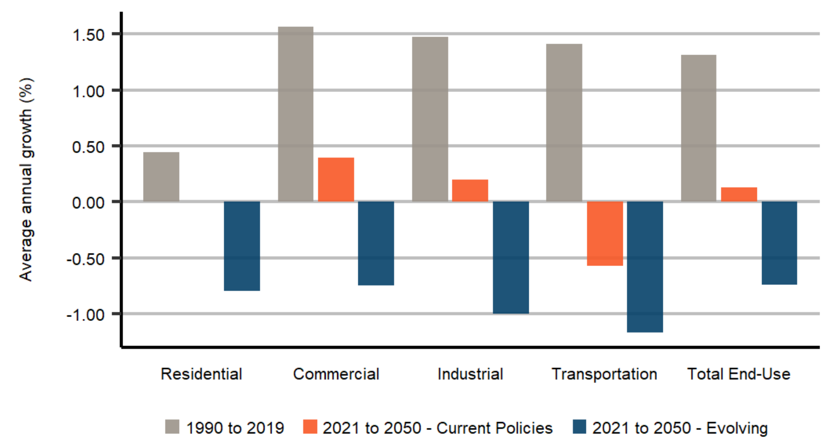
Energy Demand

This section first discusses secondary (or “end-use”) energy demand projections by reviewing energy use by sector of the economy, before turning to our economy wide primary energy demand projections. End-use demand includes electricity and hydrogen, while the fuel used to produce electricity and hydrogen is accounted for in primary energy demand. Historical data is sourced primarily from Statistics Canada’s Report on Energy Supply and Demand in Canada. This data is supplemented with additional details from Environment and Climate Change Canada (ECCC), Natural Resources Canada, and various provincial data sources.

In the near term, energy use follows macroeconomic trends. We estimate that demand declined 8% in 2020, and project it to increase in 2021 and 2022. In the long term, the Evolving Policies Scenario projects Canadian energy use to decline to 2050. Figures R.3 and R.4 break energy use down by sector, showing declines in all sectors. The largest declines are in the industrial (including upstream oil and gas) and transportation sectors. These declines are due to factors such as improved energy efficiency, increasing electrification of the transportation sector,[16] and various policies, like carbon pricing. Partially offsetting these factors, economic growth and a near-term increase in crude oil production provide some upward pressure on energy use. However, economic growth is slower than historical trends, and crude oil and natural gas production eventually declines. The Current Policies Scenario sees moderate demand growth over the projection period (though at levels lower than recent history) due to the lack of additional climate policy action beyond current policies, higher crude oil and natural gas production, and less electrification.

[16] On an energy equivalent basis, EVs use less energy to travel a given distance than conventional vehicles. As EVs gain market share, the offsetting reduction in gasoline demand will be larger than the electricity added, leading to a net reduction of energy consumption. Additional details on EV efficiency and economics can be found in CER Market Snapshot: Levelized Costs of driving EVs and conventional vehicles.

Figure R.3:
End-use Demand Declines in All Sectors in the Evolving Policies Scenario



KEY TRENDS:
Energy Demand

- Total energy use declines in the Evolving Policies Scenario and grows slowly in the Current Policies Scenario.
- Growth rates for end-use demand by sector are lower than in the past for both scenarios.
- The mix of energy sources that Canadians use continues to change in the Evolving Policies Scenario, shifting towards a majority of low- or non-emitting energy sources in the longer term.
- In the Evolving Policies Scenario, energy use declines while population and GDP continue to grow, resulting in a significant decline in energy use per person and per dollar of economic activity.

Energy use trends vary by sector and by energy type in the Evolving Policies Scenario (See Figure R.5). These trends result from many different drivers, including macroeconomics, energy production trends, energy efficiency improvements, policies, technology advancements, and market developments. Highlights include:

- In the residential and commercial sectors, improving efficiency of devices and building envelopes reduces overall energy consumption. Rising carbon prices and improving technology drive penetration of heat pump technology in buildings, reducing natural gas use. Blending of renewable natural gas and hydrogen into natural gas streams also reduces natural gas use. This is driven by a combination of policy assumptions (see the "Scenarios and Assumptions" section), and economics in the longer term as carbon prices increase and technology costs fall.

- In the industrial sector, trends vary by industry. The oil and gas sector becomes more efficient, and production growth slows and eventually peaks for crude oil production, while natural gas production stays relatively steady and then declines. Solvent-assisted production in in situ oil sands helps improve energy intensity significantly in the latter half of the projection period. In the longer term, hydrogen reduces natural gas use, especially in key sectors such as iron and steel, cement, refining, as well as the oil and gas sectors. At the same time, increasing use of CCS puts upward pressure on energy demand as the CCS process requires energy.

- The transportation sector undergoes a notable low-carbon transition. Refined petroleum products (RPPs) like gasoline, diesel, and jet fuel have historically dominated the transportation sector, and this begins to change in the Evolving Policies Scenario. The Evolving Policies Scenario assumes that the recently announced Federal goal for all new vehicle sales to be ZEVs by 2035 is achieved, and that adequate supplies of battery and plug-in hybrid electric vehicles will exist and meet demand.[17] This substantially reduces gasoline demands in the projection. Electric freight, particularly light-to-mid-duty, hydrogen-powered freight (mid-to-heavy duty), and increasingly electrified public transportation (electric bussing) grow steadily in the 2030s and 2040s. Biofuels blending into gasoline and diesel increases from current levels in both scenarios, driven by policies like the Federal Clean Fuel Regulation.

[17] Electricity demand associated with electric vehicles is included in the transportation sector in these projections, although large amounts of at-home charging are likely to occur.

Figure R.4:

End-use Energy Consumption Peaks in 2019 and Declines over the Long Term in the Evolving Policies Scenario

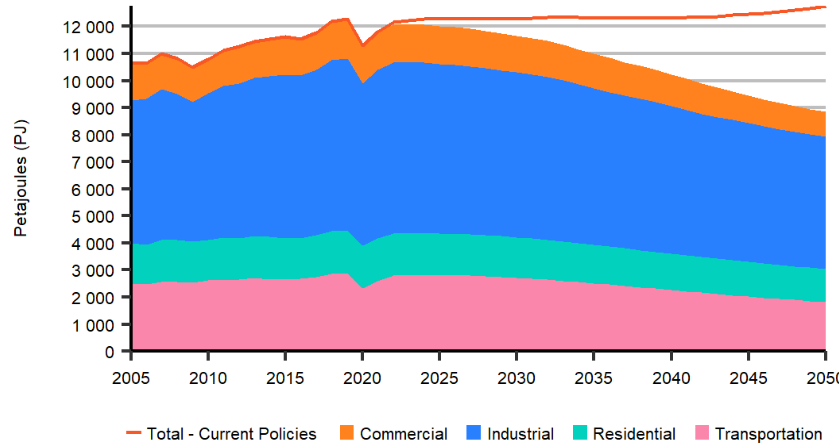


Figure R.5:

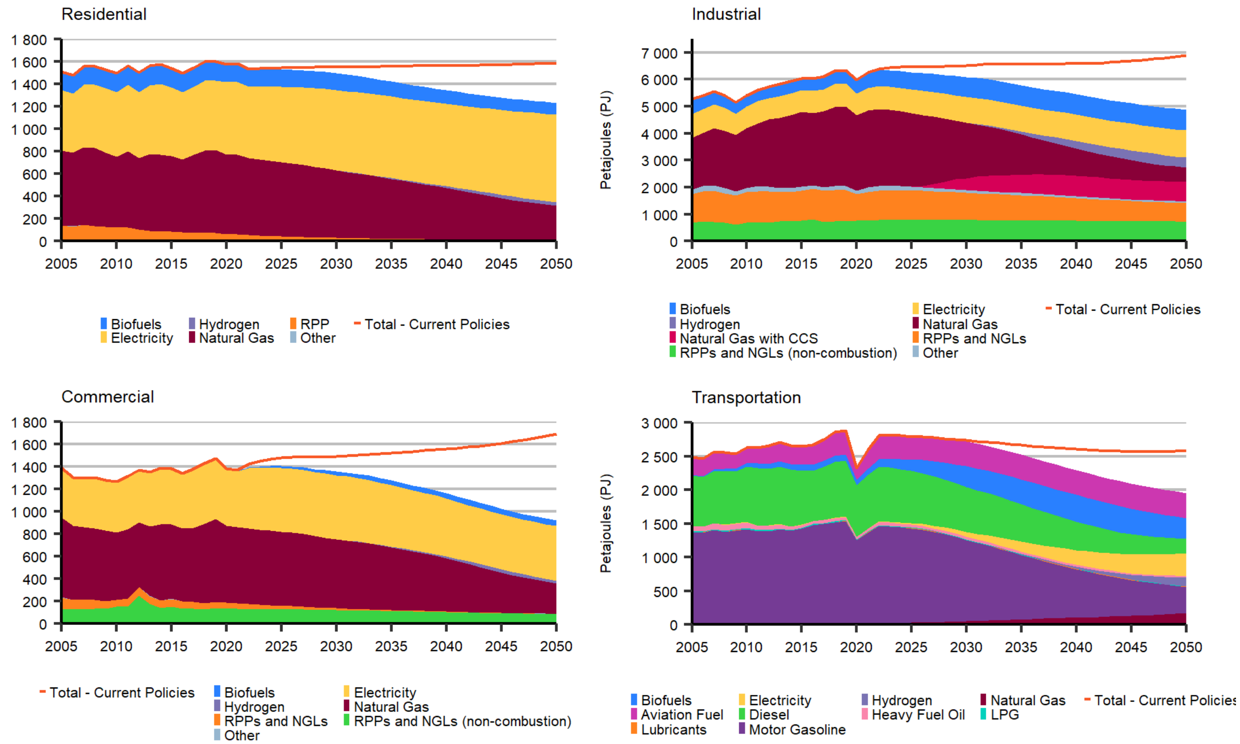
End-Use Energy Demand Trends Vary by Sector and By Fuel in the Evolving Policies Scenario



In this analysis, primary demand is the total amount of energy used in Canada. Primary demand is calculated by adding the energy used to generate electricity and hydrogen to total end-use demand, and then subtracting the end-use demand for electricity and hydrogen. Primary demand is higher than end-use demand due to factors such as heat loss in thermal electric generation, and the energy required for the hydrogen production process. This implies that it takes more than one unit of natural gas or coal to produce the same energy unit of electricity, and similarly more than one unit of natural gas or renewables to produce one energy unit of hydrogen.

Figure R.6 shows primary demand by fuel for the Evolving Policies Scenario, compared with total primary demand in the Current Policies Scenario. In the Evolving Policies Scenario, total demand gradually falls, driven by declining fossil fuel use. Coal demand declines considerably due to the phase-out of coal-fired power generation. RPP demand falls along with improving energy efficiency and electrification of the transportation sector. Demand for non-energy oil products, such as asphalt, lubricants, and feedstocks are relatively stable. Natural gas demand grows slowly to about 2025, driven by increasing crude oil production as well as its increasing role in power generation. From 2025 to 2050 total natural gas demand steadily declines, as less is used for crude oil and natural gas production (due to both increased efficiency and, eventually, less production), energy efficiency improves, renewables replace some natural gas in power generation, and renewable natural gas and hydrogen are blended into the natural gas stream. Increasing natural gas use to produce hydrogen, as well as adding CCS to natural gas use in industrial electricity generation and power, partially offsets this decline.

Driven by increased electrification at the end-use level, overall electricity demand rises steadily in the Evolving Policies Scenario. This demand leads to stable production of nuclear power and growth in renewable power as major hydro projects are completed, and wind and solar costs continue to fall. Renewables become an increasingly important part of the energy mix. Increased blending of renewable fuels in liquid fuels and natural gas also support increasing renewable demand.

Energy use falls while both the economy and Canada's population grow, implying that energy intensity–measured in energy use per capita or per $ of real GDP–declines significantly. This is shown in Figure R.7. From 2019 to 2050, real GDP increases 60% and population increases over 27% in the Evolving Policies Scenario. Primary energy use declines 25%. These different trends imply that energy use per $ of real GDP declines over 50% from 2019 to 2050, while energy use per person declines over 40% in the Evolving Policies Scenario.

Figure R.6:

Primary Demand Gradually Declines and Renewables Account for a Larger Share in the Evolving Policies Scenario Energy Mix

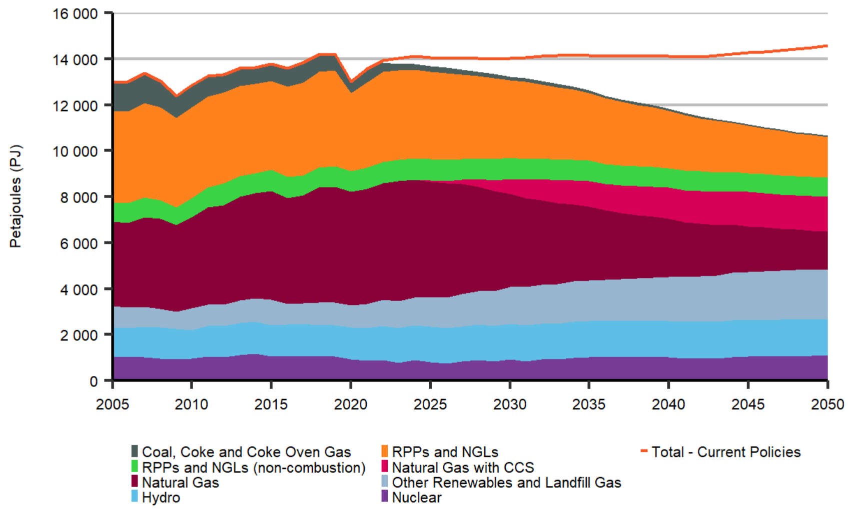


Figure R.7:

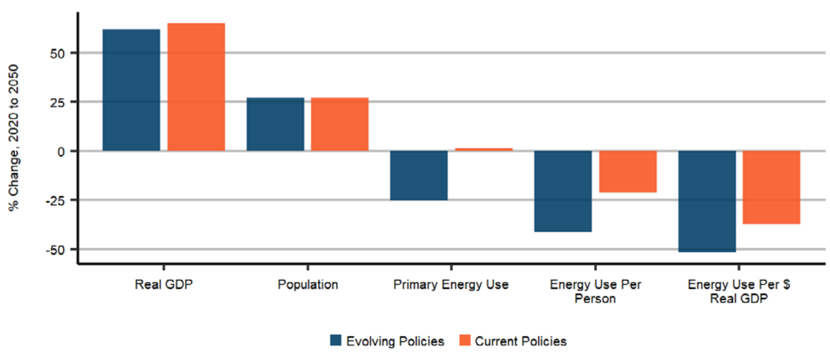
The Economy Grows Faster than Energy Use, and Energy Intensity Declines in both the Evolving Policies Scenario and the Current Policies Scenario



KEY UNCERTAINTIES:

Energy Demand

Future policy changes: In December 2020, Canada announced a significant increase to its carbon pricing pathway, and revisions to the proposed Clean Fuel Standard (published in the Canada Gazette as the Clean Fuel Regulation). Canada has recently committed to a stronger 2030 target in its Nationally Determined Contribution submitted to the United Nations, and announced intentions for 100% of passenger vehicle sales to be ZEVs by 2035. These changes illustrate how dynamic climate policy has been in recent years. This may continue if urgency and ambition to reach climate targets increases. Future policy changes will have significant impacts on energy projections.

Technological influences: The impacts of technology on the energy system are substantial and can be difficult to predict. The Evolving Policies Scenario continues the momentum for increased use of established technologies and allows for the adoption of emerging technologies currently near commercialization. The pace, types, and costs of new technological adoption are highly uncertain and likely to be different from those assumed and modelled in our scenarios.

Alternative fuels and new end-uses: Both core scenarios show a shift towards electricity, supported by the increasing use of renewables. They also feature increasing adoption of low-carbon fuel alternatives, such as hydrogen, renewable natural gas, and liquid biofuels, to varying degrees. Faster electrification of the economy, or investment and growth in alternative fuels production could lead to different trends compared to those shown here.

Crude Oil

Crude oil is produced in Canada for domestic refining as well as for export. In 2019, Canadian crude oil production averaged 4.9 million barrels per day (MMb/d) (784 thousand cubic metres per day ($10^3m^3/d$)). Production declined by 5% in 2020, largely due to the COVID-19 pandemic, but had returned to 2019 levels by the end of 2020. In recent years, most production growth has been concentrated in the oil sands. Regionally, most production is in Alberta, with additional volumes in Saskatchewan and offshore Newfoundland and Labrador.[18]

Figure R.8 shows Canadian crude oil production by type in the Evolving Policies Scenario, compared to total Current Policies Scenario production. Canadian crude oil production in the Evolving Policies Scenario peaks at 5.8 MMb/d (930 $10^3m^3/d$) in 2032 and declines to 4.8 MMb/d (756 $10^3m^3/d$) in 2050, a decrease of 4% from 2021. For comparison, production peaks at 6.7 MMb/d (1064 $10^3m^3/d$) in 2044 in the Current Policies Scenario, driven by higher crude oil price assumptions and other assumptions related to the lack of future domestic and global climate policy action.

Production growth in the oil sands continues in the near term, peaking in 2032 and declining slightly through 2050 in the Evolving Policies Scenario. Figure R.9 shows Evolving Policies Scenario oil sands production by type, while Figure R.10 shows it by vintage. Growth is dominated by in situ projects. Most production growth in this scenario are expansions to existing projects, which are profitable given Evolving Policies Scenario price levels and technology improvements that increase productivity.

[18] Information on crude oil ultimate potential and remaining reserves is available in the EF Data Appendices.

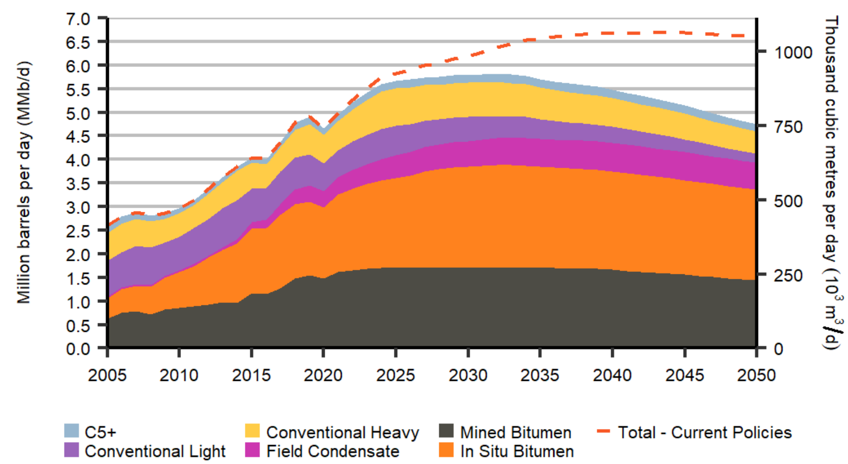
KEY TRENDS:

Crude Oil Production in the Evolving Policies Scenario

- Production grows through the start of the projection period with most growth occurring before 2025. After this point, production is relatively flat and peaks in 2032 at just under 5.8 MMb/d, before declining to 4.8 MMb/d in 2050. This compares to production of 5.0 MMb/d in 2021. Price assumptions underpin this growth. Longer term, assumptions of lower crude oil prices and increasing carbon costs lead to declines in production.
- From 2019 to 2032, crude oil production increases 19%. Between 2032 and 2050 production decreases by 19%.
- In situ bitumen production grows to 2.2 MMb/d in 2032 before declining to 1.9 MMb/d by 2050, from 1.7 MMb/d in 2021.
- Mined bitumen production peaks in 2024 at 1.7 MMb/d, declining thereafter to 1.4 MMb/d by 2050, from 1.6 MMb/d in 2021.

Figure R.8:

Total Crude Oil Production Peaks in 2032 and then Declines through 2050 in the Evolving Policies Scenario



[Conventional](), [tight](), and [shale]() production is classified as [light]() or [heavy](), depending on the [API gravity]() of the oil. In 2020, 51% of western Canadian conventional production was heavy and 49% was light. Near-term growth in production in these categories is primarily due to increases in light oil production in Alberta, along with growing heavy oil production in Saskatchewan. Light oil, particularly tight oil, growth is based on producers' preference to target wells which have higher initial production rates and a quicker return on investment. Growth in Saskatchewan's heavy oil production is due to the low cost and low decline rates of heavy oil reservoirs in the province (Figure R.11).

The majority of condensate production has and is projected to come from Alberta. Growth in condensate production in the projection period occurs in Alberta and B.C., as producers focus on liquids-rich natural gas plays like the Montney Formation and the Duvernay (Figure R.12). Condensate is used as a diluent for bitumen and heavy oil.

Newfoundland offshore production in the Evolving and Current Policies scenarios steadily declines as shown in Figure R.13. We assume no new discoveries in the Evolving Policies Scenario. Additional discoveries and developments could change these trends. In the Current Policies Scenario, we assume new discoveries are made and start producing oil beginning in 2032.

