British Columbia Utilities Commission
Suite 410, 900 Howe Street
Vancouver, BC
V6Z 2N3

Attention: Mr. Patrick Wruck, Commission Secretary

Dear Mr. Wruck:

Re: FortisBC Energy Inc. (FEI)

2022 Long Term Gas Resource Plan (LTGRP)

On February 25, 2019, the British Columbia Utilities Commission (BCUC) issued its Decision and Order No. G-39-19 accepting FEI's 2017 LTGRP and directing FEI to file its next LTGRP on or before March 31, 2022, which was subsequently extended to May 9, 2022.[1]

In accordance with the BCUC's Resource Planning Guidelines and Section 44.1(2) of the *Utilities Commission Act* (UCA), FEI submits the attached 2022 LTGRP for the BCUC's review.

There are no approvals being sought by FEI as part of this LTGRP submission. The LTGRP presents a 20-year view of the demand-side and supply-side resources identified to meet expected future gas demand, reliability requirements and provincial greenhouse gas reduction requirements at the lowest reasonable cost to FEI's customers. The LTGRP includes an action plan that identifies the activities that FEI intends to pursue during the first four years of the 20-year planning horizon. FEI will file separate applications for Certificates of Public Convenience and Necessity, if and as necessary, for any of the identified activities in accordance with the BCUC's guidelines.

FEI respectfully seeks acceptance of its 2022 LTGRP in accordance with Section 44.1(2) of the UCA.

---

[1] By letter dated March 18, 2022, the BCUC approved FEI's extension request to file its 2022 LTGRP by April 29, 2022 and by letter dated April 28, 2022, the BCUC approved FEI's further extension request to file by May 9, 2022.

If further information is required, please contact Ken Ross, Manager, Integrated Resource Planning and DSM Reporting at (604) 576-7343 or ken.ross@fortisbc.com.

Sincerely,

FORTISBC ENERGY INC.

EXECUTIVE SUMMARY

1. INTRODUCTION

FortisBC Energy Inc. (FEI) files this 2022 Long-Term Gas Resource Plan (LTGRP) under section 44.1(2) of the *Utilities Commission Act* (UCA) and is respectfully seeking acceptance by the British Columbia Utilities Commission (BCUC) of the LTGRP as being in the public interest pursuant to section 44.1(6). Consistent with the UCA, the BCUC's Resource Planning Guidelines, and prior BCUC directives, the 2022 LTGRP presents FEI's long-term plan for meeting the forecast peak demand and energy requirements of customers with demand-side and supply-side resources over a 20-year planning horizon (2023 to 2042). FEI's 2022 LTGRP objectives are to:

- Ensure cost-effective, secure and reliable energy for customers;
- Provide cost-effective Demand-side Management (DSM) initiatives and lower-carbon solutions;
- Ensure consistency with provincial energy objectives; and
- Address prior BCUC directives.

The 2022 LTGRP serves as a foundation for further evaluation of gas supply and system infrastructure options for meeting forecast customer needs under different scenarios. The LTGRP is not a substitute for the analysis done to support specific supply or expansion projects, programs or rate design in the future, but rather helps to inform the process of other initiatives. FEI will further evaluate any specific resource projects that are identified within the LTGRP that require BCUC approval and file separate applications with the BCUC as needed in the future.

This 2022 LTGRP is profoundly shaped by the developments in climate change policy in recent years and, in particular, the Province's 2018 CleanBC plan and CleanBC Roadmap to 2030 (Roadmap) which set out ambitious targets for reducing greenhouse gas (GHG) emissions. In response to these policies and the need to reduce GHG emissions, this 2022 LTGRP provides FEI's plan to transition to a low-carbon energy future and transition toward distributing renewable and low-carbon gas. Future resource plans will build on this plan as innovation in low-carbon gas production, supply and use advances.

The foundation for the 2022 LTGRP and this transformational reduction in GHG emissions is FEI's existing infrastructure, service offerings, workforce and logistics, as well as the regional gas supply infrastructure that is vital to serving the energy needs of British Columbians. Table ES-1 provides a summary of FEI customer, demand and pipeline characteristics. Table ES-2 presents the renewable and low-carbon gas resources included in the 2022 LTGRP that, over the planning horizon, along with increased DSM and growth in fuel service for the low-carbon transportation (LCT) sector, are pivotal in reaching BC's GHG emission reduction goals.

Table ES-1: FEI Service Statistics

	2016	2021	Percentage Increase Since 2017 LTGRP
Number of Customers	994,004	1,064,800	7.1%
Annual Demand (PJ)[1]	197	228	15.7%
Peak Day Demand (TJ/day)[2]	1,334	1,399	4.9%
Length of Transmission Pipeline (km)	2,959	2,970	0.4%
Length of Distribution Pipeline* (km)	45,741	47,523	3.9%

** Includes both distribution and intermediate pressure pipelines.*

Table ES-2 Fuel Types and Decarbonization Technologies Used in the 2022 LTGRP

Fuel Type	Description[3]	Life cycle Emission Factor (tCO_2e/GJ)	End use cycle Emission Factor (tCO_2e/GJ)
Natural gas	Natural gas is a naturally occurring hydrocarbon. Hydrocarbons are a class of organic compounds consisting of carbon and hydrogen. Raw natural gas (before processing) is composed primarily of methane.[4]	0.0598	0.04987[5]
Renewable natural gas (RNG)	Upgraded biogas produced from farm or municipal organic biomass. Upgraded synthesis gas (syngas) produced from wood biomass at pulp mills and some municipal organic biomass.	0.0100	0.0003
Syngas	Produced from wood to displace natural gas used in lime kilns at pulp mills. Can also be upgraded to green hydrogen.	0.0100	0.0000
Lignin	Produced from black liquor to displace natural gas used in lime kilns at pulp mills.	0.0100	0.0000
Green Hydrogen	Produced via water electrolysis using renewable electricity feedstock.	0.0000	0.0000
Blue Hydrogen	Reformed from hydrocarbon feedstock with up to 90 percent carbon sequestered.	0.0200	0.0000[6]
Natural Gas with Associated Carbon Capture, Utilization and Storage (CCUS)	Applying the carbon reduction benefits of CCUS to the delivery of natural gas on FEI's gas network.[7]	0.0148	0.0148

1 1 PJ (petajoule) = 1,000,000 GJ.
2 1 TJ per day (terajoule/day) = 1,000 GJ per day.
3 All definitions for fuel types are sourced from FEI except where specified.
4 Online at: https://www.nrcan.gc.ca/energy/energy-sources-distribution/natural-gas/natural-gas-primer/5641.
5 GHG emission factor consistent with that used by the Province as discussed in Section 9.2.
6 Updated values for the carbon intensity of hydrogen production are currently under development and will be provided in the next LTGRP.
7 The International Energy Association describes CCUS as a suite of technologies that can play an important and diverse role in meeting global energy and climate goals. CCUS involves the capture of CO_2 from large point sources,

The resource planning process begins by closely examining the planning environment in which FEI operates and by identifying expectations for future customer and demand growth. The demand- and supply-side resource alternatives for meeting future demand are then assessed, and actions recommended to ensure that the proper resources are in place to deliver the preferred energy solutions to meet future customer needs. Finally, FEI presents a four-year Action Plan, which identifies the near-term activities needed to meet the long-term resource requirements identified in the LTGRP.

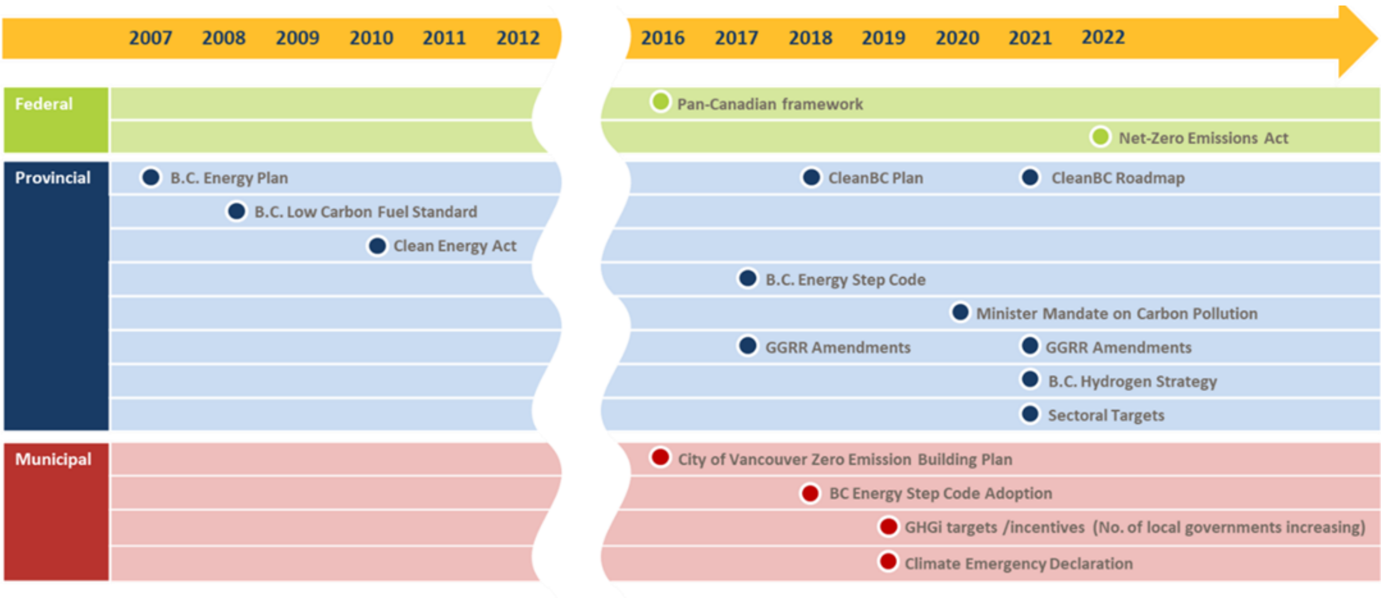
2. PLANNING ENVIRONMENT

This LTGRP involves forecasting and planning to 2042, during a time of rapid change and uncertainty in market forces, energy technologies and government policy, and at the early stages of FEI's journey to a low-carbon energy future. British Columbians, represented by all levels of government, Indigenous groups, and community representatives have been clear that a new path to a secure and low-carbon energy future must be developed. The 2022 LTGRP represents FEI's vision for how it will respond to this changing planning environment and participate in solutions to the imperatives placed on energy utilities like itself. This LTGRP represents FEI's long-term view of its transition to a low-carbon energy future, and is intended to be the catalyst for rapid progress in meeting the ambitious GHG reduction targets established by the provincial and federal governments.

Climate change is dramatically impacting the physical, political, social and economic environment in which FEI operates. Governments at all levels are enacting environmental policies and regulations aimed at reducing GHG emissions. These evolving energy and environmental policies are key factors in the LTGRP planning environment and help inform FEI regarding potential impacts on future customer demand and supply over the planning horizon. An overview of the major policies influencing FEI's planning environment and their evolution over time is illustrated in Figure ES-1.

including power generation or industrial facilities that use either fossil fuels or biomass for fuel. The CO_2 can also be captured directly from the atmosphere. If not being used on-site, the captured CO_2 is compressed and transported by pipeline, ship, rail or truck to be used in a range of applications, or injected into deep geological formations (including depleted oil and gas reservoirs or saline formations) which trap the CO_2 for permanent storage: CCUS Technology Report (2021), online at: https://www.iea.org/reports/about-ccus.

Figure ES- 1: Major Policies Adopted by All Levels of Government Demonstrate the Complexity of FEI's Planning Environment



There have also been significant legislative and policy developments with respect to the engagement with Indigenous groups since the 2017 LTGRP that have broad impacts on FEI's long-term planning. FEI recognizes and respects the constitutional rights of Indigenous peoples, and FEI's Statement of Indigenous Principles aims to ensure FEI's business operations are conducted with respect for Indigenous people's social, economic and cultural interests. Feedback and input from Indigenous groups during the development of this LTGRP emphasized the need for FEI to consider the key principles of the *United Nations Declaration on the Rights of Indigenous Peoples* and to ensure FEI considers Indigenous energy perspectives within its broader utility planning processes.

The competitive environment for FEI's products has grown more complex as a multitude of pricing and non-price considerations are influencing customer energy choices. Capital costs, installation requirements, operating and maintenance costs, government policies and public perception all play a role in this regard.

Gas markets continue to be volatile. With the anticipation of increased demand in the Pacific Northwest (PNW) and limited pipeline infrastructure becoming further constrained, regional price disconnects are expected to continue. Geo-political risk, and strained supply resources in the region during high demand periods, are creating upward price pressure and volatility risk. Infrastructure is needed to meet the pace of future demand growth, provide resiliency, and help support the clean energy transition in the PNW.

Decarbonizing FEI's gas supply in response to climate policy will put upward pressure on gas costs. This rising cost, regardless of specific cost recovery mechanisms or tariffs, will continue to be borne by FEI's customers, reducing FEI's price competitiveness when compared to other low-carbon fuel sources. Gas prices will continue to rise as renewable and low-carbon gas comprises a larger share of the fuel mix. In parallel, electricity rates associated with electrification may also rise due to the need for more transmission, distribution, and substation infrastructure required to meet increases in electricity peak demand. However, decarbonization is necessary to meet the GHG emission targets set out in the Roadmap and to respond with urgency to climate change. The 2022 LTGRP demonstrates how the Clean Growth Pathway has the advantage of leveraging the resilience and reliability of the provincial energy system as a whole, achieving GHG reductions aligned with the provincial government's objectives, and being a more affordable and practical pathway for BC than relying on electrification alone.

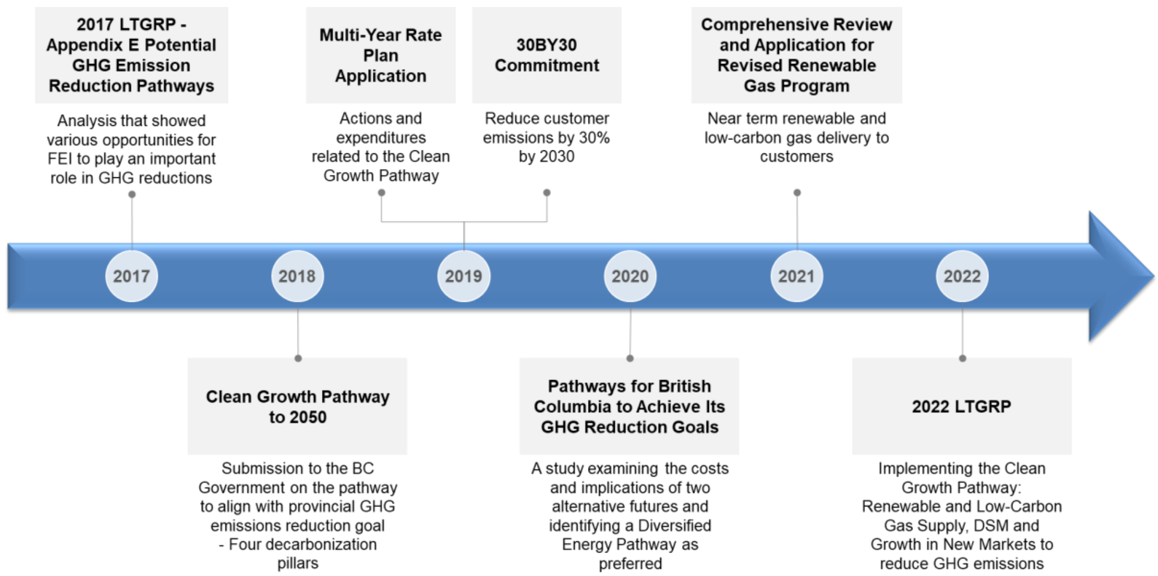
3. CLEAN GROWTH PATHWAY AND FOUR PILLARS TO A LOW-CARBON FUTURE

The 2022 LTGRP provides a comprehensive and long-term view of FEI's transition to a low-carbon future as it responds to a rapidly evolving energy landscape. FEI's Clean Growth Pathway lays the groundwork for this transition and represents FEI's 20-year vision. The Clean Growth Pathway is FEI's approach to supporting increasing government ambition and intervention to reduce GHG emissions and the adoption of policies to take greater climate action. The Clean Growth Pathway report (Appendix A-1) provides FEI's framework to transition to a low-carbon energy future and is supported by four key pillars, which figure prominently in the 2022 LTGRP:

- **Pillar 1:** Transitioning to renewable and low-carbon gases to decarbonize the gas supply;
- **Pillar 2:** Investing in DSM programs in support of energy efficiency and conservation measures to reduce energy use among residential, commercial and industrial customers;
- **Pillar 3:** Support for low-carbon transportation infrastructure to reduce emissions in this sector; and
- **Pillar 4:** Investing in LNG to lower GHG emissions in marine fueling and global markets.

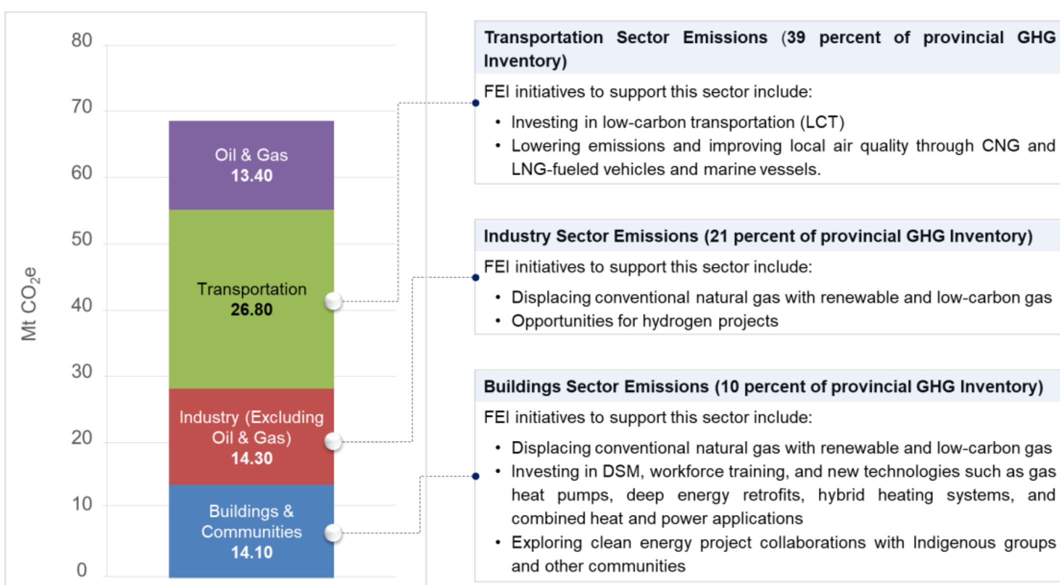
FEI's Clean Growth Pathway is a diversified pathway in that it relies on maintaining and growing both the existing gas and electricity infrastructure networks in BC to reach carbon reduction targets, catalyse energy innovation, and meet BC's growing need for energy over the long term. In addition to achieving GHG reductions aligned with the provincial government's objectives, other benefits include meeting peak demand on the coldest days of the year with the lowest risk, improving energy system resiliency, fostering emerging technologies and innovation, and economic development across the energy services supply chain. Figure ES-2 illustrates key milestones since the 2017 LTGRP that have set the stage for FEI's Clean Growth Pathway.

Figure ES-2. The Evolution of FEI's Clean Growth Pathway from 2017 LTGRP to 2022 LTGRP



The 2022 LTGRP plans for reducing BC's GHG emissions and contributing to global GHG emission reductions. Figure ES-3 illustrates BC's 2019 GHG emissions inventory by sector and describes FEI's initiatives to address these sectoral emissions.

Figure ES-3: 2019 GHG Emissions by Sector in BC[8] and FEI Initiatives to Support Decarbonization



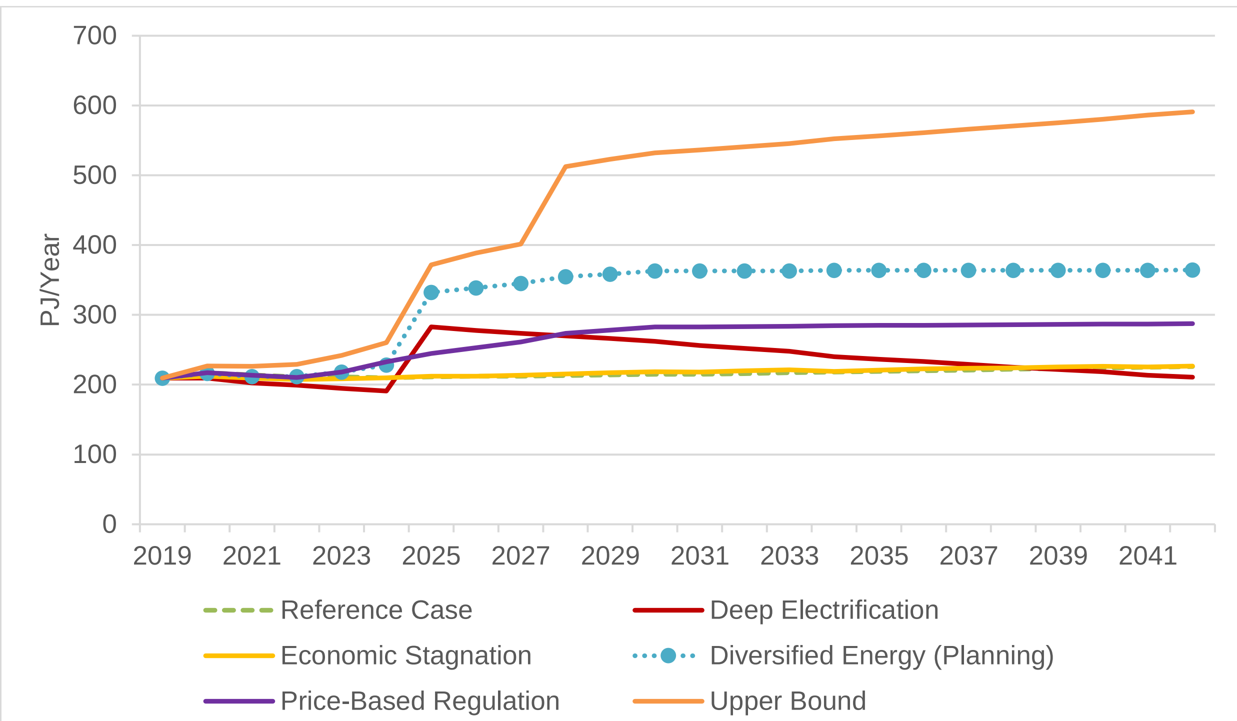
[8] BC's 2019 GHG emissions. Online at https://www2.gov.bc.ca/gov/content/environment/climate-change/planning-and-action/progress-targets#emissions.

4. ANNUAL ENERGY DEMAND FORECASTING

Forecasting customer energy demand is a key step in identifying the resources FEI needs to meet the future energy needs of customers. An annual demand forecast is the amount of gas that FEI expects its customers to use over the course of a year. This determines the amount of gas FEI needs to acquire and transport on behalf of its customers on an annual basis. The annual demand forecast also provides the basis for determining energy savings from DSM and for calculating GHG emissions and emission reductions. FEI's peak demand is discussed later in the LTGRP and is a basis for securing shorter duration peaking supply resources and planning to meet system capacity requirements.

For resource planning, FEI uses an End Use Annual Method of demand forecasting to examine different ways that end use trends could unfold over the planning horizon to impact demand for gas. FEI prepares a Reference Case forecast as well as a range of alternate future scenarios that enable FEI to examine how future demand might unfold. FEI has designated the Diversified Energy Scenario as its planning scenario, which enables FEI's Clean Growth Pathway. Figure ES-4 shows the total range of annual demand forecast including all customer categories for each of the Reference Case and alternate future scenarios examined.

Figure ES-4: Total Forecast Annual Demand– All Demand Categories, All Scenarios



FEI's expectation of future annual energy demand for planning purposes is represented by the outputs of the Diversified Energy (Planning) Scenario analysis as shown in Figure ES-4. Observed growth in annual demand in the first half of the planning horizon is driven by load growth in the transportation sector and global LNG market, primarily with the large load step increase for the addition of the Woodfibre LNG project, modelled to begin operation in 2027.

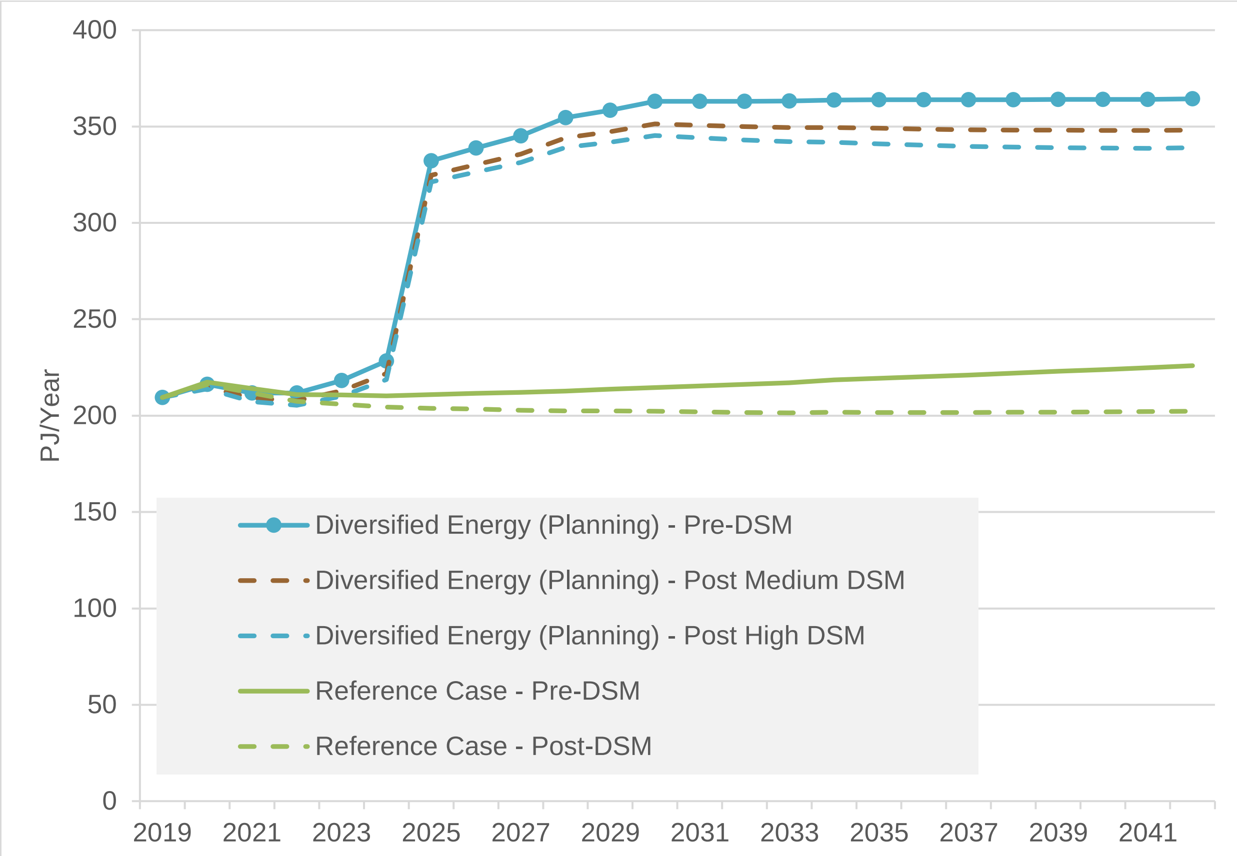
5. DEMAND-SIDE RESOURCES

FEI's adequate and cost-effective portfolio of DSM activities can result in significant energy and GHG emissions reductions over the planning horizon under the range of future scenarios examined for the LTGRP. As a pillar of FEI's Clean Growth Pathway, FEI anticipates expanding its existing DSM activities over the planning horizon to reduce GHG emissions to meet provincial GHG reduction targets. In particular, FEI's future DSM expenditure plans that will be filed with the BCUC for acceptance will be guided by the High DSM Setting analysed in this LTGRP. Under the Diversified Energy (Planning) Scenario with the High DSM Setting, FEI's savings from DSM activities are forecast to be significant, at approximately 25 PJ or 13 percent of annual load in 2042.

As directed in Order G-39-19, FEI's DSM funding scenarios reflect the results of the most recent Conservation Potential Review (CPR) (Appendix C-1), with incentive level, economic screen and budget settings applied to individual scenarios. The Diversified Energy (Planning) Scenario was used as the basis for a sensitivity analysis demonstrating the effects of the Low, Medium and High DSM settings on DSM expenditures, energy savings and cost effectiveness tests. These cost effectiveness tests include Total Resource Cost (TRC), Modified Total Resource Cost (MTRC) and Utility Cost Test (UCT) results expressed as a ratio and the Cost of Conserved Energy (CCE) expressed as $/GJ. FEI also provides a directional view of delivery rate and bill impacts for residential customers under the Low, Medium and High DSM Settings in the Diversified Energy (Planning) Scenario.

The final step in the DSM analysis is to develop total annual demand post-DSM to demonstrate the resulting energy savings effects of projected DSM activity. Figure ES-5 below illustrates the energy savings associated with DSM. In 2042, the Diversified Energy (Planning) Scenario – High Setting is 7 percent lower and the Medium Setting is 5 percent lower than the pre-DSM Annual Demand when taking into account the impact of both forecast LCT and also DSM activity. This results in 25 PJ of annual energy savings for the High DSM Setting and 16 PJ of annual energy savings for the Medium DSM Setting. In conclusion, this Diversified Energy (Planning) Scenario total annual demand after DSM (shown as Diversified Energy (Planning) – Post High DSM in the figure below) represents the annual demand that FEI is planning to in the 2022 LTGRP.

Figure ES-5: Total Annual Demand Before and After DSM for all Demand Categories



6. GAS SUPPLY PORTFOLIO

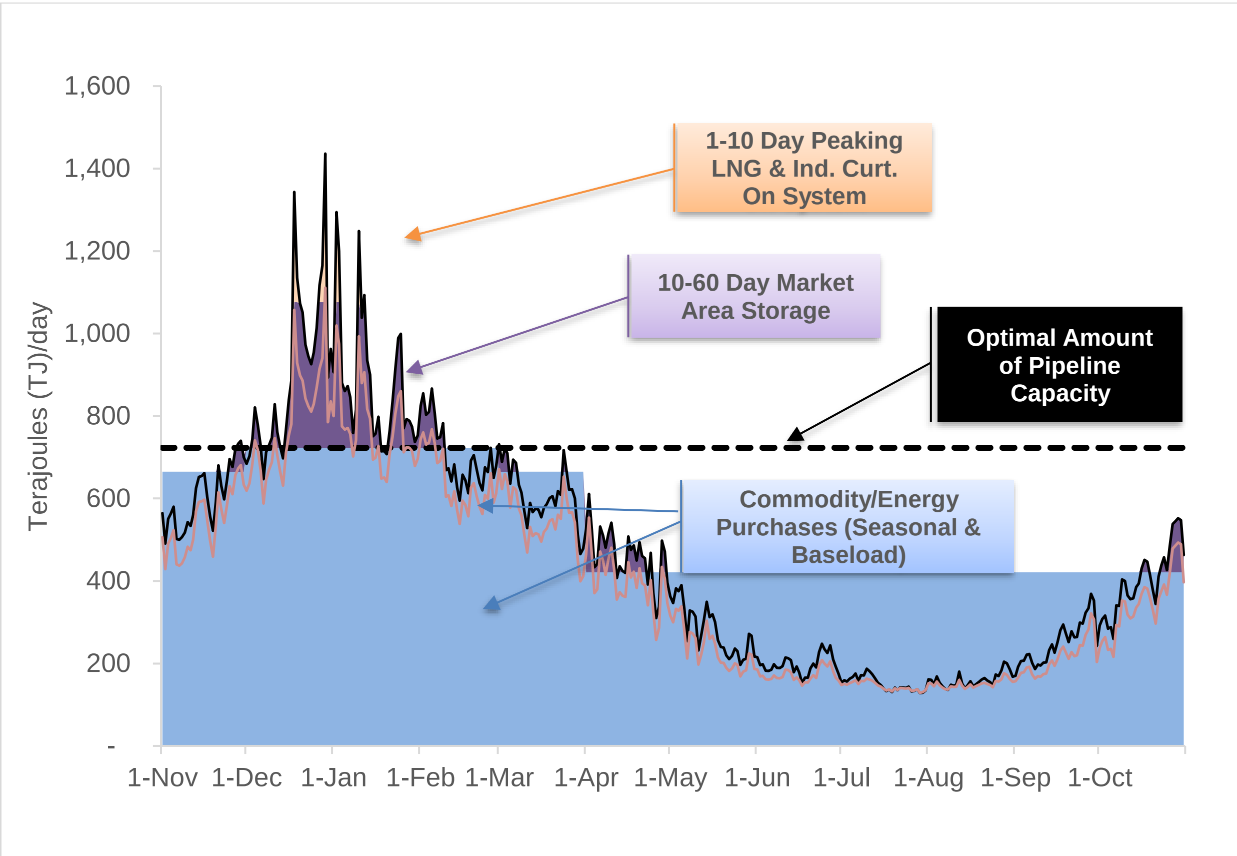
FEI's energy supply portfolio planning ensures that the forecast normal and peak day demand of core market (Core)[9] customers can be met. The planning process begins with considering the locations where FEI can purchase its gas supply resources and the physical gas storage and pipeline resources to which FEI has access. Other steps include planning for price risk management, pipeline and storage resources, potential changes in demand or market conditions, and the transition to renewable and low-carbon gas supplies through the Clean Growth Pathway.

The fundamental design principle of constructing an efficient gas supply portfolio of resources is to match the resource characteristics to the demand characteristics. Figure ES-6 provides an illustrative example of FEI's gas supply portfolio. Demand exhibits pronounced seasonality (i.e., high load in winter and low load in summer), and therefore a low annual load factor. This figure

[9] Core customers refer to Rate Schedules 1, 2, 3, 5, 6, 46 included; and Rate Schedule 4 (seasonal) excluded. FEI's gas supply portfolio includes the forecast normal, design, and peak day demand of these customers. Transportation Service customers arrange for their own supply that is then transported by FEI to their premises. System capacity planning (Section 7) needs to consider total system throughput to ensure that sufficient capacity exists on FEI's system to reliably deliver gas supply to meet the demand for both Core and Transportation service customers.

illustrates how the duration of supply resources fits the forecast annual normal and design load for Core customers.

Figure ES-6: 2021/2022 FEI Forecast Design and Normal Loads vs. Resources[10]



Constrained pipeline and storage resources in the PNW during the winter season continues to be a major concern, and market developments have caused significant supply and pricing risks in the region. Geo-political risks have added greater market uncertainty at this time. FEI has increased resiliency to a degree within the existing portfolio by holding contingency resources; however, resiliency needs to be further improved through new infrastructure projects. With the advancement of renewable and low-carbon gas supply resource in the region, FEI's future infrastructure is being planned to support the transition to a lower-carbon future by providing increased resiliency and supporting a broader range of supply resources.

Additional infrastructure and storage have been a major focus for FEI in light of recent supply disruptions, growing demand in the region, and the necessary requirements to transition to a renewable and low-carbon energy future. FEI has applied to the BCUC for a Certificate of Public Convenience and Necessity (CPCN) for the Tilbury LNG Storage Expansion (TLSE) project, which includes the construction of a new LNG storage tank and increased regasification capacity. The TLSE project would significantly increase the resiliency of FEI's gas system in the event of a

10 This forecast is for Core requirements and does not represent total system throughput.

critical disruption of regional pipeline supply by allowing FEI to continue to serve a much larger portion of the daily system in the event of a supply emergency and by providing sufficient storage to meet that load for a longer period of time. Similarly, FEI's Regional Gas Supply Diversity (RGSD) project would involve expanding the Southern Crossing Pipeline (SCP) to diversify FEI's gas supply on a separate pipeline path from those with constrained capacity.

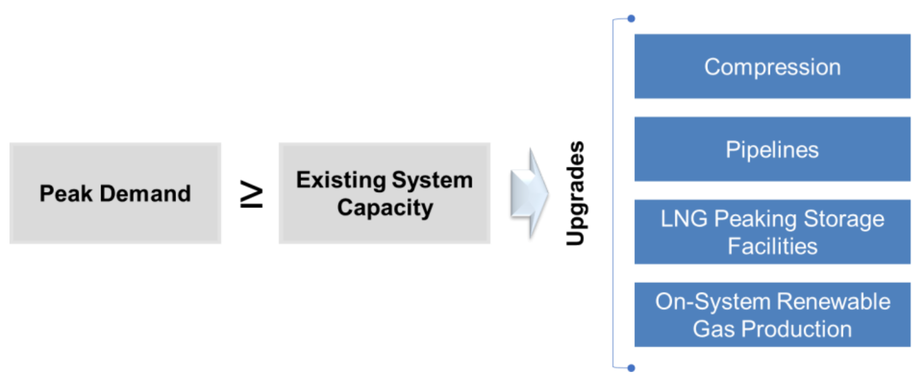
Implementing the RGSD project and expanding on-system storage resources (i.e., the TLSE project) are the most cost-effective ways to enhance resiliency, facilitate load growth opportunities, support the transition to renewable and low-carbon gas and also create diversity and flexibility within FEI's energy supply portfolio. Ultimately, the continued use of the gas infrastructure is a critical component of decarbonizing the province's energy system and, over the long term, will mitigate the cost of the low-carbon energy transition to British Columbians.

7. SYSTEM RESOURCE NEEDS AND ALTERNATIVES

A key aspect of ensuring safe, reliable, and secure delivery of gas to customers is identifying when and where any capacity constraints may appear and planning for the infrastructure and system resources that FEI requires to construct over the planning horizon. Growth in peak demand is among the most significant challenges for FEI's long-term planning. When the forecast for peak demand exceeds available capacity, a gas system expansion is required. The system resource needs discussed in the 2022 LTGRP also reflect the need to deliver renewable and low-carbon gases in increasingly larger volumes over the planning horizon and discusses the infrastructure changes required to accommodate this transition.