Oil Sands Production: Existing vs. Projected Additions in the Evolving Policies Scenario

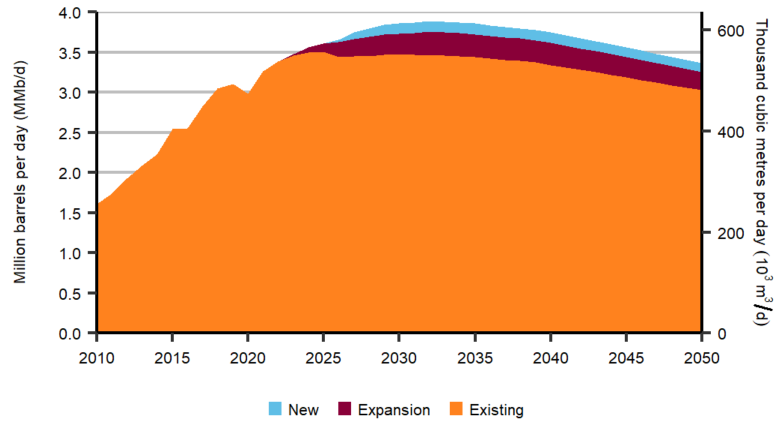

Figure R.11:
Conventional, Tight, and Shale Oil Production Decreases Steadily over the Projection in the Evolving Policies Scenario After a Brief Increase Over the Next Five Years

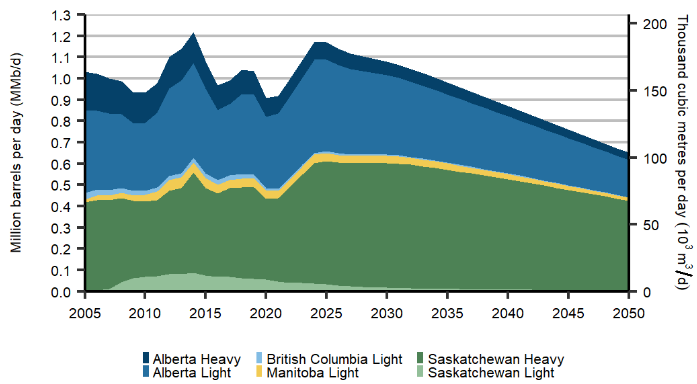

Figure R.12:
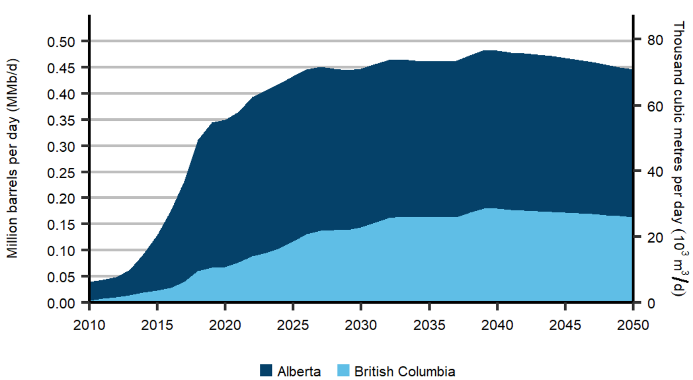
Condensate Production Driven by Increasing Diluent Demand in the Evolving Policies Scenario



New Technology in Oil Sands Production

In the Evolving Policies Scenario, we assume that technological improvement in extraction and upgrading methods of existing oil sands projects continues at the same pace as recent history. Although uncertainties exist, the improvements have the potential to reduce the per-barrel costs to produce bitumen, offsetting the higher carbon costs and lower commodity prices. These improvements also lead to lower per barrel emissions.

Much of the growth in oil sands production is in the form of expansions to existing facilities. By the end of the projection, facility expansions make up 7% of all oil sands production, or just over 0.23 MMb/d. Growth also comes from new facilities. No new oil sands mining or upgrading facilities will be created over the projection period. However, new in situ facilities make up 4% or 0.11 MMb/d of total oil sands production from 2019 to 2050.

We assume new or expanded facilities, which begin production after 2025, use the following technologies to lower their emissions intensity:

Steam and pure solvents: The injection of heated solvents (typically a mixture of natural gas liquids (NGLs)) into the reservoir to replace the steam generation units currently in use, lowering emissions. This process also leaves some of the less desirable components within bitumen (asphaltenes) in the reservoir. Pure solvents have the potential to reduce per-barrel operating costs by up to $3.50 per barrel.

In-pit extraction: A technique currently being developed by Canadian Natural Resources Limited at its Horizon Oil Sands mine, which involves separating oil sands ore into its component parts within the extraction pit of the operation. This method requires comparatively less heavy equipment and electric power, resulting in less emissions per barrel, and a potential cost savings of $2.00 per barrel.

Figure R.13:
Newfoundland Offshore Oil Production Steadily Declines to 2050 in the Evolving Policies Scenario

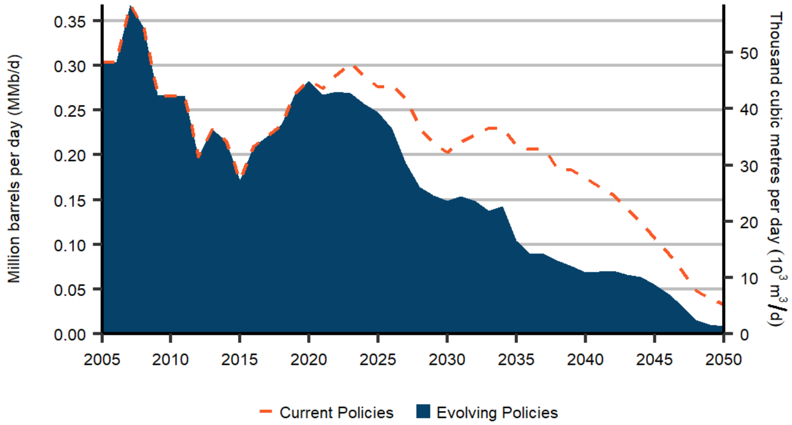


Figure R.14:
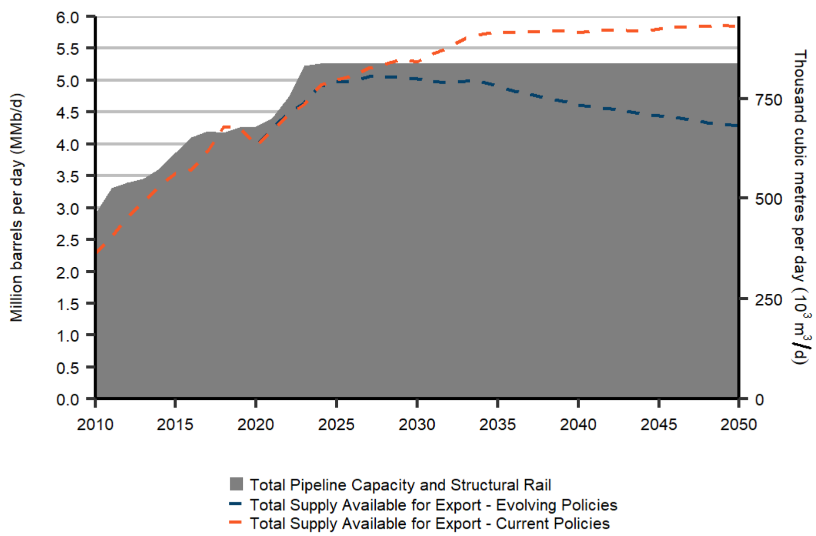
Illustrative Export Capacity from Pipelines and Structural Rail, vs. Total Supply Available for Export in the Evolving and Current Policies Scenarios



A key issue for Canada's energy system over the last number of years was the availability of crude oil export pipeline and rail capacity. This has implications for Canadian oil pricing and production trends. When total export capacity is very full, it can lead to widening differentials, particularly when there are unexpected outages. Figure R.14 is an illustrative comparison of our crude oil supply projections and the level of total export capacity that would be provided by existing pipeline capacity, planned pipeline expansions, and structural rail.[19] Making this comparison allows us to get an understanding of whether pipeline constraints might impact crude oil production in our scenarios. However, we do not adjust our crude oil production projections based on potential constraints.

In the Evolving Policies Scenario, crude oil available for export from western Canada stays below the total hypothetical export capacity throughout the projection period. However, into the mid-2030s the difference between capacity and supply is small. EF2021 does not assess whether in this scenario, additional pipeline capacity would be required to avoid constraining Canadian crude oil production below what is projected throughout the projection period.

In the Current Policies Scenario, supply exceeds capacity through much of the projection period. This clearly suggests that without additional pipeline capacity, production would be constrained below what is projected.

EF2021 does not explore the complexities of how pipeline infrastructure interacts with energy supply and demand outcomes. For example, some spare pipeline capacity can benefit crude oil producers by providing flexibility to access higher value markets or avoid the impacts of maintenance or unforeseen outages. It's also possible that excess capacity and long-term underutilization of pipelines could result in higher pipeline tolls for crude oil producers. Analysis of these considerations is beyond the scope of EF2021. We caution readers from drawing definitive conclusions from the illustrative comparison shown Figure R.14.

It is also important to note that the estimate of what total available pipeline capacity and the level of structural rail could be is uncertain and the result of many key assumptions. Table R.1 describes the infrastructure assumptions that underpin Figure R.14. Available capacity on existing pipeline systems could be higher or lower than reflected in Figure R.14, as pipeline systems evolve over time. The level of structural crude by rail could also be somewhat higher or lower than reflected in this figure.

---

19 Structural rail refers to crude oil that is exported by rail regardless of a given WCS-WTI differential. Companies may choose to export crude oil by rail in this way due to a number of factors. These include existing contractual commitments, ownership of the crude-by-rail infrastructure, and the need to access locations not well connected by pipeline.

Table R.1
Pipeline Capacity Assumptions for Figure R.14

Name	Takeaway Capacity (current or timing as noted) (Mb/d)	Notes
Enbridge Mainline	3 207	Stated capacity includes the fully completed Line 3 Replacement Project which adds 370 Mb/d of capacity to the Enbridge Mainline in late 2021.
Keystone	586	Capacity held fixed over the projection period. The cancelled Keystone XL project is not included in Figure R.14.
Trans Mountain	300	Capacity is held fixed over the projection period. This capacity approximates the crude oil portion of capacity, by removing 50 Mb/d from the full capacity of Trans Mountain (350 Mb/d) to accommodate transportation of 50 mb/d of RPPs on the pipeline.
Trans Mountain Expansion	540	The Trans Mountain Expansion Project adds capacity starting in December 2022, and increases to full capacity by the spring of 2023. As with the existing Trans Mountain system, full capacity of the Trans Mountain Expansion (590 Mb/d) is reduced to accommodate transportation of 50 Mb/d of RPPs.
Express	310	Capacity held fixed over the projection period.
Milk River	97	Capacity held fixed over the projection period.
Aurora/Rangeland	44	Capacity held fixed over the projection period.
Structural Rail	120	Capacity held fixed over the projection period.
Capacity Increases to Existing Pipelines	58	Includes announced optimizations to boost the capacity of existing pipelines. The capacity increases are reflected in 2021 to 2023.
Total	**5 262**	

KEY UNCERTAINTIES:
Crude Oil Production in the Evolving Policies Scenario

Future crude oil demand: As climate policy announcements and ambitions increase around the world, many global scenarios have shown a significant reduction in global crude oil demand. These reductions may be needed to meet Paris climate goals of keeping temperature increases to well below 2 degrees Celsius, and to preferably limit warming to 1.5. If these ambitions are realized, falling crude oil demand could have significant impacts on market prices and investment that would affect future Canadian hydrocarbon production (see box "Global fossil fuel market dynamics and implications for Canadian production trends").

Technological development in the oil sands: Reducing GHG emissions and costs are two significant factors in the future development of oil sands facilities. Technologies are currently being developed to address both aspects, although their future adoption is uncertain. As in previous editions of *Canada's Energy Future*, EF2021 assumes that companies continue to work towards lowering both the cost and GHG emissions of their operations.

Western Canadian takeaway capacity: EF2021 assumes that western Canadian crude oil prices will consistently track prices in international markets, consistent with historical averages. The balance between future export pipeline capacity and supply available for export could affect future price relationships and crude oil production levels (see box "Crude Oil Pipelines in Canada's Energy Future" in the Executive Summary).

ESG considerations: The investment community is shifting its attention towards firms that align with their environmental, social, and governance (ESG) performance criteria.[20] The extent and nature to which ESG considerations may alter upstream investment trends could affect future production trends.

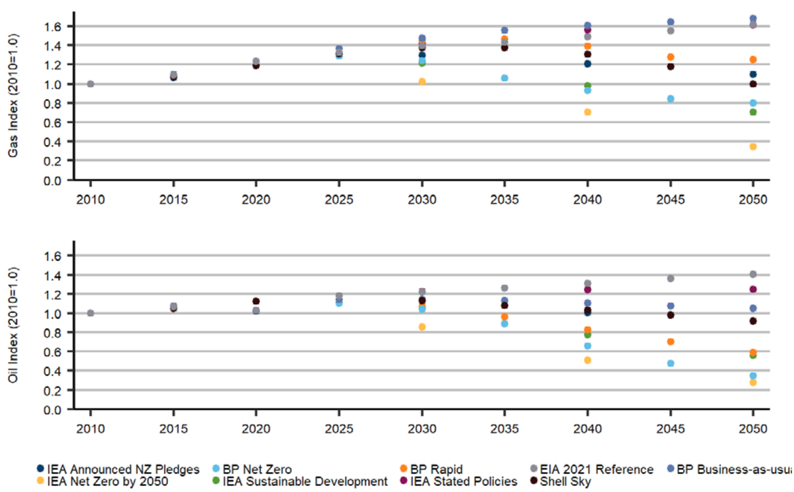
[20] Responsible Investment Association, 2018 Canadian Responsible Investment Opportunity: Trends Report, pg. 12, October 2018.

Global fossil fuel market dynamics and implications for Canadian production trends

The Evolving and Current Policies scenarios explore the impact of changing policy trends, both domestic and global, on the Canadian energy system. The results show that the different assumptions in the scenarios have a large effect on Canadian crude oil and natural gas production projections. This establishes future climate action–particularly global action, which impacts global demand and prices–as a key uncertainty for Canadian production levels. At a high level, the EF2021 production projections have a similar conclusion to global scenario work from the IEA, and companies such as BP and Shell: increasing levels of climate action will decrease production.

Over the past several years, there has been an increasing body of scenario analysis on what net-zero by 2050 means for the global energy system. Figure R.15 shows global oil and natural gas demand trends in a variety of scenarios that vary in their level of decarbonization. The range presented here is large and includes both business as usual and net-zero scenarios. For global oil demand, these scenarios have a range of 37% more to 73% lower compared to current levels by 2050. For natural gas, global demand ranges from 68% more to 54% less relative to current levels by 2050.

Figure R.15:
Growth of Global Natural Gas and Oil Demand, Various International Scenarios by Other Organizations



If the assumptions made in the global net-zero scenarios materialize, there will likely be significant impacts for global crude oil and natural gas markets. In the IEA's Net Zero by 2050 scenario, the global crude and North American natural gas prices are significantly lower than the Evolving Policies Scenario assumptions. The Canadian Institute for Climate Choices Net Zero Report finds that only scenarios with high oil prices and high levels of carbon dioxide removals see Canadian oil production similar to current levels in the long term. These results suggest that in a net-zero world, there could be significant decreases in Canadian oil and natural gas production.

Canadian fossil fuel production in a net-zero world will depend on many factors, such as:

- market prices,
- the evolution of light and heavy oil refinery demand,
- the cost of reducing the upstream emissions of Canadian oil and natural gas production, and
- the extent to which low-carbon natural gas technologies (such as CCS-equipped hydrogen production, electricity generation and industrial use with CCS, and natural gas use for direct air capture) are implemented.

In addition, oil and natural gas production is itself a large user of energy in Canada. As a result, the uncertainty in future production trends is an uncertainty for Canadian energy demand and GHG emissions trends. In the Evolving Policies Scenario, the oil and gas sector makes up about 20% of the remaining unabated fossil fuel demand in Canada in 2050, down from approximately 30% today. The future of global oil and gas trends, and how they affect Canadian investment and production trends, will therefore likely be important for Canada's own net-zero transition.

Natural Gas

In Canada, natural gas is produced for domestic use and exports. In 2020, Canadian marketable natural gas production averaged 15.5 Bcf/d or 438 million cubic metres per day ($10^6m^3/d$).

Natural gas production in Alberta has been relatively flat over the last few years, while B.C. production has been steadily increasing since 2010. This increase has been driven by a variety of factors including:

- Drilling to evaluate natural gas resources expected to supply LNG exports off of Canada's west coast.
- NGLs in the Montney tight gas play driving drilling and production despite lower natural gas prices.
- Horizontal drilling and hydraulic fracturing technological advancements.

In the Evolving Policies Scenario, natural gas production remains near 2020 levels of 15.5 Bcf/d through much of the next two decades. The additional investment in production to meet assumed LNG export volumes sustains production levels. Without these investments, production would otherwise decline, given the assumed North American natural gas prices and the costs associated with assumed domestic climate policies. After 2040, with LNG exports assumed to stay flat, total natural production begins to decline, falling to 13.1 Bcf/d by 2050. Much of the production growth related to LNG exports occurs in B.C., and production in B.C. surpasses that of Alberta by 2028.[21]

In the Current Policies Scenario, natural gas production continues increasing in the longer term, reaching 22.2 Bcf/d (627.4 $10^6m^3/d$) by 2050. Current Policies Scenario projections are driven by assumptions of higher prices, a lack of future domestic and global climate action, and higher LNG exports.

[21] EF2021 projections did not include possible effects stemming from the 29 June 2021 B.C. Supreme Court ruling in Blueberry River First Nations v. Province of British Columbia (Yahey) or the initial agreement reached on 7 October 2021 between B.C. and Blueberry River First Nations addressing, among other things, existing permits and restoration funding. Future analysis will consider any effects as appropriate.

KEY TRENDS:

Natural Gas Production

- Natural gas production is fairly level in the Evolving Policies Scenario to 2040, before declining through the remainder of the projection period.
- Production from the Montney Formation in the form of liquids-rich tight gas grows significantly and becomes the majority of Canadian production over the projection period.

Figure R.16:

Total Natural Gas Production Declines in the Evolving Policies Scenario and Increases in the Long Term in the Current Policies Scenario

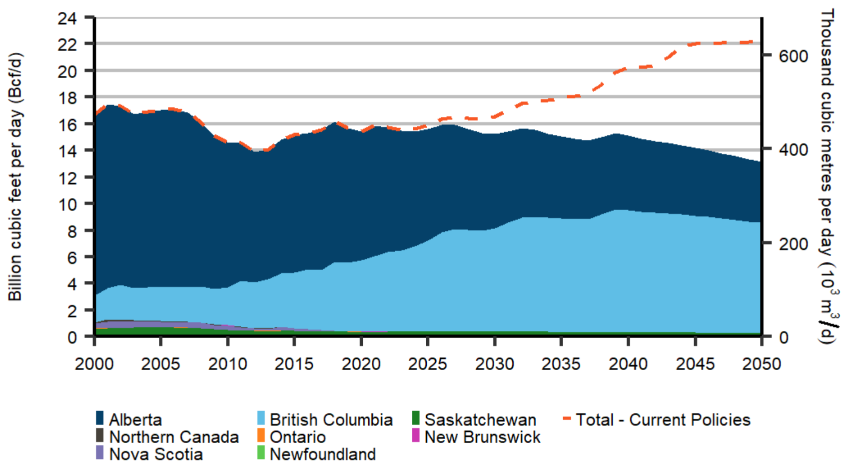


Figure R.17 shows production of natural gas by type in the Evolving Policies Scenario. Production is increasingly made up of tight natural gas produced from the Montney Formation in Alberta and B.C., which has already grown significantly over the past five years. Alberta Deep Basin tight natural gas production declines. There are minimal amounts of shale gas production from the Duvernay and Horn River shales, while solution gas declines and coal bed methane production declines significantly over the projection period.

Figure R.18 illustrates total Evolving Policies Scenario production divided into production that would result from the market prices of the Evolving Policies Scenario, and additional production due to LNG exports. The additional LNG-related production is based on our assumption that 75% of LNG feedstock comes from incremental production that only exists because LNG export capacity exits. The other 25% of LNG feedstock is supplied by the market-driven production (i.e. production that occurs based on assumed North American gas prices). Figure R.18 shows that without additional production to feed LNG exports, production would continuously decline over the projection period to 9.5 Bcf/d (267.7 $10^6 m^3/d$) in 2050.

Figure R.17:

Natural Gas Production is Increasingly Made Up of Montney Formation Tight Gas in the Evolving Policies Scenario

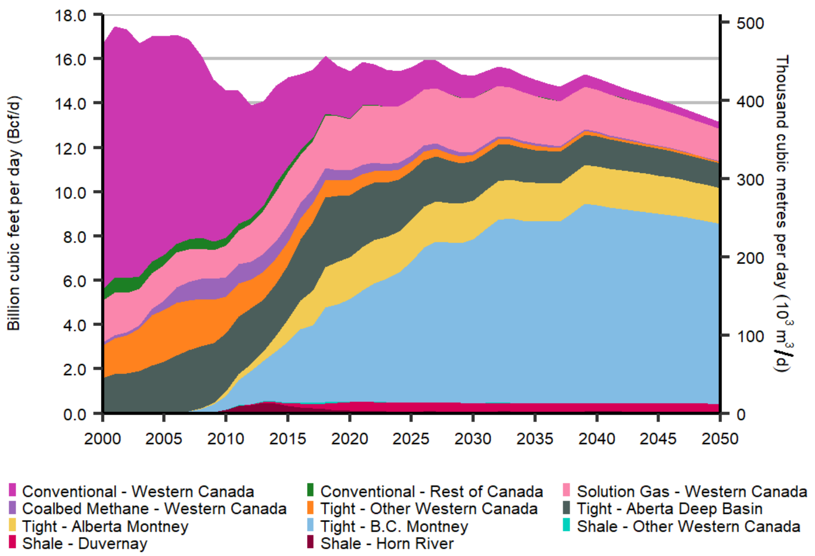

Figure R.18:

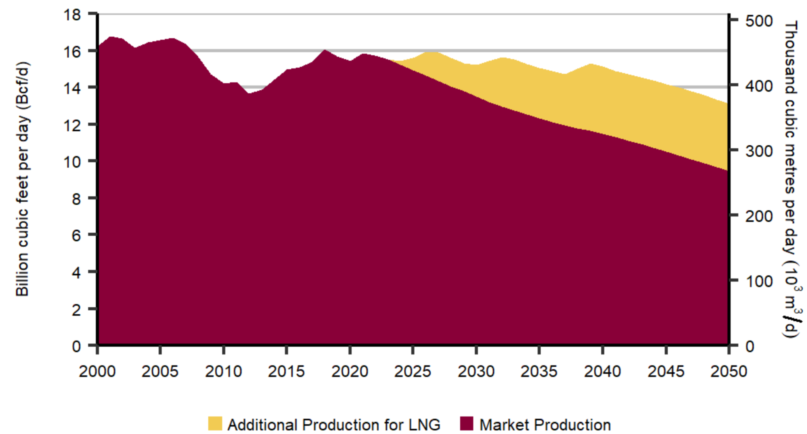
LNG Exports Support Natural Gas Production in the Evolving Policies Scenario



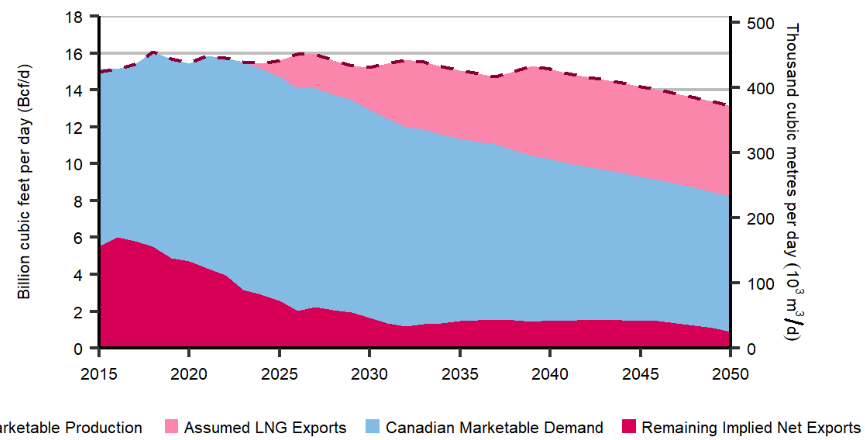
Natural gas exports to the western U.S. have increased over the last several years. Imports to Canada have been relatively steady over the last decade, ranging from 2-3 Bcf/d (57-85 $10^6 m^3/d$). Imports could potentially rise as pipeline capacity increases from the northeastern U.S. to Dawn, Ontario.