System planning includes system sustainment and renewal, integrity upgrades, and system expansion contributing to overall system resiliency. There are three primary resource options to evaluate when planning system expansions: pipelines, compression and storage as shown in Figure ES-7. Over time, FEI expects on-system renewable gas production to grow in importance as a fourth resource option. Often, some combination of the resource options leads to an optimal solution. Infrastructure projects on transmission systems to address system capacity constraints are often large and take many years to plan and execute, demonstrating the benefits of the long-term resource planning process.

Figure ES-7: Options for Gas System Reinforcements



To address specific local and regional demand, FEI considers the peak demand requirements for each of the three main transmission systems: Vancouver Island Transmission System (VITS); Coastal Transmission System (CTS); and Interior Transmission System (ITS). For each regional system, higher or lower than expected load growth could shift the timing of system expansion requirements either ahead or further out in time.

For the VITS, at this time, capacity upgrades are not required. Two pressure control station additions are currently proposed for installation in the next few years to serve the growing distribution systems of Greater Victoria and Nanaimo. The Woodfibre LNG project will require reinforcement of the existing VITS with pipeline looping and added compression near Squamish. This would match the capacity contracted by the project proponent under peak demand, while also preserving available capacity for existing customers and allowing large volumes of interruptible capacity to be available for much of the year.

For the CTS, the TLSE and RGSD projects would address demand and resiliency requirements. The Tilbury site in Delta, located on the CTS, is the location of the LNG liquefaction and storage facility used to serve demand for conventional gas from LCT initiatives, which is forecast to grow over the next 20 years. Based on FEI's demand forecasts for LNG, future phases of Tilbury LNG expansion beyond the current phase will need to be constructed. The RGSD project would expand the SCP from Oliver to the Lower Mainland to increase the CTS's supply diversity. The RGSD has also been developed in consideration of the Clean Growth Pathway and will have the capacity and capability to support FEI's plans to deliver hydrogen across the PNW, including BC.

For the ITS, capital expansion is required to meet forecast demand. FEI currently has a CPCN Application for the Okanagan Capacity Upgrades (OCU) Project in progress. The proposed OCU project would offer sufficient capacity to meet the future peak demand requirements. The preferred alternative is an approximately 30-kilometre NPS[11] 16 pipeline loop between Penticton and Kelowna, reinforcing the existing NPS 12 pipeline currently in service. Reinforcement alternatives have been identified to meet the demand forecast and would be required, in addition to completion of the OCU Project, by the winter of 2038 to 2039.

As FEI incorporates renewable gases into the gas distribution and transmission systems, the physical properties of these gases, such as density and energy content per standard volume, can have an impact on capacity. Gases with physical properties within the range of conventional gas, such as RNG, will have no net impact on delivery capacity. Delivering hydrogen or a blend of hydrogen and natural gas or hydrogen and RNG, where the gas density and energy content are different from traditional natural gas supply, will change the energy delivery capacity. Table ES-3 provides an overview of FEI's system planning considerations for integrating renewable and low-carbon gas into the individual regional transmission systems.

[11] Nominal pipe size, in inches.

Table ES-3: Overview of Considerations for Integrating Renewable and Low-Carbon Gas in FEI Systems

Fuel Type / Other Considerations	Regional Transmission and Distribution Line Considerations		
	VITS	**CTS**	**ITS**
RNG (on-system)	• Supply potential • No detrimental impact on transmission system capacity • Reliable supply from local on-system hubs will reduce upstream supply requirements and improve available capacity	• Supply potential • No detrimental impact on transmission system capacity • Reliable supply from local on-system hubs will reduce upstream supply requirements and improve available capacity	• Supply potential • No detrimental impact on transmission system capacity • Reliable supply from local on-system hubs will reduce upstream supply requirements and improve available capacity
Hydrogen	• Supply potential from blue or turquoise production potential may require system upgrades • Green hydrogen hub will reduce upstream supply requirements and improve available capacity, but reduce available capacity downstream	• By 2030, hydrogen production anticipated with hydrogen and RNG in similar proportions. • By 2042, hydrogen supplied from upstream of Huntington Control Station and comprises a much larger portion of the fuel mix • With upstream supply, hydrogen separation facility at Huntingdon anticipated • Dedicated hydrogen "backbone" pipeline likely	• Supply potential from blue or turquoise production potential may require system upgrades • Green hydrogen hubs will reduce upstream supply requirements and improve available capacity, but reduce available capacity downstream
Syngas and Lignin	• Supply potential	• No supply potential currently identified	• Supply potential
LNG and Industrial Project Impacts	• Woodfibre LNG project may preclude hydrogen blending upstream (at Eagle Mountain) • Management of hydrogen at FEI's Mount Hayes LNG facility would be required	• Flow of hydrogen likely to be separated from transmission system at Huntingdon control station due to large scale LNG production at Tilbury and Woodfibre LNG project	• Management of hydrogen at any future LNG facilities would be required

Fuel Type / Other Considerations	Regional Transmission and Distribution Line Considerations		
	VITS	CTS	ITS
System Upgrade Requirements	• Scope and location of system upgrades not yet feasible to determine as supply volumes and locations are currently in early stages of development	• Local supply hubs and small dedicated systems eventually connected to upstream by dedicated hydrogen "backbone" • Scope and location of system upgrades not yet feasible to determine as supply volumes and locations are currently in early stages of development	• Renewable and low-carbon projects could offset the need for upgrades • RGSD project under development could provide significant support for delivery of hydrogen and other renewable gas • Scope and location of system upgrades not yet feasible to determine as supply volumes and locations are currently in early stages of development

FEI's gas system must be expanded to meet future demand growth and optimize operation of the whole system. With annual increases in forecast peak demand, potential new sources of demand from LCT and industrial sources, and the introduction of renewable and low-carbon gases in significantly increasing quantities, the VITS, CTS and ITS transmission systems could all require capacity-enhancing projects to meet peak demand forecasts while enabling FEI's Clean Growth Pathway.

8. STAKEHOLDER INDIGENOUS AND COMMUNITY ENGAGEMENT

Connecting with customers, communities, Indigenous groups, and other stakeholders on long-range planning issues is of critical importance to FEI. FEI undertook a number of initiatives to offer interested participants the opportunity to contribute to the discussions that informed the 2022 LTGRP and FEI's Clean Growth Pathway initiatives. These activities continued into the first quarter of 2022 and included:

- Workshops with the dedicated Resource Planning Advisory Group (RPAG) engaged strategic representatives of municipalities, government, customers, associations, and organizations with interest, experience and/or significant industry knowledge in energy planning in the development of the LTGRP.
- Engagement workshops with First Nations community representatives provided feedback on how engagement can be strengthened for the ongoing LTGRP planning process, the development of clean energy projects, and other FEI initiatives.
- Community Engagement workshops recognizing the importance of considering diverse community perspectives and energy planning needs with respect to developing BC's energy future and FEI's role in the low-carbon transition across its service territory.

- FEI's other engagement activities that directly or indirectly inform the resource planning process, such as discussions with advisory groups, government, industry associations, customers and other stakeholders.

Through the RPAG workshop sessions, stakeholders have been able to provide FEI with input on many important factors, such as demand forecasting and scenario analysis methods, demand drivers and scenarios and feedback on FEI's Clean Growth Pathway. The workshops with Indigenous groups highlighted the need to further evolve engagement processes and in response FEI developed an Action Item accordingly. The Community Engagement workshops assisted FEI in identifying energy issues and planning opportunities in municipalities and communities throughout BC. The information gained through these activities informs FEI's market research and analysis, identifying long-term planning issues of concern to a number of stakeholder groups, feedback on FEI's transition to renewable and low-carbon gas, interest in local clean energy projects and identifying interested stakeholders who may become more engaged in the LTGRP process.

9. OUTCOMES OF THE CLEAN GROWTH PATHWAY

FEI's vision for the future of energy in BC is that of a diverse, integrated and resilient network of energy infrastructure and services, building on the strength and benefits of both the existing gas and electric energy delivery networks in the province. FEI's role in this future is to utilize, grow and strengthen its gas transmission and distribution systems for the continued delivery of safe, secure and reliable energy to customers, while reducing GHG emissions for customers through the four pillars of its Clean Growth Pathway. As FEI proceeds down this pathway, the continued commercialization of existing technologies, advancements in new technology and innovation will enable deeper carbon emission reductions, while putting BC at the forefront of emerging industries such as those that will drive BC's future hydrogen economy.

One of the key impacts of the Clean Growth Pathway is GHG emission reductions to meet the Roadmap's cap on emissions for natural gas utilities for residential, commercial and industrial customers, to be implemented as the Greenhouse Gas Reduction Standard (GHGRS). Through the Clean Growth Pathway, and based on end use demand in the Diversified Energy (Planning) Scenario, FEI's GHG emission reductions for the following categories are described below and illustrated in Figure ES-8:

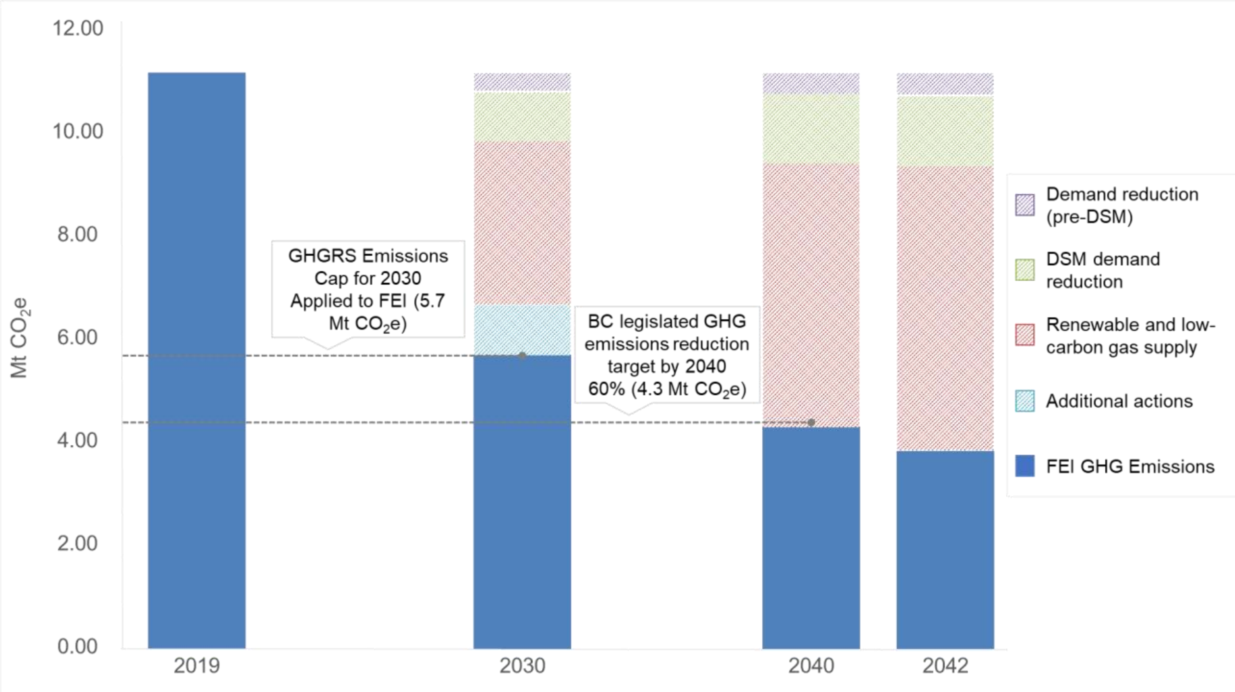
- **Changes in demand (pre-DSM)** describes the impact of natural efficiency[12] combined with a degree of electrification discussed in Section 4. This demand reduction corresponds to GHG emission reductions of 0.3 Mt CO_2e per year in 2030 and 0.4 Mt CO_2e per year in 2040;

[12] Efficiency improvements that occur through the natural replacement of older, less efficient equipment with newer, more efficient equipment as influenced by market transformation by DSM programs, regulations and other factors.

- **FEI's DSM programs** result in energy savings at the High DSM setting discussed in Section 5. This high level of energy savings results in 0.9 Mt CO_2e reductions in 2030 and 1.3 Mt CO_2e reductions in 2040;
- **The renewable and low-carbon gas supply transition** has the largest impact on GHG emission reductions as discussed in Sections 4, 6, and 7. Acquiring and allocating 60.2 PJ of renewable and low-carbon gas supply by 2030 to this group of customers' demand results in emission reductions of approximately 3.0 Mt CO_2e. In 2040, the allocation of 99 PJ of renewable and low-carbon gas to these customer groups result in 4.9 Mt CO_2e of GHG emission reductions; and
- **Additional GHG emissions reductions initiatives** were identified by FEI after completion of the demand and supply modelling for the 2022 LTGRP. Examples of these additional opportunities include further DSM opportunities and further renewable and low carbon gas reductions such as CCUS technology development. FEI expects these opportunities to result in a further 0.9 Mt CO_2e reductions or more by 2030. FEI is still considering how these additional opportunities feed into the emissions reductions later in the planning horizon and so has not included them in its assessment of 2040 emission reductions at this time. FEI will formally include these additional opportunities in its demand and GHG emission modelling for the next LTGRP.

FEI anticipates that as it proceeds along its Clean Growth Pathway, additional new opportunities and technology advancements will continue to arise for further potential GHG emission reductions for residential, commercial and industrial customers. The Roadmap states that the GHGRS emissions cap on gas utilities will be approximately 6 Mt CO_2e in 2030. Accounting for the fact that FEI is not the only gas utility in BC, the portion of the cap that applies to FEI is approximately 5.7 Mt CO_2e. Figure ES-8 shows the GHG emission reductions required to meet the GHGRS cap for gas utilities. FEI's modelling of GHG emissions reductions for the Diversified Energy (Planning) Scenario meets the Province's 2040 target emission reductions and puts net-zero GHG emissions by 2050 for these customer groups within reach. Over the long term, the Diversified Energy (Planning) Scenario has similar emission reductions to the Deep Electrification Scenario, with a somewhat deeper reduction driven by growth in the supply of renewable and low-carbon gases.

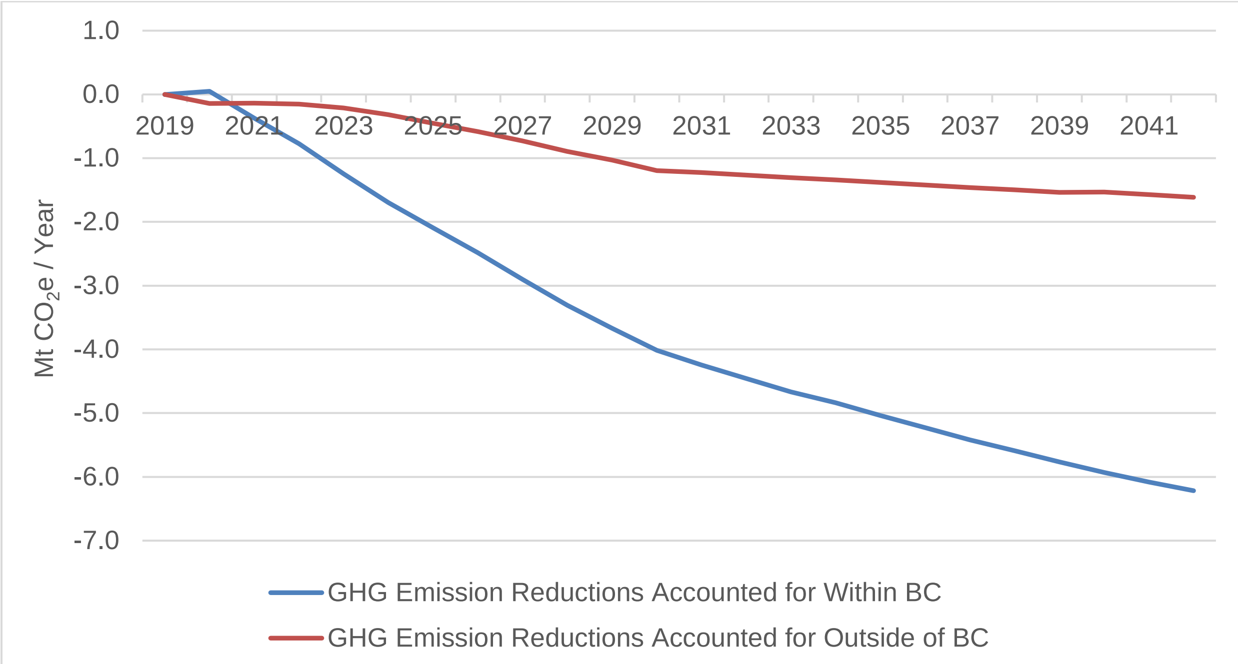
Figure ES-8. GHG Emission Reductions for Residential, Commercial and Industrial Customers Meets the GHGRS for the Diversified Energy (Planning) Scenario [13]



The total GHG emission reductions modelled in the Diversified Energy (Planning) Scenario represent the outcome of implementing initiatives outlined in the pillars of the Clean Growth Pathway. In order to provide a complete picture, GHG emission reductions from serving both the residential, commercial and industrial customer groups, and the low-carbon transportation and global LNG customers throughout the planning horizon are illustrated in Figure ES-9 (based on life-cycle emission factors). Figure ES-9 illustrates the total emissions resulting from Diversified Energy (Planning) Scenario broken out into reductions accounted for within BC and those that are accounted for outside of BC.

[13] GHG emissions reductions based on end-use emission factor in order to align with the GHGRS.

Figure ES-9: Total GHG Emission (Life Cycle) Reductions for the Diversified Energy (Planning) Scenario - BC and Outside of BC



To provide context for FEI's long-term volume forecasts and their influence on customer rates, FEI analysed the cost impacts of decarbonization initiatives and variations in demand over the planning period. Table ES-4 below summarizes the cumulative effective rate impact projections as well as the equivalent annual rate impact over the 20-year period for each select scenario.

Table ES-4: Summary and Comparison of Average Projected Delivery Rate Changes

		Effective Rate Change (2022 - 2042, %)							
	Average UPC (2022 - 2042)	**Reference**		**Upper Bound**		**Diversified Energy (Planning)**		**Deep Electrification**	
		Cumulative	Annual	Cumulative	Annual	Cumulative	Annual	Cumulative	Annual
Residential (RS 1)	60	73%	2.8%	77%	2.9%	118%	4.0%	235%	6.2%
Small Commercial (RS 2)	293	41%	1.7%	64%	2.5%	102%	3.6%	207%	5.8%
Large Commercial (RS 3)	3,253	40%	1.7%	69%	2.6%	107%	3.7%	206%	5.7%
General Firm Service (RS 5)	18,542	44%	1.9%	80%	3.0%	114%	3.9%	150%	4.7%

These cumulative effective rate impacts are made up of individual impacts in all components of FEI's rates, including delivery, cost of gas, storage & transport, and carbon tax. Using Residential (RS 1) as an example, the total residential bill is estimated to increase from approximately $1,029 in 2022 to $1,958 in 2031, and to approximately $2,215 in 2040 under the Diversified Energy (Planning) Scenario. The 118 percent cumulative effective rate impact by 2042 under the Diversified Energy (Planning) Scenario is made up of approximately 50 percent delivery rate impact, 41 percent commodity-related impact (cost of gas and storage & transport), and 9 percent carbon tax. More detailed discussion on rate impacts is presented in Section 9.4

10. ACTION PLAN

The Action Plan describes the activities that FEI intends to pursue over the next four years based on the discussion and conclusions provided in this LTGRP. The specific Action Items include the following:

1. Accelerate the development and acquisition of renewable and low-carbon gas supplies to meet customer energy needs and contribute to provincial emission reduction targets;
2. Pursue approval of DSM funding for the period beyond 2022 by submitting for BCUC approval a DSM expenditure plan in 2022;
3. Continue pursuing FEI's LCT and global LNG initiatives to address market opportunities for load growth in support of customer rates and reducing local and global GHG emissions;
4. Continually improve engagement processes and activities associated with FEI's long-term gas resource planning;
5. Seek BCUC approval for a deferral account to capture the costs of advancing the development of the RGSD project;
6. Continue to develop and implement FEI's Gas System Resiliency Plan;
7. Plan for and prepare CPCN applications for near-term system requirements identified in Section 7 to support safe, reliable and cost effective gas delivery to FEI's customers;
8. Continue monitoring, analysing, and contributing to the energy planning environment while working with government on policy framework for deep decarbonization;
9. Protect and promote the interests of FEI's customers by securing reliable, cost-effective, long-term gas supplies that include increasing proportions of renewable and low-carbon gas;
10. Continue monitoring for and evaluating system expansion needs across FEI's service regions; and
11. Prepare and submit FEI's next LTGRP.

In conclusion, FEI's Clean Growth Pathway will support BC's decarbonization initiatives by transforming and influencing energy supply service markets. Maintaining BC's gas and electric infrastructure will enable ongoing innovation and accelerate decarbonization such that provincial GHG emission reduction targets will be met at a more rapid pace. In this pathway, the gas infrastructure continues to grow and thrive by adding new customers, communities, and commercial and industrial processing. Sharing costs across a diverse set of customer segments ensures that individual customers can more readily absorb the additional costs incurred through the low-carbon transition.

FortisBC Energy Inc.
2022 LTGRP

Section 1:

INTRODUCTION

Table of Contents

1. INTRODUCTION

1.1 APPLICATION AND ORDER SOUGHT

FEI files this 2022 Long-Term Gas Resource Plan (LTGRP) under section 44.1(2) of the *Utilities Commission Act* (UCA). Consistent with the applicable requirements of the UCA, the BC Utilities Commission's (BCUC) Resource Planning Guidelines, and prior BCUC directives, the 2022 LTGRP presents FEI's long-term plan for meeting the forecast peak demand and energy requirements of customers with demand-side and supply-side resources over a 20-year planning horizon. FEI respectfully requests that the BCUC accept the 2022 LTGRP as being in the public interest pursuant to section 44.1(6) of the UCA.

This 2022 LTGRP is profoundly shaped by the developments in climate change policy in recent years and, in particular, the Province's 2018 CleanBC plan and CleanBC Roadmap to 2030 (Roadmap) which set out ambitious targets for reducing greenhouse gas (GHG) emissions. In response to these policies and the need to reduce GHG emissions, this 2022 LTGRP provides a preliminary overview of how FEI plans to transition to a low-carbon energy future and, in particular, how FEI will shift from distributing conventional gas to distributing renewable and low-carbon gas. FEI anticipates that future resource plans will provide increasingly more detail on the mechanics and progress of this transition.

FEI's planning scenario in this 2022 LTGRP is referred to as the Diversified Energy (Planning) Scenario, which is based on FEI's Clean Growth Pathway.[14] The Clean Growth Pathway is FEI's framework to transition to a low-carbon energy future and is supported by four key pillars, which figure prominently in the 2022 LTGRP:

- **Pillar 1:** Transitioning to renewable and low-carbon gases to decarbonize the gas supply;
- **Pillar 2:** Investing in Demand-side Management (DSM) programs in support of energy efficiency and conservation measures to reduce energy use among residential, commercial and industrial customers;
- **Pillar 3:** Investing in low- carbon transportation infrastructure to reduce emissions in this sector; and
- **Pillar 4:** Investing in liquefied natural gas (LNG) to lower GHG emissions in marine fueling and global markets.

As indicated by these four pillars, FEI plans to meet provincial emission reduction targets through accelerating its renewable and low-carbon gas supply, supporting the decarbonization of buildings through DSM activities, and growing customer demand in sectors that reduce GHG emissions. FEI's Clean Growth Pathway maintains a prominent role for FEI's infrastructure in achieving GHG reductions in alignment with the province's objectives. For this reason, the Clean Growth Pathway

[14] Appendix A-1: Clean Growth Pathway to 2050 (2018), online at: https://www.cdn.fortisbc.com/libraries/docs/default-source/about-us-documents/clean-growth-pathway-brochure.pdf.

is also a diversified pathway, which sustains the growth and viability of both gas and electricity infrastructure in the province to support BC's future energy needs in the most cost-effective manner. As described in Guidehouse's report titled Pathways for British Columbia to Achieve its GHG Reduction Goals (Pathways Report),[15] a diversified pathway is a more affordable, resilient and practical pathway for BC than other decarbonization alternatives.

Similar to past resource plans, the 2022 LTGRP forecasts annual energy and peak demand for a range of alternate future scenarios over the 20-year planning horizon. FEI evaluates the potential for demand reduction through FEI's DSM programs, and examines supply and demand-side alternatives for meeting the forecast peak demand and energy requirements. FEI will continue to focus on resource acquisition strategies, long-range infrastructure requirements for resiliency and meeting peak demand, all while ensuring FEI meets BC's energy and GHG emission-reduction objectives. FEI's objectives are to ensure cost-effective, secure and reliable energy for customers and provide cost-effective DSM and lower-carbon solutions, in a manner consistent with provincial energy objectives and prior BCUC directives.

The 2022 LTGRP serves as a foundation for further evaluation of gas supply and system infrastructure options for meeting forecast customer needs under different scenarios. The LTGRP is not a substitute for the analysis done to support specific supply or expansion projects, programs or rate design in the future, but rather helps to inform the process of other initiatives. FEI will further evaluate any specific resource projects that are identified within the LTGRP that require BCUC approval and file separate applications with the BCUC as needed in the future.

FEI submits that the 2022 LTGRP is in the public interest and that the BCUC should accept this 2022 LTGRP under section 44.1(6) of the UCA. A draft Order is attached as Appendix H-1.

1.2 OVERVIEW OF FEI AND THE RESOURCE PLANNING PROCESS

FEI is a Canadian-owned gas distribution utility that serves customers across its BC territory. It is a subsidiary of Fortis Inc., the largest investor-owned gas and electric distribution utility company by assets in Canada. FortisBC Inc. (FBC), which provides electric service in the BC Southern Interior, is a separate Fortis Inc. subsidiary and affiliate of FEI. The long-term planning considerations and business activities of FBC are not included in the 2022 LTGRP.

FEI provides energy distribution services to over one million residential, commercial, and industrial customers in more than 135 communities throughout BC. This ranks FEI among the largest gas utilities in Canada and the Pacific Northwest (PNW). Table 1-1 provides a summary of FEI customer counts, demand, and pipeline characteristics. Figure 1-1 illustrates the Company's service area locations.

[15] Appendix A-2: Pathways for British Columbia to Achieve its GHG Reduction Goals (2020), online at: https://www.cdn.fortisbc.com/libraries/docs/default-source/about-us-documents/guidehouse-report.pdf.

Table 1-1: FEI Service Statistics

	2016	2021	Percentage Increase Since 2017 LTGRP
Number of Customers	994,004	1,064,800	7.1%
Annual Demand (PJ)[16]	197	228	15.7%
Peak Day Demand (TJ/day)[17]	1,334	1,399	4.9%
Length of Transmission Pipeline (km)	2,959	2,970	0.4%
Length of Distribution Pipeline* (km)	45,741	47,523	3.9%

** Includes both distribution and intermediate pressure pipelines.*

[16] 1 PJ (petajoule) = 1,000,000 GJ.
[17] 1 TJ per day (terajoule/day) = 1,000 GJ per day.

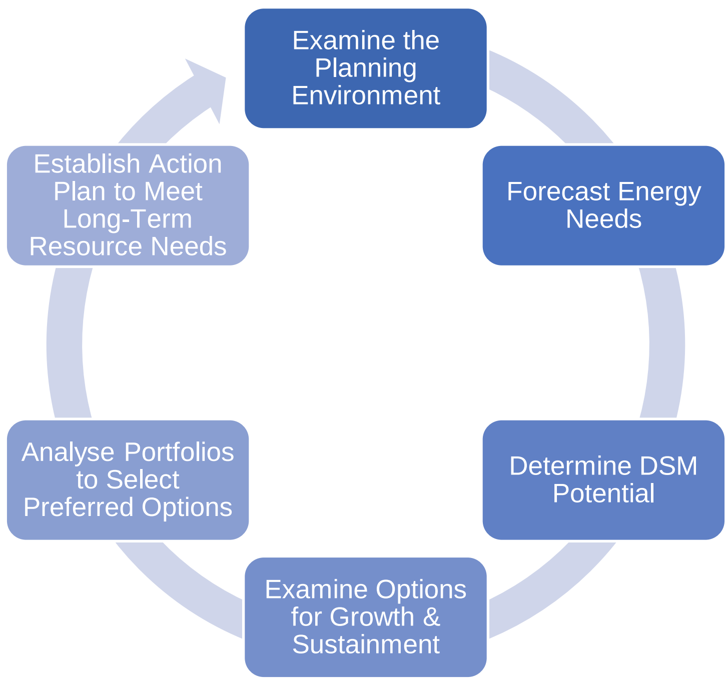
Figure 1-1: Map of FortisBC Service Areas (FEI Gas and Propane and FBC Electric)

FEI's long-term resource planning process involves several iterative steps in identifying resource options to meet expected demand. This process is one that is used by many utilities in resource planning and is consistent with the steps included in the BCUC's Resource Planning Guidelines.[18]

The resource planning process begins with examining the planning environment, which encompasses the external factors that influence future customer and demand growth. The demand- and supply-side resource alternatives for meeting future demand are then assessed, and actions are recommended to ensure that the proper resources are in place to deliver the preferred energy solutions to meet future customer needs. The final stage of the process is developing an action plan which identifies the near-term activities needed to meet the long-term resource requirements identified in the LTGRP, and to ensure continuing assessment of resource requirements and alternatives.

Figure 1-2 below summarises FEI's resource planning process:

Figure 1-2: FEI Long-Term Resource Planning Process



Consultation and engagement, which includes technical feedback from the Resource Planning Advisory Group (RPAG), engagement with Indigenous groups and community consultation, is an important element of FEI's long-term resource planning. The decisions made in long-term resource planning ultimately impact FEI's customers in terms of rates and fuel choices in the transition to low-carbon energy. In developing the LTGRP, the BCUC was updated throughout the process through their observer role on the RPAG. In addition to soliciting technical feedback

[18] BCUC, Resource Planning Guidelines (December 2003), online at: https://docs.bcuc.com/documents/Guidelines/RPGuidelines_12-2003.pdf.

from the RPAG, FEI held several community workshop sessions to advise participants about aspects of the LTGRP and gather their input and feedback to help inform the LTGRP. More details regarding FEI's consultation and engagement activities are provided in Section 8.

FEI shares common regional infrastructure with utilities in neighbouring jurisdictions, such as the PNW. This is why the competitive market environment, as well as the planning issues and resource requirements of other utilities, are important elements to consider in the planning process. It is especially critical to take into account information and developments regarding the transition to low-carbon energy. As such, FEI actively participates as a stakeholder in the resource planning efforts of other gas and electric utilities in the region, such as British Columbia Hydro and Power Authority (BC Hydro), FBC, Puget Sound Energy, Avista, and Northwest Natural Gas Company (NW Natural). To improve its understanding and response to regional resource issues, FEI also participates in planning, resource assessment activities and events conducted by regional organizations, including the Northwest Gas Association, the Northwest Power and Conservation Council, and the Pacific Northwest Economic Region. The regional outlooks provided by these utilities and organizations inform the analyses and recommendations in this LTGRP.

1.3 *FUEL TYPES AND DECARBONIZATION TECHNOLOGIES USED IN THE 2022 LTGRP*

As stated in Section 1.1, the 2022 LTGRP provides a preliminary overview of FEI's low-carbon transition from conventional gas to renewable and low-carbon sources. Table 1-2 presents a list of the different fuel types that were used in modelling the demand forecast scenarios in the resource plan. Throughout the 2022 LTGRP, FEI will generally refer to "natural gas, renewable and low-carbon gas" as a term that applies to the collective group of fuels outlined below. "Renewable and low-carbon gas" will be used to refer to renewable natural gas (RNG), syngas, lignin and (green and blue) hydrogen. FEI will use the term RNG when specifically referring to upgraded biogas. The chart also presents the emission factors that were used for each fuel source in modelling GHG emission forecasts.

Table 1-2: Fuel Types and Decarbonization Technologies Used in the 2022 LTGRP

Fuel Type	Description[19]	Life cycle Emission Factor (tCO_2e/GJ)	End use cycle Emission Factor (tCO_2e/GJ)
Natural gas	Natural gas is a naturally occurring hydrocarbon. Hydrocarbons are a class of organic compounds consisting of carbon and hydrogen. Raw natural gas (before processing) is composed primarily of methane.[20]	0.0598	0.04987[21]

[19] All definitions for fuel types are sourced from FEI except where specified.

[20] Online at: https://www.nrcan.gc.ca/energy/energy-sources-distribution/natural-gas/natural-gas-primer/5641

[21] GHG emission factor consistent with that used by the province as discussed in Section 9.2.

Fuel Type	Description[19]	Life cycle Emission Factor (tCO_2e/GJ)	End use cycle Emission Factor (tCO_2e/GJ)
Renewable natural gas (RNG)	Upgraded biogas produced from farm or municipal organic biomass. Upgraded synthesis gas (syngas) produced from wood biomass at pulp mills and some municipal organic biomass.	0.0100	0.0003
Syngas	Produced from wood to displace natural gas used in lime kilns at pulp mills. Can also be upgraded to green hydrogen.	0.0100	0.0000
Lignin	Produced from black liquor to displace natural gas used in lime kilns at pulp mills.	0.0100	0.0000
Green Hydrogen	Produced via water electrolysis using renewable electricity feedstock.	0.0000	0.0000
Blue Hydrogen	Reformed from hydrocarbon feedstock with up to 90 percent carbon sequestered.	0.0200	0.0000[22]
Natural Gas with Associated Carbon Capture, Utilization and Storage (CCUS)	Applying the carbon reduction benefits of CCUS to the delivery of natural gas on FEI's gas network.[23]	0.0148	0.0148

1.4 FEI'S FOUR LONG-TERM RESOURCE PLANNING OBJECTIVES

FEI's resource planning objectives form the basis for identifying and evaluating potential resources in the LTGRP, including major infrastructure projects, gas supply alternatives including renewable and low-carbon gas, and DSM. These objectives reflect FEI's commitment to providing customers with cost-effective, secure and reliable energy services, while playing a key role in BC's low-carbon future. FEI's four resource planning objectives are discussed below and are consistent with the objectives outlined in FEI's 2017 Long-Term Gas Resource Plan (2017 LTGRP), unless otherwise noted.

1.4.1 Ensure Cost-Effective, Secure and Reliable Energy for Customers

The most desirable resource options for meeting future customer needs will provide cost-effective service solutions and help to manage rate volatility, both in the near term, and into the future. Cost comparisons in this resource plan require more analysis than the traditional costs of natural

22 Updated values for the carbon intensity of hydrogen production are currently under development and will be provided in the next LTGRP.

23 The International Energy Association describes CCUS as a suite of technologies that can play an important and diverse role in meeting global energy and climate goals. CCUS involves the capture of CO_2 from large point sources, including power generation or industrial facilities that use either fossil fuels or biomass for fuel. The CO_2 can also be captured directly from the atmosphere. If not being used on-site, the captured CO_2 is compressed and transported by pipeline, ship, rail or truck to be used in a range of applications, or injected into deep geological formations (including depleted oil and gas reservoirs or saline formations) which trap the CO_2 for permanent storage: CCUS Technology Report (2021), online at: https://www.iea.org/reports/about-ccus.

gas. Carbon tax implications and the costs associated with decarbonization initiatives over the long term must be considered. From a broader perspective, energy affordability must be taken into consideration for all alternatives under consideration in planning BC's energy future.

A secure and reliable energy supply is essential for all FEI customers. Ensuring a sufficient supply of gas and the capacity to deliver gas to customers during anticipated peak demand periods is an ongoing objective for FEI. Acquiring resources that improve the reliability, system resiliency and security of supply will also help to reduce rate volatility and protect customers from potential outages.

1.4.2 Provide Cost-Effective DSM and Lower Carbon Solutions

Providing cost-effective DSM and other solutions to address carbon emissions have long been objectives of FEI's LTGRP. FEI used the term "cleaner customer solutions" early in the resource planning process to define FEI's decarbonization objectives. Late in the process of preparing the 2022 LTGRP, FEI adjusted this objective to read 'lower carbon solutions' in order to better align with the BC government's recent carbon reduction policy statements and to emphasize FEI's role in helping to reach provincial carbon reduction goals. Providing lower-carbon solutions reflects FEI's transition to a low-carbon energy system through the implementation of the Clean Growth Pathway.

Cost-effective DSM strategies offer value to customers by increasing energy efficiency and delivering gas more effectively. FEI's DSM programs are governed in part by the UCA and the *Demand-side Measures Regulation* (DSM Regulation).[24] In addition to FEI's DSM programs, FEI also delivers innovative energy solutions through initiatives for the transportation and marine sectors and through the development, sourcing and delivery of renewable and low-carbon gas supplies.

1.4.3 Ensure Consistency with Provincial Energy Objectives

The Province of BC's energy objectives are numerous and evolving. They include those objectives set out in the *Clean Energy Act* (CEA)[25] and are embodied in other provincial energy policies, strategies and regulations, such as *Greenhouse Gas Reduction (Clean Energy) Regulation* (GGRR) and the recent BC Hydrogen Strategy. FEI serves more than 1 million customers across BC in 135 communities. This wide reach enables FEI to play an important role in providing services to customers that help BC meet these objectives. Section 1.5.3 shows the applicable British Columbia's energy objectives and how they are supported by the LTGRP. Section 2.2.2 provides a discussion of other relevant BC energy and climate policies. In its 2022 LTGRP and the Clean Growth Pathway discussed throughout, FEI has endeavoured to maintain consistency with and support these provincial energy objectives.

[24] B.C. Reg. 236/2008, online at:: https://www.bclaws.gov.bc.ca/civix/document/id/complete/statreg/10_326_2008.
[25] S.B.C. 2010, c. 22, online at: https://www.bclaws.gov.bc.ca/civix/document/id/complete/statreg/10022_01.

1.4.4 Address Prior BCUC Directives

The BCUC set out a number of directives that apply to FEI's 2022 LTGRP. This objective has been added to the 2022 LTGRP to ensure that prior directives are highlighted and addressed as part of the resource planning process. The BCUC directives provided in the 2017 LTGRP Decision and from other proceedings that impact resource planning activities are outlined in Section 1.5.5.