Figure R.19 breaks total marketable production in the Evolving Policies Scenario into a) Canadian marketable demand, b) the assumed LNG export volumes, and c) the remaining implied net exports. The remaining implied net exports is mostly by pipeline and calculated as Canadian natural gas production minus Canadian demand and LNG exports.[22] Remaining implied net exports shrink throughout the projection period, resulting from the production, consumption, and LNG export trends discussed earlier in this section. Lower remaining implied net exports do not necessarily mean that non-LNG exports are falling, just that the difference between imports and non-LNG exports is smaller.

[22] This value of natural gas demand is lower than the primary natural gas demand value discussed earlier because it does not include non-marketed natural gas used directly by those that produce it. Examples of this include flared gas, natural gas produced and then consumed by in-situ oil sands producers, and natural gas produced and consumed by offshore oil production.

Figure R.19:

Natural Gas Supply and Demand Balance sees the Increasing Importance of LNG Exports as Domestic Demand Declines in the Long Term in the Evolving Policies Scenario



KEY UNCERTAINTIES:
Natural Gas Production

Future international natural gas prices: Benchmark U.S. prices (i.e. Henry Hub) could be higher or lower, which would lead to different production results under both EF2021 scenarios.

Western Canadian natural gas price discounts: Differentials for western Canadian natural gas relative to Henry Hub could be affected by many factors, including pipeline bottlenecks, and market dynamics. Differentials that vary from what we assume could lead to different production in the longer term.

Future natural gas demand: As climate policy announcements and ambition increase around the world, many global scenarios have shown a significant reduction in global natural gas demand (see textbox "Global fossil fuel market dynamics and implications for Canadian production trends"). If these ambitions are realized, falling natural gas demand could have significant impacts on market prices and investment that would affect future Canadian hydrocarbon production. At the same time, the extent to which natural gas is used for low-carbon hydrogen production and/or direct air capture could impact natural gas demand trends in low-emission scenarios

LNG exports: It is possible that global market conditions and the costs of constructing new LNG export capacity may change in the future, influencing future volumes of LNG exports from Canada in both EF2021 scenarios.

ESG considerations: The investment community is shifting its attention towards firms that align with their ESG performance criteria.[23] The extent and nature to which ESG considerations may alter upstream investment trends could affect future production trends.

[23] Responsible Investment Association, 2018 Canadian Responsible Investment Opportunity: Trends Report, pg. 12, October 2018.

Natural Gas Liquids

Natural gas liquids (NGLs) are produced along with natural gas, as well as from oil sands and refinery processes. Natural gas production is the main source of NGL production in Canada. Demand for certain NGLs adds value to natural gas production and has been a driver of natural gas drilling. Raw natural gas at a wellhead is comprised primarily of methane, but often contains NGLs such as ethane, propane, butane, condensate and other pentanes.

Figure R.20 shows that total NGL production grows around 10% to 2050 in the Evolving Policies Scenario, from the 1 159 Mb/d (184 10^3m^3/d) produced in 2020. Growth is dominated by condensate, which grows 28% by 2050. Condensate, along with butanes, are added to bitumen as a diluent to enable it to flow in pipelines and be loaded on to rail cars. Condensate demand has, and will continue to, influence natural gas drilling to focus on NGL-rich plays.

Propane and butane production declines slightly over the projection period in the Evolving Policies Scenario. Demand for these NGLs increases in the medium term as demand from petrochemical producers in Alberta increases, which may affect export levels of propane and butane.

Additional Detail on Crude Oil, Natural Gas, and NGL Projections

For additional data on crude oil, natural gas and NGL production, see the EF2021 Data Appendices. These datasets include additional geographical and monthly details on production and drilling trends.

Further information about these and other available EF2021 data sets can be found in the "Access and Explore Energy Futures Data" section.

The majority of ethane is extracted at large natural gas processing facilities located on major natural gas pipelines in Alberta and B.C. In 2020, ethane made up 20% of NGL production. Ethane production is flat in the Evolving Policies Scenario, as its recovery from the natural gas stream is constrained by the capacity of the ethane extraction and petrochemical facilities in Alberta, which is assumed to remain constant. Ethane produced in excess of this capacity is reinjected back into the natural gas pipeline system to be consumed by end-users as natural gas, and these volumes do not count in our ethane production numbers.

In the Current Policies Scenario, total NGL production grows 70% to 1 967 Mb/d (313 10^3m^3/d). NGL production growth is due to natural gas production growth in this scenario. Condensate also has the most significant growth in this scenario–growing 121% over the projection, from 349 Mb/d (56 10^3m^3/d) in 2020 to 770 Mb/d (122 10^3m^3/d) in 2050.

Figure R.20:

Condensate has an increasing share of NGL Production in the Evolving Policies Scenario

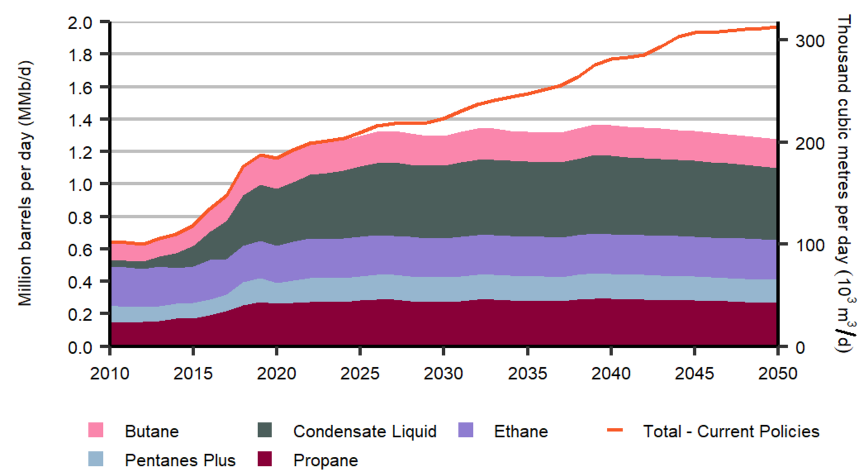


Figure R.21:
Ethane Potential

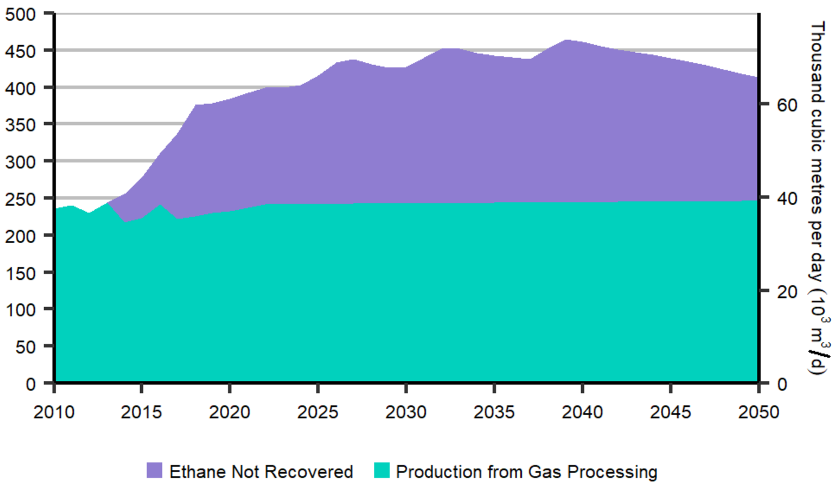

Figure R.22:
Propane Disposition

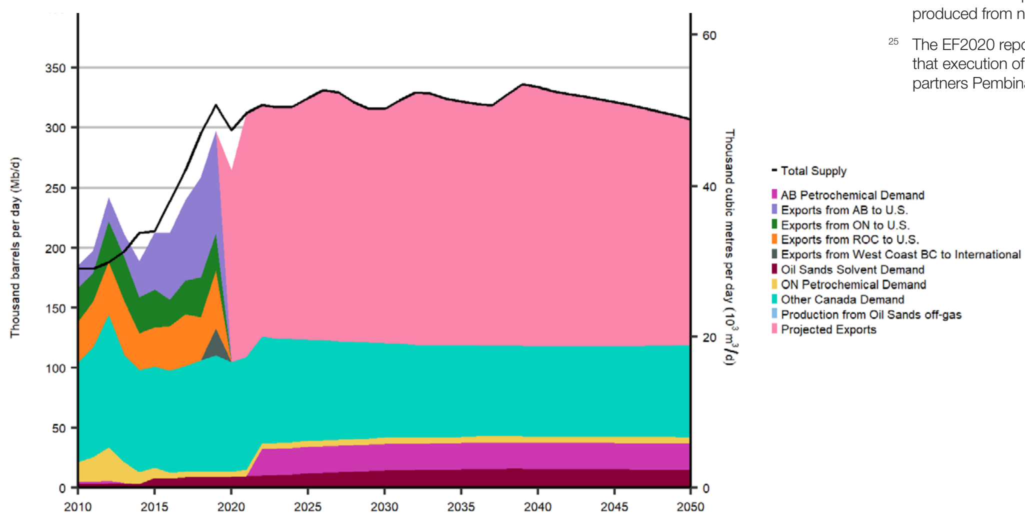

Figure R.21 shows ethane that is extracted from the natural gas stream, and ethane that is not recovered (which includes ethane reinjected in the natural gas stream). Growth in ethane that is not recovered means there is growing potential to recover more ethane, in the event of future increases in the capacity of the ethane extraction and petrochemical facilities.[24]

Figure R.22 shows total propane production broken out into its disposition. There are various uses of propane in Canada in all sectors, and over the next few years, petrochemical demand is projected to increase with the start of The Heartland Complex.[25] Propane exports to the U.S. have grown significantly this past decade as U.S. domestic demand and propane exports *from* the U.S. grew. In 2019, propane exports from the west coast of B.C. began, in the form of liquefied petroleum gas (LPG). These west coast exports could continue to increase, with potential for significant additional LPG projects and exports. Given recent export growth trends, and potential for petrochemical growth above what is projected, the Canadian propane market could see tightening in the longer term if propane production levels off then slightly declines, as projected in the Evolving Policies Scenario.

24 In May 2021 Wolf Midstream announced a positive final investment decision on the NGL North project, anticipated to be in-service in 2023 subject to regulatory and environmental approvals. This project in Alberta would recover up to 70 000 b/d of liquids. This project is not included in either scenario, and if it comes into operation it would increase ethane produced from natural gas processing.

25 The EF2020 report had a larger value for future Alberta petrochemical demand, but EF2021 has been updated to reflect that execution of one of the two proposed petrochemical complexes was suspended in late 2020, by joint venture partners Pembina Pipeline Corp. and Kuwait's Petrochemical Industries Co.

KEY UNCERTAINTIES:
Natural Gas Liquids

Natural gas: NGLs are a byproduct of natural gas production, and as such, any uncertainty discussed in the natural gas section applies for NGL projections.

Oil sands: The rate of oil sands and other heavy oil production growth, and the amount of blending, will affect the demand for condensate and butanes required for diluent. Likewise, the increased use of solvents to reduce steam requirements in the oil sands would increase demand for propane and butanes, and could influence how much they are targeted by future natural gas drilling.

Petrochemical development: There is potential for ethane recovery to increase further if there is an increase in the capacity of ethane extraction and petrochemical facilities. This could be spurred by government programs, such as royalty credit incentives for petrochemical facilities in Alberta's Petrochemicals Diversification Program.

Global LPG export market: Several large-scale facilities have been approved by provincial and federal regulators to export LPG from B.C.'s coast. Propane exports from the B.C. coast began in May 2019 and butanes also became part of the LPG mix in April 2020. Over the outlook period, propane will likely be the majority of exported LPG. The amount and composition of the LPG stream exported at proposed and existing terminals could impact domestic NGL prices and the attractiveness of drilling for NGL-rich natural gas.

Electricity

In the Evolving Policies Scenario, electricity demand grows by 44% from 2021 to 2050, as shown in Figure R.23. This is driven by growth in all sectors, with transportation and hydrogen production being emerging growth areas. In transportation, electrification provides an alternative in a sector long-dominated by RPP use. Hydrogen production is another growth area for electricity demand, as electricity is used in electrolysis to produce hydrogen.

Currently, electricity makes up approximately 16% of Canada's end-use energy demand. In the Evolving Policies Scenario, end-use electricity demand (excluding electricity to produce hydrogen) increases at an average annual rate of 1% over the projection period, which raises electricity's share of end-use demand to nearly 30% by 2050. See Figure R.24.[26]

[26] Electricity used to produce hydrogen is excluded from these figures to avoid double-counting, as hydrogen produced by electricity is included in the total and sectoral end-use demand figures. These shares are consistent with the sector demand charts earlier in this section.

Figure R.23:
Electricity Demand Grows Steadily in the Evolving Policies Scenario

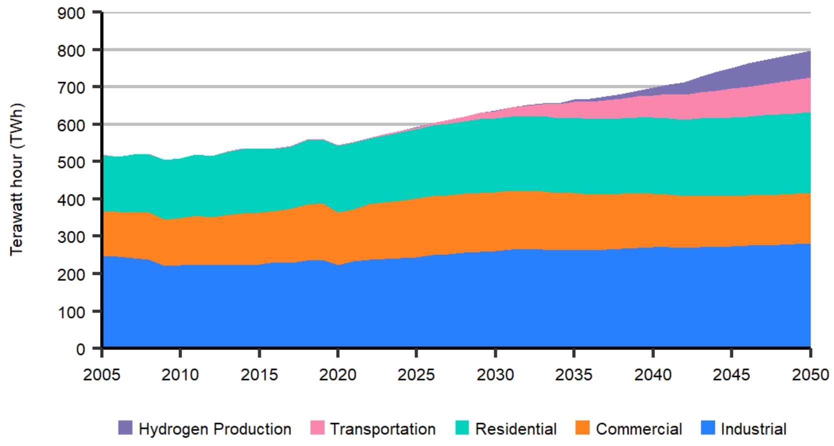

Figure R.24:
Share of Electricity in End-use Demand by Sector and Total in the Evolving Policies Scenario

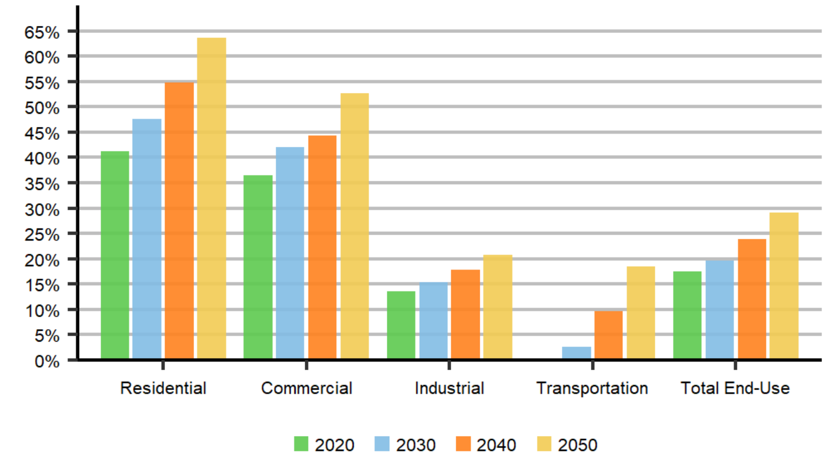

Figure R.25:

Electricity Capacity Grows Significantly in the Evolving Policies Scenario

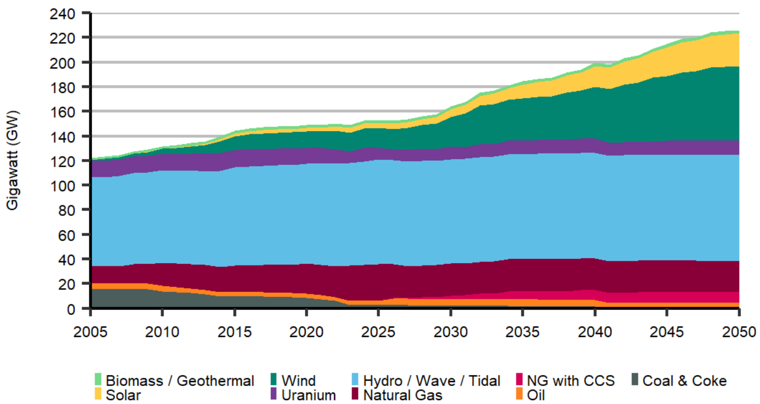

Figure R.26:

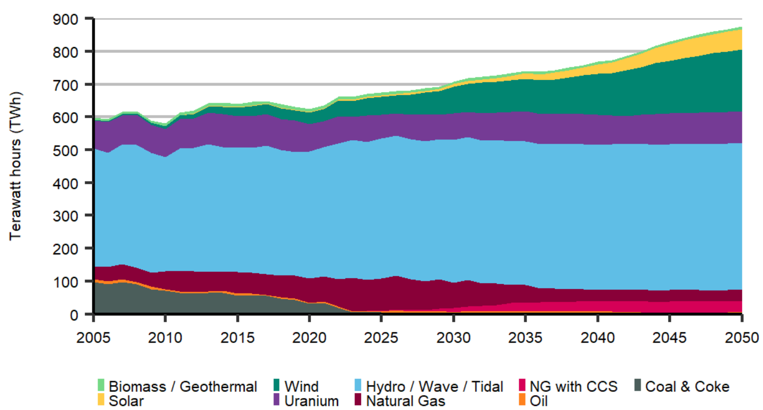
Electric Generation Trends by Primary Fuel Type in the Evolving Policies Scenario



Canada has considerable renewable resource potential including hydro, wind, biomass, and solar. Over the past decade, there have been significant changes in Canadian electricity capacity and generation trends, and it continues to evolve in the EF2021 projections. Figure R.25 shows total Canadian installed capacity by fuel type, and Figure R.26 shows electric generation by fuel type. In the earlier part of the projection, renewables and natural gas replace phased out coal generation.[27] Coal falls faster than previous projections, as recent announcements from companies suggest coal will be phased out of the Alberta electricity mix by 2023. In the longer term, falling costs lead to large growth in non-hydro renewables such as wind and solar. Nuclear generation remains relatively stable overall in the projection, with some significant year-to-year variation because of Ontario's nuclear refurbishments in the first half of the projection period. The share of low and non-emitting generation (renewables, nuclear, and fossil fuel with CCS) increases from 82% currently to 95% in 2050.[28]

Wind and solar generation also increases in the Current Policies Scenario. However, given lower carbon prices and higher wind and solar costs, wind and solar increase to a lesser degree and there is a relatively higher share of natural gas generation compared to the Evolving Policies Scenario. In 2050, natural gas makes up 16% of total generation in the Current Policies Scenario. The share of renewables and non-emitting electricity increases to 83% by 2050, compared to 95% in the Evolving Policies Scenario.

[27] Small amounts of coal with CCS generation remain to 2050, reflecting the Saskatchewan Boundary Dam project. No additional coal with CCS projects are added in the projection period based on comparative economics with natural gas with CCS and other low/non-emitting electricity.

[28] Renewable and nuclear shares refer to total electricity generation, including cogeneration.

The increase in non-hydro renewables is driven by falling costs, technological improvements, and improved integration of variable renewable energy sources such as wind and solar. Figure R.27 shows that by 2050, wind and solar capacity is added in a variety of Canadian regions. Total wind capacity rises to over 57 GW and total solar capacity rises to 26 GW. Post 2030, solar is the fastest growing renewable.

Integration of increasing wind and solar–whose generation is variable due to changing wind and sun conditions–is supported in a number of ways in the Evolving Policies Scenario. Other forms of energy, such as hydropower and natural gas, help back up these non-hydro renewables. In the Evolving Policies Scenario, energy interconnection between provinces will increase, including between Manitoba-Saskatchewan and Alberta-B.C. This adds to significant trade in Eastern and Atlantic Canada, which could increase further if projects such as the proposed Atlantic Loop increase transmission capacity. This increased ability to exchange power helps regions integrate larger amounts of variable wind and solar energy. Finally, the Evolving Policies Scenario includes around 25 GW of utility scale battery storage. This level is based on the falling costs of storage, as well as the falling costs of renewables, especially solar. Storage is particularly critical for large additions of solar.

Canada is a net exporter of electricity to the U.S., and large amounts of electricity are also traded between provinces, mainly in eastern Canada. By connecting the electricity grids of different regions, grid operators can take advantage of regional differences in electricity mixes, available variable renewable energy, and periods of peak electricity demand. Figure R.28 shows projected net exports out of Canada, as well as aggregate interprovincial trade volumes. Trade remains relatively small when compared to total generation.[29]

[29] From 2010 to 2020, annual net exports average 49 TWh, ranging between 25 and 64 TWh.