1.5 THE 2022 LTGRP ALIGNS WITH THE LEGAL AND REGULATORY FRAMEWORK

It is good utility practice to conduct long-term resource planning and FEI has a regulatory obligation to file long-term resource plans under section 44.1(2) of the UCA. The UCA outlines the requirements for resource plans and the BCUC's Resource Planning Guidelines (Guidelines) provide general guidance as to the BCUC's expectations for the development of resource plans. FEI must also adhere to any directives from the BCUC related to FEI's previously filed long-term resource plans. Resource planning must also be conducted in accordance with the principles of the United Nations Declaration on the Rights of Indigenous Peoples (the UN Declaration). These requirements and guidelines are discussed in the following sections:

- United Nations Declaration on the Rights of Indigenous Peoples;
- UCA requisite contents and considerations;
- CEA objectives;
- BCUC Resource Planning Guidelines; and
- BCUC directives.

1.5.1 United Nations Declaration on the Rights of Indigenous Peoples (UN Declaration)

Sections 2.3 and 8.3 of this LTGRP discuss FEI's Statement of Indigenous Principles and support for the overarching principles outlined in the UN Declaration.[26] FEI acknowledges that the principles of the UN Declaration will play a significant role in energy policy and the regulatory environment over the twenty-year planning horizon of this LTGRP. FEI is committed to aligning its resource plans with provincial policy, and will continue to review its engagement process to ensure that FEI is engaging in meaningful dialogue with Indigenous groups regarding its resource plans. As the UN Declaration continues to be implemented across government through the

[26] Appendix F-1: United Nations Declaration of the Rights of Indigenous Peoples (2007), online at: https://www.un.org/development/desa/indigenouspeoples/wp-content/uploads/sites/19/2018/11/UNDRIP_E_web.pdf.

development of action plans, FEI will continue to evolve its planning and business practises in alignment with this implementation.

1.5.2 *Utilities Commission Act*

Section 44.1(2) of the UCA sets out the required content for a public utility's long-term resource plan. Table 1-3 outlines the specific elements that are to be included in resource plans and indicates the corresponding sections of this LTGRP in which these requirements have been met.

Table 1-3: Requisite Contents for a Long-Term Resource Plan

Section of the UCA	Requirement Defined in the UCA	Section of LTGRP Addressing Requirement
44.1(2)(a)	An estimate of the demand for energy the public utility would expect to serve if the public utility does not take new demand-side measures during the period addressed by the plan	Demand Forecast scenarios are outlined in Sections 4.6, 4.7 and 4.8.
44.1(2)(b)	A plan of how the public utility intends to reduce the demand referred to in paragraph (a) by taking cost-effective demand-side measures	Demand-side measures are discussed in Section 5 and demand reduction in Section 5.4.2.
44.1(2)(c)	An estimate of the demand for energy that the public utility expects to serve after it has taken cost-effective demand-side measures	Energy demand after DSM is discussed in Section 5.4.3.
44.1(2)(d)	A description of the facilities that the public utility intends to construct or extend in order to serve the estimated demand referred to in paragraph (c)	FEI's System Resource Needs and Alternatives are discussed in Section 7.
44.1(2)(e)	Information regarding the energy purchases from other persons that the public utility intends to make in order to serve the estimated demand referred to in paragraph (c)	FEI's Gas Supply Portfolio and Price Risk Management are discussed in Section 6.
44.1(2)(f)	An explanation of why the demand for energy to be served by the facilities referred to in paragraph (d) and the purchases referred to in paragraph (e) are not planned to be replaced by demand-side measures	FEI's System Resource Needs after DSM are discussed specifically in Sections 7.2.3.1 and 7.3
44.1(2)(g)	Any other information required by the Commission	

In determining whether to accept a long-term resource plan, section 44.1(8) of the UCA requires the BCUC to consider several items. These are listed in Table 1-4 along with the applicable sections of the LTGRP where they have been addressed.

Table 1-4: BCUC Considerations for Accepting a Long-Term Resource Plan

Section of the UCA	Considerations for Acceptance	Section of LTGRP Addressing Requirement
44.1(8)(a)	The applicable of British Columbia's energy objectives	Section 1.5.3 below discusses the BC energy objectives applicable to the LTGRP and further information is provided in Sections 2 and 9.
44.1(8)(b)	The extent to which the plan is consistent with the applicable requirements of Sections 6 and 19 of the CEA	Section 1.5.3 below describes LTGRP's consistency with the CEA.
44.1(8)(c)	Whether the plan shows that the public utility intends to pursue adequate, cost-effective demand-side measures	Sections 3, 5 and 9 discuss demand-side measures and FEI's GHG emission reduction initiatives.
44.1(8)(d)	The interests of persons in British Columbia who receive or may receive service from the public utility	Portfolio analysis results include DSM and supply-side resource options that are cost effective, environmentally sound and provide socio-economic benefits to the province and FEI's customers. This is discussed in Section 9 and throughout the LTGRP.

1.5.3 *Clean Energy Act*

Section 44.1(8) of the UCA requires the BCUC to consider certain factors when accepting a utility's long-term resource plan, including:

- The applicable of British Columbia's energy objectives as defined in the CEA; and
- The extent to which the long-term resource plan is consistent with the applicable requirements under sections 6 and 19 of the CEA.

The CEA contains a set of sixteen specific energy objectives for the Province of BC. It provides a guide to help the Province meet its self-sufficiency goals and to reduce GHG emissions. The CEA includes several social and economic goals for the province, including a greater focus on encouraging economic development, creating and retaining jobs, and encouraging economic development for Indigenous and rural communities through the development of clean or renewable power.

The following table lists the CEA objectives applicable to FEI and how these are supported by the LTGRP. It is important to note that these are provincial objectives and some of the objectives are specific to BC Hydro, as referenced in the CEA by the term 'the authority'.

1 **Table 1-5: Applicable CEA Objectives Directly Relevant to the LTGRP**

CEA Section	CEA Objective	Supported in the 2022 LTGRP
2(b)	To take demand-side measures and to conserve energy, including the objective of the authority reducing its expected increase in demand for electricity by the year 2020 by at least 66%.	The 66 percent target is specific to BC Hydro and does not extend beyond 2020. FEI has assessed several DSM scenarios as discussed in Section 5.
2(d)	To use and foster the development in British Columbia of innovative technologies that support energy conservation and efficiency and the use of clean or renewable resources.	Sections 3, 5, and 9 address FEI's actions to support innovative and clean or renewable energy technologies in addition to portfolio analysis throughout the LTGRP. Section 5 addresses FEI's DSM analysis that provides support for energy conservation and efficiency including the use and development of innovative technologies.
2(g)	To reduce BC GHG emissions: (i) by 2012 and for each subsequent year to at least 6% less than the level of those emissions in 2007, (ii) by 2016 and each subsequent calendar year to at least 18% less than the level of those emissions in 2007, (iii) by 2020 and for each subsequent calendar year to at least 33% less than the level of those emissions in 2007, (iv) by 2050 and for each subsequent calendar year to at least 80% less than the level of those emissions in 2007, and (v) by such other amounts as determined under the *Greenhouse Gas Reduction Targets Act*.	The LTGRP demonstrates that FEI's Clean Growth Pathway is key to helping the province meet BC's GHG emission targets. FEI recommendations include transitioning the gas supply to renewable and low-carbon sources, DSM programs, zero and low-carbon transportation and LNG marine bunkering. The LTGRP focuses on FEI's transition to low-carbon energy and Section 9 addresses GHG emissions and emission reductions from FEI's forecast energy demand and initiatives.
2(h)	To encourage the switching from one kind of energy source to another that decreases greenhouse gases in British Columbia.	Sections 3, 4, 5 and 9 address FEI's fuel switching initiatives such as using compressed natural gas (CNG) and LNG as a transportation fuel to displace higher carbon fuels such as diesel and marine bunker fuel. The potential for fuel switching from gas to electricity has been considered in the development of the plan.

CEA Section	CEA Objective	Supported in the 2022 LTGRP
2(i)	To encourage communities to reduce greenhouse gas emissions and use energy efficiently.	Section 3 presents FEI's Clean Growth Pathway. Section 5 discusses energy conservation through FEI's DSM activities and the associated GHG emission reductions. Section 8 addresses FEI's community outreach. Section 9 addresses GHG emissions and emissions reductions from FEI's forecast energy demand and renewable and low-carbon supply initiatives.
2(j)	To reduce waste by encouraging the use of waste heat, biogas and biomass	Sections 2, 3, 5, 6, 7 and 9 discuss FEI's RNG and other bioenergy resources including syngas and lignin opportunities, DSM programs including waste heat recovery and portfolio analysis related to decarbonization throughout the LTGRP.
2(k)	To encourage economic development and the creation and retention of jobs	FEI's Clean Growth Pathway, discussed in Section 3, highlights opportunities for economic development and job creation. Section 9 summarizes FEI's 2022 LTGRP analysis results in light of BC's energy objectives. The LTGRP encourages the development of renewable and low-carbon gas projects, DSM activities and low-carbon transportation that will contribute to BC's economic development and job creation.
2(l)	To foster the development of First Nation and rural communities through the use and development of clean or renewable resources.	FEI will consider opportunities with Indigenous groups and local communities in the development of clean energy projects (see Sections 3, 5, 8 and 9)
2(m)	To maximize the value, including the incremental value of the resources being clean or renewable resources, of British Columbia's generation and transmission assets for the benefit of British Columbia.	LTGRP provides a framework for partnerships and strategies that maximize value as FEI transitions to a low-carbon energy future (see Sections 3, 5, 6, 7 and 9).

1.5.4 BCUC Resource Planning Guidelines

In 2003, the BCUC issued Resource Planning Guidelines, which outline a process to assist in the development of resource plans to be filed with the BCUC. According to the Guidelines, "resource planning is intended to facilitate the selection of cost-effective resources that yield the best overall outcome of expected impacts and risks for ratepayers over the long run." The Guidelines do not distinguish between utilities that provide generation, transmission or distribution services; therefore, some items (such as supply-side portfolio analysis[27]) are more relevant to integrated

[27] Supply-side portfolio analyses are conducted outside of FEI's LTGRP planning process and are submitted for approval to the BCUC through the Annual Contracting Plan (ACP) and Price Risk Management Plan (PRMP).

electric utilities. The BCUC reviews resource plans in the context of the unique circumstances of the utility in question. FEI adheres to the BCUC's Resource Planning Guidelines where relevant and applicable to FEI's operating context. Table 1-6 below outlines the key elements of the Resource Planning Guidelines and the sections of the 2022 LTGRP in which they are addressed.

Table 1-6: BCUC Resource Planning Guidelines

Resource Planning Guideline	Section of LTGRP Addressing Guideline
1. Identification of the planning context and the objectives of a resource plan	Objectives and context are discussed in Section 1.4, and Planning Environment Section 2.
2. Development of a range of gross (pre-DSM) demand forecasts	Demand forecasts (pre-DSM) are discussed in Section 4.
3. Identification of supply and demand resources	Supply and demand resources are discussed in this LTGRP as follows: • The Planning Environment, Section 2, provides context for existing resources and dynamics concerning new resources; • The Annual Demand Forecasting, Section 4, presents the future load that FEI is planning for in this LTGRP; • The amount of future demand that can be met through DSM is considered in Demand-Side Resources Section 5; and • Sections 6 and 7 discuss the need for new gas supply and system infrastructure resources respectively.
4. Measurement of supply and demand resources	Measurement of supply and demand are outlined in Sections 4, 5 and 6.
5. Development of multiple resource portfolios	FEI is not a vertically integrated utility, and does not develop and compare multiple integrated resource portfolios. Rather, in the 2022 LTGRP, FEI plans to the Diversified Energy (Planning) Scenario. However, in the future, this may change as FEI transitions to renewable, low-carbon gas and community solutions, which may require future resource plans to examine alternative supply resource portfolios. Background for this discussion is found in Demand-Side Resources Section 5, Gas Supply Portfolio Planning Section 6 and System Resource Needs and Alternatives Section 7.
6. Evaluation and selection of resource portfolios	FEI plans to the Diversified Energy (Planning) Scenario that represents the Clean Growth Pathway. As FEI transitions to renewable and/or low-carbon gas and community solutions, it may be positioned as a vertically integrated utility. In this case, future resource plans may examine alternative supply resource portfolios. Background for this discussion is found in Demand Side Resources Section 5, Gas Supply Portfolio Planning Section 6 and System Resource Needs and Alternatives Section 7.
7. Development of an action plan, including contingency plans	The 2022 LTGRP Action Plan is provided in Section 10.
8. Solicit stakeholder input during the planning process	The 2022 LTGRP stakeholder, Indigenous groups, and community engagement initiatives are described in Section 8.

Resource Planning Guideline	Section of LTGRP Addressing Guideline
9. Seek regulatory input from Commission staff	FEI has received and considered input from the BCUC and BCUC staff through: • regulatory proceedings on various FEI filings that have implications for long range planning; • periodic discussions with staff concerning various regulatory filings and proceedings; and • the BCUC request for Integrated Resource Plan modelling of common future scenarios for FEI and BC Hydro. In addition, BCUC staff participated as observers in FEI's external RPAG.
10. Consideration of government policy	The 2022 LTGRP provides an overview of policy considerations in the Planning Environment in Section 2.2 and Section 9.
11. Regulatory review once a resource plan is filed	The regulatory review process will be determined by the BCUC in consideration of FEI's recommendations provided in Section 1.7.

1.5.5 BCUC Directives from the 2017 LTGRP Decision and Other Applications

In Decision and Order G-39-19 accepting the 2017 LTGRP[28] and its decisions in other proceedings, the BCUC provided a number of directives and suggestions for FEI to integrate in future resource plans. The recent and historical directives that remain applicable to the 2022 LTGRP are outlined in Table 1-7, along with a description of where in the LTGRP they are addressed.

Table 1-7: List of BCUC Directives and FEI Actions Pursuant to Order G-39-19

Directive #	BCUC Directive	Section of LTGRP Addressing Directive
1.	In the next LTGRP filing, FEI is directed to: • Update the information filed in this proceeding to respond to the BCUC's directive in the 2014 LTRP Decision to provide an analysis of FEI's End Use Method as compared to other end use methods, including an assessment of the of FEI's method compared to other models that incorporate some form of end use modelling combined with econometric modelling; • Provide a detailed explanation of any changes to its demand forecast methodology as it evolves between now and the next LTGRP filing; and • Include high level assessment of the effectiveness of the Traditional and End Use Models compared to actual results.	Directives relating to the Traditional Annual Method versus the End Use Annual Method, including an update to the industry review of forecast methods, an explanation of changes to the End Use Method and a high-level assessment of the effectiveness of the two methods are discussed in Section 4 and Appendix B-1 and B-6.

[28] Decision and Order G-39-19, February 25, 2019, online at: https://www.ordersdecisions.bcuc.com/bcuc/decisions/en/item/363860/index.do?q=G-39-19.

Directive #	BCUC Directive	Section of LTGRP Addressing Directive
2.	FEI is directed to continue use of its Traditional Method as a comparison to test its End Use Method until such time as the BCUC approves a new demand forecast methodology.	The results of the Traditional Method as in this reference are included in Section 4 as the End Use Method. The name has been changed from Traditional to Business as Usual (BAU) forecast to better represent the nature of the forecast as discussed in Section 4.
3.	The Panel directs FEI to continue to provide the following information, in the next LTGRP: • DSM funding scenarios, reflecting the results of the most recent Conservation Potential Review, that include a "reference" DSM funding scenario with "high DSM" and "low DSM" scenarios that are relative to the reference scenario; • An analysis of each DSM scenario, at a portfolio level and for each DSM category (residential, low-income[29],[30],[31], commercial etc.), including: o Total Resource Cost/modified Total Resource Cost test results; o Utility Cost Test result, expressed as a ratio and $/GJ;	An overview of FEI's approach to the LTGRP DSM analysis, DSM funding scenarios ranging from high to low budgets, and energy savings estimates and cost-effectiveness test results are provided in Section 5. Appendix C-2 provides further detail on cost-effectiveness for DSM categories comprising sectors (residential, commercial and industrial).
	o Delivery rate impact; o Estimated total bill impact (including delivery and commodity), expenditures ($'s) and percentages (%'s), with residential split between high and low use gas customers;	Details regarding delivery rate impacts and total bill impacts are provided in Sections 5 and 9.
	o Estimated gas (GJ) and GHG emission reductions.	Details regarding gas and GHG emission reductions estimates resulting from DSM (Section 5) and other GHG reduction initiatives over the planning horizon are provided in Section 9.
4.	The Panel directs FEI to provide an update of its analysis of opportunities for DSM to be used to cost-effectively replace or defer infrastructure investments in its next LTGRP.	An update on FEI's efforts to explore the potential for DSM programs to replace or defer infrastructure investments is presented in Section 5. Appendix C-3 provides the study that examines the state of the gas utility industry in considering and implementing non-pipe solutions to provide peak energy savings and other customer benefits.

[29] In LTGRP scenarios, low income customers are modelled within the residential sector, as these customers are not differentiated in FEI's customer database. FEI estimates that about 20 percent of its residential customers would be eligible for Low Income programs. According to Statistics Canada's 2016 Census data (Appendix F-15), 14-15% of British Columbians are considered low income, based on low-income cut-offs (LICO) before tax. The DSM Regulation uses LICO multiplied by a factor of 1.3 to determine low-income thresholds. This suggests that, under the definition set out in the DSM Regulation, FEI's 20 percent estimate is reasonable.

[30] Appendix F-2: Low-Income Status Data tables (2016 Census), online at: Low-income Indicators (4), Individual Low-income Status (6), Age (8) and Sex (3) for the Population in Private Households of Canada, Provinces and Territories, Census Divisions and Census Subdivisions, 2016 Census - 100% Data (statcan.gc.ca).

[31] LICOs can be found online at: https://www150.statcan.gc.ca/t1/tbl1/en/tv.action?pid=1110024101.

Directive #	BCUC Directive	Section of LTGRP Addressing Directive
5.	In the next LTGRP, the Panel directs FEI to address the implications for FEI's long-term resource and conservation planning of the 2018 CleanBC plan released by the Government of BC on December 6, 2018 and to provide an update on its analysis of GHG targets. In particular, the Panel expects that FEI should address the long-term impacts to FEI of the following points:	• FEI has incorporated the resource planning and GHG reduction implications of the 2018 CleanBC plan; and • Where possible, FEI has also incorporated the implications of the 2021 release of the Roadmap. However, details are not yet fully known about how that update will be enacted through regulation.
	• Initiatives targeting more energy efficient buildings, in terms of gas demand and FEI's DSM activities	Initiatives targeting opportunities to decarbonize buildings are provided in Sections 3, 5 and 8.
	• Requirements for 15 percent of natural gas consumption to be from renewable gas	Initiatives related to the acceleration of renewable and low-carbon gas supply are provided in Sections 3, 6, 7 and 9. FEI has also addressed the increased renewable and low-carbon gas consumption targets outlined in the Roadmap.
	• Industrial electrification, with respect to demand for natural gas	Considerations related to industrial electrification are provided in Sections 4, 5, and 9. FEI has incorporated different assumptions about electrification percentages for all sectors into each of the future scenarios examined in the LTGRP.
	• How 2018 CleanBC's plans for clean transportation affect FEI's forecast for its low-carbon transportation (LCT) programs	Considerations related to FEI's LCT forecasts are provided in Sections 2.2.2.3.2 where the Low Fuel Standard and Greenhouse Gas Reduction Regulation for Transportation are discussed. Demand forecasts for LCT are discussed further in Sections 4 and 9.
	• Other initiatives to be developed by the Government of BC over the next 18 to 24 months	FEI has incorporated the implications of the Roadmap and other recent initiatives including the Greenhouse Gas Reduction Regulation (GGRR), emissions cap for natural gas utilities (GHGRS), provincial and federal hydrogen strategies, BC Carbon Tax and electrification strategy and other policy impacts in Section 2. The implications of government initiatives on FEI's long-term plan are discussed throughout the LTGRP.
6.	The Panel directs FEI to address security of supply concerns in its next LTGRP.	Security of supply and resiliency considerations are provided in Sections 2, 3, 6, 7, and 9. Refer to Appendix E for FEI's Gas System Resiliency Plan.
7.	The Panel directs FEI to file its next LTGRP on or before March 31, 2022. By letter dated April 28, 2022 the BCUC granted an extension to file on May 9, 2022.	2022 LTGRP filed on May 9, 2022.

The BCUC has also provided directives and suggestions for FEI related to the 2022 LTGRP in the following:

- Decision and Order C-2-21 granting a CPCN for the Pattullo Gas Line Replacement Project; and

- Decision and Order G-366-21 approving FEI's Annual Review for 2022 Delivery Rates.

These directives or suggestions and the related LTGRP section where they are addressed are outlined in Table 1-8 below.

Table 1-8: List of BCUC Directives and Suggestions from Additional Applications and FEI Actions Taken in 2022 LTGRP

Directive #	BCUC Directive	Section of LTGRP Addressing Directive / Suggestion
Order C-2-21	The Panel directs FEI to address resiliency in a comprehensive manner in its 2022 Long-Term Gas Resource Plan.	FEI's resiliency considerations are provided throughout the LTGRP and addressed specifically in Sections 3, 6, 7, 9. Appendix E provides FEI's Gas System Resiliency Plan as a consolidated and comprehensive overview.
Order C-2-21	The Panel suggests FEI may address pathways to zero GHG emissions by 2050 in its upcoming LTGRP.	FEI's Diversified Energy (Planning) Scenario provides FEI's decarbonization transition plan to 2042, which may be extrapolated to 2050. However, both FEI and BC Hydro have suggested that they would not extend resource plan scenarios to 2050 based on the uncertainties that lie beyond a twenty-year horizon.
Order G-366-21	Provide context around the Regional Gas Supply Diversity (RGSD) project and whether it is in the public interest to explore or pursue this project. This would allow the BCUC a more holistic view of how the project aligns with BC's energy objectives as set out in Section 2 of the *Clean Energy Act*, and how in combination with other infrastructure and energy purchase plans the RGSD would meet future load forecasts.	The RGSD project is explored in many aspects in the LTGRP, including sections 3.3.3 (Clean Growth Pathway), 6.3.3 (Gas Supply Portfolio Planning), 7.5.1.1 (System Resource Needs and Alternatives), 10 (Action Plan) and Appendix E (Gas System Resiliency Plan).

1.6 STATUS OF THE 2017 LTGRP ACTION PLAN

In each successive resource plan, FEI presents a list of actions that can be taken to implement the recommendations outlined throughout the plan. Table 1-9 below provides an update of the items identified in the four-year Action Plan of the 2017 LTGRP.

Table 1-9: 2017 LTGRP Action Items

Action Item	Status
1. Continue to monitor and analyse the energy planning environment.	FEI has continued monitoring and analysing the planning environment, which is becoming increasingly complex. To support its analysis of the policy planning environment, FEI, since the 2017 LTGRP, has dedicated resources specifically to public policy analysis. Section 2 presents an overview of FEI's current analysis of the planning environment.
2. Continue exploring the application of projected changes across end use patterns to peak demand forecasting.	FEI conducted extensive analysis of peak demand forecasting across end use patterns as outlined in Section 7.
3. Protect and promote the interests of FEI's customers by securing a reliable, cost-effective long-term gas supply.	The 2022 LTGRP remains committed to FEI's customers in securing a reliable, cost-effective and long-term gas supply, through the low-carbon transition over the planning horizon as outlined in Section 6. FEI develops an efficient supply portfolio on an annual basis that consists of an appropriate balance of commodity, pipeline, and storage resources to meet the forecast demand from all of FEI's gas service areas. The constrained pipeline and storage resource environment in the region during the winter season continues to be a major concern. FEI continues to manage this risk with the following contracting strategies: • Contract for firm resources directly with pipeline or storage facilities for the majority of its gas supply requirements. In FEI's view, this is a prudent strategy that protects customers from large prices spikes and limited availability of gas at Huntingdon; • Until new infrastructure is added to the region, FEI will continue to hold contingency resources within its portfolio. Contingency resources are resources (supply, LNG, and/or pipeline infrastructure) above the current load forecasts for its customers. FEI will determine the optimal amount on an annual basis based on market conditions discussed in Section 6. Over the long term, FEI's supply portfolio can also benefit from a mix of new infrastructure, specifically expansions to on-system storage (Tilbury LNG Storage Expansion (TLSE)) and a new pipeline (RGSD project). These projects will enhance gas supply resiliency in the portfolio, facilitate load growth opportunities, and help with the transition to cleaner energy.
4. Continue monitoring and evaluating system expansion needs in the Okanagan and Vancouver Island areas to maintain reliable and cost-effective gas delivery to FEI's customers.	FEI submitted a CPCN application for the Okanagan Capacity Upgrade in January 2021. FEI continues to monitor and evaluate the Interior Transmission system and expects a system capacity constraint to occur in 2023, with contingency planning for 2021 and 2027. Section 7.3.3 discusses this analysis and the project is listed in Section 7.5.1. Further capacity constraints on the Vancouver Island Transmission System (VITS) are not expected within the forecast period. It is expected that the system will meet the Traditional Peak Method forecast.

Action Item	Status
5. Plan for and prepare CPCN applications for near-term system requirements identified in Section 6 to support safe, reliable and cost-effective gas delivery to FEI's customers. The 2017 LTGRP listed the following priority project on the CTS and regional infrastructure as upcoming CPCN applications: • Upgrades to lateral pipeline segments in the interior region to enable and implement inline inspection (ILI) programs (referenced in Section 6.4 as Transmission System Laterals ILI Capability); • The Southern Crossing Pipeline Class Location Project; • The Pattullo Bridge Crossing Replacement; • The evaluation of major bridge crossings on the CTS to determine if upgrades should be considered to improve the resiliency of piping during a seismic event (referenced in Section 6.4 as Bridge Crossing Seismic Upgrade Assessment – Lower Mainland); • Implementation of advanced technology inline inspection programs (e.g. EMAT) for the transmission pipelines that are already inspected using current technology; and • A potential reliability upgrade to the Langley compressor facility.	An update on the high priority projects listed in the 2017 LTGRP consists of the following: • The BCUC granted a CPCN and FEI has commenced construction of the Inland Gas Upgrades Project to upgrade lateral pipeline segments in the Interior region to enable and implement inline inspection (ILI) programs as discussed in Section 7.6.2; • The Southern Crossing Pipeline Class Location Project, discussed in Section 7.6.3, addresses pipeline safety factors. This could be a potential future CPCN; • The BCUC granted a CPCN by Order C2-21 and FEI has commenced construction of the Pattullo Gasline Replacement Project; • FEI continues the evaluation of major bridge crossings on the Coastal Transmission System to determine if upgrades should be considered to improve the resiliency of piping during a seismic event (referenced in 2017 LTGRP as Bridge Crossing Seismic Upgrade Assessment – Lower Mainland). Major DP, IP and TP Lateral Pipeline Crossings are discussed in Section 7.5.2.1; • FEI is awaiting a BCUC decision on the CTS Transmission Integrity Management Capabilities Project for the implementation of EMAT ILI programs for the CTS. In 2022, FEI will be filing a similar application for the implementation of EMAT ILI for the Interior Transmission System as discussed in Section 7.6.4; and • Some reliability upgrades to the Langley compressor facility are occurring as discussed in Section 7.6.5. As FEI's planning efforts were and continue to be undertaken to ensure that planned improvements optimize operation of the system as a whole, these system upgrade requirements were integrated with reinforcement options that were considered to meet FEI's capacity needs.

Action Item	Status
6. Continue to implement the Company's Low-Carbon Transportation (LCT) initiatives to meet market needs while capturing an important opportunity for load growth and GHG emissions reductions.	FEI has been successful in promoting the use of both CNG and LNG vehicles in the transportation sector via its LCT initiatives. To date, FEI has provided incentive funding for approximately 850 CNG vehicles, 148 LNG vehicles, and 10 marine vessels. In addition to incentive funding for vehicles, FEI has provided funding towards the construction of 19 CNG and LNG fueling stations that are currently operating. FEI will continue to explore opportunities to construct CNG and LNG fueling stations along strategic corridors to support the continued adoption of natural gas vehicles. FEI has been focusing on the adoption of LNG in the marine market segment, particularly in the short sea marine segment in BC. This segment includes marine vessels that transit intra-provincial waterways to move goods and passengers. To date, FEI has provided vessel capital incentives to ten LNG-powered marine vessels. (Data above accurate as of March 31, 2022)
7. Pursue approval of Conservation and Energy Management (C&EM) funding for the period beyond 2018 by submitting for BCUC approval a C&EM expenditure schedule in 2018.	The BCUC approved FEI's 2019-2022 DSM Expenditures Plan. FEI is implementing this portfolio and delivers annual performance reports to the BCUC. From 2019 - 2022, FEI forecast an investment of $353 million in DSM programs. 2021 expenditures were three times greater than the 2018 investment. Over this timeframe, the programs are forecast to generate 4 Million GJ in annual savings and 40 Million GJ over the life of the installed measures. This translates to 2.4 Mt CO_2e of GHG emission reductions.
8. Pursue approvals as necessary of a funding envelope dedicated to enabling FEI to further monitor and, where applicable, support innovative conventional, renewable and low-carbon gas technologies, which may help FEI, meet market preferences while also supporting solutions for BC's emissions policy objectives.	FEI's Clean Growth Innovation Fund is committed to innovation through investments in cleantech and emissions-reducing projects that provide solutions for current and emerging energy challenges in BC. The fund provides funding to support innovative energy projects, in partnership with government, industry, communities and Indigenous groups.

The actionable items that FEI intends to pursue over the next four years are provided in Section 10 of this 2022 LTGRP.

1.7 *PROPOSED REGULATORY PROCESS*

FEI submits that, consistent with past resource plans and due to the technical nature of the material, a written hearing is appropriate for the review of the 2022 LTGRP. FEI proposes the following regulatory timetable, which includes two rounds of information requests and an opportunity for intervener evidence, followed by submissions on further process or a procedural conference. FEI also notes that it expects to file on August 12, 2022 supporting commentary regarding the energy scenarios as directed by the BCUC in the BCUC's Energy Scenarios proceeding[32] as an update to the evidentiary record in this Application. The proposed regulatory

[32] Online at: Energy Scenarios for BC Hydro and FEI (For Information Only) - BCUC.

timetable below takes into account this update as well as deadlines already established in other ongoing regulatory proceedings before the BCUC.

Table 1-10: Proposed Regulatory Timetable

ACTION	DATE (2022)
BCUC Issues Procedural Order by	Thursday, June 9
FEI Publishes Notice of Filing by	Friday, July 8
Registration of Interveners and Interested Parties	Thursday, July 21
FEI Submits Energy Scenarios Evidentiary Update	Friday, August 12
BCUC Information Request No. 1	Tuesday, August 30
Intervener Information Request No. 1	Thursday, September 8
FEI Responses to Information Requests No. 1	Thursday, October 27
BCUC and Intervener Information Request No. 2	Thursday, November 24
	DATE (2023)
FEI Responses to Information Requests No. 2	Thursday, January 26
Notification by Interveners of Intent to file Evidence	Thursday, February 9
Submissions on Further Process or Procedural Conference	To be determined

A draft Procedural Order is attached as Appendix H-2.

2022 LTGRP

Section 2:

PLANNING ENVIRONMENT

Table of Contents

2. PLANNING ENVIRONMENT

2.1 INTRODUCTION

FEI is submitting this 2022 LTGRP during a time of rapid change in government policy, emerging technologies, and global economic factors, while the effects of climate change are being experienced first-hand in BC. A wide range of factors influences FEI's long-term analysis and planning decisions especially during this pivotal time for FEI's transition to a low-carbon future. This section discusses the factors that are the most important.

Understanding the planning environment is the first step in FEI's resource planning process. The planning environment is set in the context of the evolution of FEI's Clean Growth Pathway and the many factors influencing FEI's long-term energy decisions, including the need to decarbonize in a way that maintains cost-effective, reliable and resilient service to customers. The planning environment includes relevant external factors that could impact FEI's demand-side and supply-side resource options and prices for future market purchases, influenced by an accelerated path to decarbonization.

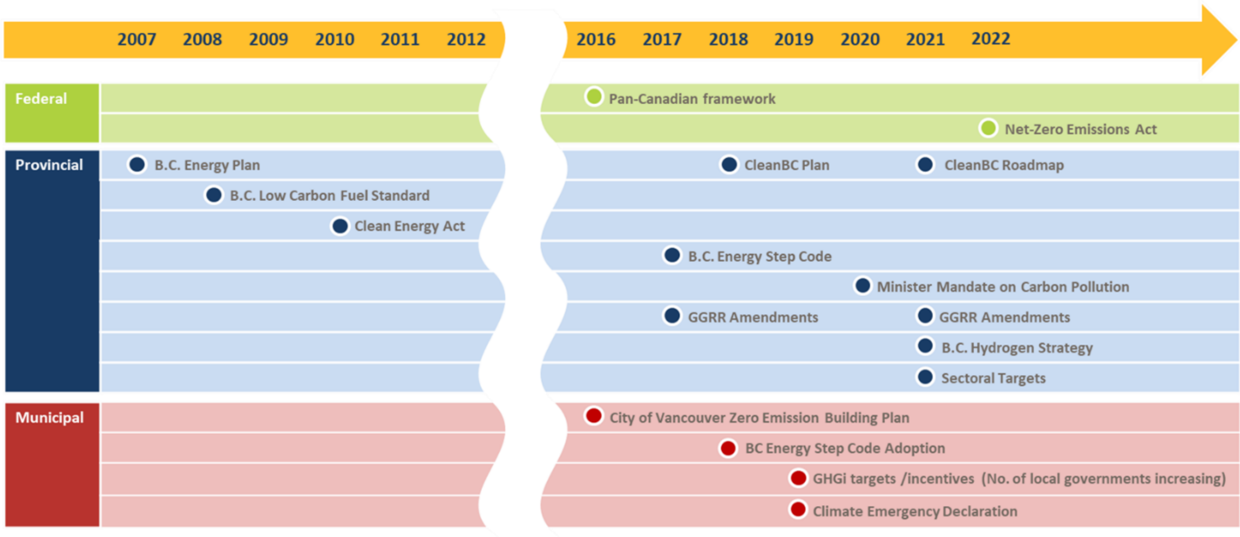
This section provides important context for the analysis, results and recommendations that are provided throughout the LTGRP by discussing the policies, legislation and competitive environment that are impacting energy planning at the time this LTGRP is being prepared. This section is organized as follows:

- Section 2.2 provides an overview of the relevant policy and regulatory context facing FEI that impact future resource options, market prices, and influence customers' behaviour regarding energy use in the future.
- Section 2.3 provides the background for FEI's engagement with Indigenous groups for long-term resource planning.
- Section 2.4 discusses the increasingly complex competitive environment for gaseous energy. Competition is influenced not only by regional energy markets and commodity pricing, but also by supply infrastructure capacity, end use equipment installation and competition.
- Section 2.5 discusses the need for resiliency in BC's energy system.
- Section 2.6 provides a summary and conclusions about FEI's planning environment and the many forces affecting the evolution of FEI's climate plan.

2.2 ENERGY AND CLIMATE POLICY DEVELOPMENTS

The urgency for climate action has resulted in environmental regulation, plans and policies from all three levels of government to promote decarbonization. Figure 2-1 provides an overview of key policy initiatives that impact FEI's business and long-range planning. As the figure shows, the majority of policies have been implemented from 2016 onwards and represent a considerable amount of change since the submission of the 2017 LTGRP.

Figure 2-1: Major Policies Adopted by All Levels of Government Demonstrate the Complexity of FEI's Planning Environment



In the sections below, FEI describes these federal, provincial and local government policies in greater detail, including those policies that have yet to be implemented.

- Section 2.2.1 outlines Canadian federal policies and initiatives.
- Section 2.2.2 outlines provincial government policies.
- Section 2.2.3 outlines local government and municipal policies.

2.2.1 Canadian Federal Energy and Climate Policies

There have been a number of Canadian federal policies and initiatives aimed at addressing climate change, reducing GHG emissions, and developing cleaner energy sources. The federal Liberal party committed to greater effort to meet and exceed the Paris targets, including a pledge to reach net-zero by 2050. In the fall of 2020, the Liberal government announced a new climate plan to exceed its 2030 targets, signaling carbon tax increases, deep energy and climate policy reform, and significant public investment into energy transition efforts. Of significance, within the plan is a proposed carbon tax escalation of $15 per tonne per year after 2022, reaching $170 per tonne by 2030. Most recently, at the COP26 conference in November 2021, the federal government announced a cap on oil and gas sector emissions[33] to reach net-zero by 2050.

The federal climate policy framework is focused on achieving Canada's 2030 GHG reduction goals with wide-ranging measures targeting all key emitting sectors (buildings, transportation and

[33] Appendix F-3: Cap and Cut Emissions from Oil and Gas (2020), online at: https://liberal.ca/our-platform/cap-and-cut-emissions-from-oil-and-gas/.

industry). However, while natural gas is one of the most widely used fuels in Canada, there is no specific federal climate policy direction on the future of the gas delivery system.

The policies, targets and initiatives discussed below illustrate that the conversation around the role of the gas system in decarbonizing Canada's GHG emissions is undefined. While public opinion and governmental objectives have become more stringent regarding climate change, there remains a lack of clarity regarding the specific actions expected of energy utilities such as FEI.

2.2.1.1 *Pan-Canadian Framework*

The *Pan-Canadian Framework on Clean Growth and Climate Change*[34] (PCF) was Canada's first national climate plan and was released in December 2016. The PCF marked a shift towards increased federal involvement in climate policy. The PCF has four main pillars:

- pricing carbon pollution;
- complementary measures to reduce emissions;
- climate change adaptation; and
- actions to accelerate innovation.

Most notably, the PCF contains measures to significantly reduce emissions in the buildings sector by making new buildings net-zero, retrofitting existing buildings, fuel switching, improving energy efficiency for appliances and equipment and supporting building codes and energy-efficient housing. In 2017, the PCF set an aspirational goal that by 2035 all space heating technologies sold will have a performance of greater than 100 percent efficiency. This would effectively ensure that only electric or gas heat pumps would be available for use by this time. The PCF signalled further electrification measures for the buildings sector and fuel switching from natural gas.

2.2.1.2 *Net-Zero Emissions Accountability Act and Emissions Reduction Plan*

The *Canadian Net-Zero Emissions Accountability Act* (CNZEAA) was passed in 2021[35] and as part of this Act, the first Emissions Reduction Plan[36] (ERP) was recently published in March, 2022.[37] The ERP outlines over $9 billion in additional funding along with policies, actions and strategies that will lead Canada to the newly updated target of a 40-45 percent GHG emissions reduction by 2030. Some of the key features of the ERP include:

---

[34] Appendix F-4: Pan-Canadian Framework on Clean Growth and Climate Change (2017), online at: https://publications.gc.ca/collections/collection_2017/eccc/En4-294-2016-eng.pdf.