Figure R.27:
Increasing Capacity of Non-Hydro Renewables in the Evolving Policies Scenario

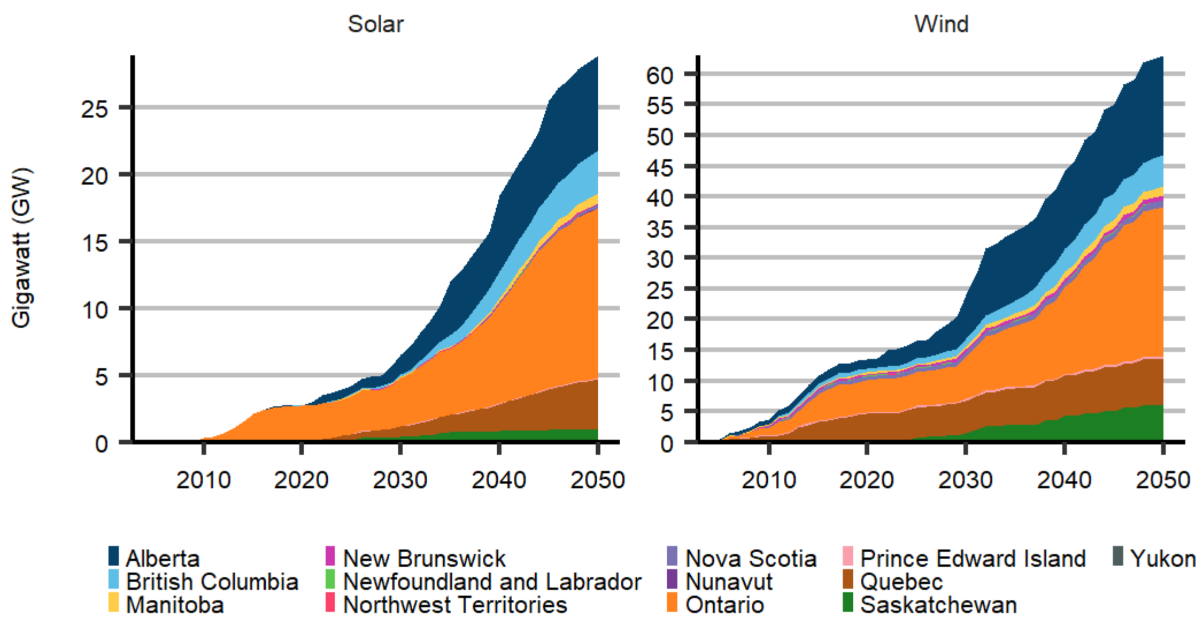


Figure R.28:
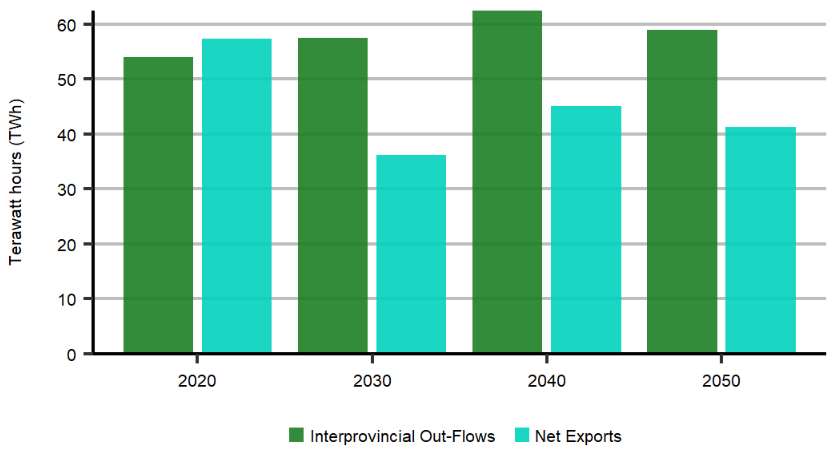
Net Exports of Electricity and Interprovincial Trade



KEY TRENDS:
Electricity Generation

- Technologies enabling Canada's transition to a low-carbon economy make inroads across the energy system, particularly in electricity generation.
- Natural gas and renewable generation is added, and most nuclear will be refurbished.
- Coal will be phased out.
- In the Evolving Policies Scenario, the share of non- and low-emitting generation increases from 82% currently, to 95% in 2050.

KEY UNCERTAINTIES:
Electricity Generation

Future cost declines of generating technology: The costs associated with different generating technologies is an important factor in determining what type of facilities are built. This is especially true with rapidly changing technologies such as wind, solar, and battery storage.

Renewable enabling technologies: Deployment of technologies to improve the integration of variable renewable energy, such as smart grids, storage, and transmission, could allow for greater levels of wind and solar in the projections.

Electricity demand growth: This is important in determining future electricity supply. As a result, the uncertainties identified in the energy demand section are uncertainties that also apply to the electricity supply projections.

Export market developments: Climate policies, fuel prices, electrification and power sector decarbonization in export markets could impact future projects and transmission developments.

Hydrogen

In recent years there has been increasing interest in low-carbon hydrogen as an important fuel in Canada and the world's transition to a low-carbon economy. Over the past few years, many countries, including Canada, have released hydrogen strategies. EF2021 is the first edition of the *Canada's Energy Future* series with a dedicated section on hydrogen supply and demand, and also introduces a hydrogen table in our online data appendix.

Our focus in this section is on hydrogen use as an energy carrier and produced by methods that emit little or no CO_2.[30] In the Current Policies Scenario, we include only currently announced projects.

In the Evolving Policies Scenario, total hydrogen demand reaches 4.7 megatonnes (MT), or 565 PJ, by 2050, as shown in Figure R.29. This accounts for 6% of total end-use energy demand. By 2050, the industrial sector accounts for 60% of hydrogen use. In this sector, hydrogen is mainly used in steel manufacturing, oil sands production, and chemical and fertilizer production. The transportation sector accounts for 15% of hydrogen demand, mostly displacing diesel in long distance freight trucking and marine transportation. The final 10% of hydrogen is used in the residential and commercial sectors, where it is blended into the natural gas stream and used for space and water heating.

Figure R.30 shows hydrogen demand by province. Hydrogen demand is the highest in Alberta, which accounts for 53% of total hydrogen demand in 2050. Alberta's relatively high demand is due to its existing industrial makeup, and its ability to produce hydrogen from natural gas with CCS, which has relatively lower costs than electrolysis earlier in the projection period. lberta's future hydrogen use is mainly in oil sands production, where it is used to replace natural gas as a source of process heat. By 2050, hydrogen demand in Alberta's industrial sector accounts for 76% of the province's total demand.

[30] Currently almost all of Canada's hydrogen is produced using a process that converts natural gas to hydrogen and CO_2, with the CO_2 being vented to the atmosphere. This hydrogen is mainly used in refineries and for fertilizer production, and is not explicitly broken out from our industrial natural gas use data.

Figure R.29:
Hydrogen Demand by Sector

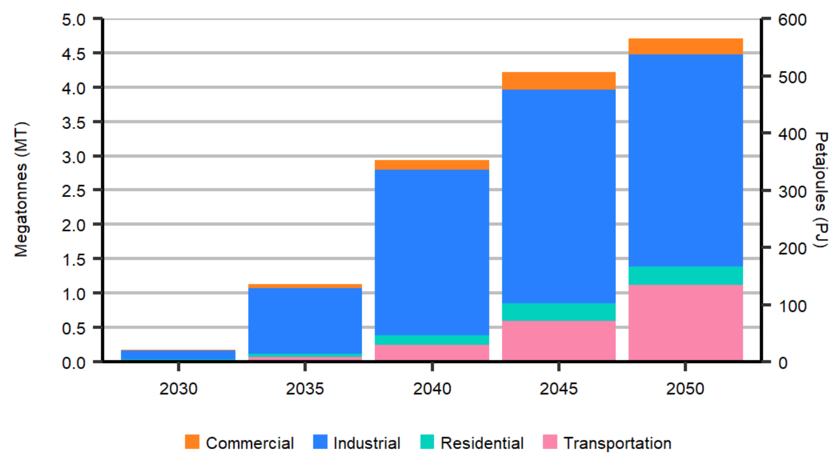


Figure R.30:
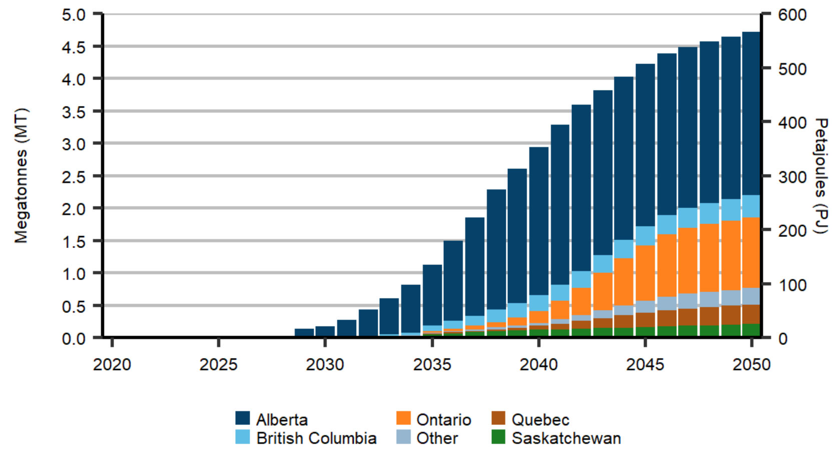
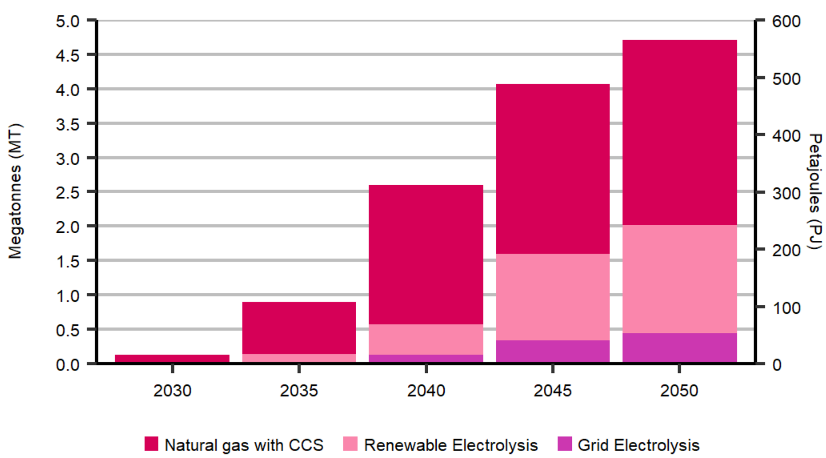
Hydrogen Demand by Region



Given that we assume hydrogen is produced to meet local demands (with no international or inter-provincial trade), hydrogen production aligns with demand. Accordingly, in the Evolving Policies Scenario, Canada produces 4.7 MT of hydrogen by 2050, matching domestic demand, and Alberta is the largest producer (with 2.5 MT of production in 2050).

In the early years of the projection, natural gas with CCS is the dominant technology for hydrogen production. Electrolysis powered by electricity from the grid and dedicated renewables becomes cost competitive towards the end of the projection. By 2050, natural gas with CCS makes up 57% of total production (Figure R.31). Production from electrolysis powered by dedicated renewables and the grid make up 33% and 9% respectively. Most regions in Canada produce hydrogen using electrolysis powered by electricity from the grid or dedicated renewables. Ontario has the highest hydrogen production from electricity, with 48% of Canada's electrolysis-based total. By 2050 close to 70 TWh of electricity is used to produce 1.8 MT of hydrogen. Similarly, natural gas with CCS uses over 422 PJ of natural gas to produce 2.95 MT of hydrogen.

Figure R.31:
Hydrogen Production by Technology



KEY UNCERTAINTIES:
Hydrogen

Infrastructure: Development of new and existing infrastructure will have an impact on the pace of hydrogen adoption in all sectors. The maximum amount of hydrogen that can be safely blended in existing infrastructure is limited to a portion of the existing pipeline capacity.

Trade: Interprovincial and international trade could alter the hydrogen supply and demand projections in this chapter. Many factors will influence the extent of trade, including whether existing transportation infrastructure is adapted to carry hydrogen, new infrastructure is built primarily for hydrogen transportation, and the evolution of costs between technologies and regions.

Future cost declines of production technology: Large scale low-carbon hydrogen production will depend on production technologies' cost decline associated with electrolyzers, CCS technology, storage, and distribution. The relative cost between various production methods will also be important, as different regions have different characteristics such as accessibility to storage, and wind and solar resource quality.

Carbon intensity: For hydrogen derived from natural gas to play a role in decarbonization, its associated emissions need to be low. Carbon capture rates greater than 90%, as assumed in this analysis, will be important. Other important areas include reducing emissions from natural gas production, including methane emissions, which are currently covered by various provincial and federal policy initiatives.

Greenhouse Gas Emissions

Currently, energy use and GHG emissions in Canada are closely related. ECCC produces Canada's official emission projections for the United Nations Framework Convention on Climate Change.[31]

The majority of GHGs emitted in Canada are a result of fossil fuel combustion. Fossil fuels provide much of the energy used to heat homes and businesses, transport goods and people, and power industrial equipment. Energy related emissions accounted for 82% of Canadian GHG emissions in 2018.[32] The remaining emissions are from non-energy sources such as agricultural and industrial processes and waste handling.

[31] Data sets are also available through the Government of Canada's Open Government portal.

[32] As defined in ECCC's national inventory report, energy related emissions includes stationary combustion sources, transportation, fugitive sources, and CO_2 transport and storage.

KEY TRENDS:

Fossil Fuel Use and GHG Emissions

- Overall unabated fossil fuel use declines in the Evolving Policies Scenario.
- Natural gas, oil, and coal each have their own distinct future trend, but use of all three falls over the long-term.
- The emission intensity of fossil fuel use falls, driven by the phase out of coal and the long-term adoption of CCS.

Does the Evolving Policies Scenario Meet Canada's Climate Commitments?

The Evolving Policies Scenario provides an energy supply and demand outlook for Canada under the general premise that global and domestic climate action continues to increase at its recent pace. EF2021 focuses on potential future outcomes for Canada's energy system. It should not be viewed as an assessment, or a pathway, for meeting Canada's climate commitments.

ECCC produces the official analysis of Canada's current emissions outlook and performance against its climate commitments. Recent ECCC projections included in Canada's updated Nationally Determined Contribution (NDC)[33] show that with the latest measures in the Strengthened Climate Plan and Budget 2021, a GHG emission reduction of 36% below 2005 levels by 2030 is achieved. This reduction exceeds Canada's original NDC pledge of 30% below 2005 levels, but additional measures could be needed to hit the updated NDC of 40-45% below 2005 levels.

The unabated fossil fuel demand trends in the Evolving Policies Scenario, as shown in this section, imply significant reduction in GHG emissions. They also imply that the Evolving Policies Scenario is unlikely to achieve net-zero emissions by 2050. Recognizing this fact, we have included the "Towards Net-Zero" section in EF2021.

[33] Submitted to the UNFCCC as part of the Paris agreement.

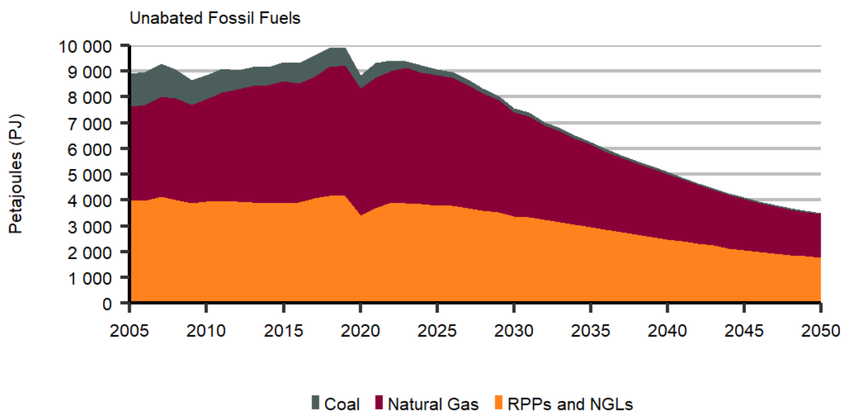
Figure R.32 breaks out total primary demand into unabated fossil fuel demand, which will make up the majority of Canadian GHG emissions, and low emission sources, which include renewable, nuclear, fossil fuels with CCS, and fossil fuels for non-combustion purposes.[34] Relative to 2020 levels, unabated fossil fuel consumption is 19% lower in 2030, 45% lower in 2040, and 62% lower in 2050. Meanwhile, low-emission energy rises, and accounts for 67% of energy use in 2050, compared to just 31% in 2021.

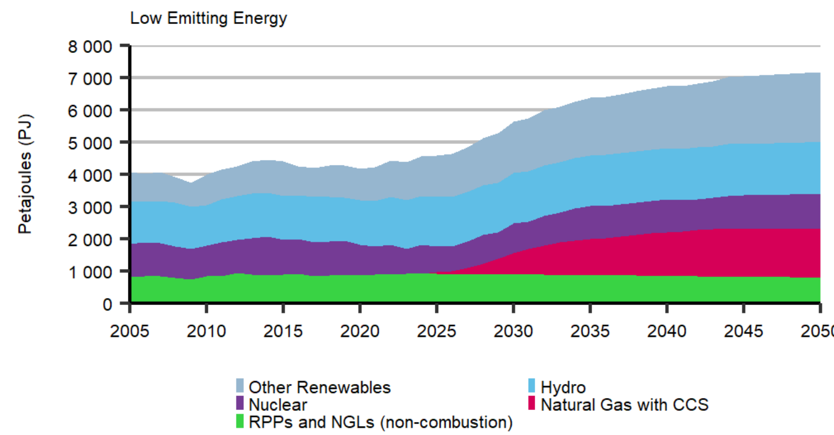
Trends vary among fossil fuels. Coal consumption significantly declines over the projection, driven by its phase-out from electricity generation by 2030.[35] Use of RPPs, such as gasoline and diesel, gradually declines throughout the projection period. In the earlier years, this decline is driven by efficiency improvements and increased blending of biofuels, and in the long term is driven by increased electrification of the transportation sector. Use of natural gas continues to grow in the very early part of the projection period, following its increased role in power generation and its use in rising oil sands production. In the longer term, its overall use falls but its use with CCS increases significantly for industrial and power generation use and low-carbon hydrogen production.

[34] Examples of fossil fuels for non-combustion purposes include petrochemical feedstocks, asphalt and lubricants. We include these non-energy demands along with energy use because they are derived from energy commodities such as crude oil and NGLs, and form part of Canada's energy balances.

[35] Small amounts of coal with CCS generation remain to 2050, reflecting the Saskatchewan Boundary Dam project. No additional coal with CCS projects are added in the projection period based on comparative economics with natural gas with CCS and other low/non-emitting electricity.

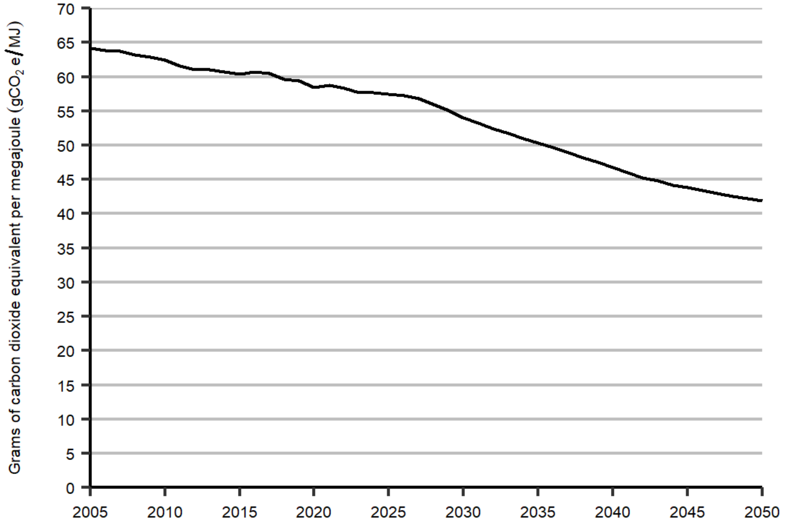
Figure R.32:
Total Primary Demand by Type





Changing proportions of which fossil fuels are consumed leads to declining combustion-related GHG emissions per unit of fossil fuel energy used in the Evolving Policies Scenario, particularly with coal use declining to 2030. Deployment of CCS technology in industrial facilities also reduces the GHG intensity of fossil fuel use in the longer term. As shown in Figure R.33, fossil fuel emission intensity in 2030 is 9% lower than 2019, and 16% lower than 2005 in the Evolving Policies Scenario. By 2050 it is 29% lower than 2019, and 35% lower than 2005 in the Evolving Policies Scenario. This decline drives emission reductions when combined with falling fossil fuel use, as 2030 total fossil fuel use is 16% lower than 2019, and 6% lower than 2005. By 2050, total fossil fuel use is 46% lower than 2019, and 40% lower than 2005. Accounting for reductions in non-combustion emissions, such as reducing methane emissions, as well as including emission credits purchased through international trading mechanisms (like Quebec's emission trading with California), could further decrease emission intensity.

Figure R.33:
Fossil Fuel Emission Intensity Falls due to Higher Shares of Natural Gas, Less Coal, and Greater Adoption of CCS in the Evolving Policies Scenario



Could Carbon Removals Bring Canada to Net-Zero in the Evolving Policies Scenario?

Global and domestic net-zero pathway exercises rely on some degree of carbon removal or negative emission technology to reach net-zero by 2050. The degree varies depending on the scenario and underlying assumptions. For example, the Net-Zero Emissions by 2050 Scenario in the IEA's Net-Zero by 2050 report includes about 1.9 gigatonnes of CO_2 that is removed by negative emissions technologies in 2050. In the Canadian context, the Canadian Institute for Climate Choices' Canada's Net Zero Future report shows availability of engineered negative emission technologies, particularly direct air capture, and accounts for 0 to 425 MT of CO_2 emission reductions in 2050 across the 62 scenarios they analyzed. However, the Canadian Institute for Climate Choices recognizes potential challenges, both technical and economic, and identifies ways to reach net-zero in the absence of negative emissions technologies.

Negative emissions technologies and enhanced biological sinks involve removing CO_2 from both the emissions' source and the atmosphere, and storing it in land, ocean, or geological reservoirs.[36] While hypothetically promising, most assessments agree that negative emissions technologies are not a replacement for conventional mitigation and adaptation methods, due to high costs, potential risks, and uncertainties involved.[37]

Notable GHG removal methods include:

Reforestation and afforestation[38]: Carbon can be sequestered in biomass through restocking of existing forests and woodlands that have been depleted, or introducing trees to areas that have not previously been forested.

Soil carbon sequestration[39]: Carbon can be removed from the atmosphere and stored in the soil carbon pool, primarily in the form of soil organic carbon. This can be accomplished through a variety of methods, including the restoration of degraded soils or widespread adoption of soil conservation practices in agriculture. For instance, reducing soil carbon loss can be achieved in certain circumstances by switching from tillage to no-till cropping.