[35] S.C. 2021, c. 22, online at: https://laws-lois.justice.gc.ca/eng/acts/c-19.3/FullText.html.

[36] Online at: https://www.canada.ca/en/environment-climate-change/news/2022/03/2030-emissions-reduction-plan--canadas-next-steps-for-clean-air-and-a-strong-economy.html

[37] Environment and Climate Change Canada, 2030 Emissions Reduction Plan (2022), online at: https://www.canada.ca/content/dam/eccc/documents/pdf/climate-change/erp/Canada-2030-Emissions-Reduction-Plan-eng.pdf.

- A cap on emissions from the upstream oil and gas sector set at 42 percent below 2019 levels and a 75 percent reduction in methane emission by 2030;
- Programs and incentives to reduce the use of fossil fuels in buildings and funding for a national green buildings strategy;
- Medium and heavy duty sales mandate to achieve 100 percent zero emissions vehicle mandate by 2040;
- A bioenergy strategy to optimize use of Canadian bioenergy resources;
- Advancement of the federal Hydrogen strategy to increase the use of hydrogen in transportation, industrial and hard to decarbonize sectors;
- A national carbon capture, utilization and storage strategy and tax credit to encourage the adoption of such technologies (potentially including hydrogen made from natural gas feedstock); and
- Funding for nature-based carbon sequestration activities.

This is the first time the federal government has published a comprehensive plan for reducing emissions that is legally binding based on the CNZEAA. The ERP is subject to change and adaptation as it has not been fully designed. The CNZEAA establishes a legally-binding process to set five-year national emissions reduction targets as well as develop a credible science-based emissions reduction plan to achieve each target. It also establishes a requirement to set national emissions reduction targets for 2035, 2040 and 2045, with plans to achieve it. Under CNZAA, the federal government formed the Net-Zero Advisory Body to provide independent advice to the Minister of Environment and Climate Change on achieving net-zero emissions by 2050. This includes recommendations on GHG emissions reduction targets for 2030, 2035, 2040 and 2045, as well as GHG emissions reduction plans by the Government of Canada, including measures and sectoral strategies the government should implement to meet GHG targets. The Net-Zero Advisory Body has the influence to direct policy at the highest level in Canada and does not include any representatives from the gas industry.

2.2.1.3 *Clean Fuels Regulations*

Under the *Canadian Environmental Protection Act, 1999*, the federal government published a draft of its *Clean Fuel Regulations*[38] at the end of 2020, which is central to the federal government's mandate to reduce GHG emissions 30 percent by 2030. The 2020 draft does not include gaseous and solids streams, and only targets liquid fuels, mainly used in the transportation sector. This means that there is currently no federal mandate for gas utilities to decarbonize their fuel and signals that there is no longer-term vision for the low-carbon solutions delivered by the gas system as part of the federal government's overall approach to climate action, despite the merits of this approach to decarbonization.

[38] Appendix F-5: Clean Fuel Regulations (2020), online at: https://gazette.gc.ca/rp-pr/p1/2020/2020-12-19/html/reg2-eng.html.

2.2.1.4 *New Federal Climate Plan: Healthy Environment and a Healthy Economy*

In December 2020, the federal government released a plan titled *A Healthy Environment and a Healthy Economy*[39] (HEHE) that builds on the PCF. The current HEHE plan includes a number of measures that promote the electrification of key emitting sectors in Canada.

A significant focus of federal energy intervention has been on improving building energy efficiency for new and existing buildings. The HEHE contains measures to improve energy efficiency in buildings and work on building codes with provincial and municipal governments. This includes an investment of up to $1.5 billion over three years in energy efficient buildings. It also includes an investment of $2.6 billion over seven years to help homeowners retrofit their existing homes, create a low-emission buildings material supply chain, design a new retrofit code for existing buildings to be put into place by 2025, and initiate Canada's first national infrastructure assessment that would undertake long-term planning towards a net-zero future.

The HEHE does not outline a specific role for the gas system to achieve the net-zero by 2050 target except for expanded program spending for clean fuels, which includes renewable natural gas.

2.2.1.4.1 CANADA GREENER HOMES GRANT

The Canada Greener Homes Grant[40] is a federal government initiative launched in 2021, under its policy umbrella of energy efficiency for homes. The aim of this grant is to help Canadians make their homes more energy efficient, create jobs across Canada for energy advisors and help homeowners make retrofits.

While FEI supports the federal government's funding for energy efficiency initiatives, the Canada Greener Homes Grant, as it currently stands, primarily uses taxpayer dollars to help citizens invest in electric technologies. In doing so, the program misses the opportunity to support high-efficiency gas appliance upgrades, which can be fuelled seamlessly by renewable and low-carbon gas over the planning horizon.

2.2.1.4.2 FEDERAL CARBON PRICE

A key aspect of the federal government's emissions reduction strategy as outlined in the HEHE is an updated approach to carbon pricing. In December 2016, the federal government announced that it planned to require the provinces to impose a price of at least $10 per tonne of carbon dioxide equivalent emissions starting in 2018. The price would rise by $10 per tonne a year for the next four years, reaching $50 per tonne by 2022.

As part of the HEHE plan, the federal government announced that it plans to increase the price on carbon as part of a push to meet and surpass Canada's goal of reducing GHG emissions by

[39] Appendix F-6: A Healthy Environment and a Healthy Economy (2020), online at: https://www.canada.ca/en/environment-climate-change/news/2020/12/a-healthy-environment-and-a-healthy-economy.html.

[40] Appendix F-7: Canada Greener Homes Grant (2020), online at: https://www.nrcan.gc.ca/energy-efficiency/homes/canada-greener-homes-grant/23441.

30 per cent below 2005 levels by 2030. The carbon price would rise by $15 per tonne a year for the next eight years beginning in 2023, to reach $170 per tonne in 2030. There are still some key unknowns on the future of carbon pricing in Canada.

2.2.1.4.3 LOW-CARBON INDUSTRY

For industrial emitters, the federal government is launching a "Net-Zero" challenge for large emitters to implement plans to transition their facilities to net-zero. To support industry's efforts in this area, the Federal government has committed to investing $3 billion over five years in the Strategic Innovation Fund's Net-Zero Accelerator. This fund will expedite decarbonization projects and scale-up new technology. The federal government is also investing $1.5 billion in a low-carbon and zero-emission fuels fund to increase the use of low-carbon fuels which include hydrogen, renewable natural gas and diesel. This plan also introduces Canada's Hydrogen Strategy,[41] which FEI discusses in Section 2.2.2.4., along with the BC Hydrogen Strategy.[42]

2.2.1.4.4 IMPACT ASSESSMENT ACT NOW REQUIRES PROJECTS TO ACHIEVE NET-ZERO BY 2050

The *Strategic Assessment of Climate Change*[43] (SACC) was released in 2019 and is conducted under the *Impact Assessment Act*[44] (IAA). It applies to designated projects as defined under the IAA and each assessment must consider the extent to which the project will hinder or contribute to Canada's ability to meet its climate change commitments and the project's potential impact on the environment. The SACC is meant to provide guidance to stakeholders and decision-makers on how climate change policies and commitments should be considered in impact assessments.[45] Included in the SACC, is the requirement for projects with a lifetime beyond the year 2050 to provide a credible plan that describes how the project will achieve net-zero emissions by 2050.

Federal guidance on evaluating net-zero projects will be needed to outline the potential mechanisms to achieve net-zero along with an appropriate designation of net-zero accounting. It is anticipated that this requirement is likely to continue to evolve as climate impacts, technologies, political and policy contexts change. Projects under development by FEI are being evaluated and designed to meet climate objectives, and FEI will continue to undertake further analysis as additional investments are made over the planning horizon.

2.2.2 Provincial Energy and Climate Policies

Similar to the federal government policies outlined in Section 2.2.1, the provincial government has intensified its efforts to address climate change through a variety of policies, measures and proposals discussed below, which suggest that both electrification and the decarbonization of the gas system are key strategies to meet the provincial government's climate goals. The depth and intensity of measures reflects that, while BC has made progress to reduce the carbon intensity of its economy, it is not on pace to achieve its 2030 target of a 40 percent reduction from 2007 levels. Therefore, further initiatives are underway to accelerate climate action, which create new opportunities and challenges for FEI and its customers.

2.2.2.1 *Climate Change Accountability Act*

In 2017, the provincial government enacted the *Climate Change Accountability Act*[46] (CCAA) which included targets for reducing GHG emissions in BC. The CCAA identified GHG reduction targets below 2007 levels as follows:

- 16 percent by 2025;
- 40 percent by 2030;
- 60 percent by 2040; and
- 80 percent by 2050.[47]

The CCAA includes a climate change accountability framework, which involves an independent advisory committee and detailed annual reporting on actions taken to reduce emissions and manage climate change risks.

The CCAA required the Minister of Environment and Climate Change to establish sector-specific targets for GHG reductions by March 31, 2021, and to then review these targets by the end of 2025 (and at least once every five years thereafter). In March 2021, sectoral targets for 2030 were established as follows, expressed as a percentage reduction from 2007 sector emissions:

- Transportation – 27 to 32 percent;
- Industry – 38 to 43 percent;
- Oil and Gas – 33 to 38 percent; and
- Buildings and Communities – 59 to 64 percent.[48]

These targets will apply a more focused and directed approach to reducing emissions in these sectors. Notably, FEI delivers the majority of its energy to the industry and buildings and

[46] S.B.C. 2007, c. 42, online at: https://www.bclaws.gov.bc.ca/civix/document/id/complete/statreg/07042_01.
[47] Government of British Columbia, "Climate Action Legislation" (2021) online at: https://www2.gov.bc.ca/gov/content/environment/climate-change/planning-and-action/legislation.
[48] Online at: https://www2.gov.bc.ca/gov/content/environment/climate-change/planning-and-action/sectoral-targets.

communities sectors, which are the sectors with the most ambitious targets. This places significant pressure on FEI to source affordable, reliable and low-carbon energy. While oil and gas are considered in the sectoral targets, the CCAA provides little detail on how various sectors are to achieve the targets and how these targets will be incorporated into future climate plans and reporting.

2.2.2.2 *CleanBC Roadmap to 2030 (Roadmap)*

On October 25, 2021, the provincial government released the CleanBC Roadmap to 2030 (Roadmap)[49] as an update to the 2018 CleanBC plan and part of its commitment to achieve BC's legislated GHG reduction target of 40 per cent below 2007 levels by 2030. The Roadmap articulates a plan to fully achieve this target and sets the course to reach net-zero by 2050. The Roadmap, includes ambitious measures that place FEI at the forefront of the global energy transition. It is also anticipated to have a significant impact on FEI's customer rates, competitiveness and throughput.

Key measures in the Roadmap that directly impact FEI include:

- An increased carbon tax which will rise to $170 per tonne by 2030;
- A GHG cap for natural gas utilities;
- A zero-carbon requirement for new buildings and highest efficiency standards for space and water heating equipment by 2030;[50]
- Amendments to the *Greenhouse Gas Reduction (Renewable & Low-carbon Fuel Requirements) Act* and the *Renewable & Low-carbon Fuel Requirements Regulation*, known collectively as British Columbia's Low-carbon Fuel Standard (BC-LCFS),[51] to decrease the carbon intensity benchmark while including marine and aviation fuels in the amendment; and
- A 75 percent reduction in oil and gas methane emissions by 2030.

The Roadmap identifies key priorities for decarbonizing the buildings and communities, transportation, and industry sectors; however, its measures rely heavily on electrification to reduce GHG emissions. This policy preference is demonstrated in the release of the BC Hydro Electrification Plan[52] which aims to increase electrification of gas end uses, including transportation, and in measures such as zero carbon new construction and energy efficiency

---

[49] Appendix A-5: CleanBC Roadmap to 2030.

[50] This includes a requirement that all space and hot water heating equipment must meet or exceed 100 percent efficiency after 2030 which cannot be met with conventional natural gas equipment.

[51] BC-LCFS, online at: https://www2.gov.bc.ca/gov/content/industry/electricity-alternative-energy/transportation-energies/renewable-low-carbon-fuels.

[52] BC Hydro Electrification Plan, online at: https://www.bchydro.com/content/dam/BCHydro/customer-portal/documents/corporate/electrification/Electrification-Plan.pdf.

standards where gas solutions are not yet established. Several aspects of the Roadmap are explored further below.

2.2.2.2.1 BC CARBON TAX

Among the measures announced in the Roadmap, the carbon price of $50 will either match or exceed the federal carbon price, which is expected to rise to $170 per tonne by 2030, with annual increases of $15 starting in 2023. This would have the effect of increasing the carbon price on natural gas to approximately $8.40 per GJ by 2030. In BC, the provincial government has recognized the emission reduction benefits of RNG through a credit providing a benefit to purchasers of RNG. The credit is equal to the carbon tax payable on the specified volume or percentage of biomethane,[53] thereby incenting customers to transition to a lower-carbon fuel.

The cap on emissions for natural gas utilities as proposed in the Roadmap, to be implemented as the Greenhouse Gas Reduction Standard (GHGRS), would put an implicit price on carbon by limiting the supply of GHG emissions that would be allowed. The GHGRS is discussed further in Section 2.2.2.2.2 below.

2.2.2.2.2 GREENHOUSE GAS REDUCTION STANDARD (GHGRS): EMISSIONS CAP FOR NATURAL GAS UTILITIES

Before the Roadmap, the 2018 CleanBC plan outlined a target for natural gas delivered to industrial and residential consumers to contain at least 15 percent renewable content by 2030. Displacing 15 per cent of the natural gas supply with renewable gas would increase the annual renewable gas supply to approximately 30 PJ and reduce emissions by approximately 1.5 million tonnes. The renewable gas target was thus a substantial part of the buildings emissions reduction strategy.

The Province’s approach was updated in the Roadmap with a cap on GHG emissions for natural gas utilities called the GHGRS. The GHGRS will establish an obligation for natural gas utilities to reduce GHG emissions from energy use in the buildings and industrial sectors. FEI expects compliance with the cap to be overseen by the BCUC and that enabling legislation will be developed that will further define how this policy will be implemented for gas utilities.

The move from a voluntary renewable gas target to a mandated GHG emissions cap is a substantial change in direction for provincial policy. While details on the GHGRS remain under development, FEI expects that it will place a stringent emissions reduction obligation on gas utilities. Compliance pathways to achieve the cap have not yet been developed; however, these pathways will be highly consequential for the overall role of gas utilities and for customers that rely on the energy that natural gas utilities deliver.

The GHGRS is the first of its kind in Canada, and will mandate FEI to invest in carbon saving technologies and solutions to displace natural gas consumption by 2030. As described in the report, “the cap will be set at approximately 6 Mt of CO_2e per year for 2030, which is approximately

[53] Part 4.1, *Carbon Tax Regulation*, B.C. Reg. 65/2021, online at: https://www.bclaws.gov.bc.ca/civix/document/id/complete/statreg/125_2008.

47 percent lower than 2007 levels."[54] The GHGRS would require a GHG reduction of approximately 5.5 Mt of CO_2e, which is equivalent to displacing approximately half of the natural gas delivered by FEI.

Additionally, the GHGRS imposes a target of a 61 percent emissions reduction in the buildings sector by 2030. This is an aggressive goal that disproportionately impacts FEI, and is more representative of a 2040 target, thereby requiring a more rapid transition in the buildings sector at greater cost and risk.

It is anticipated that the GHGRS policy framework will enable FEI to invest in a broad set of GHG-saving actions such as increasing renewable and low-carbon gases and incenting higher levels of energy efficiency and other measures. Although many uncertainties remain for FEI, the 2022 LTGRP provides context around FEI's approach to addressing the Roadmap. FEI will continue to work with the Province and other stakeholders to further clarify issues and implications for FEI and its customers.

2.2.2.2.3 BUILDINGS SECTOR

In the Roadmap, new carbon pollution standards are set for the BC Building Code, which envision a transition to zero-carbon new buildings by 2030. The standards are anticipated to be performance-based with flexible options, such as the use of renewable and low-carbon fuels like RNG. For renewable and low-carbon fuels to have a meaningful role in the buildings sector decarbonization policies, issues such as GHG reduction permanency[55] will need to be resolved. This makes new approaches such as FEI's proposed revised Renewable Gas Comprehensive Review, submitted to the BCUC in December 2021,[56] essential to aligning with the provincial government's GHG reduction objectives.

In addition to requiring low-carbon energy for new buildings, the Roadmap requires all new space and water heating equipment sold and installed in BC to be at least 100 percent efficient by 2030. Electric and high-efficiency gas heat pumps, hybrid systems, and deep energy retrofits will be used to reach this goal while incentives for conventional natural gas-fired equipment will be phased out. This suggests that the provincial government sees a declining role for conventional home heating and water heating appliances in favour of gas and electric heat pump solutions. However, gas heat pumps are not yet commercially available for residential customers, leading to uncertainty regarding gas heat pump adoption timelines in reference to the 100 percent efficiency standard in 2030.

In the 2022 provincial budget announcement, there were additional measures to support electrification. These factors included increased carbon tax on natural gas bills, elimination of

[54] Representing the average sectoral reduction required for the buildings and communities and industry sectors.

[55] Permanency of GHG emissions reductions is an important issue for municipal policymakers and refers to the extent to which FEI's measures, such as supplying RG, are voluntary in nature, allowing customers to opt out of an offering over time, thereby eroding their permanence.

[56] Exhibit B-11, FEI Comprehensive Review and Application for Approval of a Revised Renewable Gas Program (December 17, 2021), online at: https://docs.bcuc.com/Documents/Proceedings/2021/DOC_65216_B-11-FEI-Stage-2-Comprehensive-Review-Application-of-Revised-Renewable-Gas-Program.pdf.

provincial sales tax (PST) for heat pumps and increased PST on all gas combustion appliances such as furnaces, water heaters and fireplaces.[57] Each of these factors contribute to reducing FEI's price competitiveness and influence customer energy choices.

2.2.2.2.4 TRANSPORTATION SECTOR: THE BC LOW-CARBON FUEL STANDARD

The BC-LCFS focuses on reducing environmental impacts of transportation fuels by requiring decreases to the average carbon intensity of transportation fuels. In the 2018 CleanBC plan, the stringency of the BC-LCFS was doubled and the carbon intensity reduction target for gasoline and diesel rose from 10 percent to 20 percent by 2030.

Under the BC-LCFS, organizations can generate credits by using fuels with a carbon intensity below the targets and receive debits for fuels with a carbon intensity above the targets. Each credit represents 1 tonne of CO_2e that was either removed from the atmosphere or not released into the atmosphere as the result of direct, beyond business-as-usual action by a project proponent. These credits can be traded between companies or banked for future use.

Conventional natural gas is below the current carbon intensity threshold in the BC-LCFS. As such, FEI's Compressed Natural Gas (CNG) and LNG transport customers can earn credits under the BC-LCFS and sell them to other organizations, reducing the cost of adopting a low-carbon transportation solution. As an even lower carbon fuel, RNG and hydrogen present an opportunity for FEI's customers in the transport sector to further exceed the carbon intensity threshold in the BC-LCFS, earn more credits, and sell the credits to offset the costs of the supply.

The Roadmap states that the provincial government will increase the stringency of the BC LCFS. New targets will be developed for medium- and heavy-duty vehicles, as the costs and difficulty to electrify these vehicles remain high. The provincial government also intends to modernize the legislation governing the BC-LCFS, including expanding it to cover marine and aviation fuels beginning in 2023. The increased stringency of the BC-LCFS results in uncertainties for FEI's CNG and LNG vehicle programs as the volume of credits they generate may be significantly reduced or eliminated. While RNG will be able to generate more credits as a result of the BC-LCFS change, there will be pressures on RNG supply to meet FEI's other GHG reduction obligations under the GHGRS. In the Roadmap, the CI target will be raised beyond 20 percent to 30 percent.

The BC-LCFS will also be expanded to include marine and aviation fuels, which is advantageous for FEI because the inclusion of marine fuels improves the competitiveness of BC LNG. However, there is currently no detail on the timing or nature of this policy development.

2.2.2.2.5 INDUSTRIAL SECTOR

The Roadmap sets out that all new large industrial facilities need to have a plan to achieve net-zero emissions by 2030 and demonstrate alignment with BC's interim 2030 and 2040 targets. Moreover, emitters of methane will be required to reduce their emissions by 75 percent by 2030 and have emissions close to zero by 2035. FEI will explore opportunities for renewable and low-

[57] The PST on electricity consumption was eliminated in 2019.

carbon gas to serve these sectors as they seek low-carbon alternatives. It is unclear at this point how these industrial requirements overlap with the emissions cap for utilities.

2.2.2.2.6 OIL AND GAS SECTOR

The Roadmap aims to reduce methane emissions from upstream oil and gas, reduce oil and gas emissions in line with sectoral targets, advance CCUS, and engage industrial customers in GHG reduction planning. While there are few details on the cap for oil and gas emissions, the benefits of reduced emissions reduction in upstream gas production will reduce the carbon intensity of natural gas that FEI distributes and provincial emissions. However, these initiatives could potentially increase the commodity cost of gas in the province, impacting FEI customer rates.

2.2.2.3 *Support for Renewable and Low-Carbon Gases and Low-Carbon Transportation: The Clean Energy Act (CEA) and Greenhouse Gas Reduction Regulation (GGRR)*

2.2.2.3.1 RENEWABLE AND LOW-CARBON GASES

The CEA has been the key piece of legislation enabling an increase in the supply of RNG. When FEI applied for approval of what was then called the Biomethane Program in 2010, the energy objectives in the CEA, including the objectives to reduce GHG emissions and waste by encouraging the use of waste heat, biogas and biomass,[58] supported FEI's development of the program. Since that time, the Lieutenant Governor in Council has amended the GGRR to prescribe undertaking to encourage public utilities to acquire renewable and low-carbon fuels to reduce GHG emissions. These undertakings are described below.

On March 21, 2017, the Lieutenant Governor in Council issued Order in Council 161/2017 approving an amendment to the GGRR related to the acquisition of RNG as follows:

> (3.7) A public utility's undertaking that is in the class defined in subsection (3.8) is a prescribed undertaking for the purposes of section 18 of the Act.
>
> (3.8) The public utility acquires renewable natural gas
>
> > (a) for which the public utility pays no more than $30 per GJ, and
> >
> > (b) that, subject to subsection (3.9), in a calendar year, does not exceed 5percent of the total volume of natural gas provided by the public utility to its non-bypass customers in 2015.

This GGRR amendment has facilitated the growth in RNG supply projects over the last four years by allowing FEI to acquire RNG up to a maximum price (supply volumes and projects are further described in Section 6).

[58] Section 2, CFA, online at: https://www.bclaws.gov.bc.ca/civix/document/id/complete/statreg/10022_01#section2.

More recently, in 2021, the provincial government amended the GGRR to broaden its scope and further increase the production and use of renewable and low-carbon gases, including renewable energy from green and waste hydrogen in BC, to reduce GHG emissions. The changes to the GGRR supporting growth in renewable and low-carbon supply include:

- Enabling utilities to acquire green and waste hydrogen, synthesis gas[59] and lignin, in addition to RNG;
- Increasing the amount of RNG, green and waste hydrogen, lignin, and syngas that utilities can acquire from five percent to fifteen percent of the total annual supply of natural gas;
- Specifying the methods by which utilities can acquire renewable and low-carbon gases, including producing it or upgrading it themselves for injection into the pipeline, paying a third party to produce it or upgrade it for pipeline injection, or purchasing hydrogen, syngas or lignin to displace the use of natural gas at customer facilities; and
- Increasing the price cap utilities can pay to acquire renewable and low-carbon gases from $30 to $31 per GJ for contracts for purchase signed after March 31, 2021[60] and increasing the price cap annually by inflation.

The GGRR enables FEI to be more flexible, stimulates investment in renewable energy and accelerates growth of renewable and low-carbon gas supply in the gas system and acquire renewable and low-carbon gases from $30 to $31 per GJ for contracts. The changes to the GGRR enable FEI to help to achieve the CleanBC Plan objectives, which call for a 15 percent renewable and low-carbon gas content in the natural gas system by 2030. Further, with the recent introduction of the Roadmap in October 2021, FEI expects supply volumes to exceed 15 percent.

BC is the first province in Canada to pass legislation to encourage the production of renewable and low-carbon gases, including hydrogen. The GGRR supports the provincial government's hydrogen strategy, as described below, which includes goals to increase the production and use of renewable and low-carbon hydrogen to help achieve climate targets under the Roadmap.

2.2.2.3.2 LOW-CARBON TRANSPORTATION (LCT)

The GGRR also authorizes a utility to invest up to $331.5 million in low-carbon transportation (LCT) programs, with commitments for funding to be made by March 31, 2022. The Province's plans to continue to support LCT through the GGRR are not yet known. To date, funding was included for the following:

- Capital incentives to transportation fleets that use natural gas as a fuel in place of diesel (or other higher carbon emitting fuels). These fleets include marine vessels, heavy duty

[59] The CleanBC Roadmap inadvertently referred to this as synthetic gas, when it should be synthesis gas. Synthesis gas (or syngas) and lignin can be produced from biomass and used to displace the use of natural gas for industrial heat applications. Please refer to Section 2.3.1.2 for further description.

[60] Or, where the utility is producing the Renewable Gas, where the decision to construct the production facilities is made after March 31, 2021.

trucks, locomotives, mine haul trucks, and busses. Funding also includes natural gas used to produce power for remote industrial applications.

- Capital incentives to CNG and LNG transportation fleets that consume gas supply that is derived entirely from biogas or biomass;
- Developing LNG bunkering infrastructure such as shoreside fueling assets to the marine market;
- Building, owning and operating CNG and LNG fueling stations; and
- Grants to meet safety guidelines for operating and maintaining natural gas vehicles.

These prescribed undertakings in the GGRR are designed to facilitate adoption of natural gas as a transportation (or power generation) fuel to displace higher carbon emitting fuels such as diesel and heavy marine oil. For LCT customers, there are immediate benefits from adopting natural gas into their fleets, such as lower fuel and operating costs, improved air quality due to reduced emissions, and reduced environmental hazards associated with diesel and oil storage tanks.

FEI's LCT efforts will assist BC in achieving its GHG reduction goals by converting the province's transportation fleets from more carbon intensive fuels, such as diesel and gasoline, to relatively cleaner-burning natural gas. Further, the broader adoption of natural gas fuel in the transportation sector will reduce air contaminants such as particulate matter (PM), sulfur oxides (SOx) and nitrous oxides (NOx).

For FEI's customers, CNG and LNG demand also adds value by increasing the year-round load on the gas distribution system (and hence FEI's delivery revenues), thereby reducing upward pressure on delivery rates for all gas customers.

2.2.2.4 *Hydrogen Policies*

Hydrogen technology continues to evolve and is becoming an increasingly viable option for decarbonizing the gaseous fuel stream. While the potential for hydrogen has been around for many decades, the price advantage and robust natural gas supply chain has made it difficult for hydrogen to make inroads in the utility energy supply market. However, with increasing GHG reduction mandates, hydrogen is now seen as a viable option for decarbonizing the gas system, as recognized in the amendments to the GGRR permitting the acquisition of hydrogen. Both the federal and provincial governments have a hydrogen strategy each of which is outlined in this section.

2.2.2.4.1 CANADIAN HYDROGEN STRATEGY

The Hydrogen Strategy for Canada lays out a plan to position Canada as a global leader in clean renewable fuels. The strategy shows that, with the use of clean hydrogen, Canada can achieve net-zero goals by innovating and embracing new technologies. Canada is currently one of the top ten producers of hydrogen in the world and is well positioned to decarbonize many sectors of the economy. The Hydrogen Strategy aims to position Canada as a world-leading producer, user, and exporter of clean hydrogen and associated technologies. Areas of focus include:

- **Production**: Canada is rich in feedstocks such as water, electricity, fossil fuels and biomass and hence is well positioned to become a top global producer of clean hydrogen.
- **Distribution and storage**: leveraging Canada's extensive natural gas pipeline network, along with new storage and distribution assets, allows hydrogen to be transported from production to end use locations.
- **Heat and power**: developing a suite of tools and resources to blend low-carbon intensity hydrogen into Canada's natural gas networks, for use in both industry and the built environment.
- **Feedstocks for industry**: developing policies that will ensure long-term certainty to encourage private sector investment and innovation for hydrogen as an energy source and feedstock in industrial processes.

2.2.2.4.2 BC HYDROGEN STRATEGY

For BC to meet its climate targets, hydrogen will play a critical role. The BC Hydrogen Strategy lays out the actions that the provincial government will take to grow the hydrogen economy. Recognizing the potential for hydrogen in the province, industry and researchers will work together to carry out the provincial government's plan to accelerate the production and use of hydrogen and be a leader in the growing hydrogen economy. These government supply strategies provide the backdrop for growing FEI's renewable and low-carbon gas supply portfolio.

The provincial government's hydrogen strategy includes 63 actions the province intends to pursue over the short, medium and long-term. The BC Hydrogen Strategy includes:

- **2020 to 2025**: Support for blending hydrogen with natural gas.
    - Establish a regulatory framework for injecting hydrogen into the natural gas and propane distribution systems.
    - Include hydrogen as a prescribed undertaking under the GGRR.
    - Partner with a utility to review the infrastructure requirements to accommodate up to 100 percent hydrogen in the distribution system.[61]
- **2025 to 2030:** Support hydrogen injection trials into natural gas and propane distribution systems.
    - Mandate that new or modified natural gas or propane pipelines be hydrogen compatible.
    - Support the introduction of hydrogen-tolerant equipment.

[61] Some of these activities are already underway.

  - Explore the role of hydrogen in meeting the CleanBC 15 percent renewable gas target.

- **2030 and beyond**: Support large-scale hydrogen injection into the natural gas and propane distribution systems.

In 2019, FEI, BC Bioenergy Network, and the Province commissioned the BC Hydrogen Study[62] which identified the significant role that hydrogen could play in achieving provincial deep decarbonization goals. Securing additional supply from a diversified group of providers will provide greater reliability to FEI's renewable and low-carbon gas supply. The study also identifies how the gas infrastructure is a strategic asset both for the transportation and storage of hydrogen and identifies the potential for blending hydrogen into the gas system.

2.2.3 Municipal Actions Addressing Energy and Climate Policy

Evolving municipal and local government policies to address climate change at the local level are primarily focused on further electrification. Many municipalities in FEI's service area are developing updated versions of their climate action plans, with a major focus on reducing GHG emissions while setting ambitious targets out to 2050. Most of the targets address emissions in the transportation and building sectors, with the use of alternative energy sources and energy efficiency helping to reduce the reliance on fossil fuels. Before the provincial government released the Roadmap in October 2021, climate and energy policy at the local government level was evolving at a much faster pace than both provincial and federal policy.

The majority of local governments in BC have signed the BC Climate Action Charter, a voluntary agreement between the provincial government and the Union of BC Municipalities under which each local government signatory commits to take action on climate change. In doing so, municipalities and local governments began undertaking their own initiatives, in addition to provincial efforts, to reduce emissions. In recent years, 30 municipalities in BC have also declared climate emergencies, including the Cities of Surrey, North and West Vancouver, Vancouver, Burnaby, Richmond, New Westminster, and Port Moody.

Along with these commitments, a growing number of local governments are implementing changes to their building codes[63], planning guidelines, and zoning bylaws in order to reduce GHG emissions in new building construction projects and in some cases with existing building retrofits and improvements. This is being achieved by:

- establishing GHG target limits for new construction, necessitating the use of low- carbon or renewable energies; and

---

[62] Appendix A-6: British Columbia Hydrogen Study (2019), online at: https://bcbioenergy.ca/resources/bcbn-publications/british-columbia-hydrogen-study/.

[63] Specifically, the City of Vancouver is enabled under the Vancouver Charter to adopt by-laws to regulate the design and construction of buildings. Other municipalities must follow the provincial building code but can provide zoning by-laws that can be enforced.

- incenting developers to use electricity as a low-carbon solution (or in some cases to not connect to a "fossil fuel supply grid" system).

2.2.4 Energy and Climate Policy in Relevant US States

US energy policy influences markets and energy distribution throughout BC's broader energy trading region and is therefore a consideration in FEI's long-term resource planning environment. Electricity, natural gas, and RNG are supplied and distributed throughout networks across North America. It is therefore important to consider the North American perspective in energy planning and GHG reduction strategies. Overall, the US policy context impacts BC's natural gas use environment in the following ways:

- Upstream natural gas resources in northeast BC and Alberta serve large portions of Western US demand for natural gas and natural gas used for electricity generation.
- US policy may influence Canadian policy due to potential impacts on the relative economic competitiveness of each jurisdiction. Various legislative and policy developments of the federal and state governments in the US may affect demand for natural gas from natural gas utilities and electricity generation facilities, and therefore impact the interconnected wholesale electricity market and subsequently natural gas and renewable gas markets in the western US.
- Initial efforts had been placed on decarbonizing the electricity sector (primarily by retiring coal-fired generation), and more recently, promoting electrification as the subsequent initiative for GHG emission reduction. Across the North American grid, there remains a high proportion of higher carbon electricity that needs to be considered. In a comprehensive review of energy planning, it is becoming clear that electricity will not be able to service all the needs for energy across residential, commercial and industrial sectors and that a diversified approach is critical to meet a growing population and economy.[64]

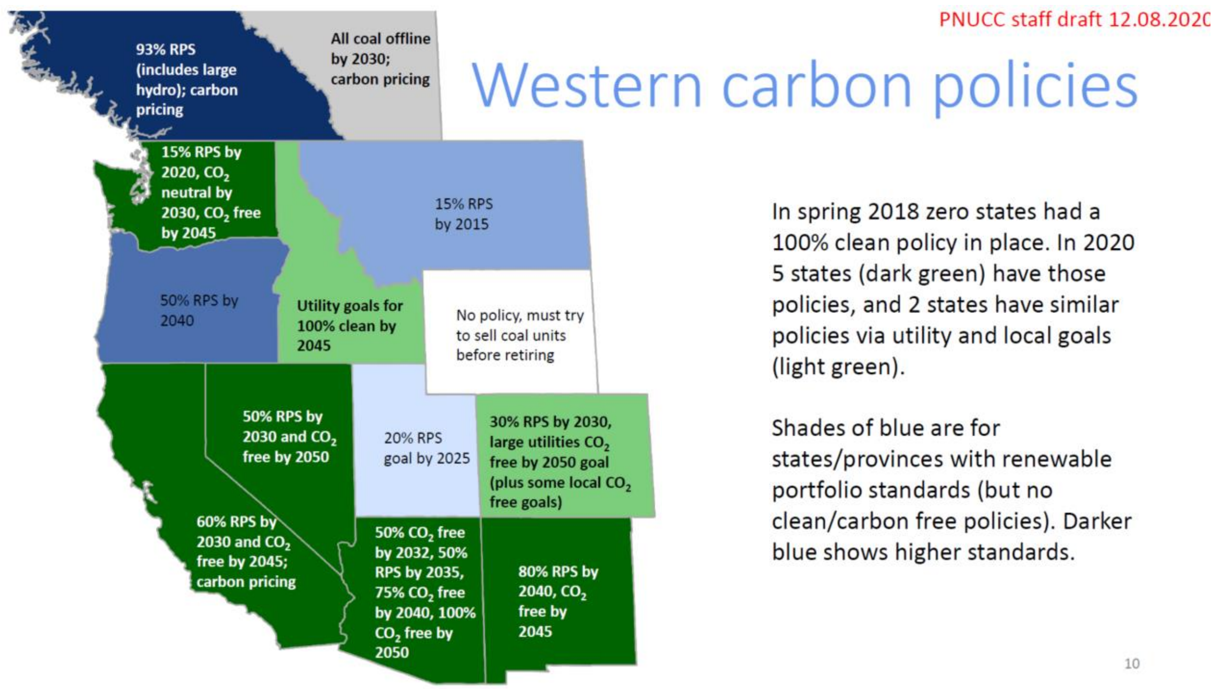
Renewable Portfolio Standards (RPS) are policies designed to increase generation of electricity from renewable sources. These policies require or encourage electricity producers within a given jurisdiction to generate and supply a minimum share of their electricity from designated renewable resources such as wind, solar, biomass, some forms of hydro-electricity and other alternatives to fossil fuel and nuclear electricity generation. The adoption of these standards demonstrates the speed of change and innovation in the energy sector.

The 2017 LTGRP highlighted the increase in the introduction of RPS. Since 2017, these policies have been rapidly accelerated to address the effects of climate change. US policy objectives include decarbonizing the power sector towards net-zero emissions by 2035, and for the US as a whole to achieve net-zero emissions by 2050. Figure 2-2 illustrates the speed of change of

[64] Appendix A-7: Guidehouse (for the American Gas Foundation), Building a Resilient Energy Future: How the Gas System Contributes to US Energy System Resilience (2021), online at: https://gasfoundation.org/wp-content/uploads/2021/01/Building-a-Resilient-Energy-Future-Full-Report_FINAL_1.13.21.pdf.

western US states with regards to the adoption of RPS or voluntary targets, versus those without any standard or target. The following two sections detail recent policy action affecting natural gas utilities in two relevant PNW states, Washington and Oregon, as these policies may impact BC's energy market.

Figure 2-2: Western Carbon Policies[65]



2.2.4.1 *Washington Policy Actions*

In March 2020, Washington released its climate targets to reduce GHG emissions by 45 per cent below 1990 levels by 2030 and 95 per cent below 1990 levels by 2050.[66] This was put into legislation in April 2021, when Washington obtained senate approval of its *Climate Commitment Act* (CCA).[67] One of the key components of the CCA includes a program with a declining cap on carbon emissions. The CCA targets the largest emitters in the state to help ensure that Washington can meet its climate targets. The CCA was passed in 2021, with the program beginning January 1, 2023.

Additionally, as part of the *Clean Energy Transformation Act* [68] passed in 2019, Washington state enacted legislation that requires total natural gas costs to include the social cost of GHGs and related upstream carbon emissions, which is expected to increase total natural gas costs.

[65] Northwest Power System Trends 2021, slide 10, as presented in Pacific Northwest Utilities Conference Committee System Planning Committee meeting December 16, 2020.

[66] Governor Jay Inslee's Medium Page, "Inslee announces bold climate legislation as part of supplemental budget rollout" (December 19, 2019).

[67] Online at: https://app.leg.wa.gov/RCW/default.aspx?cite=70A.65.

[68] Online at: https://lawfilesext.leg.wa.gov/biennium/2019-20/Pdf/Bills/Session%20Laws/Senate/5116-S2.SL.pdf.

A potential piece of legislation, Washington HB 1084,[69] the *Healthy Homes and Clean Buildings Act*, could substantially reduce, and potentially eliminate, natural gas utilities' role in delivering energy to many state ratepayers. This bill would require all new buildings in Washington to be zero-carbon by 2030 and seek to eliminate fossil fuel consumption in existing buildings by 2050, through providing a roadmap to phasing out gas utility service in Washington. However, this could potentially increase the replacement of conventional natural gas with RNG and other low-carbon gas, as a new policy in Washington State provides utilities the flexibility to develop RNG programs.[70] This legislation, if enacted, would put Washington on pace to become the first US state to implement statewide restrictions on natural gas infrastructure in new construction, while simultaneously tackling retrofits in existing buildings.

2.2.4.2 *Oregon Policy Actions*

Oregon has a Climate Action Plan (OCAP) that was issued in March 2020, when an executive Order 20-04 was released that stated that Oregon needs to reduce its GHG emissions by at least 45 per cent below 1990 levels by 2035, and 80 per cent below 1990 levels by 2050.[71] Further specifics on this executive order will be outlined in the upcoming years on carbon costs and programs such as a cap and reduce program to buy or sell offsets. In terms of energy, the plan targets the transportation, buildings, innovation, and clean energy sectors. In the buildings sector, OCAP set new energy efficiency goals for residential and commercial construction, representing at least a 60 percent reduction in new building energy consumption from 2006 levels. The new energy efficiency standards for appliances will also be consistent with tougher standards set by more stringent jurisdictions, specifically California. In the clean energy section of OCAP, the state utility commission will prioritize proceedings that advance decarbonization and make reductions to GHG emissions in the utility sector.

As a result of the OCAP, in December 2021, Oregon enacted a Climate Protection Program which will set enforceable limits on GHG emissions from fossil fuel use[72]. Beginning in 2022, Oregon has set an emissions cap for fossil fuel providers, which includes natural gas utilities, and the cap will tighten each year through 2050. However, the Climate Protection Program provides several compliance pathways for fossil fuel providers, which includes companies incorporating renewable fuels into their supply mix or contributing to projects that support communities' transition from fossil fuels. Lastly, Oregon governor signed Senate Bill 98 in 2019, setting voluntary RNG goals

[69] S&P Global, "Washington State proposes legislation to phase out natural gas utility service" (January 6, 2021), online at: https://www.spglobal.com/marketintelligence/en/news-insights/latest-news-headlines/washington-state-proposes-legislation-to-phase-out-natural-gas-utility-service-61819435.

for gas utilities in the state. This means that as much as 30 percent of RNG could be added into the system by 2050.[73]

2.2.5 Energy and Climate Policies Influence FEI's Long-Term Planning

The evolving federal, provincial and regional energy and environmental policies are key factors in the LTGRP planning environment and help inform FEI regarding potential impacts on future customer demand and supply over the planning horizon. Section 2.2.1 discussed how the federal climate policy framework is focused on achieving Canada's 2030 GHG reduction goals with wide-ranging measures targeting all key emitting sectors (buildings, transportation and industry). However, while natural gas is one of the most widely used fuels in Canada, there is no specific direction on the future of the gas delivery system. Furthermore, its role in decarbonizing Canada's GHG emissions remains undefined. Sections 2.2.2 and 2.2.3 discussed how the provincial and municipal policy frameworks are in alignment with the climate policy objectives. Section 2.2.4 discussed how US energy policy influences markets and energy distribution throughout BC's broader energy trading region and outlined the current policy environment in Washington and Oregon.

Overall, the policy preference at all three levels of government for the use of electricity across many end uses puts downward pressure on FEI's demand and upward pressure on FEI's rates. Demand is reduced though the focus on energy efficiency of buildings and appliances, and policies which limit FEI's ability to attach new customers. Rates are increased by the need to invest in higher cost gaseous energy in response to emission reduction pressures and these costs are borne across the energy value chain. Taxes add additional upward rate pressure. Downward pressure on FEI's ability to add customer attachments could eventually result in a smaller customer base resulting in higher costs per customer to support decarbonization initiatives.

From a broader perspective, these initiatives change the economics of customer and builder energy-use decisions and underpin the weakness of electrification-centric plans that overlook the opportunity for the gas system to contribute to decarbonization. As economic signals, they also confound the ability for customers to choose the right energy for the right use at the right time, and may result in unintended consequences, such as high energy rates, supply and capacity issues and destabilization of the province's energy system.

Currently, there is a lack of broader understanding associated with the long-term costs and infrastructure requirements needed to completely re-engineer BC's energy system and the implications of electrification policies on the western regional energy system as whole. Absent from energy planning are insights related to the long-term requirements for peak electricity demand, how customers' energy needs will be met in extreme and cold weather events, and the associated costs of ensuring the system meets demand and capacity for a deep electrification scenario. It has yet to be seen if clean electricity could provide more effective decarbonization

[73] Bill 98, ORS 757.390 – 757.398, online at: https://oregon.public.law/statutes/ors_757.390.

and further reduce GHG emissions if a broader perspective is employed for its use in the PNW rather than focusing on energy plans at the local level.

These evolving energy and environmental policies are key factors in the LTGRP planning environment and help inform FEI regarding potential impacts on future customer demand and supply over the planning horizon. Market forces create a measure of uncertainty in the market and thus FEI must be prepared for a range of possible outcomes as presented in the LTGRP planning scenarios. FEI's customer demand is discussed in Section 4 and energy supply is discussed in Section 6.

2.3 *INDIGENOUS GROUPS - LEGISLATIVE AND POLICY DEVELOPMENTS*

There have been significant legislative and policy developments with respect to the engagement with Indigenous groups since the 2017 LTGRP that have broad impacts on FEI's long-term planning. FEI recognizes and respects the constitutional rights of Indigenous Peoples, and FEI's Statement of Indigenous Principles[74] aims to ensure FEI's business operations are conducted with respect for Indigenous people's social, economic and cultural interests. The development of infrastructure has become more complex and may take longer due to increased engagement, consensus seeking, consideration of cumulative effects, and regulatory decision making processes. This section highlights a number of developments that will need to be taken into consideration over the planning horizon.

2.3.1 BC Has Passed Legislation to Give Effect to the UN Declaration of the Rights of Indigenous Peoples

In November of 2019, the BC Legislature passed the *Declaration on the Rights of Indigenous Peoples Act* (Declaration Act)[75] into law and in June 2021, the federal *United Nations Declaration on the Rights of Indigenous Peoples Act* (UNDRIP Act)[76] became law. The Declaration Act and the UNDRIP Act provide for BC and Canada's laws, respectively, to be brought into alignment with the UN Declaration and the development of action plans to meet the objectives of the UN Declaration.[77]

BC released the final version of its Action Plan in March 2022.[78] The BC Action Plan articulates the actions that the Province will take in consultation and cooperation with Indigenous peoples from 2022-2027, including modernizing and reforming legislation to be aligned with the UN Declaration; implementing joint decision-making and consent agreements; co-developing

[74] Appendix A-8: FEI's Statement of Indigenous Principles, online at: https://www.fortisbc.com/in-your-community/indigenous-relationships-and-reconciliation/our-statement-of-indigenous-principles.

[76] S.C. 2021, c. 14, online at: https://laws-lois.justice.gc.ca/eng/acts/U-2.2/page-1.html.

[77] Declaration Act, ss. 3 and 4.

[78] Appendix F-10: Declaration on the Rights of Indigenous Peoples Action Plan (2022), online at: https://www2.gov.bc.ca/assets/gov/government/ministries-organizations/ministries/indigenous-relations-reconciliation/declaration_act_action_plan.pdf.

environment, land and resources policies; and identifying and supporting First Nations-led clean energy opportunities.

At this point, the federal action plan has not been developed and the priorities for that plan are unknown. However, the legislative review and action plans of both governments may result in amendments to provincial and federal legislation or policy which may impact FEI's operations. Currently, the BC Action Plan contemplates the reform of provincial forestry legislation and the *Mineral Tenure Act*, and the establishment of a Secretariat that would be tasked with ensuring legislation is consistent with the UN Declaration.

The Declaration Act empowers the provincial government to enter into decision-making agreements with Indigenous groups. Such agreements could require the exercise of statutory decision-making powers jointly by an Indigenous governing body and the BC government, or the consent of an Indigenous governing body before the exercise of a statutory power.[79] The BC Action Plan identifies entering into such decision-making agreements and seeking all necessary legislative amendments to enable the implementation of such agreements to be one of the focuses for the years 2022-2027.

Both the Declaration Act and the UNDRIP Act have raised questions and differing perspectives as to the meaning of "free, prior and informed consent" (FPIC) in the UN Declaration and what obligations may exist with respect to seeking consent from Indigenous groups. At this point, neither the Declaration Act nor the UNDRIP Act include a definition of consent or FPIC. Many Indigenous groups assert that FPIC requires that consent be obtained from Indigenous groups for a project to proceed. The conflicting perspectives on FPIC's meaning have created new risks for FEI, including cost escalation, project delays, uncertain timelines and risks that authorizations may be challenged where decisions are made without the consent of Indigenous groups.

Further, BC's "Draft Principles that Guide the Province of British Columbia's Relationship with Indigenous Peoples" include the principle that meaningful engagement aims to secure FPIC when BC proposes to take actions which impact Indigenous peoples and their rights, and identifies that BC will look for opportunities to build processes and approaches aimed at securing consent and mechanisms to build deeper collaboration and consensus.[80] The BC Action Plan includes the finalization of the Draft Principles as an Action Item for 2022-2027.[81] The development of such processes and mechanisms may impact the method and timing for obtaining FEI project approvals.

81 Declaration_Act_-_Draft_Action_Plan_for_consultation.pdf (gov.bc.ca), Action 2.2.

2.3.2 Legislation Relevant to FEI's Planning Is Being Amended to Align with the UN Declaration

In BC, legislation related to project permitting is being adopted to align with the UN Declaration. For example, the new *Environmental Assessment Act* (EAA),[82] which was brought into force in December 2019, introduces changes to the environmental assessment process in BC to incorporate the concept of FPIC. Under the new EAA, Indigenous groups can self-select which project assessments they wish to participate in as a "Participating Indigenous Nation". The Environmental Assessment Office must then seek to achieve consensus with the Participating Indigenous Nations at various stages of the environmental assessment process.[83] Although not all FEI's projects or operations require an environmental assessment, the EAA provides an opportunity for a person (including an Indigenous group) to apply to have a project that is not otherwise reviewable designated as a reviewable project.[84] These changes could significantly increase FEI's engagement and consultation obligations with Indigenous groups in environmental assessments. In the context of resource planning, FEI must therefore take into account longer lead times for project development and the potential to enter into agreements with Indigenous groups with respect to projects.

2.3.3 Summary of Legislative and Policy Developments for Indigenous Groups

The evolving legislative and policy developments and FEI's commitment to engagement with Indigenous groups will have impacts that will be taken into consideration in FEI's long-term planning. In Section 5.2.1.2, FEI discusses opportunities to collaborate on DSM activities. In Section 8.3, FEI summarizes its consultation with Indigenous groups on this LTGRP and the opportunity to improve ongoing activities for resource planning and implementation of the low-carbon transition. In Section 10, FEI acknowledges the need to continually evolve its engagement process to ensure the outcomes of this LTGRP and future resource planning processes meaningfully integrate the input from Indigenous groups. In summary, feedback and input from Indigenous groups throughout the development of this LTGRP emphasized the need for FEI to consider the key principles of the UN Declaration and to ensure FEI considers Indigenous energy perspectives within its broader utility planning processes.

2.4 COMPETITIVE ENVIRONMENT FOR THE TRANSITION FROM NATURAL GAS TO INCREASED RENEWABLE AND LOW-CARBON GAS

The competitive environment for FEI's products has grown more complex as a multitude of pricing and non-price considerations are influencing customer energy choices. In terms of pricing, forecasting energy prices into the future is a complex and challenging task with significant uncertainty. FEI recognizes that the natural-gas-focused approach in the 2017 LTGRP is no

[82] S.B.C. 2018, c. 51, online at: https://www.bclaws.gov.bc.ca/civix/document/id/complete/statreg/18051.
[83] EAA, see for example ss. 16, 19, 27, 28, 29, 31 and 32.
[84] EAA, s. 11.

longer the environment in which FEI will be operating. Therefore, this section addresses both natural gas pricing and the influence of adding renewable and low-carbon gas to customer rates.

Non-price considerations include of a number of factors influencing FEI's competitive position. For example, consumer, builder and developer, commercial and industrial end user preferences influence the use of gas versus electricity, choice among alternative energy solutions and potential use of other sources of energy. Factors influencing non-price considerations may include the following:

- GHG emission concerns;
- Type of housing mix, the size of new dwellings, and commercial building requirements;
- Builder and developer preferences;
- Capital costs, installation requirements, operating and maintenance costs over the lifetime of the equipment;
- Customer perceptions;
- Availability of new technologies;
- Availability of utility and government incentives and rebates for new construction, retrofits, commercial buildings and industrial facilities;
- Commercial and industrial end user requirements; and
- Government policies (such as local governments' support for non-fossil fuel alternatives through updates to building codes and bylaws, which is discussed in Section 2.2.3).

FEI discusses the competitive forces influencing customers' energy choices in the following sections:

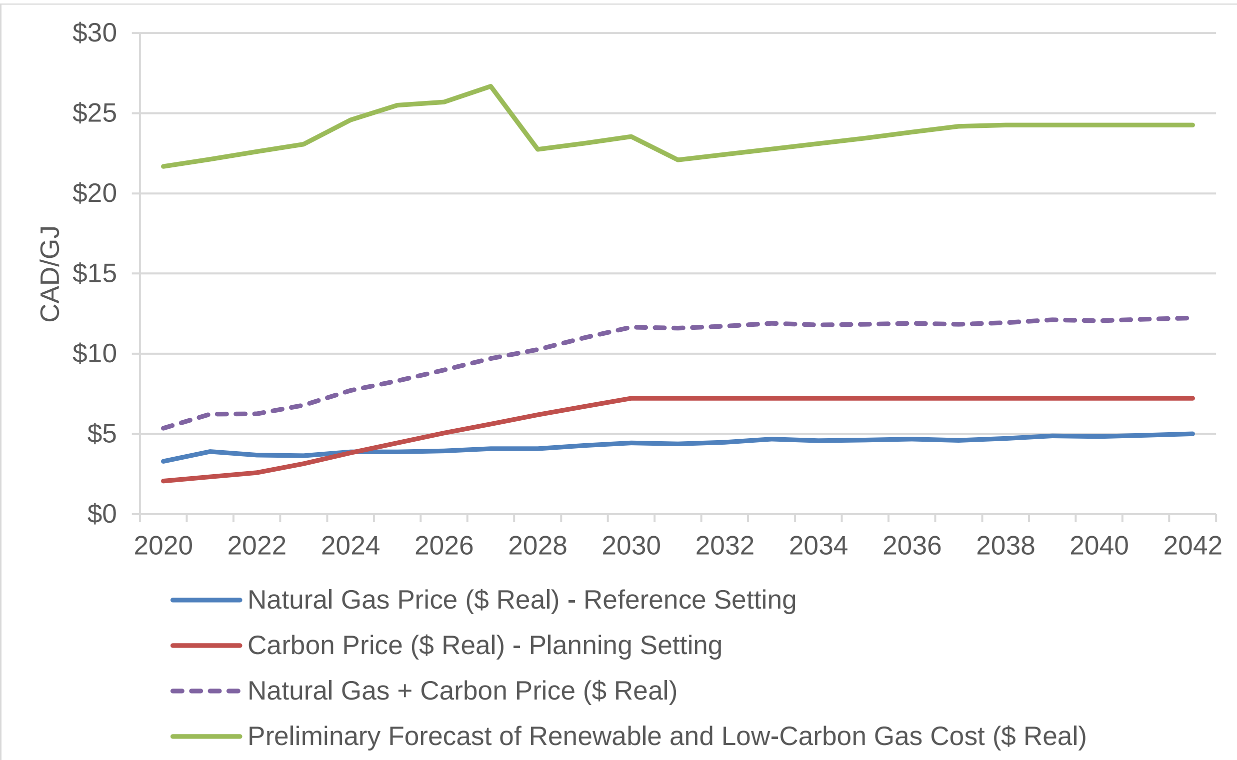
- Section 2.4.1 provides an overview of pricing considerations for renewable, low-carbon and natural gas supply and commodity pricing. Further information about natural gas supply and a market overview is provided in Section 6 and Appendix D-1;
- Section 2.4.2 provides an overview of energy choices facing FEI's customers. Residential rate comparisons are provided based on current natural gas and electricity rates, and estimated annual fuel costs for space heating in the Lower Mainland. The section then discusses relative upfront capital and installation costs of gas appliances compared to electric appliances on customer rates; and
- Section 2.4.3 provides a summary of FEI's increasingly complex competitive environment over the planning horizon.

2.4.1 Energy Pricing Considerations

Figure 2-3 below illustrates the energy prices that were used to generate outcomes for the scenario analyses undertaken in Sections 4, 5, and 6, and the Rate Impact Analysis provided in

Sections 5.4.2 and 9.4. The renewable and low-carbon gas price reflects the mix of fuels developed for use in the demand forecasting analysis presented in Section 4. These forecasts are based on FEI's current understanding of what the long-term pricing could be for natural gas, renewable and low-carbon gas, electricity, and carbon taxes. However, market uncertainties, such as socio-political and environmental risks, will influence North American and world energy prices. The costs for renewable and low-carbon gas are expected to go down over time and will be influenced by technological improvements that will positively impact production volumes and associated benefits resulting from economies of scale. GHG emission reduction policy and many other factors will influence energy prices over the planning horizon. Figure 2-3 helps set the stage for reviewing FEI's competitive pricing landscape over the planning horizon as discussed further in this section in greater detail.

Figure 2-3: Outlook of Energy Costs for Fuel Types Used in the Development of the LTGRP[85,86]



2.4.1.1 *Renewable and Low-Carbon Gas Price Considerations*

FEI recognizes that it is difficult to predict long-term prices for renewable and low-carbon fuel types; however, by developing and considering a range of price forecasts for analysis within different future scenarios, the resource planning process provides a number of different outcomes that are considered within the 2022 LTGRP demand forecasting analysis (Section 4). Section 6

85 Critical Uncertainty Input Settings for Each Future Scenario described in Section 4.5.3.
86 Fuel costs include inflation assumption of 2.0 percent.

further discusses how FEI plans to meet demand in the long-term through its energy supply arrangements. Section 9 discusses the resulting projected rate impacts of decarbonization.

Renewable and low-carbon gas will play an integral role in allowing FEI to meet its GHG reduction targets. The blend of fuel types is currently expected to be more expensive than natural gas plus carbon tax and, as more is incorporated into FEI's energy portfolio, fuel costs and rates will face upward pressure.

In summary, decarbonizing FEI's gas supply in response to climate policy will cause the average cost of gas to increase. This rising cost, regardless of specific cost recovery mechanisms or tariffs, will continue to be borne by FEI's customers, reducing FEI's price competitiveness when compared to other energy alternatives. However, this action is necessary to meet the GHG emission targets set out in the Roadmap and to respond with urgency to address climate change, just as electrification will also result in increased costs for ratepayers and taxpayers.

2.4.1.2 *Conventional Natural Gas Commodity Price Considerations*

This section provides a high-level overview of natural gas prices and volatility and how they affect FEI's competitive position. More details on the North American and regional natural gas marketplace are provided in Appendix D-1, Natural Gas Market Overview. Section 6 also addresses how FEI plans to meet demand in the long-term through its energy supply arrangements.

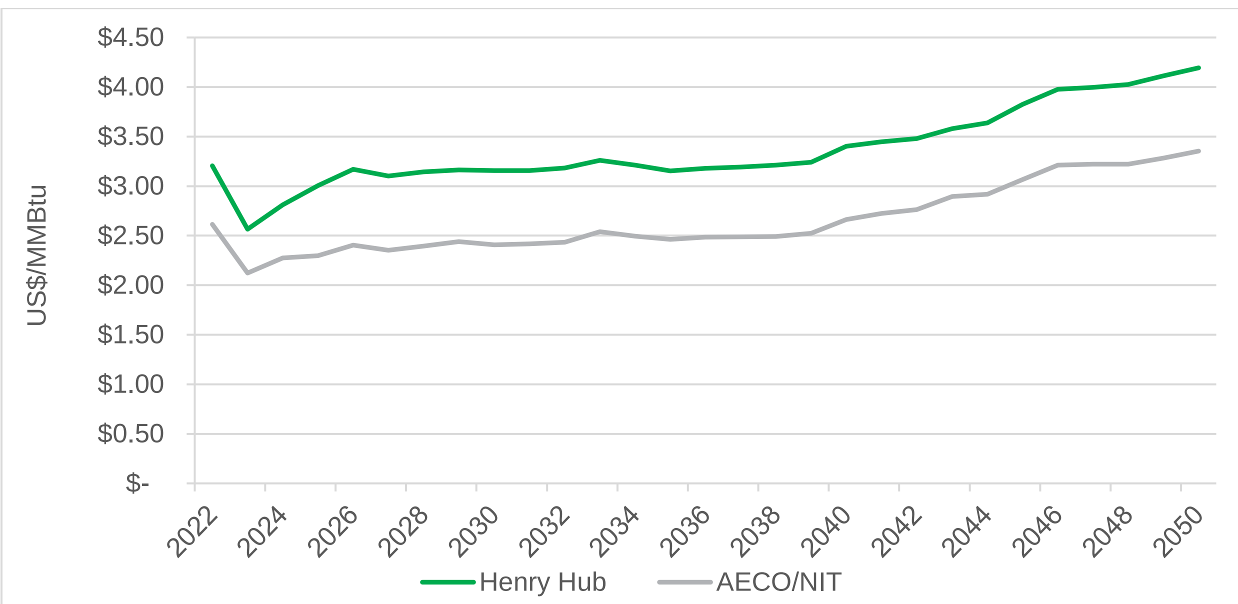
In general, commodity rates in the natural gas utility sector reflect the utility's cost of purchasing gas on behalf of its customers, without mark-up. Natural gas prices are set in an open and competitive market and are influenced by many variables throughout North America, as well as each utility's operating region. Commodity rates will therefore fluctuate in response to changes in supply and demand conditions for natural gas.

The shale gas potential in North America and the technological efficiencies in extracting it have had a major impact on actual natural gas commodity prices and long-term forecasts. Gas market analysts currently predict that North America could produce over 100 years of economically-recoverable supply, based on current consumption levels. The significant shale gas potential in North America and the improvements in drilling technologies have provided North America with an abundance of low-cost natural gas supply. The majority of Canada's supply originates within the Montney formation, located in the northwest of the Western Canadian Sedimentary Basin. As in the 2017 LTGRP, the abundance of natural gas supply in North America and comparatively low price levels have supported the commodity's competitiveness with other sources of energy. This has improved the price competitiveness of using natural gas on an operating cost basis, even though natural gas direct-use applications (such as space and water heating) typically require higher capital, installation and maintenance costs than electric appliances, as outlined in Section 2.4.2.

With an abundance of supply, North American natural gas became more economically attractive relative to other fuel sources as it was significantly disconnected from other competing fuels, such as heating and fuel oil. Figure 2-4 shows IHS Markit's (S&P Global) long-term price forecast for natural gas based on the Henry Hub and AECO/NIT markets in real 2021 dollars. The forecasts do not include temporary price spikes or dips that can occur due to extreme weather events or other supply/demand imbalance events, as evident due to the current supply/demand imbalances and geopolitical events in Europe. The figure illustrates natural gas price forecasts for the following:

- **Henry Hub** is the official pricing point for natural gas futures on the New York Mercantile Exchange (NYMEX) and is used as the benchmark for the North American natural gas market. The notable growth of shale gas supply in recent years has resulted in a significant drop in natural gas prices.
- **AECO/NIT** and **Station 2** are the supply hubs from which FEI procures most of its supply. These hubs are forecast to trade at a significant discount to the Henry Hub price. After the TC Energy North Montney Mainline was placed into service in January 2020, Station 2 prices have strengthened relative to AECO/NIT and now typically trade at parity to AECO/NIT, and therefore only AECO/NIT is shown.

Figure 2-4: Natural Gas Price Forecast (2021 Real Dollars) [87]



The natural gas market continues to be volatile[88] and this volatility has increased since the development of the 2017 LTGRP. Natural gas prices remained relatively low after 2016, however became more volatile after oil prices dropped significantly in March 2020 due to decreasing demand and rising supply corresponding to the trajectory of the recovery from the COVID-19 pandemic. Following the collapse of world energy prices in 2020, prices began rising once again

[87] Source: © 2022 S&P Global. All rights reserved. The use of this content was authorized in advance. Any further use or redistribution of this content is strictly prohibited without prior written permission by S&P Global.

[88] This forecast was completed prior to the Russian invasion of Ukraine and thus does not include the impact of the current geopolitical climate and does not illustrate the volatility of prices or the current futures price market.

due to the rebalancing of the global supply and demand. The combination of increasing demand, producers cutting production and a global energy shortage caused natural gas prices in Europe and world LNG prices to surge above $30 USD per MMBtu. This combination also caused North American prices to rise significantly, with current prices being above $5 USD per MMBtu. Current political and social unrest demonstrates the volatility exhibited in the energy market for many commodities, and is illustrated further in Appendix D-1.

With the anticipation of increased demand in the PNW and already limited pipeline infrastructure becoming more constrained, regional price disconnects are expected to continue. This will continue to strain resources in the region during high demand periods, and creates upward price pressure and volatility risk at the Sumas price hub for the Huntingdon marketplace in BC. This gas price volatility is one reason why FEI has identified the need for system upgrades and expansion (such as the TLSE and RGSD projects) as part of FEI's resiliency plans.

Future demand growth in North America has been driven by relatively low natural gas prices, and the majority of anticipated growth will be through the LNG export market. In terms of the regional market, in recent years, natural gas usage for power generation has increased in the PNW, due to the retirement of coal plants. As power generation from coal is replaced with renewable electricity resources in the region, it is uncertain what the future usage will be, as these resources are not sufficiently available at this time, and will be intermittent (i.e., dependent on weather conditions). Therefore, natural gas demand and power prices in the PNW will continue to become more interconnected, consequently increasing price volatility.

This regional market price volatility is expected to continue in the future. While regional infrastructure additions can help mitigate some of the regional price disconnection risk, these additions require a long time to plan, secure shipper commitments, receive regulatory approval, and construct. The Southern Crossing Pipeline, Westcoast T-South, Mist, and Jackson Prairie storage facilities expansions are examples of regional infrastructure projects that were approved and subsequently constructed to meet growing regional demand and helped to reduce some regional constraints. However, further infrastructure is needed to meet the pace of future demand growth, provide resiliency, and help support the clean energy transition in the PNW.

In summary, the significant shale gas potential in North America and the improvements in drilling technologies have provided North America with an abundance of low cost supply of natural gas. This ability to maintain production even with a relatively low commodity price has resulted in supply outpacing demand. FEI will continue to accelerate the procurement of renewable and low-carbon gas over the planning horizon; however, natural gas is likely to have a long-term role to play in storage and other specialized needs that are still under development as FEI transitions to a low-carbon future.

2.4.2 Competitive Environment in BC for Energy End Uses: Gas Versus Electricity

A potential natural gas customer often compares the cost of gas space heating and water heating equipment with the alternative electric options before making a purchase decision. As such, price competitiveness of natural gas versus electricity is an important factor that needs to be considered in the LTGRP as customer energy choices impact the number of customer additions and retention over the twenty-year planning horizon.

In the following sections, the price competitiveness of natural gas is compared with electricity from both the energy cost and total cost (energy cost plus capital and maintenance costs) perspectives. In comparison to electricity in BC, natural gas prices are more volatile, primarily because natural gas costs are market based, whereas electricity supply is primarily cost based. Furthermore, electricity prices are heavily influenced by BC Hydro's low embedded costs and provincial government policies. Natural gas competitiveness in BC and in other provinces in Canada is further challenged by the implementation of the carbon tax as well as other non-price factors. In Section 2.4.2.1 FEI compares its energy rates (excluding upfront capital and installation costs) against BC's electricity rates. Section 2.4.2.2, illustrates the current cost comparisons influencing residential customer energy choices for new construction, based on the upfront capital and installation cost differences between gas and electricity end use applications (space and water heating) including the adoption of new technologies which support the use of electricity.

2.4.2.1 *Natural Gas and Electricity Rates for Residential Sector*

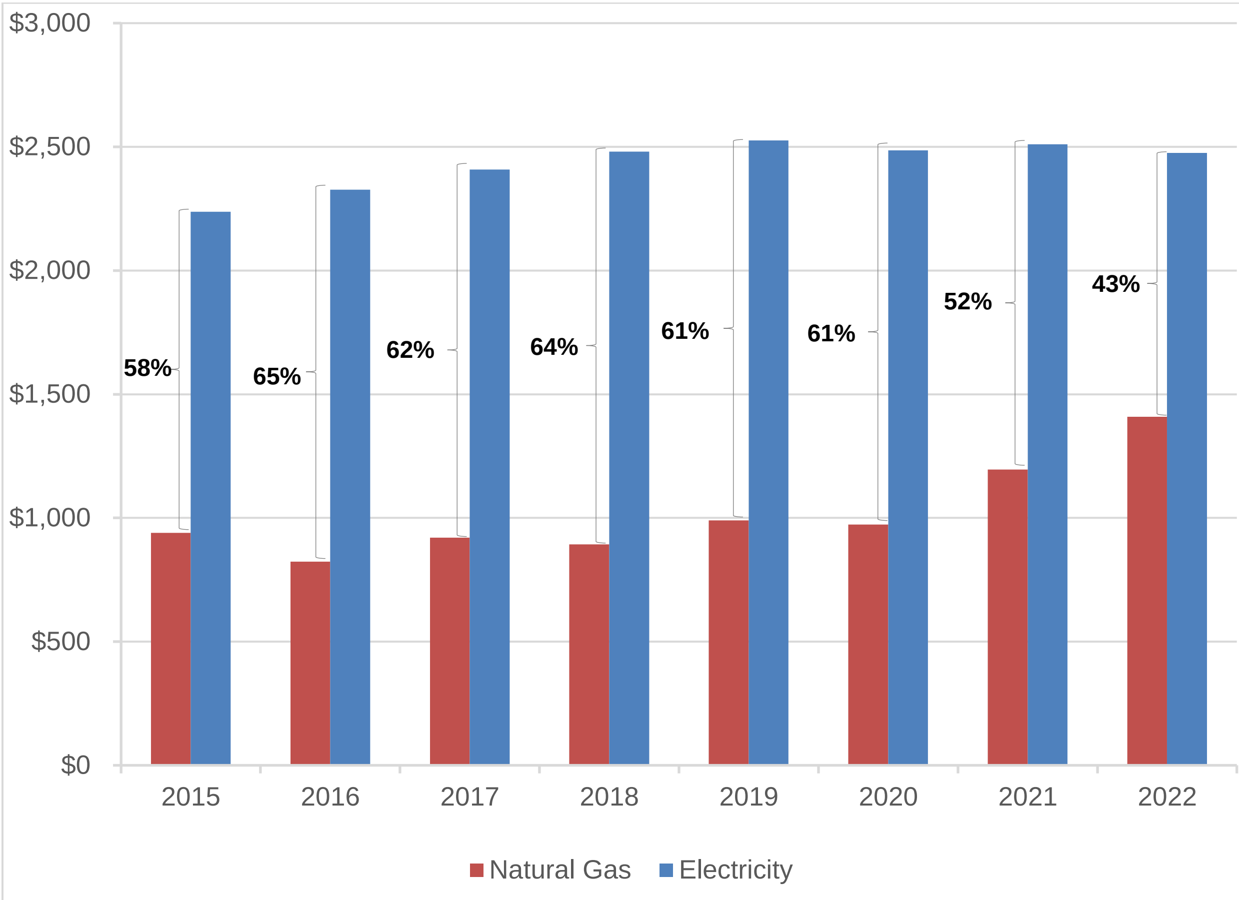
In this section, FEI compares its energy rates (excluding upfront capital and installation costs) against BC Hydro's electricity rates. A review of the trend in the energy cost differential between natural gas and electricity indicates that over time natural gas's cost advantage has declined. Figure 2-5 below shows the trend in annual bill amounts based on FEI's burner tip[89] rates versus BC Hydro's electric equivalent rates, with the favourable energy cost advantage held by gas decreasing from 58 and 65 percent (2015 and 2016) to 43 percent (2022). Further detail on FEI's total effective rate for a typical residential customer is illustrated in Figure 2-6. The share of carbon tax as a proportion of the total effective rate has increased from 13 percent in 2015 to 16 percent in 2022. Once the announced carbon tax increase to $170 per tonne is in place in 2030, the carbon tax rate will have increased by more than 5.5 times, to $8.40 per GJ.

The decrease in energy cost differential between natural gas and electricity in the 2021-2022 period can be attributed to higher natural gas commodity cost as well as delivery rate and carbon tax increases. All else equal, and considering the projected increases to provincial carbon tax, as well as BC Hydro's proposed rate changes in its recently-filed 2023-2025 Revenue Requirements Application,[90] FEI expects the decline in price differential to continue in the coming years. Gas prices will continue to rise as renewable and low-carbon gas comprises a larger share of the fuel mix. However, electricity rates associated with electrification may also rise due to the need for more transmission, distribution, and substation infrastructure to meet increases in electricity peak demand.

89 FEI's burner tip rate includes the commodity charge, storage and transport charge, fixed basic, and delivery charges, and the carbon tax to provide a comparison against the electric equivalent (based on an average annual use rate of 90 GJ per year).

90 BC Hydro Fiscal 2023 to 2025 Revenue Requirement (August 31, 2021), Online at: https://www.bcuc.com/OurWork/ViewProceeding?ApplicationId=921.

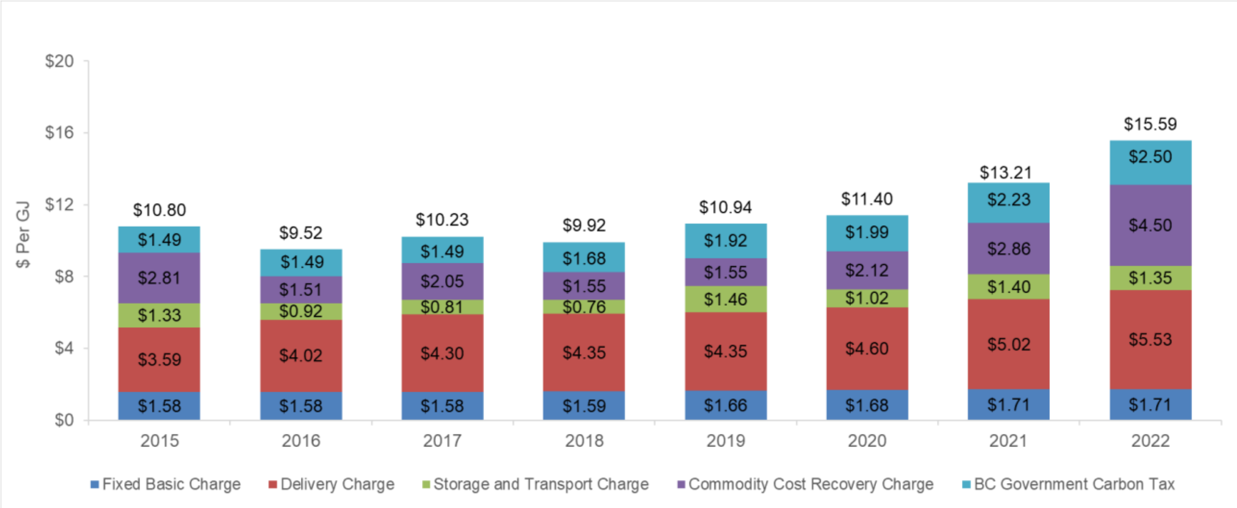
Figure 2-5: Residential Annual Bill Amount Trend in BC



Assumptions:

- Estimated residential bills are based on prevailing rates on April 1 of each specified year. BC Hydro bill estimates exclude the basic charge since a household already pays the basic electric charge for non-heating use.
- The average efficiency of gas equipment is assumed to be 92 percent relative to 100 percent for electricity to determine equivalent electric rates.
- Estimated bills are calculated based on annual use rate of 90 GJ.
- FEI bills are inclusive of the BC carbon tax and exclude other applicable taxes.

Figure 2-6: Breakdown of FEI's Historical Total Effective Rate for Residential Customers



Assumptions:

- Natural gas use of 90 GJ per year assumed for Fixed Basic Charge.
- FEI rates and the BC carbon tax are weighted averages (where applicable), to reflect rate changes which occur throughout the year.
- All delivery and commodity rates are inclusive of applicable rate riders.

While today's low natural gas rates contribute to a natural gas operating cost advantage relative to electricity, commodity price is only one factor that impacts the price competitiveness of natural gas in BC relative to electricity. Other factors include natural gas price volatility (discussed in the Natural Gas Market Overview, Appendix D-1) and the upfront capital and installation cost of natural gas appliances relative to electric appliances as discussed in the following section. Non-price considerations are also a factor in a customer's energy use choices as discussed earlier in the section.

2.4.2.2 *Installation and Operation Comparisons Provide Total Cost Perspective (New Construction)*

Section 2.4.2.1 provided an overview of natural gas price competitiveness on the basis of average annual bill amounts. In this section, price competitiveness will be analysed by also considering the upfront capital cost differences between gas and electricity end use applications (space and water heating) for new construction, including the adoption of new technologies which support the use of electricity. In addition to capital costs, efficiency rates and maintenance costs affect the total cost of the appliance over its measure life. Today's gas appliances have typically higher capital and maintenance costs and lower efficiency rates than electric alternatives, which tend to decrease the total price competitiveness of gas versus electric alternatives.

Table 2-1 below provides the upfront capital costs and efficiency estimates for new construction that are used in FEI's total cost comparison analysis. For space heating, a gas furnace is compared with electric baseboard heating, as well as an electric heat pump. The electric heat pump is a relatively new space heating option (which also provides an attractive cooling option) that is being increasingly promoted by policymakers and gaining market share,[91] and therefore has been added to the space heating analysis.