Bioenergy with carbon capture and storage (BECCS)[40]: Carbon can be captured and stored by geological sequestration or land application, as energy is extracted from biomass through combustion, fermentation, or other conversion methods. Limiting factors for BECCS include the availability and sustainability of feedstock biomass, and the availability of carbon storage capacity.

Direct air capture: Carbon can be captured from the atmosphere to produce a concentrated stream of CO_2. It can then be sequestered (resulting in emission removals), or used to make carbon-neutral synthetic fuels. Direct air capture uses a lot of energy, so large scale deployment could impact energy supply and demand trends.

The Evolving Policies Scenario shows a 60% drop in unabated fossil fuel use by 2050, which would result in a significant reduction in emissions. The Evolving Policies Scenario does not include assumptions related to deployment of large-scale carbon removals. Whether the Evolving Policies Scenario could be net-zero with deployment of carbon removals depends on two key considerations:

1. Although unabated fossil fuel use falls, it is still a significant part of the energy mix, and implies significant levels of emissions. This would require a large deployment of carbon removal technology. The feasibility of this deployment would depend on many factors, including cost reductions of emerging technologies such as direct air capture, and the availability and costs of BECCS and nature-based solutions. Given these are emerging solutions, large deployment is highly uncertain.

2. Deployment of large-scale carbon removals would likely change the Evolving Policies Scenario projections. For example, large scale direct air capture deployment would involve a significant increase in natural gas and/or electricity use. Likewise, a large deployment of BECCS could change the Evolving Policies Scenario electricity projections.

Given the uncertainty with removal technologies, especially at large scales, and the fact that large scale removals would affect the projections, the Evolving Policies Scenario as described in this section should not be considered a net-zero pathway.

Towards Net-Zero

Electricity Scenarios

A key objective of the 2015 Paris Agreement is to hold the increase in the global average temperature to well below 2 degrees Celsius and pursuing efforts to limit the temperature increase to 1.5 degrees above pre-industrial levels. Scientific assessments have shown that limiting the temperature increase at those levels requires deep GHG emission reductions, with a key milestone being achieving net-zero emissions or carbon neutrality by 2050.[41] As of August 2021, about 130 countries, including Canada, have set or are considering net-zero by 2050 emissions targets.[42] Canada has set targets to reduce the country's GHG emissions by 40-45% below 2005 levels by 2030 and to achieve net-zero GHG emissions by 2050.

Over 82% of Canada's GHG emissions are from energy producing and consuming processes. To achieve net-zero emissions by 2050, transformational changes are required to the way Canadians produce and consume energy. The pathway to achieving net-zero will likely require a greater level of change than we model in EF2021 or previous reports in the *Canada's Energy Future* series.

In this section, we introduce six new scenarios that explore net-zero pathways for Canada's electricity sector. This analysis is an important step in modeling related to a net-zero energy system in *Canada's Energy Future* series.

[41] For example, the IPCC Special Report on Global Warming of 1.5 °C (SR15) finds that limiting global warming to 1.5°C would reducing anthropogenic emissions of CO_2 by about 45 percent from 2010 levels by 2030, reaching 'net zero' around 2050.

[42] Based on data reported by the Energy and Climate Intelligence Unit.

Why the Electricity Sector?

In this analysis, we focus on the electricity sector, recognizing the pivotal role of electricity in the pathway to net-zero. Many climate modeling and energy system assessment studies have shown that an electricity sector with net-zero or net-negative emissions, and an increasing share of electricity in the end-use fuel mix, is a cornerstone of an energy system in a carbon neutral world. For example, the *IPCC Special Report on Global Warming of 1.5 °C* shows that pathways that would limit global warming below 1.5 °C include a rapid decline in the carbon intensity of electricity and an increase in electrification of energy end-use.

There are some unique aspects of electricity that make it an important part of most deep decarbonization pathways. Mature and commercially ready technologies exist for decarbonizing electricity. The costs of many low or zero GHG emission generation technologies have declined over the past decade, making them attractive for electric utility investors. Electricity is also a highly versatile form of energy. Converting electricity into end-use energy services can be done at high efficiencies and without any emissions at the point of consumption.

One major challenge for economy-wide deep decarbonization is the distributed nature of GHG emissions. For example, millions of vehicles emit GHGs when fossil fuels are combusted to move the vehicles around. Similarly, millions of buildings combust fossil fuels for space heating, emitting a significant amount of GHGs. When energy end-uses are electrified, no GHGs are emitted at the point of consumption. When energy end-uses are electrified in a decarbonized electricity sector (i.e. where the electricity is generated with low or zero GHG emissions), economy-wide deeper GHG reductions can be component of climate action.

In pursuit of net-zero emissions, the electricity sector in Canada has an early advantage. About 82% of Canada's electricity already comes from non-GHG emitting sources such as hydro, nuclear power, wind, and solar. This share has been growing, and emissions associated with the remaining generation have declined significantly over the past two decades. The GHG emissions intensity of Canada's electricity generation has declined by 45% from 220 grams CO_2 equivalent (gCO_2e)/kWh in 2005 to 120 gCO_2e/kWh in 2019.[43]

The critical role of Canada's electricity sector in achieving net-zero emissions has received the attention of policy makers across Canadian jurisdictions. As outlined in the Policy Appendix, many programs and policies have been implemented by the federal, provincial, and territorial governments of Canada to reduce GHG emissions from the electricity sector and to promote electrification of end-use energy. For example, Canada's strengthened climate plan, A Healthy Environment and a Healthy Economy, commits about $4 billion of investment to expand the supply of cleaner electricity, modernize Canada's electricity systems, and make electrification of energy end-uses affordable.

[43] Obtained from National Inventory Report 1990 – 2019: Greenhouse Gas Sources and Sinks in Canada.

What is "Net-Zero"?

"Net-zero" GHG emissions refers to the concept of balancing human-caused GHG emissions with removals from the atmosphere. This includes non-energy emissions from land use, agriculture, and industrial production, in addition to emissions from the energy system. Reaching net-zero emissions does not necessarily require eliminating all emissions everywhere. Instead, residual emissions can be balanced by enhancing biological sinks and using negative emission technologies. What the exact balance might be between removing and emitting GHGs into the atmosphere is uncertain. However, it is clear that Canada's likelihood of achieving our net-zero target increases as our energy system emissions fall.

See the Towards Net-Zero section in our Energy Futures 2020 report for a discussion of what "Net-Zero" means, and what achieving net-zero GHG emissions could mean for Canada's energy system.

Methods and Assumptions

The basis for our modelling of Canada's electricity sector in a net-zero world begins with the electricity production and consumption results of the Evolving Policies Scenario. We build on those results in three main ways:

1. We dive deeper into the electric power sector by applying an electric power system planning and operations simulation model. It selects and operates the optimal set of power generation technologies that minimize the total cost while satisfying future power demand.
2. For each province, we assume a specific higher electricity demand level than the Evolving Policies Scenario to capture an increased level of energy end-use electrification consistent with expectations of a net-zero future.
3. We assume more stringent climate action in the form of a higher carbon price than the Evolving Policies Scenario. The expected result is that a sufficiently high carbon price will drive the electricity sector towards net-zero emissions.

Given the uncertainty around the costs and viability of different low-carbon technologies, there are many potential pathways to achieve a net-zero electricity system. For this reason, the analysis is developed around six scenarios that explore some of the key uncertainties. Across scenarios we change key inputs such as demand, carbon prices, and technology availability. The main scenario we developed for this part of the analysis is called Net Zero Electricity (NZE) Base scenario. The premise and main characteristics of the NZE Base and other alternative scenarios are presented in Table NZ.1.

Table NZ.1:

Premise and Characterizing Features of Net-Zero Electricity Scenarios

Scenario	Scenario Rationale	Allowable Capacity Expansions	Other Features
NZE Base	Continually increasing Canadian climate policies may lead to a higher carbon price and a higher level of end-use energy demand electrification than the assumptions made in the Evolving Policies scenario.	Generation technologies: natural gas fired combined cycle, natural gas fired simple cycle, and natural gas fired combined cycle with CCS* units, wind, solar, hydro, conventional nuclear, and SMR. Electricity storage. Inter-provincial transmission.	Electricity demand is 10-30% higher than the Evolving Policies Scenario, depending on the province. Carbon pricing is higher than the Evolving Policies Scenario, reaching $2020 300/tonnes CO_2 by 2050.
Higher Carbon Price	It is plausible that more aggressive climate action is needed to drive the energy systems towards net-zero, leading to a higher carbon price than the value assumed in the NZE Base scenario.	Same as NZE Base.	Same electricity demand as Base. **Carbon pricing reaches $2020 800/t$CO_2$ by 2050.**
Higher Demand	A higher level of electrification is possible due to uncertainty around specific climate action and technology development.	Same as NZE Base.	**Electricity demand is 15-45% higher than the Evolving Policies Scenario, depending on the province.** Same carbon pricing as NZE Base.
Limited Transmission	Interprovincial transmission expansion is costly, and the timing of investments is uncertain. Therefore, new interprovincial transmission development may not be feasible.	Same as NZE Base, but **no new inter-provincial transmission is allowed.**	Same electricity demand and carbon pricing as NZE Base.
Hydrogen	There is a high level of interest in hydrogen as a technology path to decarbonize the economy. Accordingly, there is the possibility of low-cost low/zero carbon hydrogen being available for electricity generation.	All NZE Base options and **hydrogen fired generation technologies.**	Same electricity demand and carbon pricing as NZE Base.
BECCS	Negative emissions technologies feature prominently in previous net-zero scenarios. Within that scope, biomass-fired electricity generation with CCS is attractive as it simultaneously produces electricity and removes carbon dioxide from the atmosphere. Therefore, it is plausible that biomass-fired electricity generation with CCS is available in the near future.	All NZE Base options and **biomass CCS* generation technology.**	Same electricity demand and carbon pricing as NZE Base.

* CCS technologies including natural gas with CCS and BECCS are only allowed to be built in Alberta and Saskatchewan due to the greater availability of proven geological potential to store CO_2 and availability of active CCS projects in these provinces.

A core set of assumptions including technology costs, fuel prices, and hourly demand profile shapes were held constant across scenarios. Assumed capital costs of generation and storage technologies are listed in Table NZ.2.

Table NZ.2:
Assumed Technology Capital Costs ($2020 CDN/kW) by Investment Year

Technology	Aggregated Group	Capital Cost in Investment Year		
		2030	2040	2050
Natural Gas Simple Cycle	Natural Gas	950	950	950
Natural Gas Combined Cycle	Natural Gas	1 300	1 300	1 300
Natural Gas Combined Cycle with CCS	Natural Gas CCS	3 000	2 500	2 000
Solar	Solar	972	604	376
Wind	Wind	1 115	868	676
Hydropower	Hydro	4 000	4 000	4 000
Nuclear	Nuclear	7 000	7 000	7 000
Small Modular Reactor	Nuclear	7 000	6 000	5 000
Hydrogen Simple Cycle	Hydrogen	1 625	1 560	1 430
Hydrogen Combined Cycle	Hydrogen	1 813	1 813	1 813
Biomass with CCS	Biomass CCS	4 752	4 512	4 299
Battery Electricity Storage (4 h storage duration)	Storage	425	275	190

Notes
Where applicable, capital cost reduction due to technology development and learning is considered.
In results figures, some generation technologies are aggregated into a group as indicated in the column "Aggregated Group."

Other simplifying assumptions in the net zero electricity analysis:

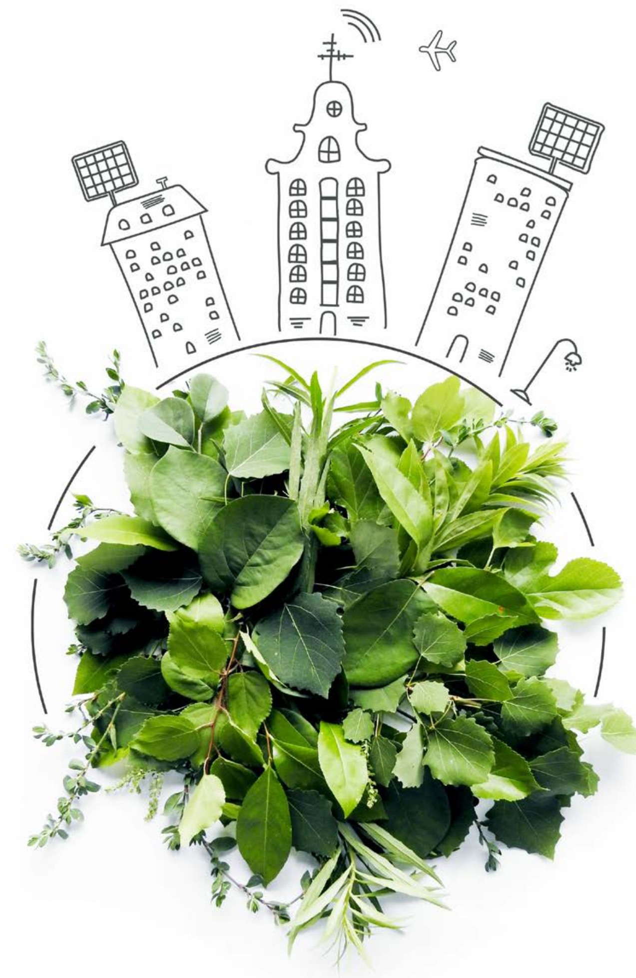
- The analysis is limited to the ten provinces. Electricity systems of the three territories are excluded from the analysis.
- A few other low carbon generation technologies that have attracted recent interest, including geothermal, tidal, conventional biomass, and offshore wind are excluded.
- Electricity storage is limited to battery electric storage with four-hour storage capacity.
- Demand-side management and distributed electricity resources are excluded.
- Only grid-connected generation is modelled.
- Electricity trade with the U.S. is not modelled.

This analysis is based on the hourly electricity module of the Energy Futures Modeling System (see Appendix 2). It optimizes the capacity investments and operations of the provincial electricity systems at one-hour intervals. Interprovincial electricity trade is also modelled. The main objective of the model is to construct and operate an optimal generating unit fleet that would minimize the total cost of satisfying electricity demand in Canada under the particular scenario assumptions. We complete this analysis for the period 2030-2050. Here we present the results for 2030 and 2050, the two years for which Canada has set major emission reduction targets.

Approach to Electricity Sector Emissions in this Net Zero Electricity Analysis

The net-zero electricity scenarios described in this section are intended to explore how Canada's electricity system might evolve in the broader context of Canada moving towards net-zero for the entire energy system. In an economy-wide net-zero transition, it is possible that some specific sectors could continue to emit GHGs, which would have to be offset by emission removals in other sectors at a given price.

Therefore, in our analysis, we do not force the electricity sector to be purely non-emitting in any year. Rather, we use the assumed carbon price, which serves as a proxy for the cost of carbon removal, as well as potential technology options to determine the ultimate carbon emissions of the sector. Our emission intensity results show that if bioenergy with CCS is available, the electricity sector could be negative emitting. Other scenarios show a dramatic reduction in grid emission intensity compared to current levels, but achieving net-zero could require moderate levels of offsets from carbon removal options such as nature-based solutions or direct air capture.



Results

NZE Base Scenario Electricity Supply

We first discuss the results for the NZE Base scenario and visit the other scenario results later in the section. Figure NZ.1 shows the installed electricity generation capacity mix in Canada by technology in the NZE Base scenario.

In the NZE Base scenario, non-emitting generation technologies (i.e., hydro, nuclear, solar, and wind) and electricity storage account for 80% of the installed generation capacity in 2030. By 2050, that share increases to 89%. Additionally, low-emitting natural gas CCS units are built in Alberta and Saskatchewan. Our results see an addition of about 5.6 GW of natural gas CCS units by 2050. Natural gas CCS account for about 2% of all provincial capacity and 8% of capacity in Alberta and Saskatchewan.

At a combined capacity of 134 GW, which is about 41% of the installed capacity, solar and wind dominate the electricity generation fleet in 2050. Wind capacity doubles from 2019 levels by 2030, and is five times greater by 2050. Solar capacity is twenty times larger compared to 2019 levels by 2050. Electricity storage is installed to facilitate the operations of variable renewables and support grid operations. At an average annual growth rate of about 1.7 GW/year, storage sees a rapid growth throughout the analysis period. From 2019 capacity of about 0.01 GW, storage capacity reaches 52 GW by 2050.

New hydropower capacity additions are relatively small and only see a cumulative new capacity addition of about 4.2 GW in the period 2030 to 2050, a 5% increase from 2019. Similarly, the growth of nuclear power is also comparatively small. All new nuclear additions are through small modular reactor (SMR) technology. About 6.6 GW of SMR units are added by 2050. Based on our cost assumptions, no new nuclear capacity is added until 2040. In combination, hydropower and nuclear represent 5% of new capacity additions. Despite the lower share of new capacity additions, as discussed later in this section, hydropower and nuclear power play an important role in supporting Canada's electricity supply on the path towards net-zero.

Fossil fuel-based technologies, mainly natural gas units, represent approximately 20% of total generating capacity in 2030 and decline to 11% by 2050. Natural gas unit additions are dominated by simple cycle gas turbines and primarily provide grid balancing.

Figure NZ.2 shows electricity generation by technology in the NZE Base scenario. In general, the electricity system must constantly balance electricity generation with electricity use. Electricity use varies with minute-to-minute changes in demand by homes, businesses, and industry. Electricity generation then must vary to match this demand. Some generation types are flexible and can be altered by system operators to meet demand. Other resources are less flexible, and others, such as wind and solar, are not flexible and instead vary based on wind or sunlight availability. Our model takes these factors into account and chooses the optimal generation mix based on level of demand, relative costs, and resource constraints.

Figure NZ.1

Installed Electricity Generation Capacity in Canada in the NZE Base Scenario

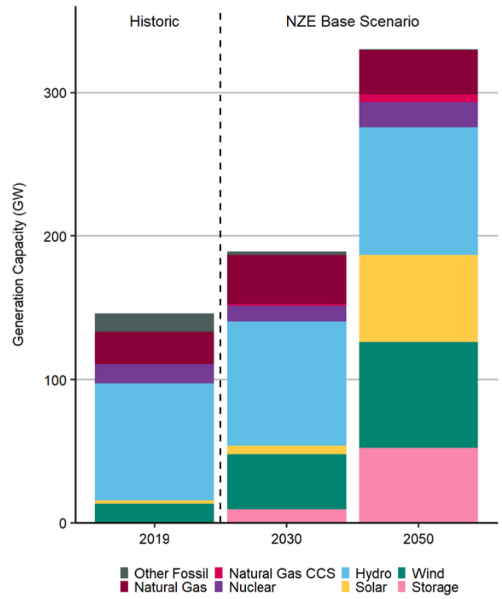


Figure NZ.2

Electricity Generation in Canada by Technology in the NZE Base Scenario

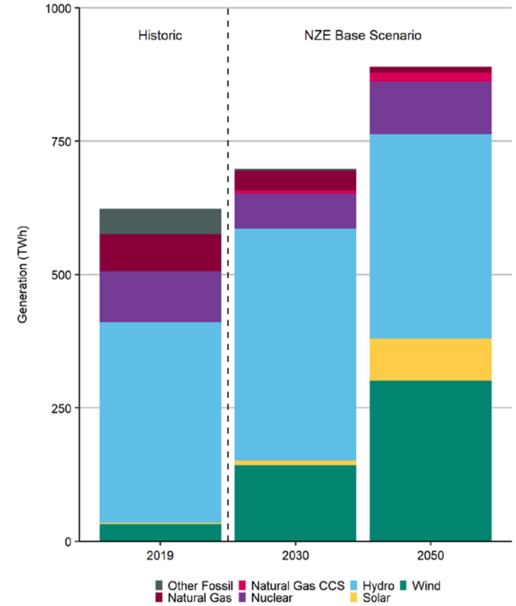

Figure NZ.2 Notes: Since storage is not a primary generator of the electricity it stores and ultimately dispatches, it is not included in this figure. By 2050, storage is primarily used to store electricity produced by wind and solar in low demand periods, for use in high demand periods. About 7.5% of the electricity produced in 2050 by solar and wind is first stored in storage units and later delivered to the consumers.

KEY TRENDS:

Electricity Supply in the NZE Base Scenario

- Wind and solar dominate new capacity additions. These two technologies account for 59% of new capacity additions through 2050.
- Electricity storage sees a rapid growth and reaches 15% of total installed capacity in 2050.
- New demand growth is primarily satisfied by wind and solar with other low carbon technologies such as SMR, hydropower, and natural gas CCS providing supplemental energy.
- All new nuclear additions are SMR units, which begin to make inroads after 2040.
- Natural gas CCS plays an important role but is restricted to the provinces with greater carbon storage potential.
- Almost all conventional fossil fuel-fired electricity supply comes from natural gas simple cycle units.
- The importance of hydropower remains high. However, there are not major hydropower capacity additions due to relatively high assumed capital costs.

In the NZE Base Scenario, non-emitting generation (e.g., hydro, nuclear, solar, and wind) produces 93% of electricity in 2030, and 97% in 2050. Overall, by 2030, 94% of electricity is generated by low- and non-emitting technologies (renewables, nuclear, and CCS-enabled fossil fuel), rising to 99% in 2050. Hydropower and nuclear power provide the largest share of the electricity supply in both periods. However, the amount of electricity provided by those two technologies remains relatively unchanged from 2019 levels, at roughly 50 TWh throughout the projection period. New demand growth is primarily satisfied by wind and solar, with electricity storage systems and to a lesser degree, simple cycle gas turbines, ensuring system reliability.

The current share of fossil fuel-based electricity generation is 19%, and this decreases over the projection period. By 2050, the total share of electricity produced by natural gas-fired generation reaches 3% of the total electricity supply. About two-thirds of that comes from natural gas units equipped with CCS technology. The remainder consists of natural gas simple cycle units that provide some grid balancing services to maintain system reliability.

Storage systems do not produce electricity but rather store electricity produced by other generating units for later delivery to consumers. This is a critical service needed to operate electricity systems with larger shares of variable generating sources such as solar and wind. Our results show that storage is primarily used to move electricity produced by wind and solar in low demand periods to high demand periods. We find that about 7.5% of the electricity produced by solar and wind is first stored in storage units and later delivered to the consumers.

Canada has a diverse energy system. Figure NZ.3 shows the generation mix for each province in the NZE Base scenario. We find that electricity generation in B.C., Manitoba, Quebec, and Newfoundland and Labrador continues to see the supply dominated by hydropower. In the three former provinces, however, new demand is satisfied by wind and solar. Nuclear power[44] is limited to Ontario and New Brunswick and represents about 41% and 24%, respectively of the provincial electricity supply in 2050.

[44] Nuclear power includes the electricity produced by both legacy units and new SMR units.

Natural gas-fired electricity generation remains a relatively important share, about 12% and 15%, respectively of the electricity supply of Alberta and Saskatchewan in the NZE Base scenario in 2050. However, by 2050, about 80% of the natural gas-fired generation in these two provinces is from natural gas CCS units.

In the NZE Base scenario, inter-provincial electricity transmission capacity expansions increase, mostly among the four western provinces. The combined electricity transfer capacity of the three western inter-provincial electricity corridors (i.e., B.C.–Alberta, Alberta–Saskatchewan, Saskatchewan–Manitoba) almost triples in the NZE Base scenario. Outside of the western region, only the New Brunswick–Prince Edward Island inter-provincial corridor sees transmission expansion at about 30% growth compared to current levels.[45]

[45] Other assessments have suggested that inter-provincial transmission expansion among eastern Canadian provinces, particularly among the Atlantic provinces, would facilitate the electricity system decarbonization efforts. Our analysis does not capture that under the assumptions we make, with a potential factor being our simplifying exclusion of electricity trade with the U.S.

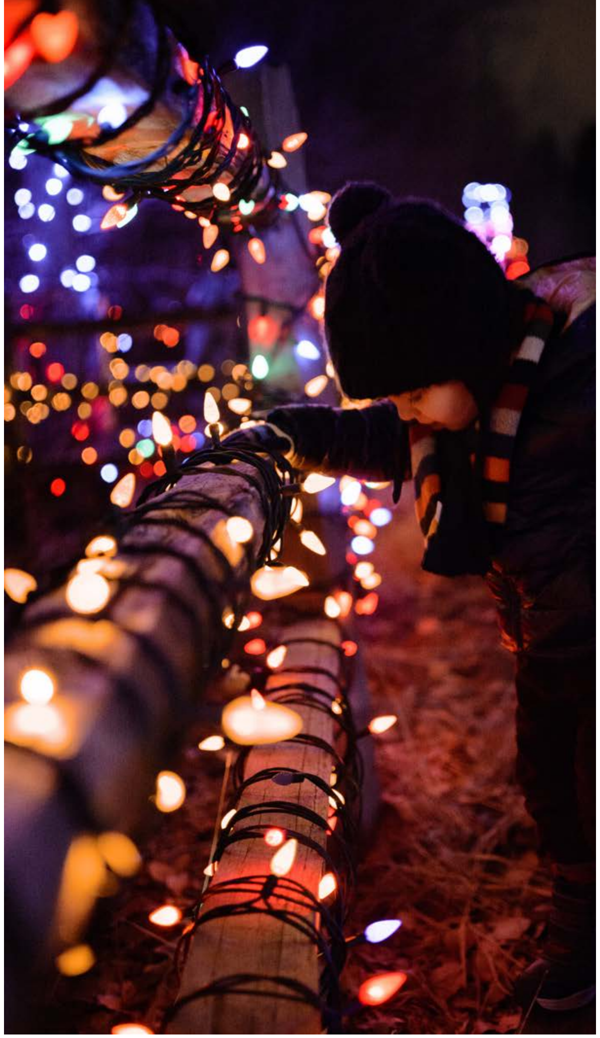

Figure NZ.3

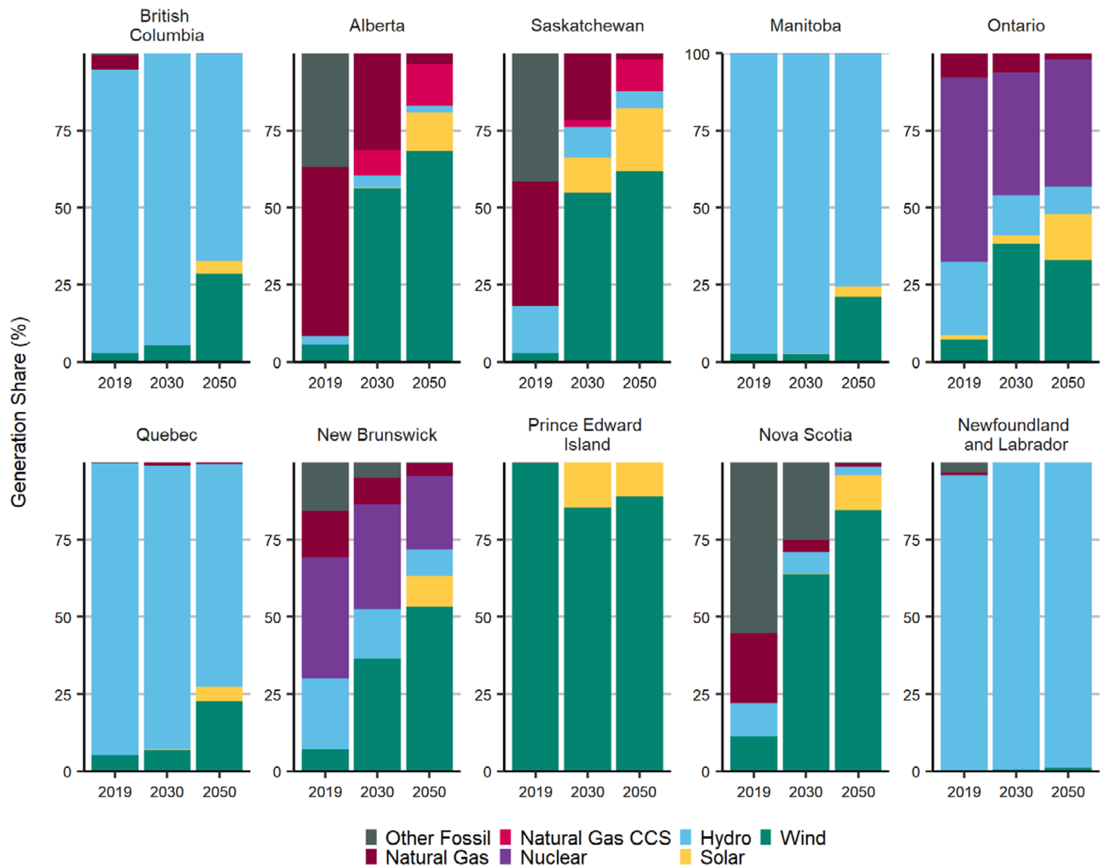
Share of Electricity Generation by Technology in Canadian Provinces in the NZE Base Scenario



As noted above, in the NZE Base scenario the share of electricity supplied by technologies with zero carbon intensities increases to about 97%, while another 2% is from low-emission natural gas CCS units. This is driven by two main factors. First, the capital cost of wind, solar, and electricity storage declines significantly in this scenario, thereby reducing their average cost of production. Second, the increasing carbon price leads to higher generation costs for fossil fuel-fired generating units, making them less competitive against other options.

Similar results were observed in other scenarios, but some noteworthy observations are discussed below.

Electricity Supply in Alternative Scenarios

In this section, we compare the results in other electricity scenarios with the NZE Base scenario. All alternative scenarios see a nearly identical level of inter-provincial transmission expansion as the NZE Base scenario. The exception is the Limited Transmission scenario, where no additional transmission expansions are allowed. Furthermore, similar to the NZE Base scenario, most of the new demand is satisfied by wind and solar, while high GHG emission generation technologies see rapid decline.

Figure NZ.4 shows installed capacity by technology in different scenarios. Figure NZ.5 shows the cumulative new capacity additions by technology type by 2050 in different scenarios. Figure NZ.6 shows the amount of electricity generation.

Figure NZ.4:
Installed Capacity by Technology in Different Scenarios

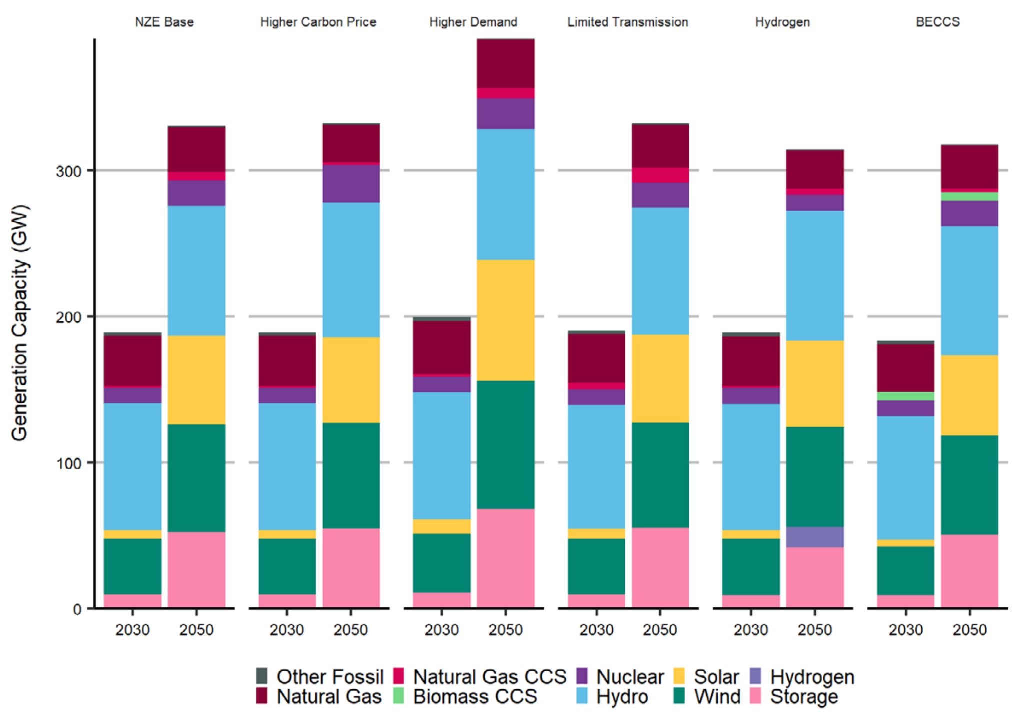


Figure NZ.5:
Cumulative New Capacity Additions by 2050 in Different Scenarios

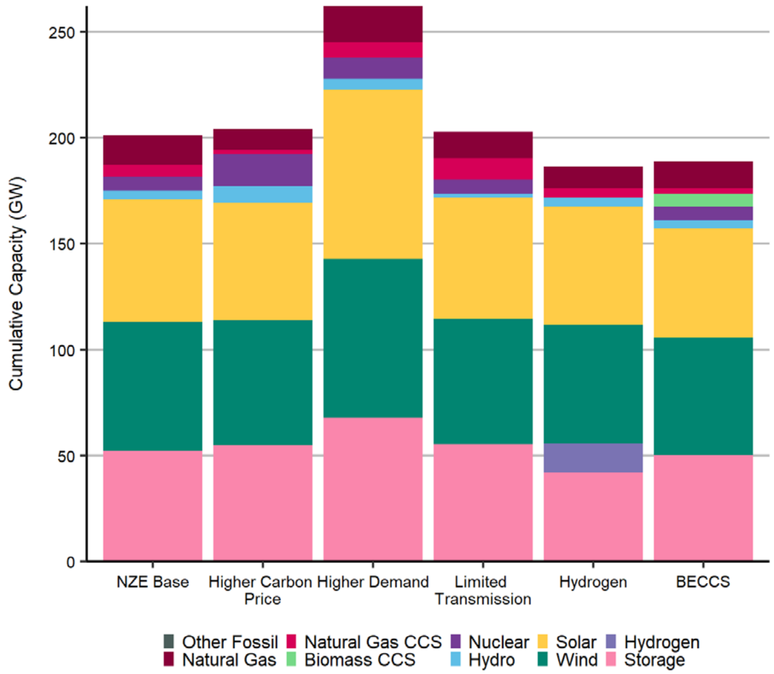

Figure NZ.6:
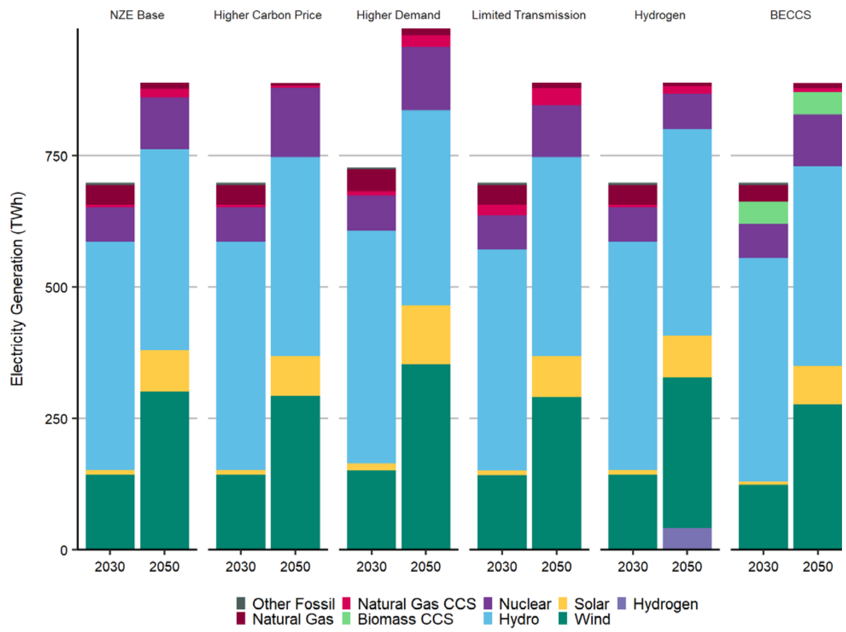
Electricity Generation by Technology in Different Scenarios



KEY TRENDS:

Electricity Supply in Alternative Net Zero Electricity Scenarios

- The Higher Carbon Price scenario increases nuclear and hydro but reduces natural gas generation, relative to the NZE Base scenario.
- The Limited Transmission scenario increases natural gas CCS generation in Alberta and Saskatchewan, relative to the NZE Base scenario.
- The BECCS scenario provides a technology pathway for economy wide GHG emissions reductions.
- Increased demand in the Higher Demand Scenario is mainly satisfied by solar, wind, and nuclear power.
- The Hydrogen scenario reduces the capacity and generation levels of all other low/zero-carbon emissions technologies except those of hydropower, relative to the NZE Base scenario.

Higher Carbon Price Scenario

In the Higher Carbon Price scenario, we see reductions in capacity and electricity generation by natural gas units in 2050 compared to the NZE Base scenario. Cumulative new natural gas capacity additions are 30% lower than NZE Base by 2050. Compared to NZE Base, natural gas-fired generation is 60% lower in 2050. Natural gas CCS is also impacted by the higher carbon price. Our assumption is that any residual CO_2 emissions that are not captured by the CCS process (10% of the combustion emissions) will see the full carbon price. Even though the carbon price only applies to this 10%, the higher carbon price increases the average cost of electricity produced by natural gas CCS by about 50% relative to the NZE Base scenario. That makes natural gas CCS less competitive. Compared to NZE Base, natural gas CCS cumulative capacity additions are 60% lower and electricity generation is 70% lower. The reductions in natural gas-fired generation capacity is offset by an increase in hydropower and nuclear SMR. Hydropower and SMR see a doubling of cumulative new capacity additions compared to the NZE Base scenario. Furthermore, this is the only scenario where we observe the addition of SMR units outside of Ontario and New Brunswick, with Alberta, Saskatchewan, and Nova Scotia seeing SMR additions.

Higher Demand Scenario

The Higher Demand scenario assumes a higher level of electrification and therefore about 12% higher electricity demand overall, or about 104 TWh in 2050. In 2050, the higher electricity demand in this scenario is satisfied by increased solar (+ 33 TWh), wind (+51 TWh), nuclear (+23 TWh), and natural gas CCS (+5 TWh) generation compared to NZE Base. Compared to the NZE Base scenario, those four technologies see a supply increase of 42%, 17%, 23%, and 31%, respectively. The installed storage capacity is 30% or about 16GW higher than NZE Base. The level of hydropower generation remains relatively unchanged.

Limited Transmission Scenario

The Limited Transmission scenario only sees notable changes in the four western provinces. In the NZE Base scenario the hydropower resources in B.C. and Manitoba partially provide system flexibility to manage variable wind and solar power supply in Alberta and Saskatchewan. This process is facilitated by the addition of new transmission capacity. The Limited Transmission scenario inhibits new transmission capacity additions and consequently the combined wind and solar power generation declines by about 5% relative to NZE Base. This reduction in generation is filled by a higher level of natural gas CCS units in Alberta and Saskatchewan. Compared to NZE Base, the Limited Transmission scenario sees a doubling of natural gas CCS capacity and generation.

Hydrogen Scenario

In many net-zero scenarios in previous studies,[46] low-carbon hydrogen plays an important role in many sectors, and hydrogen production increases. Our Hydrogen scenario assumes the existence of a relatively mature market for hydrogen in Canada, where hydrogen costs through electrolysis and natural gas with CCS have fallen significantly and supplies of low-carbon hydrogen are accessible for electricity producers. This supply of hydrogen is assumed to be exogenous to the producers, that is, they do not have to produce the hydrogen themselves, but purchase hydrogen at a delivered price, assumed to be about $2020 US$1.00/kg by 2050. We assume two hydrogen-fired generation technologies, hydrogen combined cycle and hydrogen simple cycle. In this scenario, we observe a cumulative hydrogen-fired generation capacity addition of 13 GW. Hydrogen technologies impact other technologies in a complex manner.

Under the assumed conditions, hydrogen technologies have lower overall economic costs compared to all natural gas technologies. Consequently, we see a 25% reduction in 2050 of non-CCS natural gas capacity (i.e., combined cycle and simple cycle) compared to NZE Base. Furthermore, the GHG emissions intensity of hydrogen combined cycle technology is lower than natural gas CCS. Therefore, natural gas CCS sees a 20% capacity reduction in 2050 compared to NZE Base.

[46] For example, the IEA's Net Zero by 2050 report projects the hydrogen-based fuel in the global energy mix to grow from about 90 Mt in 2020 to 530 MT in 2050. According to the IEA about 100 MT of hydrogen will be used to produce electricity in 2050, where currently the contribution of hydrogen for electricity generation is negligible.

The Hydrogen scenario also sees a 10% reduction in wind and solar capacity relative to NZE Base in 2050. The overall economics of the use of hydrogen for electricity supply is more favorable than building wind, solar and the additional flexible capacity they necessitate to balance supply and demand. Similarly, hydrogen technologies are more competitive than nuclear under the assumed conditions in most of the analysis period. Therefore, no new nuclear growth is seen in this scenario. Hydropower capacity remains unchanged compared to NZE Base.

Finally, hydrogen units also displace 32% of the storage capacity in 2050 compared to NZE Base as hydrogen-fired generating technologies can partially satisfy the overall electric power system's flexible capacity requirements.

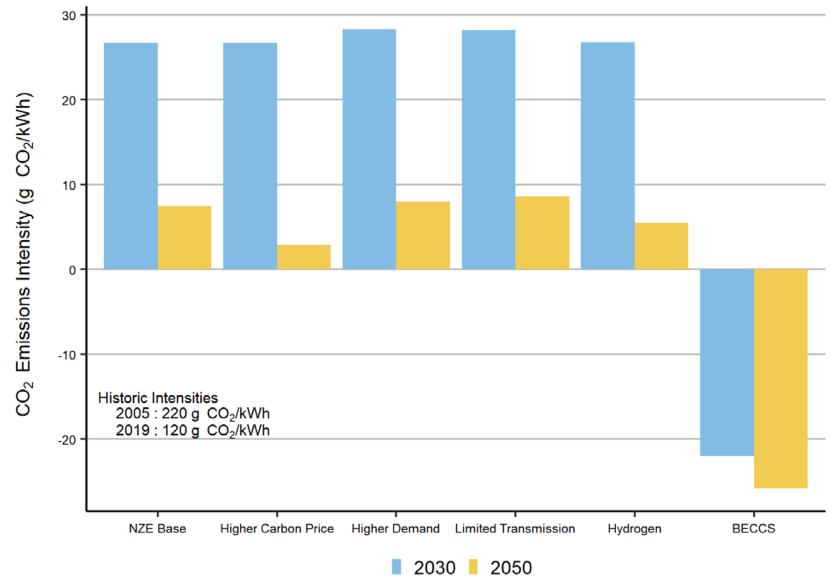
BECCS Scenario

The BECCS scenario assumes the availability of biomass CCS units for electricity generation in Alberta and Saskatchewan. Biomass CCS is considered to have negative GHG emissions, and we assume that the technology would get credit for carbon removal from the atmosphere. The credit is assumed to be calculated using the full carbon price. As the carbon price increases, biomass CCS units become a negative cost generation option, where its average cost of electricity in 2050 is -$85/MWh. Therefore, biomass CCS partially displaces all other generation technologies in Alberta and Saskatchewan. Relative to NZE Base, we estimate the resulting reduction in natural gas CCS generation in 2050 to be 56% and that of combined wind and solar to be about 15%.

The cumulative biomass CCS capacity addition by 2050 is 6 GW. Due to the limitations in available biomass resources, we assume this is the maximum possible biomass CCS capacity. At higher carbon prices, it may be economically competitive to import biomass for electricity production from other regions into Alberta and Saskatchewan, where CCS is viable. However, further analysis is required to verify this assumption.

Due to the carbon removal capability of biomass CCS, the electricity system in Canada becomes a net negative emissions economic sector in the BECCS scenario.

Figure NZ.7:
GHG Emissions Intensity of the Electricity Sector in Canada in Different Scenarios



GHG Emissions Intensity of Electricity Sector in Canada

Figure NZ.7 shows the GHG emissions intensity of the electricity sector in Canada in 2030 and 2050 in all scenarios we considered, compared to 2005 and 2019 levels.

In all scenarios, except the BECCS scenario, the GHG emissions intensity of Canada's electricity sector reaches about 27 grams of carbon dioxide equivalent per kilowatt-hour (gCO_2/kWh) in 2030. The value is 78% lower than the electricity sector emissions intensity in 2019. The emissions intensity further reduces in 2050 but varies across scenarios. The NZE Base scenario emissions intensity in 2050 is 8gCO_2/kWh, a 93% reduction compared to the emissions intensity in 2005. The Higher Carbon Price scenario sees the 2050 emissions intensity declining to 3gCO_2/kWh. While significant emissions reductions are achieved, none of the scenarios, except BECCS, see the overall electricity sector reaching net-zero.