As shown below, a gas furnace is considerably more costly than an electric baseboard heater yet less expensive than an electric heat pump.[92] For the purpose of this analysis, a new gas furnace is assumed to be 96 percent efficient, an electric baseboard heater is assumed to be 100 percent efficient, and an electric heat pump is assumed to be 200 percent efficient.[93]

For water heating, a gas hot water tank is compared with an electric water heater. Gas water heaters continue to be more costly than the electric alternative. The efficiency of a gas water heater is assumed to be 67 percent while the electric water heater tank is assumed to be 100 percent efficient.

Table 2-1: Upfront Costs and Efficiency Estimates for Space and Water Heating[94]

	Space Heating Options			Water Heating Options	
Equipment	**Gas Furnace**	**Electric Baseboard**	**Electric Heat Pump**	**Gas Water Heater Tank**	**Electric Water Heater Tank**
Capital Cost[95]	$18,000	$9,200	$21,000	$2,800	$1,550
Efficiency Rate	96%	100%	200%	67%	100%

To compute the total cost differential between gas and electric options, the upfront and installation cost differential is first converted into an annualized format using the builder's assumed interest rate and measure life of the equipment. In the next step, the sum of the annualized upfront capital cost and annual maintenance cost[96] differentials are divided by the assumed space heating and water heating consumption levels for new construction to calculate the capital and maintenance cost difference per GJ.

As demonstrated in Table 2-2, the cost difference per GJ between a gas furnace and an electric heat pump is negative, reflecting the fact that, all else equal, a gas furnace has a lower capital cost than a heat pump, but is not able to provide the cooling benefits of a heat pump. As gas heat

91 According to FEI's 2017 Residential End Use Study, 14 percent of new Single Family Dwellings (constructed in 2016 or after) use an air source heat pump as their main space heating equipment.

92 The provincial and municipal governments provide various rebates for electric heat pumps to decrease the upfront costs and make them price competitive with gas furnaces.

93 Electric heat pumps are often advertised to have 200 percent or even higher efficiency. However, the actual efficiency of heat pumps may be lower than the nameplate efficiency depending on outside temperature and other factors.

94 Cost estimates were provided to FEI by an independent consultant (Ecolighten Energy Solutions Ltd.).

95 Both gas furnace and central heat pump cost estimates include the cost of ductwork that is usually contracted out to the sheet-metal contractor who does all the ducting and exhaust fans in a new home. Per the BC Building Code, the electric baseboard cost estimate includes the cost of a mechanical ventilation system that would be needed in a house with no forced-air space heating system.

96 Manufacturers may recommend a certain maintenance schedule, however homeowners may not always follow these recommendations. As such, annual maintenance cost is situational and can change from one household to the other. These numbers are FEI's best estimates.

pump technology for the residential sector is still in the pre-commercialization phase, installed costs are still under investigation, but may be considered in the next LTGRP.

Table 2-2: Difference in Costs for Space and Water Heating over Measure Life[97]

	Space Heating (Gas Furnace)		Water Heating (Gas vs Electric)
	vs Heat Pump	vs Baseboard	
Difference in capital costs	**($3,000)**	**$8,800**	**$1,250**
Annual payments for recovery of capital costs	($257)	$753	$137
Difference in maintenance costs per year	$0	$100	$0
Total costs per year to pay off difference in capital cost	**($257)**	**$853**	**$137**
Energy consumption (GJ)/year	38	38	22
Difference in capital and maintenance costs between gas and electric equipment ($/GJ)	**($6.8)**	**$22.4**	**$6.2**

Finally, the annualized capital and maintenance cost differentials are compared to the difference between FEI's burner tip rate and efficiency adjusted electric rates.[98] If the operating cost advantage of natural gas (calculated as the difference between FEI's burner tip rate and efficiency adjusted electric rates) is greater than the difference in capital and maintenance costs between gas and electric options, then the natural gas equipment is assumed to be the more economic option for the consumer. However, if the natural gas operating cost advantage is smaller than the upfront capital and maintenance cost differential, then the electric option will be more economical. The results of this analysis are shown in the table below.

[97] Assumptions based on the new construction of a home in the Lower Mainland (Medium Size Dwelling), interest rate of 5 percent and the measure life of 18 years for a natural gas space heating furnace and 13 years for hot water tank. The annual payments to recover the difference in upfront capital costs are calculated based on the present value of an annuity formula where PV of an annuity = annuity * [(1-(1+r)^-n)/r] (r is interest rate and n is the measure life of the equipment).

[98] To calculate the electric equivalent rate, the electric to gas efficiency ratio is applied to the Step 1 and Step 2 BC Hydro RIB rate. For example, to compare a gas furnace with an electric heat pump, the assumed 96 percent efficiency of a new gas furnace is divided by the heat pump's assumed efficiency of 200 percent and multiplied with Step 1 and Step 2 rates.

Table 2-3: Operating Cost Advantage vs Capital Cost Differential between Gas and Electric Equipment[99]

	Space Heating (Gas Furnace)		Water Heating (Gas vs Electric)
	vs Heat Pump	vs Baseboard	
BCH Step 1 Rate Adjusted for Efficiency	$12.3	$24.7	$17.2
BCH Step 2 Rate Adjusted for Efficiency	$18.5	$37.0	$25.9
FEI's Burner Tip Rate	$15.6	$15.6	$15.6
FEI's Operating Cost Advantage vs BCH Step 1 Adjusted Rate	**($3.3)**	**$9.0**	**$1.6**
FEI's Operating Cost Advantage vs BCH Step 2 Adjusted Rate	**$2.9**	**$21.4**	**$10.2**
Difference in capital and maintenance costs between gas and electric equipment ($/GJ)	**($6.8)**	**$22.4**	**$6.2**

The results can be summarized as follows for each of the three columns shown in Table 2-3.

Gas Furnace as Compared to Electric Heat Pump

The analysis above shows that a gas furnace is less costly than a heat pump, with the difference estimated at $6.80 per GJ over the measure life. BC Hydro's efficiency adjusted Step 2 rate is $2.90 per GJ higher than FEI's burner tip rate and its Step 1 rate is $3.30 per GJ lower; therefore, without a means of reducing the heat pump's high capital costs, the gas furnace option will be more economic. Currently, both provincial and local governments as well as BC Hydro provide generous rebates to households who install heat pumps or convert their fossil fuel heating systems to central heat pumps. As such, when the heat pump's higher rebates are considered, the gas furnace's cost advantage can be reduced or eliminated in favour of the electric heat pump, depending on the rebate amount available at the time of installation.

Gas Furnace as Compared to Electric Baseboard

The table above shows that a gas furnace is significantly more costly than electric baseboard heating, with the difference estimated at $22.40 per GJ over the measure life. The upfront capital costs associated with the installation of a gas furnace eliminates FEI's competitive position against both Step 1 and Step 2 efficiency-adjusted electric rates, as FEI's operating cost advantage over both Step 1 and Step 2 efficiency-adjusted rates is less than $22.40 per GJ. This price advantage in favour of electricity is even more persuasive when considering smaller multi-family dwellings, such as townhouses and apartment units, are more likely to have electric baseboards as their main space heating. For these units, lower consumption means lower savings in annual energy costs to offset the higher capital cost of a gas furnace.

[99] Based on FEI's Approved Rates for 2022 and BC Hydro's proposed rates in its 2023-2025 RRA.

Gas as Compared to Electric Water Heating

The table above shows that gas water heating is somewhat more costly than electric water heating, with the difference estimated at $6.20 per GJ over the measure life. The upfront capital costs associated with the installation of a gas water heater eliminates FEI's competitive position against the Step 1 efficiency adjusted rate and greatly reduces its competitiveness with efficiency-adjusted Step 2 rate.

Over time, the price competitiveness of natural gas versus electricity has reduced, from both the energy price and total price perspectives. The capital cost differentials have increased, decreasing FEI's total price competitiveness. Electric heat pumps have higher upfront capital costs but the current government rebates (ultimately funded by taxpayers) effectively change the price advantage in favour of heat pumps. Further, ongoing increases in carbon taxes, as well as increases in natural gas and renewable gas costs, will further reduce FEI's price competitiveness in the coming years.

2.4.3 Summary of FEI's Competitive Environment

This section addresses the competitive environment influencing customers' energy choices and demonstrates how the environment has grown more complex since the 2017 LTGRP. The section provided background on fuel pricing for all fuel types and the cost impacts of transitioning to renewable and low-carbon gas supply as it takes on an increasing portion of the energy mix over the planning environment. The section also discussed natural gas pricing considerations, as although it is declining, it will continue to be part of the energy mix for FEI over the planning environment. Finally, the section provided a summary of comparisons between natural gas and electricity rates. Comparisons of current residential rates for electricity, and natural gas demonstrate the factors customers are facing in home energy choices and the rapidly changing competitive environment for FEI.

The competitive environment for FEI's products has grown more complex as a multitude of non-price considerations are influencing customer energy choices. Consumer, builder and developer, commercial and industrial end user preferences influence the use of gas versus electricity, renewables and other sources of energy. FEI will continue to monitor the complex competitive environment influencing customer energy choices over the planning horizon.

2.5 RESILIENT ENERGY INFRASTRUCTURE CONTINUES TO BE A CRITICAL CONSIDERATION

The planning environment needs to consider BC's energy system resiliency as a whole, taking into consideration the need to optimize both the gas and electric systems. Policymakers and regulators need to recognize that resilience is best achieved through a diversified approach to long-term resource planning in the interest of providing safe, reliable and affordable energy. Reliable and resilient energy delivery is especially critical on the coldest days of the year when British Columbians are most reliant on a secure energy supply to heat their homes and businesses. This was dramatically illustrated by the loss of life from hypothermia due to the gas and electric outages in the state of Texas during the February 2021 winter storm.[100] Climate change, in terms of extreme weather events, highlights the need for increased system resiliency to be incorporated in all system planning discussions regarding BC's energy future.

BC's current energy system relies on the gas system's ability to withstand extreme weather events and meet peak and seasonal demand provided through storage resources inherent in the gas system. The value of resilience should not be overlooked or jeopardized in an electrification-centric policy environment in which a single-minded pursuit of decarbonization goals could face unintended consequences such as system outages and other disadvantages. Technological advances in renewable and low-carbon gas will make decarbonization a reality, and long-term planning can recognize the importance of resilient gas infrastructure as a critical component in providing a strong future energy system for British Columbia. Section 3.2.2.3 further discusses resiliency as a benefit in the Clean Growth Pathway and introduces FEI's Gas System Resiliency Plan (Appendix E).

2.6 *SUMMARY OF FEI'S PLANNING ENVIRONMENT*

The planning environment outlined above provides the backdrop to the factors setting the stage for decarbonization in FEI's Clean Growth Pathway to 2050. There is an overwhelming trend in the increasing stringency of energy and environmental policy in Canada, the US, and internationally as federal, provincial, state, and municipal governments implement initiatives to reduce GHG emissions and transition to low-carbon sources. These initiatives are key factors in the LTGRP planning environment and help inform FEI regarding potential impacts on future customer demand and supply over the planning horizon.

Federal government policies and initiatives outlined in Section 2.2.1 are aimed at addressing climate change, reducing GHG emissions, and developing cleaner energy sources. The federal climate policy framework is focused on achieving Canada's 2030 GHG reduction goals with wide-ranging measures targeting all key emitting sectors (buildings, transportation and industry). However, while natural gas is one of the most widely used fuels in Canada, there is no specific federal climate policy direction on the future of the gas delivery system and its role in decarbonizing Canada's GHG emissions is undefined.

Provincial government energy and environmental policies and initiatives outlined in Section 2.2.2, demonstrate that both electrification and the decarbonization of the gas system are key strategies to meet the provincial government's climate goals. While BC has made progress to reduce the carbon intensity of its economy, it is not on pace to achieve its 2030 target of a 40 percent reduction from 2007 levels. Therefore, the provincial climate policy framework is focused on achieving the CleanBC Roadmap's GHG reduction goals with wide-ranging measures targeting all key emitting sectors (buildings, transportation and industry). Local government policy is also rapidly evolving in support of similar goals for GHG emission reduction.

[100] Online at: https://www.dallasnews.com/news/weather/2021/04/30/number-of-texas-deaths-linked-to-winter-storm-grows-to-151-including-23-in-dallas-fort-worth-area/.

Section 2.3 addressed FEI's commitment to engagement with Indigenous groups as another key consideration in FEI's long-term planning. FEI recognizes and respects the constitutional rights of Indigenous Peoples, and FEI's Statement of Indigenous Principles aims to ensure the Company's business operations are conducted with respect for Indigenous people's social, economic and cultural interests. As FEI considers working with Indigenous groups on clean energy projects, FEI will be taking all reasonable steps to ensure these developments are given consideration over the planning horizon.

Section 2.4 addressed the increasingly complex competitive environment influencing customers' energy choices. The section provided background on energy pricing and transitioning to renewable and low-carbon gas supply. Pricing considerations for natural gas, although declining in use, will continue to be part of the energy mix for FEI over the planning horizon. Finally, the section discussed end use comparisons of current residential rates for electricity, natural gas, and renewable and low-carbon natural gas to demonstrate the factors customers are facing in home energy choices.

Finally, Section 2.5 discusses the need for the planning environment to consider resiliency of BC's energy system as a whole, taking into consideration the need to optimize both the gas and electric systems. System resilience is best achieved through a diversified approach to long-term resource planning in the interest of providing safe, reliable and affordable energy to British Columbians even on the coldest days of the year and during extreme weather events that are occurring more frequently due to the effects of climate change.

The planning environment sets the stage for the discussion of the four pillars of FEI's Clean Growth Pathway in Section 3. Scaling the supply of renewable and low-carbon gas and expanding DSM investment for decarbonizing the built environment are fundamental objectives in FEI's low-carbon transition. FEI's low-carbon transportation, marine bunkering, LNG initiatives and support of emerging technologies, will further reduce BC's GHG emissions and positively impact global emissions.

FortisBC Energy Inc.
2022 LTGRP

Section 3:

CLEAN GROWTH PATHWAY – FOUR PILLARS TO A LOW-CARBON FUTURE

Table of Contents

3. CLEAN GROWTH PATHWAY – FOUR PILLARS TO A LOW-CARBON FUTURE

3.1 *INTRODUCTION*

The Clean Growth Pathway is FEI's response to the rapid changes in policy described in Section 2 and provides the framework and FEI's 20-year vision[101] for a low-carbon energy future. The Clean Growth Pathway is described in FEI's Clean Growth Pathway to 2050 report attached as Appendix A-1. Through the Clean Growth Pathway, FEI will support increasing government ambition and intervention to reduce GHG emissions and take greater climate action.

The Clean Growth Pathway is a "Diversified Pathway", as it includes a mix of expanded electrification and renewable and low-carbon gas, with a prominent role for FEI's infrastructure to achieve decarbonization objectives. As concluded in the Guidehouse Pathways Report in Appendix A-2, a Diversified Pathway has the advantage of leveraging FEI's extensive existing infrastructure and the resilience and reliability of the provincial energy system as a whole. The Diversified Pathway achieves GHG reductions aligned with the provincial government's objectives, and is a more affordable, resilient and practical long-term pathway for BC. A number of other studies included in Appendix 9 outline the benefits of comprehensive energy system planning akin to that achieved by the Diversified Pathway, while highlighting that there are unintended consequences and risks of pursuing an electrification-centric approach to energy planning in BC.

FEI's Clean Growth Pathway is supported by four key pillars:

- **Pillar 1:** Transitioning to renewable and low-carbon gases to decarbonize the gas supply;
- **Pillar 2:** Investing in DSM programs in support of energy efficiency and conservation measures to reduce energy use among residential, commercial and industrial customers;
- **Pillar 3:** Investing in low-carbon transportation infrastructure to reduce emissions in this sector; and
- **Pillar 4:** Investing in LNG to lower GHG emissions in marine fueling and global markets.

Each of these pillars are essential elements to achieving a low-carbon future, and are described in detail in this section and throughout the 2022 LTGRP.

The remainder of this section is organized as follows:

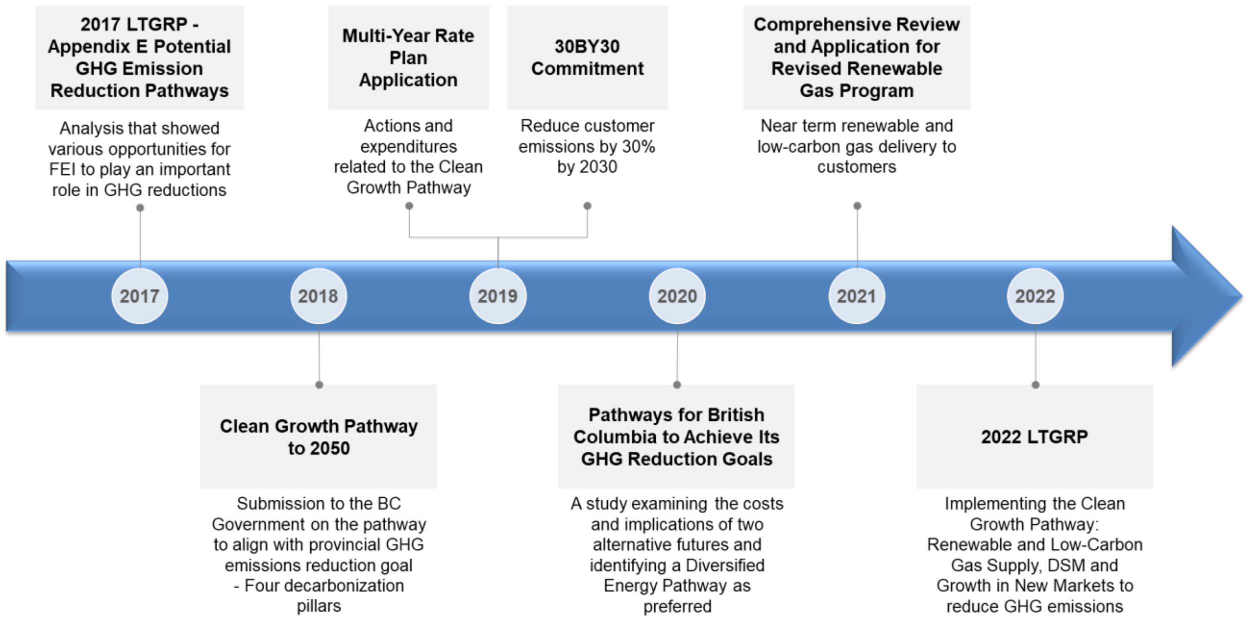
[101] FEI has provided a 20-year vision in its resource plans since the directive from the BCUC in its Decision on the 2010 LTGRP to include a 20-year vision in the 2014 LTRP: "This vision could describe what [the FEU] may look like in the future: its business lines, its customers, the expectations for supply and demand and the major issues it will deal with over the 20 year resource plan timeframe."

- Section 3.2 discusses the benefits of the Clean Growth Pathway to British Columbians in terms of GHG reductions, affordability, peak demand, resiliency, innovation, and economic development;
- Section 3.3 describes the first pillar of the Clean Growth Pathway: transitioning to renewable and low-carbon gases to decarbonize the gas supply;
- Section 3.4 describes the second pillar of the Clean Growth Pathway: investing in DSM programs in support of energy efficiency and conservation measures to reduce energy use among residential, commercial and industrial customers;
- Section 3.5 describes the third pillar of the Clean Growth Pathway: investing in low- carbon transportation infrastructure to reduce emissions in this sector;
- Section 3.6 describes the fourth pillar of the Clean Growth Pathway: investing in LNG to lower GHG emissions in marine fueling and global markets;
- Section 3.7 describes research studies that support a complementary and diversified approach to energy system planning; and
- Section 3.8 presents a summary and conclusion of the background and benefits of the Clean Growth Pathway.

3.2 THE CLEAN GROWTH PATHWAY WILL REDUCE GHG EMISSIONS AND PROVIDE OTHER SIGNIFICANT BENEFITS

FEI initiated the Clean Growth Pathway to address BC's GHG emissions and realize additional non-GHG-related benefits. The Clean Growth Pathway will leverage the decarbonization potential of both the gas and electric energy systems in supporting provincial GHG emission reductions, as well as the affordability, reliability, resiliency, and economic development advantages in pursuing a diversified approach to decarbonization. Figure 3-1 below describes the evolution of FEI's Clean Growth Pathway, which began in 2017 when FEI provided analysis demonstrating its important role in decarbonizing BC's energy system in the 2017 LTGRP.

Figure 3-1: The Evolution of FEI's Clean Growth Pathway from 2017 LTGRP to 2022 LTGRP



The figure demonstrates the climate action milestones FEI has achieved since the 2017 LTGRP to set the stage for the diversified decarbonization pathway that FEI is taking over the 20-year planning horizon. In particular, in 2020, FEI commissioned the Pathways Report, which defines and compares two pathways to achieve BC's GHG emissions targets as follows:

- The "Diversified Pathway" which includes a mix of expanded electrification and low-carbon gas, with a prominent role for FEI's infrastructure to achieve the deep decarbonization objectives of FEI's Clean Growth Pathway; and
- The "Electrification Pathway", which is primarily focused on deep electrification of BC's energy system.

The Pathways Report concludes that "the Diversified Pathway can achieve the same level of provincial GHG emissions reductions as the Electrified Pathway at a significantly lower cost to British Columbians. Although initiatives are used to different extents, both pathways defined in this study would require transformative changes in every sector of BC's economy. By 2050, the societal value of achieving the Diversified Pathway is expected to be in excess of $100 billion higher than the Electrification Pathway."

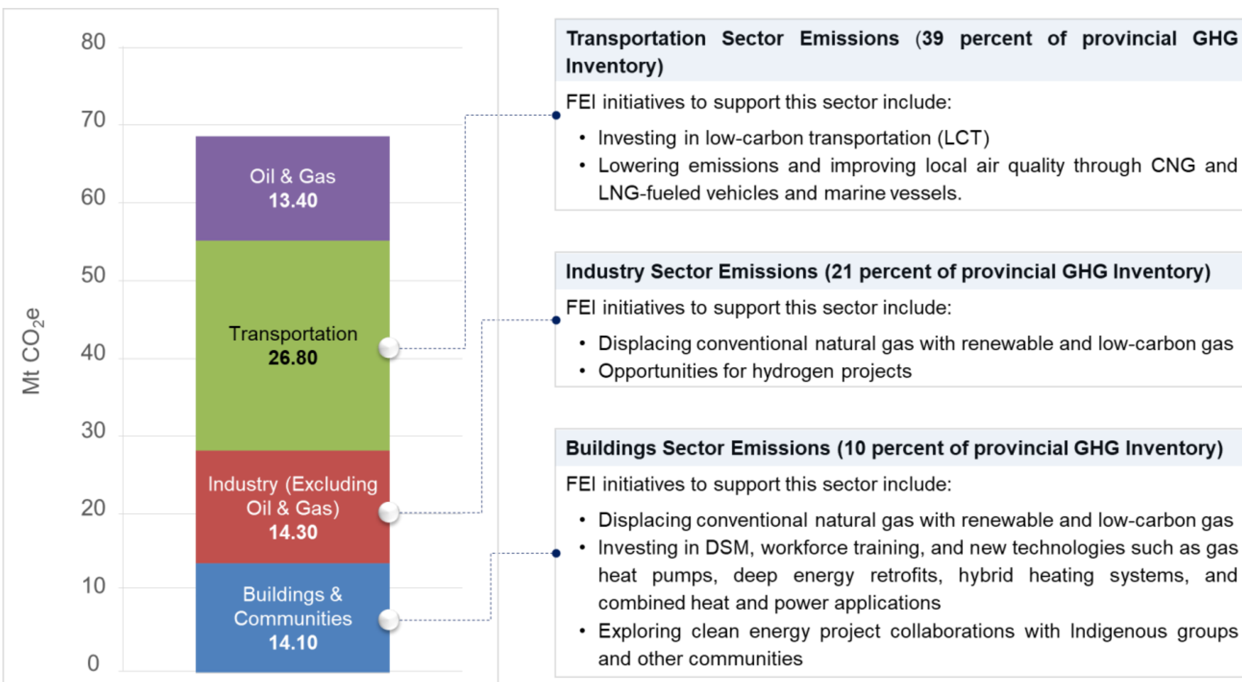
These and other benefits of the Clean Growth Pathway are explored below.

3.2.1 The Clean Growth Pathway Addresses BC's GHG Sectoral Emissions

As part of the consultation process for the BC government's CleanBC plan in 2018, FortisBC released its Clean Growth Pathway report (see Figure 3-1). This report outlines FortisBC's actions to align with the provincial government's GHG emission reduction goals. Building upon the Clean Growth Pathway, FortisBC established its first emissions reduction target in 2019, "30BY30", setting an initial and voluntary target of reducing the GHG emissions associated with FortisBC's customers' energy use by 30 percent by the year 2030[102]. In October 2021, the Province announced the Clean BC Roadmap to 2030, with even more aggressive policy measures, including the introduction of a cap on gas utility emissions in BC of approximately 6 Mt of CO_2e annually (as discussed in Section 2.2.4.2). Although the elements of the plan have not yet been enacted into law, FEI has considered these additional targets within this 2022 LTGRP where possible and will continue to build on its previously developed GHG emission reduction initiatives. These initiatives are leading the way to a lower carbon economy through active partnerships with customers, communities, industry, and government. Ultimately, FEI's decarbonization targets demonstrate FEI's understanding of the importance of a low-carbon future and serve as a way to measure progress on the actions outlined in the Clean Growth Pathway.

FEI's Clean Growth Pathway will substantially reduce BC's GHG emissions and contribute to global GHG emission reductions. Figure 3-2 illustrates BC's 2019 GHG emissions inventory by sector and describes FEI's initiatives to address these sectoral emissions. This emissions inventory is used to compare FEI's customers' GHG emissions in the comparative analysis provided in Section 9.2.

Figure 3-2: 2019 GHG Emissions by Sector in BC[103] and FEI Initiatives to Support Decarbonization



[102] From a 2007 baseline year, which is used in BC's provincially legislated emission targets.
[103] BC's 2019 GHG emissions. Online at https://www2.gov.bc.ca/gov/content/environment/climate-change/planning-and-action/progress-targets#emissions.

3.2.2 Benefits of the Clean Growth Pathway Beyond GHG Emission Reduction

The Clean Growth Pathway is a holistic approach to energy system planning. It provides not only for GHG reductions that align with government objectives, but also other whole-system benefits. Decarbonization is achieved under the Clean Growth Pathway without detracting from traditional planning considerations such as cost to the customer and ability to meet peak demand.

In addition to GHG reductions, the key benefits of the Clean Growth Pathway over deep electrification are greater affordability, the ability to meet peak demand on the coldest days of the year, energy system resiliency, integrated community energy systems, and economic development and job creation for the clean energy sector. A Diversified Pathway realizes the GHG abatement potential of a complementary approach that ensures both the gas and electric system contribute to BC's low-carbon energy future. This approach is optimal for decarbonizing BC's economy as it makes use of existing and largely paid-for energy delivery infrastructure to reduce emissions while supporting BC's economy in retaining and creating jobs in the clean energy sector of the economy.

3.2.2.1 *The Clean Growth Pathway Optimizes Energy Affordability*

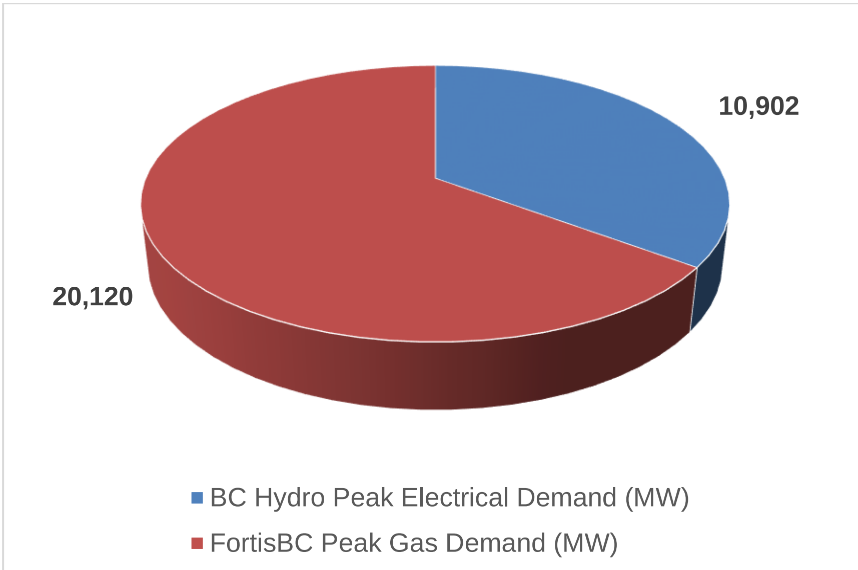
One key benefit to the Clean Growth Pathway is its potential contribution to energy affordability for British Columbians. The Diversified Pathway is a lower-cost approach than a deep electrification pathway primarily because it optimizes the gas and electric systems by fully utilizing the 50,000 km of energy delivery infrastructure of FEI's gas system, avoiding the need for extensive build-out of the electricity system. The cost savings are significantly more pronounced after 2030 when new electric infrastructure would be required and load on the gas system would otherwise decline markedly. This emphasizes the importance of having a longer-term view beyond 2030 for decarbonization strategies employed today. According to the Pathways Report, pursuing the Diversified Pathway is approximately $100 billion dollars less costly by 2050 than a deep-electrification pathway. Even though renewable and low-carbon gases are expensive compared to conventional natural gas, maintaining a role for the gas distribution system is less costly than sole reliance on firm electric power capacity. Both pathways will require significant levels of investment and collaboration across all stakeholders will be required to make decarbonization a reality.

3.2.2.2 *The Clean Growth Pathway Provides Lowest Risk to Meeting Peak Demand*

The Clean Growth Pathway provides the lowest risk to British Columbians as it relies on multiple systems to deliver energy, including for peak day demand on the coldest days of the year when British Columbians need energy the most. Relying on multiple systems enhances the resilience of the overall provincial energy system and helps ensure the overall operational and financial health of utilities in BC.

BC's exceptionally cold weather on December 27, 2021, provides an excellent illustration of the necessity of ensuring factors such as peak demand and resiliency are considered when creating policy direction. On that day, BC's two main energy delivery systems were operating near capacity. Throughput on FEI's gas system nearly reached its peak design capacity while BC Hydro reached a record level of peak demand.[104] Figure 3-3 illustrates the distribution of energy supply between gas and electricity on this historic day.

Figure 3-3: FEI[105] and BC Hydro Peak Hour Energy Demand – December 27, 2021



The fact that the provincial energy system successfully met this landmark demand reflects the critical role for both gas and electric infrastructure in meeting BC's energy needs during the coldest days of the year. Moreover, this event, when the gas system delivered approximately double the electric peak energy needs of British Columbians, demonstrates the significant and important delivery capacity of the gas system and the need to ensure BC continues to benefit from a robust gas delivery system that is operationally and financially healthy.[106]

3.2.2.3 *The Clean Growth Pathway Offers Energy System Resilience*

BC's energy system resilience is best achieved through keeping both gas and electric energy systems thriving to ensure British Columbians are not relying on a single energy system. A diversified approach is of even greater importance with the advent of extreme weather events caused by climate change, which can catalyse unanticipated system outages. Where one system is experiencing a supply disruption, other systems can supplement energy to meet customer demand in the interim. The deep electrification pathway requires reliance on only one source of supply, whereas the Clean Growth Pathway leverages the supply potential of both gas and

[104] BC Hydro Operational Update December 28, 2021, described that between 5 and 6 PM on December 27, 2021, demand for electricity hit an all-time high of 10,902 megawatts.

[105] Peak gas demand in equivalent MW using standard unit conversion of 1 MW = 3.6 GJ/hour.

[106] The gas system is also superior at meeting prolonged or multiple peaks due to its energy density and storage capacity. In contrast, the emergence of summer and winter peak events on BC's electric systems represents a growing challenge given the seasonal replenishment of storage reservoirs.

electricity infrastructure to protect British Columbians from the consequences of supply disruptions.

FEI has provided safe and reliable gas service in the province for many years and as part of the Clean Growth Pathway it will continue to provide this service for many years, even if the fuel composition changes. To provide reliable service, FEI has maintained the integrity of its assets, and ensured the adequacy and security of gas supply. FEI has completed a number of projects that have significantly enhanced the resiliency of its system, such as the Southern Crossing Pipeline (SCP) and Mt. Hayes LNG facility. While FEI has long regarded resiliency as an important system attribute, the T-South pipeline rupture that occurred on October 9, 2018, and the capacity restrictions imposed thereafter on the Westcoast Energy Inc. (Westcoast) T-South system[107] (T-South incident) underscored the pressing need for FEI to make new investments in its system to enhance overall resiliency. In 2021, the T-South system experienced another concerning event during the flooding in the Coquihalla region, leading to a washout of its NPS 30 pipeline.

FEI is dependent on the T-South system for approximately 85 percent of the gas entering its system, leaving FEI and its customers at risk of experiencing significant consequences resulting from a supply disruption. The T-South incident underscored the value that additional resiliency in FEI's system would provide, given that the T-South incident resulted in a complete loss of gas supply from the two T-South pipelines. FEI's system was at risk of pressure collapse for a period of approximately 48 hours, and that outcome was narrowly avoided as a result of FEI's efforts and due to mild weather that had reduced heating load in the broader PNW, thereby allowing some gas to physically flow northwards across the border.

FEI's system resilience is a key consideration in all of FEI's initiatives and major projects. Sections 6 and 7 provide more information on FEI's approach to resiliency and Appendix E provides FEI's Gas System Resiliency Plan.

3.2.2.4 *The Clean Growth Pathway Supports Emerging Technologies and Innovation in BC*

Developing integrated and innovative energy solutions to support a low-carbon energy system is multi-faceted. In Section 3.3 below, FEI discusses its approach to decarbonizing the gas supply through renewable and low-carbon gas production, CCUS and other technologies that generate low-carbon gas. In parallel, there will be continued innovation to the electric system bringing on renewables, and upgrades to transmission and distribution networks. Innovative energy solutions can span the spectrum from individual projects at single building end uses such as gas adsorption heat pumps, to a dedicated pipeline for delivering hydrogen into a community or industrial project. Some specific examples of FEI's role in advancing emerging technologies and innovation in BC are outlined below and discussed throughout the section.

[107] The T-South system is owned and operated by Westcoast Energy Inc. which is a wholly owned subsidiary of Enbridge Inc.

3.2.2.4.1 FEI SUPPORTS INNOVATIVE TECHNOLOGIES IN THE BUILT ENVIRONMENT

FEI is contributing to various projects that support commercializing innovative gas utilization technologies that will help FEI meet its customers' needs while also addressing societal plans for reducing GHG emissions. Such technologies achieve this goal by raising the efficiency of gas end uses and also reducing the GHG emissions intensity of both the gas stream as well as individual end uses. The initiatives include:

- Working with the Canadian Gas Association and its member companies to explore injection of hydrogen into the natural gas pipeline system;
- Researching the commercialization of gas-driven heat pumps to provide gas equipment which exceed 100 percent end use efficiency;
- Evaluating the potential for dual-fuel (hybrid) heating systems with smart controls, replacing a conventional air-conditioner with a higher efficiency air-source heat pump, and pairing it with a gas furnace and smart controls;
- Support for small-scale residential and commercial carbon capture projects to capture carbon emissions from end use appliances and make them commercially usable, including from appliances such as commercial furnaces;
- Research into micro combined heat and power appliances that increase the aggregate energy use efficiency of gas end use appliances by generating heat and power from the gas stream;
- Support for commercializing small-scale residential natural gas end use appliances that are designed to meet the reduced heating requirements of more energy efficient newly constructed buildings; and
- Exploratory research and pilot programs to support deep energy retrofits for residential and commercial buildings.

There are many new end use technologies that will increase the system performance of heat and water heating equipment. Gas heat pumps are a gas-consuming technology that represent an opportunity for research and development and innovation. Gas heat pumps are more efficient than conventional natural gas space heating systems, but they have not yet reached their full market potential in Canada due to cost, availability, and other factors. However, gas heat pumps are expected to be instrumental in helping Canada meet its 2030 and 2050 emissions reductions targets.

3.2.2.4.2 FEI'S CLEAN GROWTH INNOVATION FUND SUPPORTS THE IMPLEMENTATION OF THE CLEAN GROWTH PATHWAY

FEI's Clean Growth Innovation Fund helps advance the adoption of clean technologies by providing grant funding for pre-commercial technologies that can lower emissions or reduction the cost of low-carbon solutions for customers. The fund collects approximately $5 million per year from customers to the end of 2024 that is available to support innovative energy projects, in partnership with government, industry, and communities. Organizations can apply for project funding, and an external advisory council comprised of representatives from customer groups, academia, government and industry provide feedback to FEI in selecting projects that support GHG emission reductions while providing value to FEI customers. Some examples of projects funded to date include:

- A project with the University of British Columbia (UBC) School of Engineering and another partner, with the goal to develop a novel scalable and automated hydrogen-enriched natural gas laboratory. The laboratory will be setup for conducting an integrated experimental study on the performance and feasibility of hydrogen-enriched natural gas with respect to injection, mixing quality, material exposure, separation, combustion and emissions;
- A feasibility and pilot study of a coupled anaerobic digester and pyrolyzer for co-processing organic waste to RNG and biochar (a charcoal-like carbon-rich solid);
- Several proposals that would create blue or green hydrogen: a catalytic converter to turn bioethanol into green hydrogen; a proton exchange membrane electrolyser; a process using electrochemistry to split mineral salt and water to generate hydrogen and hydroxide; a continuous reactor to convert waste polyethylene to hydrogen and carbon black using sulphur; and two pyrolysis-based initiatives that would generate hydrogen and carbon black from methane;
- A proposal for developing a combination forced air furnace and water heating unit capable of running on 100 percent hydrogen;
- A proposal for developing and piloting a molten alloy reactor for methane pyrolysis to produce hydrogen and solid carbon;
- Several initiatives related to carbon capture, including a tandem carbon recycling system for carbon capture and utilization from exhaust flue gas stream, a modular decarbonization system using membrane contractors, and a system that uses flue gas to cultivate microalgae in photobioreactors for capture and utilization; and
- Proposals that would create syngas from woody biomass, displacing the use of natural gas at lime kilns.

The CGIF will continue to be an important catalyst for the transition to a lower-carbon energy future in British Columbia.

3.2.2.4.3 EXPLORING ADVANCED METERING AND ENERGY UTILIZATION SOLUTIONS

FEI is exploring a number of innovative solutions to modernize the gas infrastructure through the automation of load management, energy management systems that enable customers to review and manage their energy consumption, and programs that support customers in reducing their energy use. These new technologies and innovations ultimately offer customers greater autonomy over their energy use than the traditional utility model. The Advanced Metering Infrastructure (AMI) Project and Demand Response programs are examples of these innovative energy utilization solutions; however, more energy utilization solutions will undoubtedly be available over the planning horizon for end users to use energy as efficiently as possible and provide the ability to regulate peak demand more effectively.

In May 2021, FEI filed its AMI project CPCN application with the BCUC. AMI represents a significant opportunity for modernizing the gas infrastructure and adding additional components to support system resiliency. The AMI solution will be capable of collecting gas consumption and other information from all customer meters and will add capacity for the collection of information on infrastructure and pipeline assets through use of communicating sensors. System resiliency will be enhanced by providing FEI with the ability to strategically manage system load and prevent system pressure collapse during an extended loss of supply.

The AMI system will also allow customers to access their hourly consumption information through a secure online customer information portal. The ability to access hourly consumption data will result in more opportunities for DSM program support and evaluation, consumption pattern awareness, and ultimately behaviour modification programs and energy savings for both residential and commercial customers. As such, AMI is a foundational step in energy management systems, upon which more innovative technologies will be built in time.

Some gas utilities are starting to explore the deployment of novel Demand Response programs. Broadly, these refer to curtailment of gas demand over a specific set of hours during peak demand periods through an automated system or a planned schedule. Interruptible Rates are the traditional gas utility resource analogous to Demand Response. A broader variety of technologies and price-based solutions are becoming available such as advanced thermostats, behavioural programs, and direct load control (i.e., remotely controlled curtailment). These approaches might help shift natural gas demand that has traditionally been served with firm service away from natural gas during peak periods. Though still being explored, Demand Response may prove useful at reducing peak demand in cases where gas utilities can remotely dispatch during peak events. Demand Response may be able to alleviate day-long constraints at city gates or hourly constraints on the distribution system.

FEI will continue to explore energy utilization technologies to assist customers in using energy more efficiently and regulating periods of peak demand over the planning horizon. The exploration of innovative technologies as a DSM activity is discussed in Section 5.2.1.5.

3.2.2.5 *The Clean Growth Pathway Supports Economic Development in BC*

The Clean Growth Pathway will provide a wide range of economic benefits to the province from offering customer benefits achieved from lower energy costs and economic development through FEI's investment in its four pillars. Clean energy projects to develop renewable and low-carbon gas, increased DSM investment in buildings and industry, investment in low-carbon and marine transportation, and global LNG export will result in higher gross domestic product, tax revenue and jobs in British Columbia. FEI's investments will support communities, including Indigenous groups, across BC in the low-carbon transition.

3.3 *PILLAR ONE: TRANSITIONING TO RENEWABLE AND LOW-CARBON GASES TO DECARBONIZE THE GAS SUPPLY*

The first pillar of the Clean Growth Pathway is the transition to renewable and low-carbon fuels to decarbonize the gas supply. FEI's gas distribution infrastructure has a critical role in providing low-carbon and renewable energy, which has enormous potential to reduce BC's GHG emissions by 2030 and throughout the 20-year planning horizon of the LTGRP. As FEI continues to increase RNG supply for its customers, it is also looking at adding clean-burning hydrogen, syngas and lignin to its renewable and low-carbon gas supply portfolio. Hydrogen has a number of benefits, including its versatility as an energy carrier that is carbon-free at the point of use. It can also be made from a range of feedstocks that are abundant in BC. As such, hydrogen is poised to play a key role in decarbonizing the gas network and FEI is working to find the most cost effective ways to integrate and scale up all renewable and low-carbon gas.

3.3.1 Overview of FEI's Renewable and Low-Carbon Gas Program

Transitioning to renewable and low-carbon gas is central to meeting the challenge of reducing emissions in BC by 40 percent by 2030. Since 2010, FEI has recognized the significant role a renewable and low-carbon gas supply will play as a fundamental pillar in providing low-carbon energy to its customers. Residential and commercial customers, public sector building owners, municipalities, and public transportation entities continue to express interest in purchasing significant volumes of renewable and low-carbon gas over the planning horizon. This interest was evident in the community engagement session discussions outlined in Section 8.4. Through its Renewable Gas Program and other efforts, FEI has been a leader in decarbonizing to meet policy objectives and customer demand.

FEI has offered a Renewable Gas Program since 2010, with cost recovery of the acquired renewable gas volume from voluntary program participants through the Biomethane Energy Recovery Charge (BERC) which was set to match projected supply costs. In February 2020, the BCUC accepted FEI's first acquisition of renewable gas outside of BC as a prescribed undertaking under the GGRR. In May 2021, the provincial government amended the GGRR, increasing the acquisition cost cap and volumes and expanding acquisition opportunities for FEI as discussed previously in Section 2.2.2.3.

In December 2021, FEI filed its Comprehensive Review and Application for a Revised Renewable Gas Program (RG Program Application), which, along with other revisions, seeks to blend renewable gas volumes with natural gas to be sold to all sales customers as part of their gas service. As renewable gas supply increases to meet government emission reduction targets, FEI intends to distribute that supply to all sales customers.[108] As shown in Figure 3-4 below, the program has changed over the years with respect to the maximum volumes, supply projects, service offerings and pricing.

[108] FEI's sales customers include those in RS 1, 2, 3, 4, 5, 6 and 7.

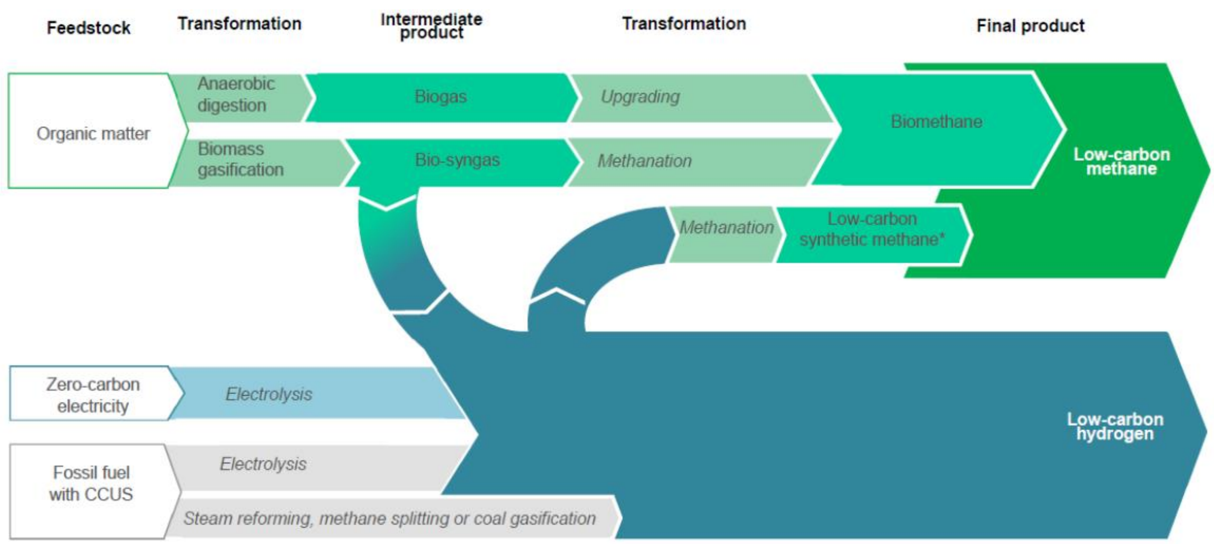
Figure 3-4: Overview of key milestones in the development of FEI's Renewable Gas Program

Characteristic	Phase 1 Pilot Program 2010-2013	Phase 2 Permanent Program 2014-2016	Phase 3 New Renewable Gas Rate (BERC) 2016-2017	Phase 4 GGRR amended to include RG 2017-2021	Phase 5 GGRR amended to further support RG; RG Application 2021 and future years
Volumes and Acquisition Cost Cap	0.25 PJ/Yr @ $15.28/GJ	1.5 PJ/Yr @ $15.28/GJ	1.5 PJ/Yr @$15.28/GJ	8.9 PJ/Yr @$30/GJ	>31 PJ/Yr @ $31/GJ
Supply Projects	First two projects	Added projects	Continued to add projects	Out-of-province projects added	Acquisition opportunities expanded
Offerings	Customer program initiated	Expanded customer offering	Long-term contracts available	No Change	RG Application Section 7.4
Price Mechanism	BERC = Program Costs	BERC = Program Costs	BERC = Market Price	No Change	RG Application Section 8

3.3.2 Renewable and Low-Carbon Gas Supply Technology Will Facilitate the Clean Growth Pathway

The GGRR now prescribes undertakings for the acquisition of hydrogen, lignin, and syngas, in addition to RNG. Other low-carbon gas resources can also be brought to bear on the transition to low-carbon energy using FEI's infrastructure, such as by combining CCUS with gas production. This section describes these new types of renewable and low-carbon gas that are now becoming commercially viable solutions to reducing GHG emissions from gas combustion. Figure 3-5 below demonstrates a number of production pathways for renewable and low-carbon gases that will facilitate FEI's Clean Growth Pathway, not all of which are currently authorized by the GGRR.

Figure 3-5: Production Pathways for Renewable and Low-Carbon Gas for FEI's Low-Carbon Transition[109]



FEI has been working with suppliers of RNG, hydrogen, syngas and lignin in BC and other jurisdictions to expand its portfolio of renewable and low-carbon gases. CCUS[110] provides a suite of emerging technologies that FEI can explore for furthering its decarbonization objectives. Taking advantage of new technologies, will not only reduce GHG emissions, but also diversify FEI's energy system and supply. The benefits of such diversity extend to the provincial and the PNW energy systems as a whole.

3.3.3 FEI's Clean Growth Pathway Supports BC's Hydrogen Economy

FEI's vision for a hydrogen economy is built around evolving policy and technology developments in BC,[111] Canada[112] and internationally. Hydrogen is a versatile energy source and carbon-free at the point of use. It broadens opportunities for renewable and low-carbon fuels, as it can be used as an energy carrier, energy storage medium, gaseous fuel alternative to natural gas, and as a chemical feedstock to address difficult-to-decarbonize end use applications such as high temperature industrial processes, space heating, and long-haul transportation. As the BC Hydrogen Study indicates, it has the potential to be produced at scale in BC using commercially available technology. Developing and delivering hydrogen through or enabled by existing gas infrastructure would give FEI the opportunity to create new partnerships, expand business

operations and contribute to significant GHG emission reductions. BC's economy will benefit from hydrogen resource development projects, dedicated hydrogen infrastructure, domestic hydrogen market growth and hydrogen for export, given that the global hydrogen demand is projected to increase across multiple sectors. FEI intends to be a key player in establishing the foundation for a hydrogen economy in BC.

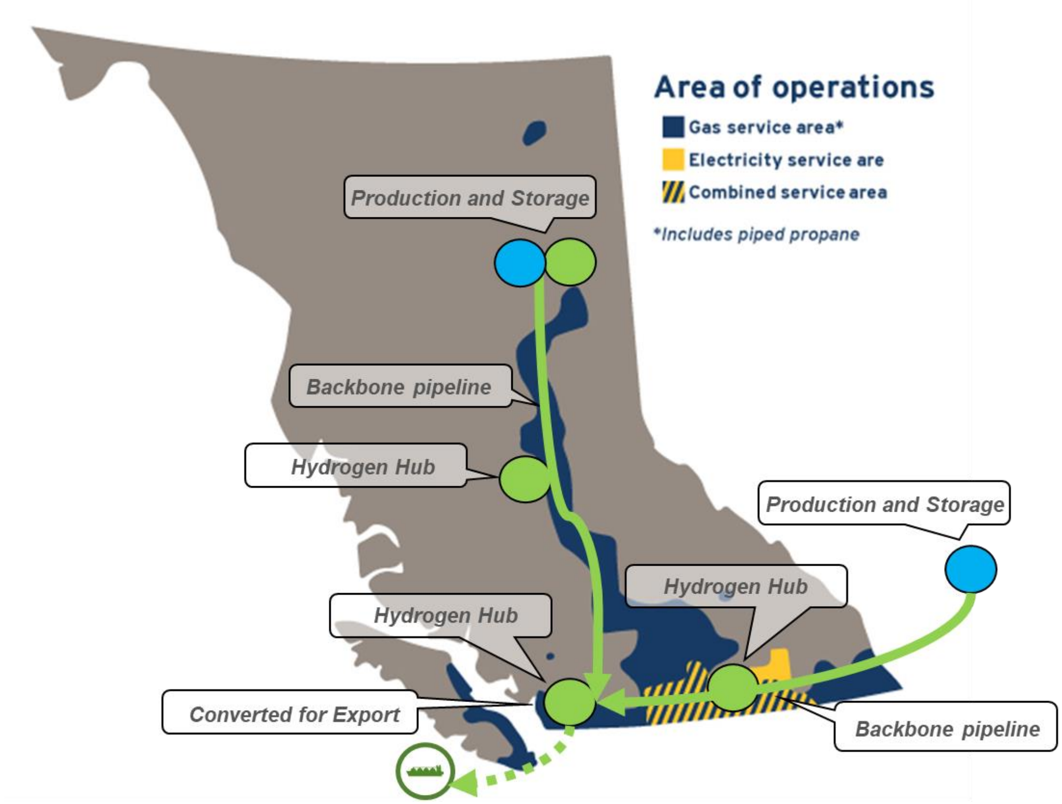
There are a number of pathways FEI can undertake for hydrogen distribution, including:

- Supplying the existing gas grid at low concentrations or blends;
- Directly supplying to customers that are hydrogen ready (initially, large commercial and industrial end users);
- Delivering supply to end users through purpose-built pipeline systems;
- Combusting directly or converting to electricity using fuel cells;
- Utilizing power-to-gas technologies that could strategically couple the gas and electric grids to convert electrical energy to chemical energy in the form of hydrogen or methanized hydrogen for storage and delivery; and
- Supplying for transportation applications.

Hydrogen is a clean-burning molecule that can be used to displace natural gas and liquid fossil fuels to decarbonize a range of end use applications. Hydrogen demand will need to grow in BC and there is the opportunity to develop initial market nodes or "hydrogen hubs" in the Lower Mainland, Interior, and Northern regions of BC. Over time, as demand grows, existing pipeline corridors will be expanded, retrofitted and upgraded to transport hydrogen. A low-carbon "backbone system" would provide the necessary capacity to link hydrogen hubs,[113] producers, and consumers over longer distances and enable a regional market. Pipeline capacity at scale would also support development of the supply chain for marine fuel and offshore demand. Figure 3-6 illustrates some of the ways that FEI's infrastructure can facilitate the incorporation of hydrogen production, transmission and use.

[113] A hydrogen hub integrates a number of hydrogen-based energy services through centralized infrastructure and supporting technology. Online at: hydrogenhub.org.

Figure 3-6: Illustrative Example of FEI's Transition to a Hydrogen-Enabled System



Over the next five years, FEI will be considering a number of approaches to locally displace conventional natural gas in the gas system and opportunities to distribute hydrogen directly to gas customers. This analysis is necessary to establish hydrogen demand in BC and inform new market segments of the versatility and safety of hydrogen as a mass market consumer fuel. To support this goal, FEI is enabled under the GGRR to acquire hydrogen to meet near-term objectives including:

- Blending hydrogen in the gas distribution system to displace conventional natural gas (similar to RNG) including either hydrogen produced by FEI or through a third party; and
- Purchasing hydrogen that could be distributed through dedicated infrastructure (new or repurposed) to gas customers to displace conventional natural gas usage.

In the medium term (projected to be by 2030), FEI envisions that blending of hydrogen would expand across the low-pressure gas distribution system, with the potential for segments within the system to expand to include hydrogen hubs which can distribute 100 percent hydrogen.

Over the longer term (between 2030 and 2050), and as demand for hydrogen grows, the existing gas system's high pressure transmission pipeline corridors will be retrofitted, upgraded, and expanded to transport an increasing share of hydrogen and RNG in a progressively decarbonized gas system. Similarly, and with this goal in mind, FEI's RGSD project, discussed in sections 6.3.3 and 7.5.1.1, will be developed to be hydrogen-enabled.

Gas system planning will play a pivotal role in the transition to hydrogen as outlined in Section 7.4. Safety, reliability and resiliency of the energy delivery system will continue to be key priorities for FEI. Due to its different properties from biomethane, hydrogen will require particular attention to be successfully integrated into FEI's and BC's existing gaseous energy supply chain. The unique physical, chemical, interchangeability, and utilization characteristics when compared to conventional natural gas may limit hydrogen gas as a drop-in replacement fuel, beyond a percentage blend expected to be in the concentration range of 2 to 20 percent by volume. As hydrogen is less dense, it will require somewhat larger pipes and more compression to deliver similar amounts of energy. Introducing hydrogen into the existing gas network, the potential impacts on end users, and supporting the development of codes, standards, and regulations are all areas FEI is evaluating. Hydrogen pilots are currently anticipated to become operational in the 2023 to 2024 timeframe as demonstrations for proof of concept. FEI's first hydrogen supply project is anticipated as early as 2025. All of the necessary system planning considerations will be developed and implemented over the planning horizon.

3.3.4 Potential for Hydrogen to Decarbonize the Industrial Sector

Decarbonization of the industrial sector represents a large opportunity to reduce provincial GHG emissions. In 2019, GHG emissions in BC surpassed 68 Mt CO_2e as illustrated in Figure 3-2. At that time, BC's industry sector emissions represented 21 percent of BC emissions. A large portion of these emissions are a result of industrial heat and unavoidable process emissions. Industrial heat requirements are difficult to decarbonize by electrification, due to the nature of the established processes and equipment involved such as kilns and furnaces. Industries such as pulp mills and cement manufacturing are among the largest industrial contributors to GHG emissions in BC and good candidates as hydrogen projects.

FEI envisions low-carbon hydrogen playing a critical role in decarbonizing BC's industrial sector, which is expected to be most difficult to decarbonize to reach the Province's 2030 and 2050 climate goals. Transitioning BC's industry to hydrogen as a heating solution supports the concept of a BC hydrogen backbone system that will involve repurposing and upgrading sections of the existing gas grid to reliably supply clean, low-carbon hydrogen to industrial end users.

Currently, there is an opportunity to start transitioning pulp mills and cement manufacturing facilities to using low-carbon hydrogen. This transition can be initiated with minimal upgrades and process impacts by blending low-carbon hydrogen into the end user's existing natural gas supply, starting at as low as 2 percent by volume. An industrial hydrogen blending test program will be conducted, administering appropriate safety and impact assessments in order to allow for safe incremental increases of hydrogen blending, by up to 20 percent.

During the blending period, existing technology for 100 percent hydrogen burners is to be investigated and piloted for use in cement kilns. Once commercialized, hydrogen burner technology can be tested and rolled out at industrial facilities, with the goal of converting pulp mills and cement manufacturing facilities to 100 percent low-carbon hydrogen, which would help to achieve net-zero carbon for BC by 2050.

FEI is working with industry and government to identify opportunities to begin the industrial transition to low-carbon hydrogen. In these difficult-to-decarbonize sectors, FEI believes innovation in hydrogen technology will best serve the needs of British Columbians by preserving clean electricity for other uses and regions where electrification may present greater opportunities for GHG reductions.

3.3.5 Renewable and Low-Carbon Gas Production Potential in BC and North America

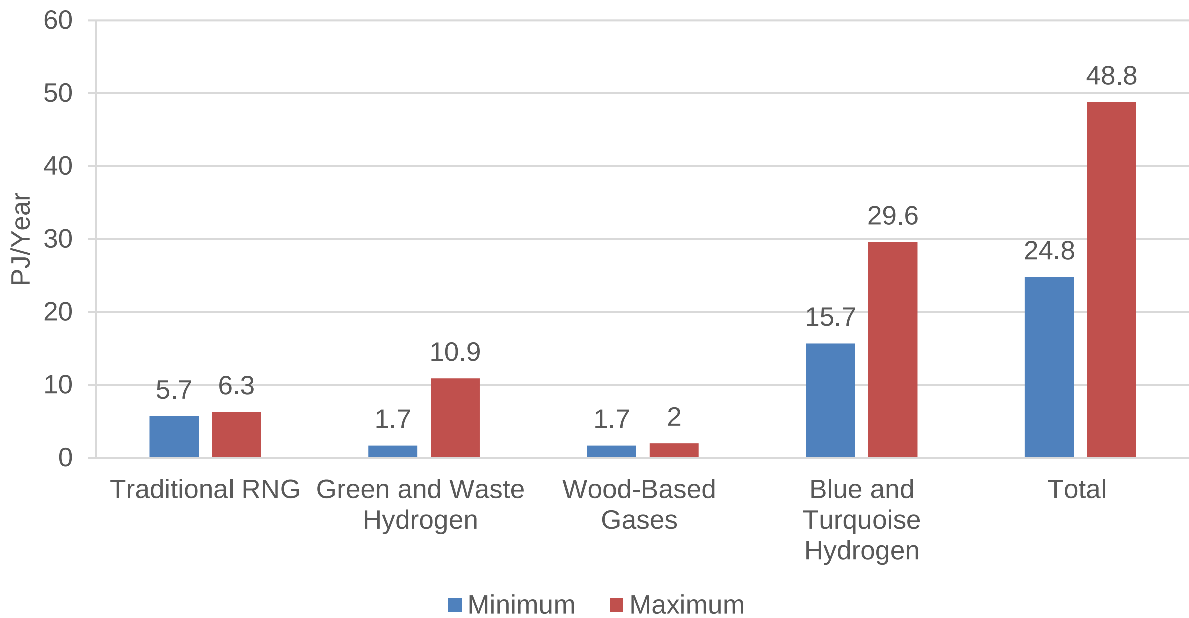
As described in Section 2.2.2.2, the Roadmap includes plans to establish a GHG emissions cap for natural gas utilities. This would require natural gas utilities in BC to reduce the carbon emissions related to their gas sales to the Buildings and Industrial Sectors to approximately 6 Mt of CO_2e per year by 2030, which is approximately 47 percent lower than 2007 levels. It is anticipated that this cap will, in part, drive the production and acquisition of renewable and low-carbon gas as a key measure to displace conventional natural gas.

In response to the need for renewable and low-carbon gas production, FEI, the BC Bioenergy Network, and the Province of British Columbia commissioned a report to conduct a detailed assessment of the supply potential and production costs of renewable and low-carbon gas in BC through 2050 (see Appendix D-2). The report, titled B.C. Renewable and Low-Carbon Gas Supply Potential Study, describes the potential for renewable and low-carbon gas[114]. The report includes hydrogen derived from renewable electricity, woody biomass and natural gas feedstocks[115] as well as RNG, syngas and lignin derived from woody biomass feedstocks. The study developed a “Minimum Scenario” based on pessimistic assumptions with respect to the availability and cost of supply by 2030 and 2050 in BC. In this scenario, 25 PJ of renewable and low-carbon gas supply is projected to be available by 2030 and over 100 PJ by 2050. In the Maximum Scenario based on optimistic assumptions on the availability of and costs of feedstocks and technology development and lower costs 49 PJ of renewable and low-carbon gases is projected to be available in BC by 2030 and 444 PJ by 2050. Figures 3-7 and 3-8 describe the potential by gas and feedstock in more detail.

[114] The study did not consider alternative options, such as switching natural gas heating to wood pellets, heat pumps, or increased energy efficiency.

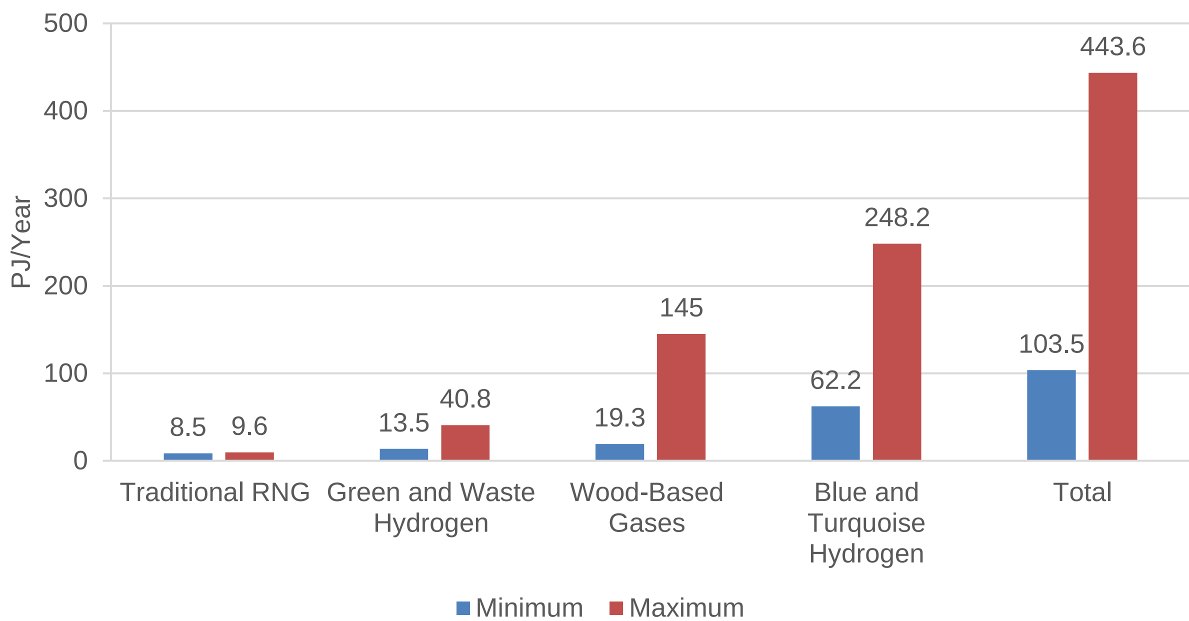
[115] Natural gas feedstocks in this analysis require carbon capture and sequestration or other technologies that ensure that the hydrogen is low-carbon.

1 **Figure 3-7: 2030 Renewable and Low-Carbon Gas Supply Potentials by Scenario**



2

3 **Figure 3-8: 2050 Renewable and Low-Carbon Gas Supply Potentials by Scenario**



4

5 Competition for both the supply and use of renewable and low-carbon gas will be growing
6 nationally and in the US as evidenced by the increasing requirements and compliance monitoring
7 of California's Low-carbon Fuel Standard, which has set a minimum price threshold per unit of
8 renewable energy in order to increase the range of low-carbon and renewable fuel alternatives
9 available to the transportation sector.

Collaborative partnerships and a favourable regulatory environment are crucial for the development of a BC-based industry. All levels of government, communities and Indigenous groups, utilities, and other industry players must work together on innovative research, policy development and joint ventures to fund and support development and production of these projects.

The transition to low-carbon energy is discussed throughout this LTGRP and discussed specifically in the following sections:

- For forecasts on costs, refer to Section 2.4;
- For forecasts on rate impacts, refer to Sections 5.4.2 and 9.4;
- For incorporation in demand forecasts, refer to Section 4;
- For incorporation in supply portfolio planning, refer to Section 6;
- For incorporation in system resource needs, refer to Section 7;
- For the Outcomes of FEI's Clean Growth Pathway, refer to Section 9 and;
- For related Action Items, refer to Section 10.

3.4 *PILLAR TWO: INVESTING IN DSM PROGRAMS TO REDUCE ENERGY AMONGST RESIDENTIAL, COMMERCIAL AND INDUSTRIAL CUSTOMERS*

The second pillar of the Clean Growth Pathway is the continued and expanded investment in energy efficiency and conservation measures across FEI's residential, commercial and industrial customer uses. As discussed in Section 3.2, these activities focus on initiatives to further reduce the 21 percent of provincial GHG emissions attributed to buildings and communities through high performance buildings initiatives such as energy efficiency and energy management.

FEI has long invested in energy efficiency to ensure that customers have options to moderate their energy use and improve affordability. To make further progress on improving energy efficiency in residential, commercial and industrial sectors, since 2017, FEI has tripled its annual DSM investment to reach $107 million in 2021. In addition, FEI is piloting next generation equipment, innovative technologies and new approaches to efficiency in the buildings sector such as deep energy retrofits, gas heat pumps, dual-fuel heating systems and buildings controls to leverage new emissions reduction energy technologies.

In the residential and commercial buildings sector, FEI is incorporating a broader, high performance, whole-buildings approach that will likely involve activities beyond traditional equipment-focused DSM activities for both retrofit and new construction. These activities broadly include:

- An envelope-first approach to deep energy retrofits;

- Customized programs to support income-qualified customer segments and Indigenous communities;
- Activities to accelerate market transformation to gas heat pump technology, dual-fuel hybrid heating systems, and other innovative technologies that will reduce GHG emissions while enhancing resiliency to utilize the strengths of both the gas and electric systems during periods of peak demand;
- Support for economic development and job growth through the expansion of trades and industry support to increase contractor capacity and training across all sectors to support quality best practices in existing buildings and new construction;
- Advancing digital platforms for virtual home energy audits, energy literacy, demand response, behaviour modification, commissioning or maintenance programs, and energy management systems to optimize building performance. FEI's current AMI application may enhance the capability to provide these services;
- Working with local governments, Indigenous communities, associations and buildings science professionals to accelerate the adoption of high performance buildings in retrofit and new construction; and
- Continuing to work with BC Hydro and the Ministry of Energy, Mines and Low Carbon Innovation to advance building decarbonization activities across the province.

Expanding FEI's low- and zero-carbon solutions in buildings will be a key component of this pillar in the Clean Growth Pathway. FEI's Conservation and Energy Management group and supporting teams throughout the organization are focused on this key objective. Transitioning the buildings sector to low-carbon energy is discussed throughout this LTGRP and discussed specifically in the following sections:

- For the incorporation of DSM initiatives in demand forecasts, refer to Section 5.4;
- For the Outcomes of FEI's Clean Growth Pathway, refer to Section 9 and;
- For related Action Items, refer to Section 10.

3.5 PILLAR THREE: INVESTING IN LOW-CARBON TRANSPORTATION INFRASTRUCTURE TO REDUCE EMISSIONS IN THIS SECTOR

The third pillar of the Clean Growth Pathway is investing in low-carbon transportation (LCT) infrastructure[116]. GHG emissions from transportation make up the largest share of overall provincial emissions at 39 percent and freight transportation is one of the most challenging sectors to decarbonize. FEI is working to convert medium-duty and heavy-duty fleet vehicles and marine

[116] FBC is also investing in EV infrastructure and provides customers with clean electricity to support the transition to zero and low-carbon transportation in the passenger vehicle market. However, this activity will not be discussed in the 2022 LTGRP.

vessels to lower carbon alternative fuels like CNG and LNG. In addition to a significant GHG reduction benefit, using CNG and LNG in vehicles and marine vessels can dramatically improve air quality by reducing particulate matter as well as sulfur and nitrogen oxides released into the environment.

Supplying fuel for LCT and remote power generation for non-grid connected communities and industrial sites currently using higher carbon fuels are key opportunities for FEI to serve the energy needs of customers and help reach the ambitious GHG reduction targets legislated by the province. In the LCT and remote power generation sectors, FEI is looking to displace petroleum fuels such as diesel with cleaner-burning natural gas and RNG. Natural gas is a lower-carbon alternative to conventional transportation and remote power generation fuels and can play a significant role in reducing emissions and reducing reliance on petroleum-based fuels. Where opportunities exist, substituting conventional natural gas with RNG can increase emission reductions further. RNG is a direct substitute for conventional natural gas in vehicles, and requires no incremental capital investment to the vehicles or infrastructure that are already capable of operating on natural gas.

To capture the LCT benefit, customers must make investments in vehicles, equipment and marine vessels designed to use natural gas or RNG. Given the investment dollars at stake for early adopters of natural gas as a transportation fuel, customers view FEI as a partner that can be depended upon to deliver the energy they need to facilitate the shift from conventional petroleum fuel to cleaner sources of energy.

The GGRR is one mechanism that utilities in the province have used to begin the market transformation process of converting applicable transportation and power generation applications to natural gas and RNG as a feedstock fuel. However, the prescribed undertaking period for investment in LCT infrastructure under the GGRR ended on March 31, 2022. At the time of writing, the Province's plans to continue to support LCT through the GGRR are not yet known.

LCT is discussed throughout this LTGRP and discussed specifically in the following sections:

- For the incorporation of LCT initiatives in demand forecasts, refer to Section 4.6.2;
- For the Outcomes for LCT in the Clean Growth Pathway, refer to Section 9 and;
- For related Action Items, see Section 10.

3.6 *PILLAR FOUR: INVESTING IN LNG TO LOWER GHG EMISSIONS IN MARINE FUELING AND GLOBAL MARKETS*

The fourth pillar of the Clean Growth Pathway is investing in LNG to lower GHG emissions in marine fueling and global markets. Natural gas is increasingly becoming a viable fuel for the global marine vessel market. Global environmental regulations have been implemented which will likely continue to drive out the use of higher carbon fuels that have traditionally been consumed by the global marine market. Due to these tighter restrictions on marine vessel emissions, natural gas in the form of LNG is an attractive alternative fuel for vessel operators to comply with these tighter restrictions. It is expected that more and more end users will transition to natural gas to meet the restrictions.

The Province of BC and FEI are strategically positioned to be leaders in this transition and help reduce global GHG emissions. BC has significant natural gas resources, with remaining raw reserves of approximately 1.165 trillion cubic metres. Over 60 billion cubic metres of natural gas were produced in 2018.[117] However, domestic use of conventional natural gas may possibly decrease over time to reach CleanBC's 2050 domestic target. In that scenario, BC's natural gas could then be exported as LNG to Asia to displace higher carbon and higher polluting fuels such as coal and oil, which could result in a net reduction of global GHG emissions.

BC's LNG can also power large ocean vessels, which would displace higher-emissions fuels like diesel and heavy oil. An analysis conducted by Thinkstep concluded that LNG from BC used in marine shipping could reduce GHG emissions by up to 27 percent compared to the global average for LNG supply.[118] As the policies in CleanBC are implemented (e.g., electrifying upstream gas production and implementing regulations to reduce methane emissions), the carbon intensity of the LNG supply chain in BC could be half that of the current global average by 2030.[119] To support provincial and federal objectives to become a world leader in LNG bunkering,[120] FEI is promoting use of LNG for marine use to replace the world's most carbon intensive fuels.

3.6.1 GHG Emissions Opportunities from LNG Exports

There have been discussions over the past number of years with several overseas customers who have expressed interest in exporting LNG from Tilbury to destinations in Asia. Exporting LNG can help countries overseas reduce their reliance on higher carbon fuels, such as coal, and make immediate emissions reductions more affordably. As an added benefit, LNG from Tilbury has a production carbon intensity up to 30 percent lower than global average LNG carbon intensities.

By replacing conventional coal with LNG, approximately 40 to 45 percent and 26 to 32 percent emissions reductions can be obtained for Chinese textile and chemical industries, respectively. The highest emissions reduction of approximately 60 percent is observed when coal is replaced with natural gas from LNG for district heating.[121] The Liquefaction Facility component of Tilbury

117 Pathways Report, p. 29.
118 Pathways Report, p. 20.
119 Pathways Report, p. 20.
120 The Province's CleanBC Roadmap aims to "make our ports attractive to global shipping fleets transitioning to LNG as a lower cost, lower GHG transition fuel": Roadmap, p. 61. Further, in a news release issued in October 2019, the Province of BC announced its plan to partner with the Vancouver Fraser Port Authority and FortisBC to establish the first ship-to-ship LNG marine bunkering service on the west coast of North America, which "will allow B.C. to have a direct impact on global emissions by reducing the amount of greenhouse gas emissions from visiting vessels": Government of British Columbia, "Province supports proposal for LNG ship-refueling facility" (October 23, 2019), online at: https://news.gov.bc.ca/20855. The federal government also supports LNG marine bunkering goals, as the Prime Minister of Canada has directed the Minister of Transport to work with partners to support efforts to convert marine vessels and infrastructure toward "more environmentally friendly fuels, like liquefied natural gas": Office of the Prime Minister, Ministry of Transport Mandate Letter (December 13, 2019), archived online at: https://pm.gc.ca/en/mandate-letters/2019/12/13/archived-minister-transport-mandate-letter .
121 Kotagodahetti, Ravihari et.al, Liquefied natural gas exports from Canada to China: An analysis of internationally transferred mitigation outcomes (ITMO) (2022). Online at:

Phase 2 LNG Expansion Project is being developed by a non-regulated FortisBC entity for bulk export, and is currently undergoing an environmental assessment under the direction of the BC Environmental Assessment Office.

3.6.2 Marine Fueling Opportunities in BC Will Reduce GHG Emissions

Bunkering is the act of supplying a marine vessel with fuel, and can include truck-to-ship or ship -to-ship fueling. Various incumbent fuels are used in marine transportation, including marine gas oil, marine diesel oil, intermediate fuel oil and heavy fuel oil.[122] Currently, heavy fuel oil accounts for the majority of the fuel used for tankers, bulk carriers and container ships globally; as such, it presents an immense opportunity for growth. LNG is a relatively new fuel in the marine bunkering market. Its adoption is being driven by operating cost advantages, sulphur emission limits and the opportunity to replace some of the world's highest carbon intensity fuels with clean LNG sourced from BC.

The LNG marine bunkering opportunity is a key part of FEI's strategy to reduce GHG emissions and will positively impact FEI's customer rates. The opportunity leverages pre-existing FEI-owned assets and operational expertise to drive growth in new markets and contribute to BC's economy. Although the original Tilbury LNG facility serves as a winter peaking facility, over time, the expansions to the facility have evolved and expanded to produce LNG to serve a variety of new LNG markets.

In general, a ship requiring bunkering is either loading or unloading at the cargo berth, or anchored at the port. LNG marine bunkering is most frequently performed via an LNG bunkering vessel that pulls up alongside the vessel requiring fuel, and the fuel is transferred from the bunkering vessel to the receiving vessel.