Almost all of the remaining emissions come from natural gas-fired conventional units, which generate electricity infrequently, and uncaptured emissions from natural gas CCS units. Blending renewable natural gas with natural gas could potentially further reduce the small amount of remaining emissions in the sector, or provide a pathway for negative emissions if coupled with CCS. However, we have not assessed the potential of renewable natural gas to decarbonize Canada's electricity sector in this analysis.

The BECCS scenario sees the emissions intensity of the electricity sector going net negative, through carbon removal by the biomass CCS units. This would provide some emissions allowances for other economic sectors in Canada's path towards a net-zero future.

The electricity sector could play an important role in achieving deeper emissions reductions in Canada's energy system, both by reducing emissions from generating electricity and by reducing emissions in other sectors by electrification. Our analysis shows that there are many technological pathways to achieve significant emission reductions in the electricity sector. The majority of technologies required are available today, and Canadian electric utilities have experience in building and operating them. In Canada's pathway towards a net-zero future, the country's electricity sector will have multiple roles, including the supply of energy and potentially carbon removal through investing in negative emissions technologies.

KEY UNCERTAINTIES:
Net-Zero Electricity Results

Economics: The results and trends presented in this section are driven by the economic assumptions made on capital and operating costs of generating technologies, storage, and transmission lines. Any changes to our assumptions, particularly the ones made for variable renewables and storage, could potentially alter the results.

Policy Assumptions: The analysis makes hypothetical carbon pricing assumptions. The level of stringency and mechanisms of the carbon pricing system could potentially change the results.

Transmission System Representation: The current analysis does not model intra-provincial transmission systems. A need for significant increases in intra-provincial transmission in a given scenario can vary the results.

Demand profile: The demand profiles (i.e., how electricity demand changes over different time periods) used are constructed using historic observations. Changes to end-use energy demand, particularly under higher electrification, could impact the results.

Technology Representation: The analysis models only a limited number of generation technologies. Several other zero/low emissions technologies as well as grid management options such as demand side management exist. The inclusion of them could potentially change the comparative results.

Access and Explore Energy Futures Data

Datasets related to EF2021:

- **Figure Data:** Download the EF2021 figure data [EXCEL 365 KB]
- **Data Appendix:** The Energy Futures Data Appendix has customizable, downloadable tables arranged by variable (macroeconomic drivers, end-use demand, crude oil production, etc.) and publication year.
- **Machine Readable Files:** Looking to download all of the EF2021 data at once? It is available on Open Government.

Energy Futures Fact Sheets

- Deep dive into the projections with more detailed datasets, including monthly projections for:

  EF2021 Overview | Electricity | Energy Demand | Conventional Oil | Natural Gas | Natural Gas Liquids | Oil Sands

Explore Energy Futures – Interactive Data Visualization

Explore Canada's Energy Future with an interactive tool that allows users to visualize, download, and share the data behind long-term energy outlooks.

Student Resources

In partnership with Ingenium, the CER developed educational activities based on Canada's forecasted energy demand and supply.

Targeted at students between the grades of 9 and 11, the activities encourage students and educators to explore Canada's energy ecosystem using an interactive tool. This tool allows users explore how the future of energy in Canada over the long term. The material and student resources are available here.

Data Science with Open Data

Partnered with Fireside Analytics, this course is an introduction to Data Science with Open Data sets and R Studio. Learners will learn common buzzwords used in Data Science and will do hands-on labs visualizing and analyzing Open Data from the Canada's Energy Future series. This course is designed for learners who are new to computer programming and data science.

About the Canada Energy Regulator

The Canada Energy Regulator (CER) works to keep energy moving safely across the country. We review energy development projects and share energy information. We enforce some of the strictest safety and environmental standards in the world in a manner that respects the Government of Canada's commitments to the rights of the Indigenous peoples of Canada. The CER regulates:

- Oil & Gas Pipelines – Construction, operation, and abandonment of interprovincial and international pipelines and related tolls and tariffs.
- Electricity Transmission – Construction and operation of international power lines and designated interprovincial power lines
- Imports, Exports & Energy Markets – Imports and exports of certain energy products; monitoring aspects of energy supply, demand, production, development and trade.
- Exploration & production – Oil and gas exploration and production activities in the offshore and on frontier lands not covered by an accord.
- Offshore renewables – Offshore renewable projects and offshore power lines.

The Energy Information Program is one of four core CER responsibilities. We collect, monitor, analyze, and publish fact-based information on energy markets and supply, sources of energy, and the safety and security of pipelines and international power lines. Using tools like interactive pipeline maps and visualizations, we make complex pipeline and energy market data user-friendly and accessible.

Our Commitment:

- Canadians have access to and use energy information for knowledge, research, and decision making.
- Canadians have access to community specific information about CER-regulated pipelines, powerlines, and other energy infrastructure.
- Broader and deeper collaboration with stakeholders and partners informs our energy information.

About this Report

The CER's Energy Information core responsibility is closely linked to its mandate and responsibilities under the Canadian Energy Regulator Act (Act), which includes advising and reporting on energy matters. As well, under Part 7 of the Act, the CER regulates the export and import of natural gas and the export of natural gas liquids, crude oil and petroleum products, and electricity. The CER must ensure that, if authorized, oil and gas exports are surplus to Canadian requirements. The CER's monitoring of energy markets and assessments of Canadian energy requirements and trends helps support the discharge of its regulatory responsibilities. This report, Canada's Energy Future 2021: Energy Supply and Demand Projections to 2050, is the continuation of the Canada's Energy Future series, and projects long-term Canadian energy supply and demand trends.

General Questions

energyfutures@cer-rec.gc.ca

If a party wishes to rely on material from this report in any regulatory proceeding before the CER, it may submit the material, just as it may submit any public document. Under these circumstances, the submitting party in effect adopts the material and that party could be required to answer questions pertaining to the material.

Appendix 1:

Domestic Climate Policy Assumptions

This appendix reviews the domestic climate policy assumptions included in the Evolving Policies Scenario and the Current Policies Scenario. The Current Policies Scenario includes only domestic policies currently in place. The Evolving Policies Scenario assumes greater policy action over time, at roughly the same pace as recent historical policy implementation. It does this by assuming a hypothetical suite of domestic policy initiatives that build upon current policies. Some Evolving Policies Scenario policies increase the stringency or coverage of Current Policies Scenario policies. In these cases, the Evolving Policies Scenario policy in question takes over from the Current Policies Scenario policy. For example, in the Evolving Policies Scenario Canada's carbon pricing increases from the Current Policies Scenario schedule of $170/t by 2030 to $470/t by 2050.

In addition to extending Current Policies Scenario policies, the Evolving Policies Scenario also includes support for technologies that currently have limited commercial application. This means that these technologies see greater adoption through our Evolving Policies Scenario projection compared to the Current Policies Scenario, without adoption necessarily being explicitly driven by a particular policy. Examples include high-efficiency natural gas heat pumps for buildings, hydrogen fuel cells for heavy trucking and industry, utility scale battery storage, electrification and efficiency improvements in the industrial sector, and reduced emission intensity of oil and gas production.

Policy inclusion criteria for the Current Policies Scenario

The Current Policies Scenario includes energy and climate policies that were expected to be implemented in Canada at the time of analysis. To determine whether a policy was included in the analysis we applied the following criteria:

- the policy was publicly announced by 1 August 2021;
- there was sufficient information available to model the policy; and
- the policy was expected to significantly change our energy system projections.

Policy inclusion criteria for the Evolving Policies Scenario

The Evolving Policies Scenario includes all Current Policies Scenario policies. It adds to these a hypothetical suite of future policy developments, which aim to approximate "greater policy action over time, at roughly the same pace as recent historical policy implementation." Hypothetical Evolving Policies Scenario policies are designed based on the following premises:

- Announced policies that are being developed are included to the extent possible. Simplifying assumptions are made as required by a lack of regulatory detail.
- The types of hypothetical future policies that are modelled have historical precedent in those implemented by federal, provincial, or municipal governments.
- Policies gradually strengthen over time, as opposed to a concentration of policy development at a given time.

Table A1.1 provides an overview of the major policies included in the Current Policies and Evolving Policies Scenarios. All dollar values are given in nominal terms, unless otherwise stated.

Table A1.1

Overview of Domestic Climate Policies and EF2021 Assumptions[47]

Region	Policy or Strategy	Description	Assumption in EF2021 *Evolving and Current Policies scenarios unless otherwise noted*
Federal	Backstop Carbon Pricing	Applies a regulatory charge on fossil fuels at the end-use level. Industrial sectors that qualify for the Output Based Carbon Pricing System are exempt from fuel charge.	The fuel charge rises from \$30/t in 2020 to \$50/t CO_2e by 2022, then to 170\$/t by 2030. **Current Policies:** The fuel charge is constant from 2030 to 2050. **Evolving Policies:** The fuel charge increases \$15/t annually from 2030 to 2050, rising to 470\$/t by 2050.
Federal	Output Based Carbon Pricing System	A performance-based carbon pricing system for industrial facilities. Applies a regulatory charge to industrial sectors based on their emissions intensity of output.	**Current Policies:** Most industrial sectors are required to reduce their emissions intensity of output by 20% relative to their 2014 to 2016 average from 2020 to 2050. The backstop carbon price is applied to residual emissions. **Evolving Policies:** Most industrial sectors are required to reduce their emissions intensity of output by 20% relative to their 2014 to 2016 average from 2020 to 2050, which then declines by 2% annually until 2050. The backstop carbon price is applied to residual emissions.
Federal	Phase out of coal-fired generation of electricity	A carbon intensity performance standard for coal-fired power plants.	Limits emissions intensity of existing coal-fired electricity generation to 370 CO_2e/GWh by 2030. No new coal-fired power plants are built.
Federal	Methane Regulations for the Upstream Oil and Gas Sector	Oil and gas facilities are required to adopt minimum standards for methane control technologies.	A minimum methane control technology is required to take market share from 2020 to 2030.
Federal	Zero emission passenger vehicle incentives	Market shares are adjusted to account for zero-emission passenger vehicles for federal policies.	Major policies include the iZev subsidy program, funding for charging network initiatives and tax write-offs for businesses. Quebec and B.C.'s zero emission vehicle mandates are modelled separately (described below). **Evolving Policies:** Zero emissions passenger vehicle new sales reach 100% by 2035. Remote communities and the territories are assumed to be exempt. Given that a federal mandate or regulation to reach 100% ZEV sales does not currently exist, we make several simplifying assumptions: ZEVs are available to meet Canadian demands, Canadian demands for vehicle types (such as car vs trucks/SUVs) are similar to current levels, ZEV adoption accelerates as we approach 2035, and increased deployment of electric vehicle infrastructure underlies ZEV adoption.
Federal	Northern REACHE Program	Program to reduce diesel use for electricity and heat in remote communities.	Increased market share for alternative technologies.
Federal	Energy Efficiency Regulations	Minimum energy efficiency standards for energy using technologies in the residential, commercial, and industrial sectors (e.g. space conditioning equipment, water heaters, household appliances, lighting).	Includes Amendment 16 to the Energy Efficiency Regulations. Major standards include minimum fuel utilization efficiencies for natural gas furnaces, a minimum energy factor for gas water heaters and ban of incandescent light bulbs. **Evolving Policies:** Includes Amendment 17 to the Energy Efficiency Regulations. Major standards include increasing the energy efficiency performance of home appliances, in addition to commercial space conditioners.

[47] For an exhaustive review of climate measures in Canada, see Environment and Climate Change Canada's Fourth Biennial Report on Climate Change, and Canada's revised NDC

Region	Policy or Strategy	Description	Assumption in EF2021 *Evolving and Current Policies scenarios unless otherwise noted*
Federal	Light-duty vehicle GHG emissions standards	New passenger vehicles and light-commercial vehicles/light trucks sold in Canada must meet progressively more stringent GHG emission standards.	**Current Policies:** We assume the fuel economy of new passenger cars and light trucks improves by 5% annually from 2022 to 2030, driven by increasing standards which will be aligned with the U.S. Environmental Protection Agency and currently under development. From 2031 to 2050 fuel economy improves by 2% per year for both passenger cars and light trucks. **Evolving Policies:** The fuel economy of new passenger cars and light trucks improves by 5% annually from 2020 to 2050. The fuel economy of new light trucks improves by 5% per year from 2022 to 2030, and 3.5% from 2031 to 2050.
Federal	Heavy-duty vehicle GHG emissions standards	New heavy duty vehicles sold in Canada must meet progressively more stringent GHG emissions standards.	**Current Policies:** We assume the fuel economy of new heavy duty vehicles improves by 2.25% per year from 2020 to 2030, driven by more stringent standards that require improvement covering up to model year 2027. Improvement slows over the later decades to 0.5% from 2031 to 2050. **Evolving Policies:** The fuel economy of new heavy duty vehicles improves by 2.25% per year from 2020 to 2050.
Federal	Clean Fuel Standard	Reduction in carbon intensity of gasoline and diesel over time, through several mechanisms, including: supplying low-carbon fuels (e.g. ethanol), end-use fuel switching in transportation fuels (e.g. electric and hydrogen vehicles), and upstream projects (e.g. carbon capture and storage).	**Current Policies:** Carbon intensity decrease of 12gCO_2e/MJ below 2016 levels by 2030. **Evolving Policies:** Continues same rate of decrease (about 1.2g CO_2e/MJ) from 2031 to 2050. Increased renewable natural gas blending, incentivized by credit creation mechanism.
Federal	Small Modular Reactor (SMR) Action Plan	Plan for the development, demonstration, and deployment of SMRs for multiple applications.	**Evolving Policies:** Assumes SMR development in Ontario and New Brunswick.
Federal	National energy code for buildings	Sets out technical requirements for the energy efficient design and construction of new buildings.	Assumes that the 2017 building code applies throughout the projection period, with marginal efficiency improvements to building shells and space conditioning. Evolving Policies: Assumes that new buildings are "net-zero energy ready" by 2030 across provinces and territories by substantially increasing the efficiency of building shells and space conditioning technologies.
Federal	Renewable Fuels Regulations	Minimum renewable fuel content for all regions except for Newfoundland and Labrador, and the Territories.	Specifies a minimum renewable fuel content of 5% for gasoline and 2% for diesel fuel sold in Canada by volume.
British Columbia	Zero- emissions vehicle mandate and incentives	Requires automakers to sell a minimum share of zero- or low- emission vehicles in addition to government-funded purchase subsidies and charging network incentives.	Follows the zero-emission vehicles act; Achieves 10% light duty zero-emission vehicles sales by 2025, 30% by 2030, and 100% by 2040.
British Columbia	CleanBC Better Homes and Better Buildings programs	Incentives for residential and commercial building efficiency improvements.	Rebates for switching to high-efficiency space and heating equipment, and building shells. Includes $3,000 rebate for types of residential heat pumps if switching from fossil fuel heating.
British Columbia	CleanBC industrial electrification		Electrification of planned natural gas production in the Peace region. **Evolving Policies:** Increased electrification of other industrial sectors.

Region	Policy or Strategy	Description	Assumption in EF2021 *Evolving and Current Policies scenarios unless otherwise noted*
British Columbia	CleanBC Industry Fund	Government investment in greenhouse gas-reducing projects and clean technologies.	Gradual market adoption of near-commercial clean industrial technologies.
British Columbia	Clean Energy Amendment Act	Sets a minimum percentage of electricity generation that must be provided by non-fossil fuels.	100% of provincial electricity generation must be provided by renewable or "clean" sources by 2025.
British Columbia	Energy Efficiency Act	Sets energy efficiency performance standards for energy using technologies.	Minimum energy efficiencies for household appliances, heating and cooling systems, lighting, industrial equipment.
British Columbia	Renewable Fuel Regulation	A minimum renewable fuel content for gasoline and diesel fuel.	5% ethanol content in gasoline, 4% biodiesel content in diesel
British Columbia	Low Carbon Fuel Standard	Requires a decrease in average carbon intensity of transport fossil through several compliance pathways.	Decrease in average carbon intensity of transport fossil fuels by 20% in 2030 relative to 2010.
British Columbia	Renewable Natural Gas Regulation	Requires that a portion of natural gas consumption be renewable natural gas by 2030.	Requires that 15% of natural gas consumption be provided by renewable natural gas by 2030. **Evolving Policies:** Renewable natural gas consumption increases to 20% by 2050.
Alberta	Technology Innovation and Emissions Reduction (TIER) Regulation	Carbon pricing system for large industrial emitters. Emitters pay a carbon price if they fail to meet the required emissions intensity reductions, and can earn credits if they surpass their required reductions.	Oil sands producer's emissions intensity benchmarks are the maximum of facility specific benchmarks (these decline 1% annually), or TIER "high performance" benchmarks from 2020 to 2030. Benchmarks remain at 2030 levels from 2031 to 2050. Evolving: Emissions intensity benchmarks decline at 2% relative to 2020 levels from 2031 to 2050.
Alberta	Renewable Fuels Standard	Requires renewable fuels to be blended into gasoline and diesel fuel.	5% ethanol content of gasoline, 2% biodiesel content of diesel.
Alberta	Methane Emissions Reduction Regulation	Requires the reduction of methane emissions from oil and gas operations by 45% by 2025 relative to 2014 levels.	A minimum methane control technology is required to take market share from 2020 to 2030.
Saskatchewan	Boundary Dam Carbon Capture Project	This project stores and captures CO_2 emissions from a 115MW coal plant	CCS projections account for the project.
Saskatchewan	Ethanol Fuel Act and Renewable Diesel Act.	Requires renewable fuels to be blended into gasoline and diesel fuel	7.5% ethanol content of gasoline, 2% biodiesel content of diesel.

Region	Policy or Strategy	Description	Assumption in EF2021 *Evolving and Current Policies scenarios unless otherwise noted*
Saskatchewan	Methane Action Plan	Requires a reduction in methane emissions from oil and gas extraction by 40 to 45% of 2015 levels	A minimum methane control technology is required to take market share from 2020 to 2030.
Manitoba	Strengthened Biofuels Act	Requires renewable fuels to be blended into gasoline and diesel.	Minimum of 10% ethanol in gasoline, and 5% biodiesel in diesel.
Manitoba	Efficiency Manitoba Act	Provides consumers with rebates and other incentives.	Includes lighting, space conditioning, and building shell rebates across residential, commercial, and some industrial sectors.
Manitoba	Green Energy Equipment tax credit	Tax credit for residential and commercial geothermal heat pumps.	15% tax credit.
Ontario	Strengthened Greener Gasoline Regulation and Greener Diesel Regulation (O Reg 97/14)	Requires renewable fuels to be blended into gasoline and diesel.	Requires 15% ethanol blending in gasoline by 2030and 4% biodiesel blending in diesel by 2020.
Quebec	Roulez vert program	Incentives for electric vehicles and charging station installations.	Rebates include $8,000 for new vehicles and $600 for home charging stations.
Quebec	Zero-emissions vehicle standard	Requires automakers to sell a minimum share of zero- or low-emission passenger vehicles via a credit market.	Credit target increases gradually to reach 22% by 2025. **Evolving:** Credit target increases to 100% zero-emissions vehicle new sales by 2035.
Quebec	Renewable Natural Gas Mandate	Requires that a portion of natural gas consumption be renewable natural gas.	1% of total by 2020 and 5% of total by 2025. **Evolving:** Increases gradually to 20% by 2050.
Quebec	Chauffez Vert program	Rebates for residential renewable energy space or water heating systems, if replacing fossil fuel system.	$1,275 for light fuel oil system replacements, $850 for propane system replacements.
New Brunswick	Renewable Portfolio Standard	Requires a minimum share of in-province electricity sales to be generated by renewable sources by 2020.	Minimum share is set to 40%. Imports from other jurisdictions and energy efficiency improvements qualify for compliance.
New Brunswick	Energy Efficiency Programs	Provides purchase incentives for energy efficient appliances in residential, commercial, and industrial sectors	Various rebates for approved technologies

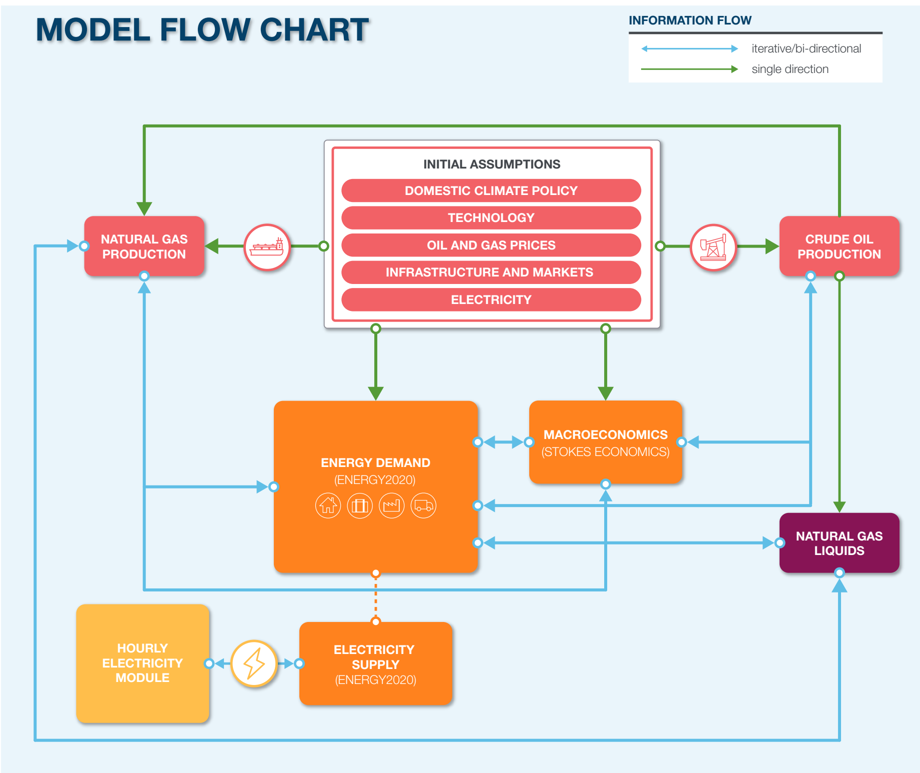
Region	Policy or Strategy	Description	Assumption in EF2021 *Evolving and Current Policies scenarios unless otherwise noted*
Nova Scotia	Electricity Generation GHG emissions cap.	Requires declining GHG emissions from in-province electricity generators.	Requires emissions from the electricity sector to decline to 4.5Mt by 2030.
Nova Scotia	Renewable Electricity Regulations	Requires a minimum percentage of electricity consumption be provided by renewable resources.	Set at 40% by 2020.
Nova Scotia	Maritime Link	High-voltage transmissions line that will connect Nova Scotia to the Muskrat Falls hydroelectric project in Newfoundland.	Included.
Nova Scotia	EfficiencyNS Programs	Incentives for residential, commercial, and some industrial sectors.	Included.
Newfoundland	Energy Efficiency Programs	Incentives for residential, commercial, and some industrial sectors.	These programs include a home energy savings program, heat pump rebates, and commercial sector rebates for select appliances.
Prince Edward Island	EfficiencyPEI Rebates	Incentives for residential, commercial, and some industrial sectors.	Various rebates on energy efficient appliances, such as heat pumps, solar systems, biomass heating, and fuel-efficient furnaces.
Northwest Territories	2030 Energy Strategy	Measures that aim to support low-carbon energy for transportation and space heating. Incentives for energy efficiency and conservation.	Key measures include: promoting the use of wood as an alternative source of energy to fossil fuels, supporting the development and implementation of community energy plans, incentives for energy efficiency and alternative energy projects, support for alternatives to diesel electricity generators, rebates for zero and low emissions vehicles.
Yukon	Our Clean Future	Various measures that aim to reduce greenhouse gas emissions.	Key measures include: 10% zero emissions vehicles new sales by 2025 and 30% by 2030, zero-emission vehicles rebates, blending of renewable fuels into diesel and gasoline, energy efficiency incentives and regulations, and renewable energy projects for remote communities.

Appendix 2:

Overview of the Energy Futures Modeling System

Energy Futures includes a wide range of projections for Canadian energy supply and demand. These projections are the result of a modeling system consisting of several interactive components (or modules) which produce future Canadian energy trends. Figure A2.1 outlines the system in a diagram.

Figure A2.1:
Energy Futures Modelling Framework Flow Chart



In EF2021, the full Energy Futures Modeling System is used to create projections for the Evolving and Current Policies Scenarios. The six Towards Net-Zero electricity scenarios were modeled using the hourly electricity module.

Overview of Model Components

Initial Assumptions: The starting point for Energy Futures analysis is the development of initial assumptions on various aspects of the global and Canadian energy system. Benchmark crude oil and natural gas price assumptions are based on a survey of projections by other forecasting agencies like the IEA and the U.S. Energy Information Administration, complemented by internal analysis. It is important to note that these assumptions are not predictions of future crude oil and natural gas prices, but necessary inputs for the analytical process. Other starting assumptions include energy and climate policies and programs, scenario details such as technology fuel pathways, and volumes of LNG exports.

Oil Production: This module provides crude oil production projections for the various regions and crude types in Canada, based on our price assumptions and other factors such as carbon pricing and technological improvements. It includes an oil sands module, and non-oil sands deliverability module for western Canada, and analysis of other regions in Canada.

Gas Production: This module estimates the production of natural gas throughout Canada. The module relies upon oil and natural gas price assumptions, LNG export assumptions, as well as a crude oil production estimated from the oil supply module and other factors such as technological change and policies. The module includes the Western Canadian Sedimentary Basin natural gas deliverability model, as well as trend analysis for other producing regions (e.g. New Brunswick).

Macroeconomics: Macroeconomic projections for each of the scenarios were provided by Stokes Economic Consulting Inc. Stokes developed unique projections of key macroeconomic indicators such as GDP, exchange rate, and industry gross output for each of the scenarios, based on the price assumptions and output of the CER's supply and demand models.

Demand: The demand projections are developed using ENERGY2020: a detailed energy model created by Systematic Solutions Incorporated. It creates projections for energy demand and electricity generation based on historical energy data and, where needed, assumed future trends for parameters such as supply, demand, economic growth, efficiency, prices, and investment.

Electricity: The electricity projections are developed using ENERGY2020: a detailed energy model created by Systematic Solutions Incorporated. It creates projections for energy demand and electricity generation based on historical energy data, and where needed, assumed future trends for parameters such as supply, demand, economic growth, efficiency, prices, and investment. The ENERGY2020 projections are guided by the hourly electricity module, which provides increased temporal granularity which is important for analyzing how the system responds to increasing levels of variable renewable energy, storage, and transmission.

Natural Gas Liquids: This module provides estimates of NGL supply and demand in Canada. The module simulates various categories of liquids: ethane, butane, propane, condensate and pentane plus. For each liquid, the module provides estimates of production, supply and demand at the individual provincial/territorial level.

Appendix G

GLOSSARY OF TERMS AND ACRONYMS

APPENDIX G – GLOSSARY OF TERMS AND ACRONYMS

Acronym or Term	Definition
ACP	Annual Contracting Plan
AECO/NIT	Alberta Energy Company/Nova Inventory Transfer - refers to an important storage and exchange point for Canadian natural gas. AECO/NIT is commonly used to refer to the benchmark pricing index for the Alberta natural gas marketplace.
AMI	Advanced Metering Infrastructure
Annual demand	The cumulative daily demand for natural gas over an entire year.
BAU	Business as Usual
BC	British Columbia
BC Hydro	British Columbia Hydro and Power Authority (BC Hydro)
BC-LCFS	*Greenhouse Gas Reduction (Renewable & Low Carbon Fuel Requirements) Act* and the 5 *Renewable & Low Carbon Fuel Requirements Regulation*, which are collectively known as British Columbia's low carbon fuel standard.
Bcf	One billion cubic feet
Bcf/d	One billion cubic feet per day
BCUC	British Columbia Utilities Commission, or Commission - the BCUC is the provincial body regulating utilities in British Columbia.
BERC	Biomethane Energy Recovery Charge
CCA	Washington's *Climate Commitment Act*
CCAA	*Climate Change Accountability Act*
CCE	Cost of Conserved Energy - a standard method for expressing cost-benefit test results for energy efficiency initiatives in dollars per unit of energy savings. Electric utilities use the CCE to express the net cost of saving one unit of utility-supplied energy. In the 2017 LTGRP, FEI uses the CCE to express in dollars per GJ the UCT results; thus the CCE represents annualized and, where applicable, discounted UCT costs divided by annual energy savings.
CCUS	Carbon capture utilization and storage
CEA	*Clean Energy Act*

Acronym or Term	Definition
CEUS	Commercial End-use Study
Clean Growth Pathway	Clean Growth Pathway to 2050
CNG	Compressed natural gas
CNZEAA	Canadian Net-Zero Emissions Accountability Act
Commission	*see British Columbia Utilities Commission, BCUC*
CO_2e	Carbon dioxide-equivalent - a unit to express an amount of greenhouse gas emission in terms of carbon dioxide (CO_2) based on the relative global warming potential of each gas. Commonly expressed in million tonnes, i.e. $MtCO_2e$.
CPCN	Certificate of Public Convenience and Necessity - a certificate obtained from the British Columbia Utilities Commission under Section 45 of the *Utilities Commission Act* for the construction and/or operation of a public utility plant or system, or an extension of either, that is required, or will be required, for public convenience and necessity.
Company	FortisBC Energy Inc.
Core	A category of FEI customers rely on FEI to both procure their gas supply and also deliver this supply to their meters in a non-interruptible manner. This includes Rate Schedules 1, 2, 3, 4, 5, and 6.
CPR	Conservation Potential Review - a comprehensive economic analysis of energy conservation potential that looks at where energy savings opportunities exist
CTS	Coastal Transmission System
Daily demand	The amount of natural gas consumed by the Utilities' customers throughout each day of the year.
Declaration Act	The Canadian *Declaration on the Rights of Indigenous Peoples Act*
Demand forecast	A prediction of the demand for natural gas into the future for a given period and under a specified set of expected future conditions.
DEP	Diversified Energy (Planning) Scenario
DP	Distribution pressure
DSM	Demand-side management - commonly defined as any utility activity that modifies or influences the way in which customers utilize energy services.

Acronym or Term	Definition
DSM Regulation	Demand-Side Measures Regulation: one of the regulatory instruments that govern utility demand-side measure programs in BC.
Design day, or design hour demand	The maximum expected amount of gas in any one day or hour required by customers on the utility system. Since core customers' demand is primarily weather dependent, design-day or design-hour demand is forecasted based upon a statistical approach called Extreme Value Analysis, which provides an estimate of the coldest day weather event expected with a 1-in-20-year return period. For transportation customers, the design-day is equivalent to the firm contract demand (*also see Peak day*).
EAA	*Environmental Assessment Act*
EECAG	Energy Efficiency and Conservation Advisory Group
EMAT	Electro-Magnetic Acoustic Transducer - a type of advanced in-line inspection technology for pipelines.
ERP	Emissions Reduction Plan
FBC	FortisBC Inc.
FEI	FortisBC Energy Inc.
Firm Transportation	A category of FEI customers who procure their own gas supply but rely on FEI to deliver this supply to their meters in a non-interruptible manner. This includes Rate Schedules 23, 25, and the contracted firm delivery component of Rate Schedule 22 (including 22A and 22B) and other special Rate Schedules.
FIS	Forecast Information System
FPIC	Free, prior, and informed consent
GGRR	Greenhouse Gas Reduction (Clean Energy) Regulation
GHGRS	Greenhouse Gas Reduction Standard
GHG	Greenhouse gas
GJ	Gigajoule - a unit of energy equivalent to one billion joules. One joule of energy is equivalent to the heat needed to raise the temperature of one gram (g) of water by one degree Celsius (ºC) at standard pressure (101.325 kPa) and standard temperature (15ºC).
HEHE	*A Healthy Environment and a Healthy Economy* (a plan released by the federal government)
HP	Horsepower

Acronym or Term	Definition
Huntingdon-Sumas	Gas flow regulating stations on either side of the British Columbia /Washington state (U.S.) border through which much of the regional gas supply is traded.
I-5 Corridor	The natural gas regional market area served by infrastructure located along Interstate-5 in the northwestern U.S. The I–5 corridor includes B.C.'s Lower Mainland and Vancouver Island, Western Washington and Western Oregon.
IAA	*Impact Assessment Act*
IG	Island Generation (BC Hydro) - a cogeneration plant located at Elk Falls, Campbell River that supplies electricity and thermal energy on Vancouver Island.
IGU	Inland Gas Upgrade project
ILI	In-line inspection
IP	Intermediate pressure
ITS	Interior Transmission System
km	Kilometer
kPa	Kilopascal - a metric measurement unit of pressure. Gauge pressure is often given in units with a 'g' appended, e.g. 'kPag'.
kW	kilowatt (a unit of energy equal to one thousand watts) - the commercial unit of measurement of electric power. A kilowatt is the flow of electricity required to light ten 100-watt light bulbs.
kWh	Kilowatt hour (equal to one thousand watts used for a period of one hour) - the basic unit of measurement of electric energy. On average, residential customers in B.C. use about 10,000 kWh per year.
LCT	Low-Carbon Transportation
LICO	Low Income cut-offs
LMIPSU	FEI Lower Mainland Intermediate Pressure System Upgrade Project
LNG	Liquefied Natural Gas - natural gas stored under low temperature, which turns to liquid form. Approximately 600 times as much natural gas can be stored in its liquid state than in its typical gaseous state; however, specialized storage facilities must be constructed.
Load	The total amount of gas demanded by all customers at a given point in time.

Acronym or Term	Definition
LTERP	Long Term Electric Resource Plan – FortisBC Inc.'s LTERP examines future electric demand and supply resource conditions over the next 20 years and recommends actions needed to ensure customers' energy needs are met over the long term.
LTGRP	Long Term Gas Resource Plan – FEI's LTGRP examines future gas demand and supply resource conditions over the next 20 years and recommends actions needed to ensure customers' energy needs are met over the long term.
mm	Millimeter
MMBtu	One million British Thermal Units
MMcf/d	One million cubic feet per day
MMscfd	One million standard cubic feet per day, sometimes also mmscfd
MOP	Maximum operating pressure
MRPO	Minimum Resiliency Planning Objective
$MtCO_2e$	One megatonne of CO_2 equivalent (*also see* CO_2e).
MTRC	Modified Total Resource Cost - a modification to the Total Resource Cost test that is set out in the B.C. Demand-side Measures Regulation to recognize the environmental value of energy conservation.
MW	Megawatt - a unit of power equal to one million watts or one thousand kilowatts, commonly used to measure both the capacity of generating stations and the rate at which electric energy can be delivered.
NGTL	Nova Gas Transmission Ltd.
NOx	Nitrogen oxides - a form of atmospheric pollutants that are regulated in many jurisdictions.
NPS	Nominal Pipe Size (in inches) - a North American set of standard pipe sizes.
NRCan	Natural Resources Canada
NW Natural	Northwest Natural Gas Company
OCAP	Oregon Climate Action Plan
OCU	FEI Okanagan Capacity Upgrade Project
OEM	Original Equipment Manufacturer
Pathways Report	Pathways for British Columbia to Achieve Its GHG Reduction Goals Report

Acronym or Term	Definition
PCF	The Pan-Canadian Framework on Clean Growth and Climate Change
Peak day, peak demand, peak day demand	The maximum expected amount of gas in any one day or hour required by customers on the FEI system. Since Core customers' demand is primarily weather dependent, design-day or design-hour demand is forecasted based upon a statistical approach called Extreme Value Analysis, which provides an estimate of the coldest day weather event expected with a 1 in 20 year return period. For transportation customers, the design-day is equivalent to the firm contract demand (*also see: design day*).
PGR	FEI Pattullo Gasline Replacement Project
PHF	Peak Hour Factor – the ratio of peak hour consumption to peak day consumption
PJ	Petajoule - a unit of energy equal to 1,000 terajoules or 10^6 gigajoules
PM	Particulate matter - the sum of all solid and liquid particles suspended in the atmosphere; most PM particles form as a result of chemical reactions between pollutants.
PNW	Pacific Northwest - a region that is commonly referred to as the three northwestern states of Washington, Oregon, Idaho and the Province of B.C.
Posterity	Posterity Group
PRMP	Price Risk Management Plan
Rate volatility	The amount to which natural gas rates fluctuate and the frequency of those fluctuations.
Resources	The demand side and supply side means available to meet forecasted energy needs. Examples of supply-side resources within the context of resource planning are pipeline looping, compression and storage.
REUS	Residential End Use Study
RG Program Application	FEI's Comprehensive Review and Application for a Revised Renewable Gas Program filed December 17, 2021
RGSD	Regional Gas Supply Diversity Project
RNG	Renewable natural gas
Roadmap	CleanBC Roadmap to 2030
RPAG	Resource Planning Advisory Group

Acronym or Term	Definition
RPS	Renewable Portfolio Standard – a form of regulation requiring a specified percentage of energy/fuel provision to contain renewable energy/fuel.
SACC	Strategic Assessment of Climate Change
SCP	Southern Crossing Pipeline
SCGT	Simple cycle gas-fired turbine – typically for electricity generation.
SFC	Seaspan Ferries Corp.
SOx	Sulfur oxides – a form of atmospheric pollutants that are regulated in many jurisdictions.
TAC	Technical Advisory Committee – a group of members of the public with significant interest, stake, and experience in determining energy conservation potential in BC; this group provides input and feedback during development of the BC CPR.
TJ	Terajoule - a unit of energy equal to 1,000 gigajoules.
TJ/d	Terajoules per day
TLSE	Tilbury LNG Storage Expansion Project
TP	Transmission pressure
Traditional Annual Method	FEI's traditional time-series based method for forecasting annual energy demand.
Traditional Peak Method	FEI's longstanding and well-established method for forecasting peak energy demand.
TC Energy	TC Energy Corporation (formerly TransCanada PipeLines Limited).
TRC	Total Resource Cost - a standard cost-benefit test for energy efficiency initiatives that compares the present value of all costs of efficiency for all members of society with the present value of benefits in order to assess the impacts of a portfolio of energy efficiency initiatives on the economy at large.
TSA	(FEI-BC Hydro) Transportation Service Agreement, which expired April 2022
T-South incident	The Westcoast Energy Inc. (Westcoast) T-South pipeline rupture that occurred on October 9, 2018 and which resulted in capacity restrictions thereafter on the T-South system.
UCA	*Utilities Commission Act*
UN Declaration	United Nations Declaration on the Rights of Indigenous Peoples

Acronym or Term	Definition
UNDRIP Act	*United Nations Declaration on the Rights of Indigenous Peoples Act*
UPC	Use per customer
UPC_{peak}	Peak hour use per customer
UCT	Utility Cost Test - a standard cost-benefit test for energy efficiency initiatives that compares the present value of all costs of efficiency for the utility which offers an energy efficiency program with the present value of benefits in order to assess the impacts of a portfolio of energy efficiency initiatives on the utility specifically.
VBBL	Vancouver Building Bylaw
VIGJV	Vancouver Island Gas Joint Venture - a joint venture of industrial customers (primarily large mills) on Vancouver Island who contract for transportation services as a single entity.
VITS	Vancouver Island Transmission System, also referred to as VI Transmission System
Westcoast	Westcoast Energy Inc. A wholly-owned subsidiary of Enbridge Inc.
Woodfibre LNG project	A small-scale LNG export and processing facility proposed on the site of the former Woodfibre pulp mill near Squamish.

ORDER

WHEREAS:

A. On May 9, 2022, FortisBC Energy Inc. (FEI) filed its 2022 Long Term Gas Resource Plan (LTGRP) pursuant to section 44.1 of the *Utilities Commission Act*, for acceptance by the British Columbia Utilities Commission (BCUC). FEI is not seeking approval of any particular elements identified within the LTGRP;

B. By Order G-##-22 dated [DATE], the BCUC established a written hearing process to review the LTGRP;

C. The BCUC has reviewed the LTGRP and the evidence submitted in the proceeding and considers that acceptance of the LTGRP is warranted.

NOW THEREFORE for the reasons set out in the Decision accompanying this order:

1. The BCUC accepts the FEI 2022 LTGRP as being in the public interest, pursuant to subsection 44.1(6) of the *Utilities Commission Act*.

2. The BCUC directs FEI to comply with all determinations and directives as set out in the Decision.

DATED at the City of Vancouver, in the Province of British Columbia, this (XX) day of (Month Year).

IN THE MATTER OF
the *Utilities Commission Act*, RSBC 1996, Chapter 473

and

FortisBC Energy Inc.
2022 Long Term Gas Resource Plan

BEFORE:
[Panel Chair]
Commissioner
Commissioner

on Date

ORDER

WHEREAS:

A. On May 9, 2022, FortisBC Energy Inc. (FEI) filed its 2022 Long Term Gas Resource Plan (LTGRP) for acceptance by the British Columbia Utilities Commission (BCUC), in accordance with section 44.1(2) of the *Utilities Commission Act* (UCA);

B. FEI's 2022 LTGRP presents FEI's long term view of the demand-side and supply-side resources identified to meet expected future gas demand, reliability requirements, and Provincial greenhouse gas reduction requirements, taking into consideration the cost to FEI's customers over the 20-year planning horizon (2022-2041). The 2022 LTGRP includes a 20-year vision for FEI and culminates in an Action Plan that identifies the activities that FEI intends to pursue over the next four years;

C. In order to inform the 2022 LTGRP, FEI offered stakeholders the opportunity to participate in discussions including, but not limited to, workshops with a resource planning advisory group, community engagement workshops and dialogue with Indigenous communities, industry associations and other advisory groups;

D. FEI's previous LTGRP, the FEI 2017 Long Term Gas Resource Plan, was accepted by the BCUC by Order G-39-19 on February 25, 2019;

E. Section 44.1(5) of the UCA provides that the BCUC may establish a process to review long term resource plans; and

F. The BCUC considers that a public hearing process for the review of FEI 2022 LTGRP is warranted and that a regulatory timetable should be established.

NOW THEREFORE pursuant to section 44.1(5) of the UCA, the BCUC orders as follows:

1. A written public hearing process is established for the review of the FortisBC Energy Inc. (FEI) 2022 Long Term Gas Resource Plan (Application) in accordance with the regulatory timetable as set out in Appendix A to this order.

2. FEI must publish the Public Notice, attached as Appendix B to this order, in display-ad format in appropriate news publications, such as but not limited to, local and community newspapers to provide adequate notice to those parties who may have an interest in or be affected by the Application, as soon as reasonably possible, but no later than Friday, July 8, 2022.

3. FEI of the Application on its social media platforms, no later than Friday, July 8, 2022. FEI must also publish weekly reminder notices on each of these platforms until the conclusion of the intervener registration period on Thursday, July 21, 2022.

4. As soon as is reasonably possible, FEI is directed to publish the Application, this order, and the regulatory timetable on its website and to provide a copy of the Application and this order to:

    a. All invitees and attendees of the stakeholder engagement process outlined in Section 8 of the Application; and

    b. Registered interveners and interested parties in the:

        i. FEI 2017 Long Term Gas Resource Plan proceeding; and

        ii. FEI Annual Review for 2022 Delivery Rates proceeding.

5. Parties who wish to actively participate in the proceeding are to register with the BCUC by completing a Request to Intervene Form, available on the BCUC's website at https://www.bcuc.com/get-involved/get-involved-proceeding.html, by the date established in the regulatory timetable, and in accordance with the BCUC's Rules of Practice and Procedure attached to Order G-15-19.

DATED at the City of Vancouver, in the Province of British Columbia, this (XX) day of (Month Year).

PUBLIC NOTICE

FortisBC Energy Inc. 2022 Long Term Gas Resource Plan

On May 9, 2022, FortisBC Energy Inc. (FEI) filed its 2022 Long Term Gas Resource Plan (LTGRP) for acceptance by the British Columbia Utilities Commission (BCUC), in accordance with section 44.1(2) of the *Utilities Commission Act*.

FEI's long term view of the demand-side and supply-side resources identified to meet expected future gas demand, reliability requirements, and Provincial greenhouse gas reduction requirements, taking into consideration the cost to FEI's customers over the 20-year planning horizon (2022-2041). The 2022 LTGRP includes a 20-year vision for FEI and culminates in an Action Plan that identifies the activities that FEI intends to pursue over the next four years.

HOW TO PARTICIPATE

- **Submit a letter of comment**
- **Register as an intervener**
- **Request intervener status**

IMPORTANT DATES

- **Thursday, July 21, 2022** – Deadline to register as an intervener with the BCUC.

For more information about the Application, please visit the **Proceeding Webpage** on bcuc.com under "Our Work – Proceedings". To learn more about getting involved, please visit our website at **www.bcuc.com/get-involved** or contact us at the information below.