FEI has had initial success advancing the LNG marine bunkering market in BC, as evidenced in the following milestones:

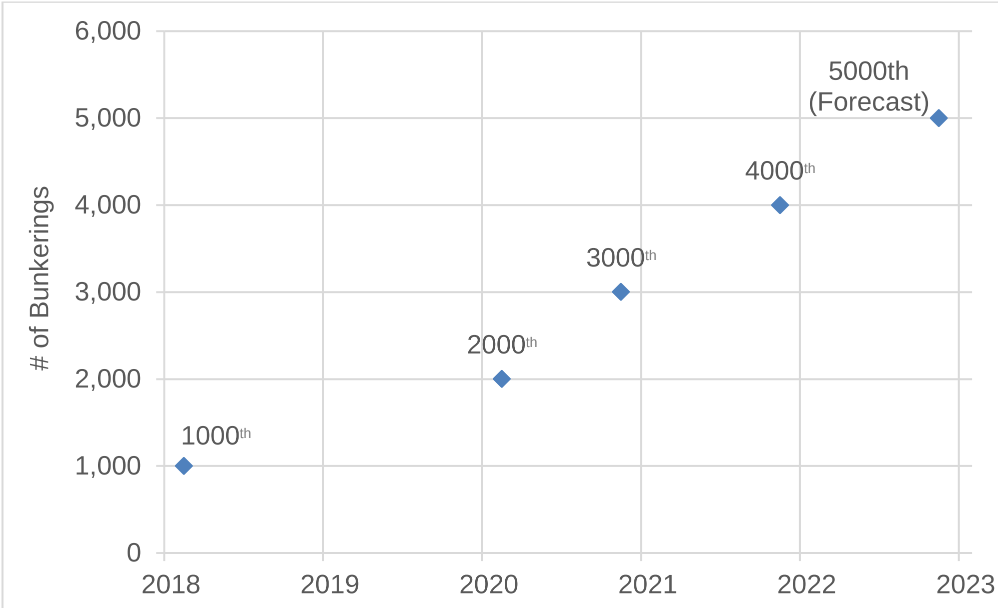
- In late 2016, FEI bunkered a Seaspan Ferries Corp. ferry using an LNG tanker truck to transfer the LNG directly into the ship, eliminating any stationary LNG fueling infrastructure (truck to ship bunkering). This innovative method of bunkering had never previously been performed in the marine sector. The success of the innovative process was a product of over two years of collaboration with Seaspan, BC Ferries, Class Societies and Transport Canada, among others. The success of the first truck to ship bunkering led to increased adoption of LNG vessels. From 2017 to 2019, Seaspan's LNG vessel fleet grew to three and BC Ferries added five LNG vessels.
- FEI celebrated its 1000th bunker event in 2018 and expects to reach its 5000th bunker event in late 2022. This annual growth is illustrated in Figure 3-9.

---

https://www.sciencedirect.com/science/article/abs/pii/S0959652622009210

[122] These four marine fuels are ordered from lightest to heaviest in terms of density and weight (i.e., least emitting to highest emitting).

Figure 3-9: Timeline of FEI's Annual Bunkering Milestones (2018-2023)



- In 2022, FEI increased its LNG delivery frequency with the addition of two Seaspan LNG vessels and one LNG vessel from BC Ferries.

Leveraging FEI's success in marine bunkering, an FEI Affiliate is exploring a potential marine jetty next to the Tilbury LNG storage facility that would allow for ship-to-ship LNG bunkering using LNG from FEI's Tilbury LNG facility for Trans-Pacific customers and for bulk delivery to overseas markets. It is important to note that the jetty will be owned by a non-regulated entity with services provided to it by FEI. This is not part of FEI's initiatives included in the LTGRP, however this initiative needs to be considered in terms of gas supply and any system contracting requirements, as it is expected the marine jetty will enable significant sales under Rate Schedule 46. The marine jetty is currently completing an environmental assessment under the direction of the BC Environmental Assessment Office. The environmental assessment is expected to conclude in 2022. If approved, the jetty could provide service for LNG marine fueling by 2024 or 2025.
FEI will continue to advance its interests in the LNG marine bunkering market as an LNG fuel. FEI's early progress in this market, coupled with recent supportive market conditions, creates a favourable opportunity for further helping to reduce customer rate pressures and reducing GHG emissions.

The LCT opportunities are further discussed generally throughout this LTGRP, and discussed specifically in the following sections:

- For the incorporation of LNG initiatives in demand forecasts, refer to Section 4.6.2;
- For the Outcomes in the Clean Growth Pathway, refer to Section 9 and;
- For related Action Items, refer to Section 10.

3.7 STUDIES SUPPORTING THE DIVERSIFIED PATHWAY APPROACH

Appendix A-9 provides a number of studies outlining the benefits of comprehensive energy system planning akin to that achieved by the Diversified Pathway, while highlighting that there are unintended consequences and risks of pursuing an electrification-centric approach to energy planning in BC. These studies are described below.

3.7.1 Studies on Diversified Energy Approaches in Other Jurisdictions

3.7.1.1 *Canadian Gas Association*

The Canadian Gas Association study from 2019[123] highlights the implications for moving away from an integrated multi-fuel, multi-grid energy system towards a fully electrified system. The study presents the significant and costly expansion of Canada's electrical system required to replace refined petroleum products and natural gas in homes, businesses, industry, and vehicles with electricity. Further, the incremental costs associated with meeting increased peak load for extreme cold events will require additional investments. Diversified energy approaches can be optimized to provide a reliable, more affordable, low emissions energy system by allowing for system integration and the leverage of natural gas for peak loads on very cold days.

3.7.1.2 *American Gas Association*

The American Gas Association study[124] emphasized how energy system resiliency is increasingly essential to all sectors of the US economy and communities served and the ways in which the gas system contributes to the overall resilience of the US energy system as a whole. Service disruptions create economic and social hardships, including lost productivity, safety and health risks - and has even led to the loss of life. Future energy infrastructure design must incorporate resilience at a system-wide level. The energy sector is transforming at a rapid pace, and the study concludes with the importance of understanding "the increasing interdependence of gas and electric systems and their role in creating a more resilient future".[125]

3.7.1.3 *Ontario Energy Association*

The Ontario Energy Association released a comprehensive energy-use plan[126] with the key objectives of finding the most affordable, reliable, and sustainable pathway to fulfill energy requirements and emission reductions objectives. The plan outlines the need for all levels of government, utilities, and other stakeholders to work together on a costed and complementary emissions reduction strategy, optimizing the use of existing infrastructure, while investing in new

[124] Appendix A-7.

[125] Appendix A-7. Page 1.

[126] Appendix A-9.2: Ontario Energy Association, Energy Platform (2022), online at: https://energyontario.ca//Files/PDF%20files%20to%20share/OEA_Energy_Platform_2022_FinalWEB.pdf.

infrastructure, technology, energy efficiency and behaviour change in developing a coordinated response to energy planning for Ontario.

3.7.1.4 *The European Union*

The European Union is envisioning an integrated energy system across Europe as the best path to decarbonization. Their plan[127] proposes "coordinated planning and operation of the energy system 'as a whole', across multiple energy carriers, infrastructures, and consumption sectors – as the pathway towards an effective, affordable and deep decarbonisation of the European economy in line with the Paris Agreement and the UN's 2030 Agenda for Sustainable Development". The report summarizes the complementary energy system approach as follows:

> Energy system integration will translate into more physical links between energy carriers. This calls for a new, holistic approach for both large-scale and local infrastructure planning, including the protection and resilience of critical infrastructures. The objective should be to make the most of the existing infrastructure while avoiding both lock-in effects and stranded assets. Infrastructure planning should facilitate the integration of various energy carriers and arbitrate between the development of new infrastructure or re-purposing of existing ones. It should consider alternatives to network based options, especially demand-side solutions and storage.[128]

3.7.1.5 *Energy and Utilities Alliance – United Kingdom*

A 2021 UK study sponsored by Energy and Utilities Alliance in partnership with Leeds Beckett University[129] reviewed opportunities to decarbonize residential buildings. They concluded that net-zero carbon missions could only be achieved through complementary energy systems including repurposing gas networks for hydrogen. The study highlighted some of the constraints in electrifying home heating and the benefits of gas-based technologies and a decarbonized gas network.

3.7.2 Independent Academic Studies on Energy Capacity in BC

In the following section, FEI highlights key messages from two independent academic studies examining decarbonization approaches for BC's energy systems. These studies highlight the importance of taking a diversified, complementary systems approach to energy system planning in BC, one in which peak demand and resiliency are incorporated into critical decision-making to serve the energy needs of residential, commercial and industrial energy needs in BC.

[127] Appendix A-9.3: European Commission, Powering a climate-neutral economy: An EU Strategy for Energy System Integration (July 2020) p.2

[128] Appendix A-9.3: European Commission, Powering a climate-neutral economy: An EU Strategy for Energy System Integration (July 2020) p.17

[129] Appendix A-9.4: Energy and Utilities Alliance (EUA) in partnership with Leeds Beckett University and UK gas distribution networks Cadent, Northern Gas Networks, SGN and Wales & West Utilities, "Decarbonising heat in buildings: putting consumers first" (April, 2021).

3.7.2.1 *University of Victoria's Institute for Integrated Energy Systems*

The University of Victoria's Institute for Integrated Energy Systems studied[130] the decarbonization of the building heating systems in Metro Vancouver by comparing two transition pathways: one that substitutes natural gas with electricity (electrification pathway), and the other that substitutes natural gas with biogas and electrolytic hydrogen (renewable gas pathway). Preliminary results indicated that exclusive electrification could increase peak electricity demand beyond available hydropower requiring significant electricity storage that comes at a high cost. Replacing natural gas with renewable and low-carbon gas can avoid increasing the peak electricity demand and use surplus electricity during off-peak times to produce hydrogen. At low heat demand, the existing hydroelectric capacity is almost sufficient to serve the additional electric power demand, making electrification the lowest cost option. If variable wind and solar power are not available during very cold periods, then the renewable gas pathway is lower cost because this pathway avoids the high cot of electricity storage. Overall, under certain circumstances either pathway can be lower cost, but the electrification pathway has greater cost uncertainty.

3.7.2.2 *The University of British Columbia's Clean Energy Research Centre (CERC)*

The University of British Columbia's Clean Energy Research Centre reviewed[131] the use of clean energy in achieving the GHG emission reductions outlined in the Roadmap to 2030 and to 2050. Economic and population growth will result in increased demand for heating, transportation and industrial production. Energy efficiency and demand reduction to meaningful levels (i.e. 25 percent) will require transformative change. The study found that neither hydroelectric electricity nor bioenergy alone are sufficient to meet demand. The CERC developed a number or models to examine some alternatives, stated in their report as follows:

> Although electrification is seen as a core strategy for GHG mitigation in BC, electricity supply is insufficient to meet the growth in demand inherent in the electrification-centered strategy. Even with Site C and radical demand reduction, about 60 PJ of additional supply will be needed to meet the 2030 target, and 160 PJ for carbon neutrality in 2050. New electricity generation will be needed by 2030 and beyond, comparable in magnitude to the projected output of the current Site C project. This implies installing hundreds of wind turbines and millions of solar panels. The bioenergy-centered strategy is an alternative to a strategy dominated by electrification; it would dramatically increase demand for bioenergy. As the first step, it must fully exploit existing waste biomass, predominantly woody waste. Even then, roughly 250 and 450 PJ of additional primary bioenergy supply will be needed for 2030 and 2050, respectively. This is well beyond any foreseeable waste supply within BC.

[130] Appendix A-9.5: Palmer-Wilson, Rowe, Wild, "Decarbonization of the building heating system in Metro Vancouver: comparison of two transition pathways" (May, 2021).
[131] Appendix A-9.6: Wang, Clift, and Bi, "Clean Energy Pathways to Meet British Columbia's Decarbonization Targets" (January, 2022), Part I and Part II, 35p.

> **Hence, strategies that rely solely on either electricity or bioenergy will raise demand beyond sustainable and manageable supplies.** There is no single 'silver bullet' renewable energy source to meet BC's GHG mitigation targets: it is essential to utilize all the available bioenergy and renewable electricity resources and promote a balanced renewable energy portfolio. The limited time frame to 2030 emphasizes the difficulty of securing the renewable energy needed and the urgency of action to reduce demand. For the long-term target of carbon neutrality, the supply problems emphasize the need for a balanced renewable energy strategy.
>
> [Emphasis added.]

3.8 *CLEAN GROWTH PATHWAY - CONCLUSION AND RECOMMENDED ACTIONS*

In response to the planning environment described in Section 2, FEI has developed its Clean Growth Pathway that leverages the decarbonization potential of both the gas and electric energy systems in supporting provincial GHG emission reductions. In addition to GHG emission reductions, in pursuing a diversified approach to decarbonization, the Clean Growth Pathway offers many benefits to British Columbians. These benefits include energy affordability, lowest risk to meeting peak demand on the coldest days of the year, energy system resiliency, fostering emerging technologies and innovation and economic development across the energy services supply chain. The section also provides research and reports in support of a diversified and complementary energy systems approach.

The Clean Growth Pathway provides FEI's framework to transition to a low-carbon energy future through four key pillars:

- **Pillar 1:** Transitioning to renewable and low-carbon gases to decarbonize the gas supply;
- **Pillar 2:** Investing in DSM programs in support of energy efficiency and conservation measures to reduce energy use among residential, commercial and industrial customers;
- **Pillar 3:** Investing in low-carbon transportation infrastructure to reduce emissions in this sector; and
- **Pillar 4:** Investing in LNG to lower GHG emissions in marine fueling and global markets.

Through the low-carbon energy transition, FEI's focus on resilience will be key for both the gas and electric energy systems in providing the energy requirements of British Columbians, especially on the coldest days of the year when provincial energy demand is highest. FEI's Resiliency Plan, which includes reducing the reliance of FEI's Lower Mainland customers on the Westcoast T-South transmission system, is even more critical in ensuring energy is available to meet peak day demand now and into the future. New infrastructure will be built to accommodate the low-carbon transition including hydrogen-enabled pipelines and transmission systems.

In the sections of the LTGRP below, FEI's Clean Growth Pathway is reflected in FEI's Diversified Energy (Planning) Scenario. This scenario and alternate future scenarios are examined in the LTGRP with respect to their impacts on annual and peak demand, DSM activities, conventional, renewable and low-carbon gas supply portfolio planning and system resource needs over the planning horizon.

FortisBC Energy Inc.
2022 LTGRP

Section 4:

ANNUAL ENERGY DEMAND FORECASTING

Table of Contents

4. ANNUAL ENERGY DEMAND FORECASTING

4.1 *INTRODUCTION AND BACKGROUND*

Two key elements that underpin FEI's resource planning activities are the 20-year forecasts of annual demand and peak demand for gas. FEI's demand forecasts are used to ensure adequate system capacity, plan gas supply resources, and provide a baseline against which to analyse the impact of proposed or potential future initiatives such as expanded energy efficiency and conservation activities or growth in conventional natural gas sales for fueling transportation.

The annual demand forecast discussed in this section represents annual consumption by region and customer class before consideration of energy savings from incremental new DSM activities,[132] and allows FEI to determine directional rate impacts and annual gas supply needs in long-term planning. The peak demand forecast provides an estimate of the maximum daily gas demand that would be expected under extreme weather conditions. Gas supply planning uses system-wide daily peak demand (discussed in Section 6) and relies on the annual shape of the load curve to model prolonged periods of high demand to plan the supply resources FEI requires throughout the year. In contrast, system capacity planning relies on regional peak day and, in certain cases, peak hour demand (each discussed in Section 7) to design FEI's regional system infrastructure to meet that peak day or peak hour demand.

The current planning environment is undergoing rapid change and therefore subject to more uncertainty than seen in resource planning processes over the past two decades or more. FEI recognizes that its customers are using gas in different ways and amounts than they did in the past and that reducing global carbon emissions is a key priority. Heating equipment installed in new buildings and in retrofit situations is more efficient and, in some cases, results in a different demand profile than the older equipment it replaces. Potential new demand from the transportation and industrial sectors may also impact FEI's overall demand profile. While recent demand history is appropriate for short-term demand forecasting, a method which relies on modelling long-range changes in energy end uses is more appropriate for longer forecast horizons.

The discussion of forecast future demand in this section is organized into the following three demand categories:

- **Residential, Commercial and Industrial**: This is FEI's traditional base of residential, commercial and industrial customers;
- **Low-Carbon Transportation and Global LNG**: These are FEI's CNG and LNG customers, representing an important opportunity for FEI to build system load while reducing GHG emissions; and

[132] Gas savings from incremental new DSM activities are discussed in Section 5, Demand-side Resources.

- **Potential New Large Industrial Load:** This represents the potential for substantial load requirements from single, atypical industrial customers that could cause a large step change in the annual demand forecast from one year to the next, such as Woodfibre LNG project.

The modelling of forecast annual gas demand for each of these three categories is discussed separately, as are the resulting demand forecasts. These forecasts are then summed to present a view of total annual gas demand.

This section is organized as follows:

- Section 4.2 presents FEI's customer counts and demand as of 2019 forms the base year for the 2022 LTGRP's annual demand forecast;
- Section 4.3 explains and presents the forecasting of customers for each of the demand categories over the forecast period of 20 years;
- Section 4.4 describes the methods used to forecast future demand for the 2022 LTGRP. This section contains information about the Traditional Annual Demand Method, which is used for short-term planning for the Residential, Commercial and Industrial Demand Category, and the End Use Annual Method, which is FEI's long-term planning forecast method for the 2022 LTGRP, for each of the demand categories described above;
- Section 4.5 explains the process of developing alternate future scenarios for FEI's forecasting analysis. This section identifies the planning scenario for the 2022 LTGRP as the Diversified Energy (Planning) Scenario and explains why the Reference Case is not an appropriate planning forecast for the 2022 LTGRP. This section also explains the critical uncertainties and modelling input settings used to model future demand for each of the future scenarios, with additional explanation provided in Appendix B-3;
- Section 4.6 presents the demand forecast results for each of the demand categories described above. This section also explains that the amount of electrification that has been modelled in the Deep Electrification and Lower Bound scenarios is determined to be not plausible and presents the context for limiting their further consideration within the 2022 LTGRP; and
- Section 4.7 presents the total annual demand for the Diversified Energy (Planning) Scenario. Section 4.8 presents the demand results for all scenarios and Section 4.9 provides a summary and conclusion for Section 4.

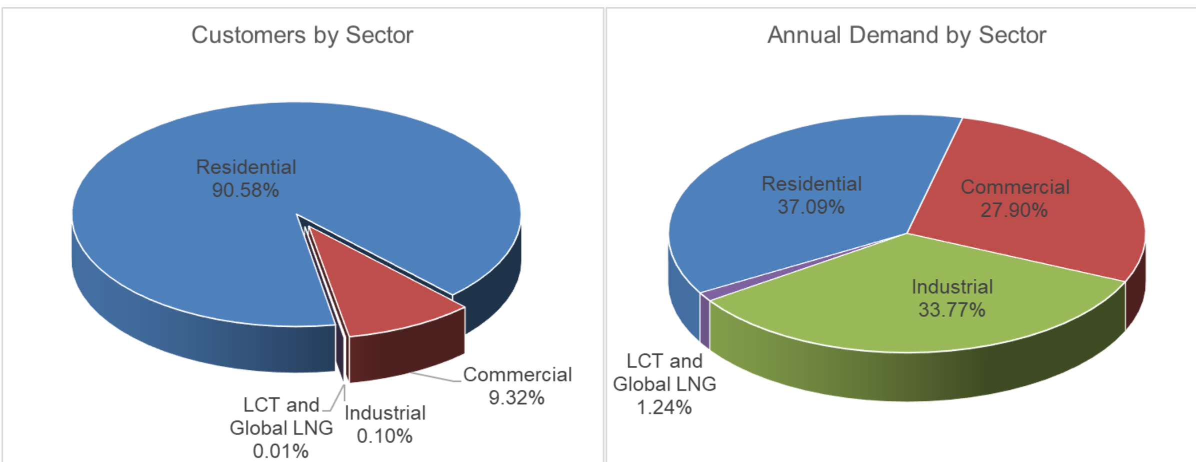
4.2 *2019 BASE YEAR DEMAND*

The base year for FEI's demand forecasts and alternate future scenarios in the 2022 LTGRP is 2019. To meet an early 2022 filing date, FEI commenced the analysis phase of the 2022 LTGRP in early 2020. During this phase, FEI needed to complete the Reference Case demand forecast to inform the 2021 Conservation Potential Review. At that time, 2019 actual data was the most current data available. The following sections discuss the 2019 base year demand for the Residential, Commercial and Industrial, LCT and Global LNG, and potential new large industrial demand categories.

4.2.1 Residential, Commercial and Industrial, and LCT and Global LNG Customers

At the end of 2019, FEI's customer base included more than one million customers. While residential customers account for approximately 91 percent of the number of customers as shown in Figure 4-1 below, there is a more even split among the residential, commercial and industrial groups on an annual demand basis. The makeup of FEI's customer base and their demand patterns has implications for infrastructure requirements and conservation goals as discussed throughout this LTGRP.

Figure 4-1: FEI 2019 Customer Base and Demand Overview[133]



4.2.2 New Large Industrial Demand

The purpose of examining alternative forecasts of large industrial customer additions is to make sure that FEI understands what the impact of a very large demand customer on its system would be and is prepared for such an event. An example of this potential step change in demand is the expected addition of demand from the Woodfibre LNG project. By its nature, therefore, the current annual demand for this category is zero and there are no current customers as of 2019. All existing industrial demand is captured in Figure 4-1 as "Industrial".

[133] Due to the weather sensitive nature of residential and commercial demand, the base year demand for these customers has been weather normalized.

4.3 *LONG-TERM CUSTOMER FORECAST METHOD AND RESULTS*

4.3.1 Residential, Commercial and Industrial Customers

As an input into the annual demand forecast for Residential, Commercial and Industrial demand FEI establishes a base customer forecast for these customer segments. FEI uses a well-established method that remains consistent with previous LTGRP filings. The forecast of residential customers is based on the Conference Board of Canada housing starts forecast for BC, while commercial customers are forecast based on recent trends in growth for the commercial customer group. The forecast of industrial customers includes existing customers at the end of the base year (2019 year-end) along with any known commitments from customers to either join or leave the system. Explanation of the customer forecast method is provided in Appendix B-1.

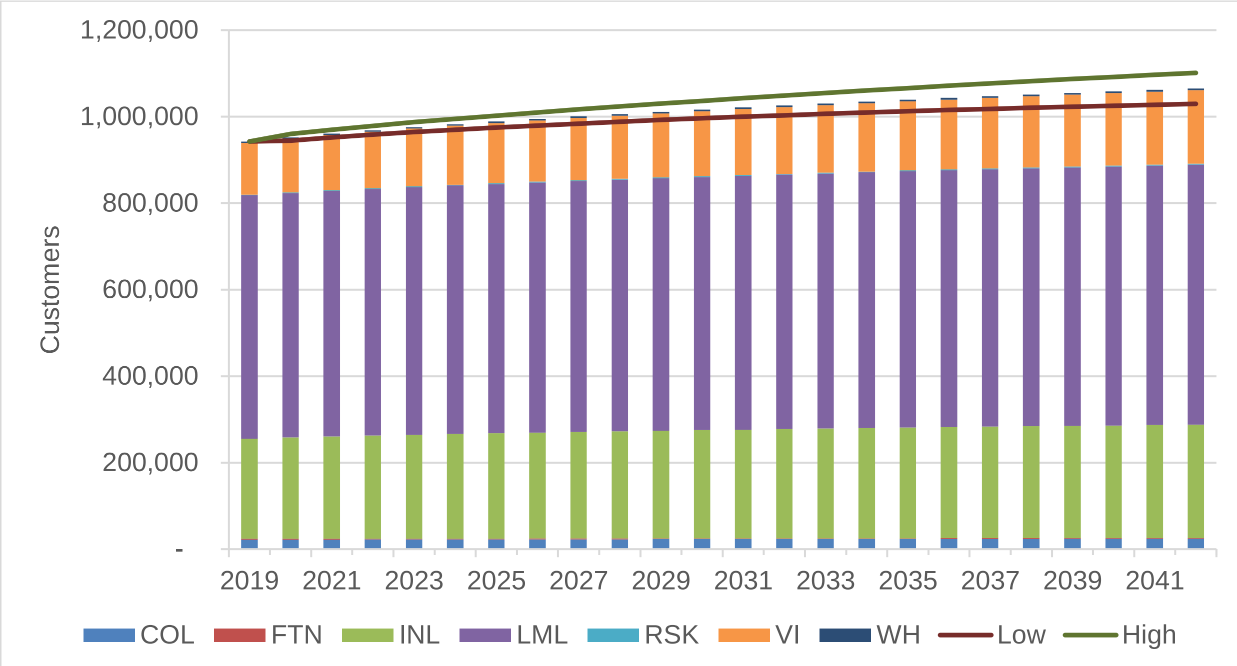
The 2022 LTGRP uses statistical 95 percent confidence intervals of historical customer additions for each customer segment to augment the base customer forecasts with high and low uncertainty bands. The high and low uncertainty bands act as alternative high and low customer additions sensitivities to provide an understanding of what range of potential high and low customer forecast trajectories could unfold over the planning horizon.

The base customer forecast is used in both the Traditional Annual Method and the End Use Annual Method of demand forecasting. Section 4.5.3 explains how the LTGRP uses the different customer forecast trajectories as one of the critical uncertainties for its scenario analysis in the End Use Annual Method. It should be noted that considerations for future uncertainties around end use energy, such as potential for new large industrial demand, or potential for electrification, are addressed as part of the demand forecast and not as part of the customer forecast.

4.3.1.1 *Residential Customer Forecast*

Figure 4-2 shows the residential customer forecast by region in the bar chart along with the high and low confidence intervals shown as the dark green and red lines. The FEI aggregate forecast predicts a compound annual growth rate of 0.48 percent across the 20-year planning period, with the regional distribution remaining relatively unchanged.

Figure 4-2: Long-Term Residential Customer Forecast by Region[134]



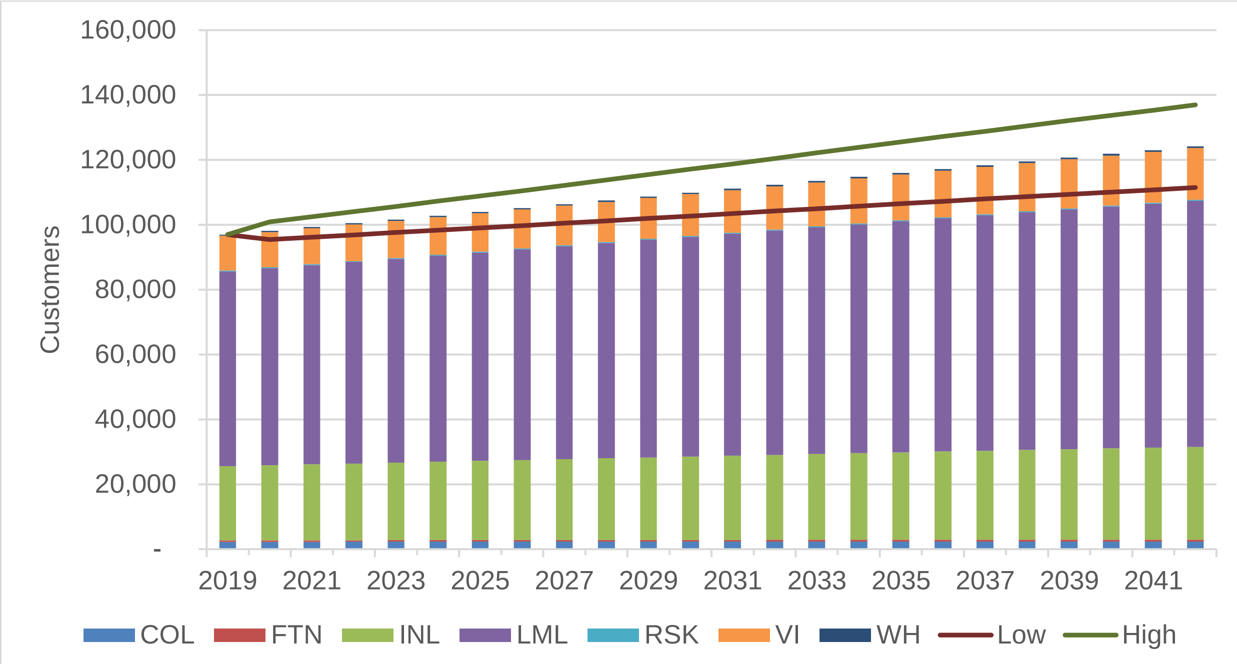
COL: Columbia	**INL:** Inland	**RSK:** Revelstoke	**WH:** Whistler
FTN: Fort Nelson	**LML:** Lower Mainland	**VI:** Vancouver Island	

4.3.1.2 *Commercial Customer Forecast*

Figure 4-3 shows the commercial customer forecast, excluding LCT customers, by region in the bar chart along with the high and low confidence intervals shown as the dark green and red lines. The FEI aggregate forecast predicts a compound annual growth rate of 1.06 percent across the planning horizon with the regional distribution remaining relatively unchanged.

[134] In the 2022 LTGRP analysis, customer counts represent the number of FEI accounts. All 2022 LTGRP annual demand, customer, GHG, and rate impact graphs, tables, and results exclude data for the Vancouver Island Gas Joint Venture (VIGJV), BC Hydro Island Generation, and Company Use.

Figure 4-3: Long-Term Commercial Customer Forecast by Region (Excluding LCT)



COL: Columbia	**INL:** Inland	**RSK:** Revelstoke	**WH:** Whistler
FTN: Fort Nelson	**LML:** Lower Mainland	**VI:** Vancouver Island	

4.3.1.3 *Industrial Customer Forecast*

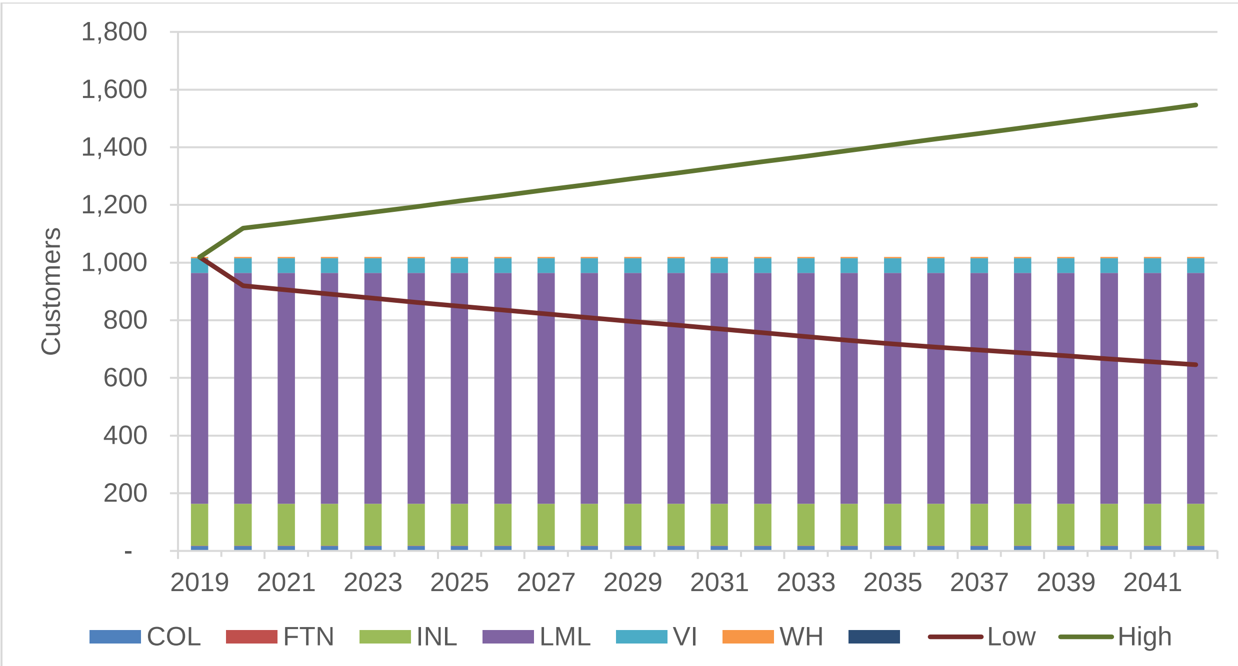
The Company had 1,019 industrial customers at the end of 2019. At the time the long-term forecast was prepared, there were no firm commitments for new industrial customers to take conventional natural gas service or for existing customers to close their accounts. Hence, there is no forecast growth or decline in the industrial customer forecast.

FEI notes the inclusion of a simple cycle gas turbine fueled by RNG in the preferred portfolio of FBC's 2021 Long Term Electric Resource Plan[135] beginning in 2031. At the time of preparing the 2022 LTGRP, no firm request has been made by FBC for gas service from FEI, therefore this addition has not been included in FEI's industrial customer (or demand) forecast at this time. Further, FEI notes that since this facility would provide a peaking resource to FBC, its operation would be for short durations only and as such the annual demand implications for FEI are relatively small compared to the total industrial load over the forecast period. The implications of such a customer addition for peak demand is discussed in Section 7.3.3.5.

[135] FortisBC Inc. 2021 Long-Term Electric Resource Plan. Section 11.3.9, page 195, online at: https://www.cdn.fortisbc.com/libraries/docs/default-source/about-us-documents/regulatory-affairs-documents/electric-utility/210804-fbc-2021-lterp-lt-dsm-plan.pdf?sfvrsn=9d1e2f27_0#page=225&zoom=100,92,114.

Figure 4-4 below shows the long-term industrial forecast by region, excluding LCT customers, along with the high and low confidence intervals shown as the dark green and red lines.

Figure 4-4: Long-Term Industrial Customer Forecast by Region (Excluding LCT)



COL: Columbia	**INL:** Inland	**RSK:** Revelstoke	**WH:** Whistler
FTN: Fort Nelson	**LML:** Lower Mainland	**VI:** Vancouver Island	

4.3.2 Low-Carbon Transportation and Global LNG Customer Forecast

For the LCT and Global LNG category, FEI does not create a base forecast of customer additions over the planning horizon in the same way that it does for the Residential, Commercial and Industrial Demand Category. This difference is because, for LCT, each customer represents a fleet of vehicles that can vary widely in size from one customer to another. Growth in demand is therefore caused by both the addition of new customers and the expansion of fleets belonging to single customers. FEI discusses the demand forecast settings for the LCT and Global LNG demand category in Sections 4.4.2 and 4.6.2.

4.3.3 New Large Industrial Customer Forecast

FEI's consideration of new large industrial customers is limited to two customers, each with similar, very large annual demand. The first of these is Woodfibre LNG project, for which expected demand and operational timing have been announced publicly. The second customer is a generic industrial customer with a similar annual demand expectation to that of Woodfibre LNG project. Such a customer has not currently been identified by FEI and is modelled generically to ensure that FEI is assessing what system impacts might be required if such a customer were to come forward during the planning horizon. FEI incorporates either zero, one or two large industrial customers in the future scenarios, as discussed in Section 4.5.3 and Appendix B-3.

4.4 LONG-TERM ANNUAL GAS DEMAND FORECAST METHODS

This section discusses the methods that FEI used to forecast energy demand for the three categories of demand: the residential, commercial and industrial customers, LCT and Global LNG customers, and potential new large industrial customers, over the next 20 years. The amount of gas that FEI expects its customers to use over the course of a year determines both the amount of gas that FEI needs to acquire and transport on behalf of its customers on an annual basis, and the number of units of energy per year over which FEI is able to recover its cost of service. Hence, the forecast of annual demand is a key step in identifying the resources FEI needs to meet the future energy needs of customers.

4.4.1 Residential, Commercial and Industrial Demand

FEI employs an End Use Annual Method to forecast long-term annual demand for energy on its system. For this demand, FEI also uses a more traditional time series approach (the Traditional Annual Method) to estimating future demand with which to compare the results of its End Use Method. Since application of the Traditional Annual Method is limited to the residential, commercial and industrial demand[136] and only used as a comparator to the End Use Annual Method results, this section first explains the Traditional Annual Method, then discusses the End Use Annual Method and finally presents the results of a jurisdictional review of demand forecasting methods.

4.4.1.1 *Traditional Annual Method of Demand Forecasting for the Residential, Commercial and Industrial Demand Category*

For the purpose of rate setting, FEI use its Traditional Annual Method to produce short-term demand forecasts based on historical data and the short-term Forecast Information System (FIS), which has been in use since 2002. Using historical data to prepare short-term time series forecasts of future consumption is a common and accepted industry practice. This method provides a high level of confidence for near-term business and operational decision making. The Traditional Annual Method is described in detail in Appendix B-1.

By extending the short-term time series forecast, FEI uses the Traditional Annual Method to produce a single BAU forecast. Extending the Traditional Annual Method over the longer-term planning horizon for the LTGRP in this manner provides a reference point against which to compare the outcomes of FEI's End Use Annual Method under various future scenarios. As it is based on historical data, however, the Traditional Annual Method is limited in its ability to

[136] The traditional time series forecast method cannot be applied to the LCT and New Large Industrial demand categories since there is little historical information for these two categories on which to conduct such an analysis.

incorporate rapid change in the planning environment and uncertainty in how the longer-term future could unfold.

4.4.1.2 *End Use Annual Method of Demand Forecasting for the Residential, Commercial and Industrial Demand*

For resource planning purposes, FEI uses the "End Use Annual Method" of demand forecasting. As described in Section 2.4, end use energy solutions and the way in which customers are using energy is changing and historical trends are not robust enough to provide the best basis on which to forecast the long-term potential range of FEI's future demand. For this reason, FEI uses the End Use Annual Method to demand forecasting which involves examining different ways that end use trends in energy utilization could potentially impact future demand for gas. This method produces a Reference Case annual demand forecast and enables FEI to examine how future demand might unfold under alternate future scenarios.

In its Decision on the 2017 LTGRP, the BCUC directed FEI to update its detailed analysis of the relative benefits and shortcomings of its particular end use method as compared to other end use methods. The original analysis for the 2014 LTRP was completed by Boreas Consulting Ltd. (Boreas). In that study, Boreas concluded that almost half of the 30 surveyed North American entities use end use models for all or part of their long-term forecasts and that FEI's end use model compares well with other North American end use methods. The update to the Boreas study for the 2017 LTGRP was conducted by Energitix Consulting.[137] Energitix confirmed that using an end use demand forecasting method remains a common practice among gas and electric utilities, particularly those that are of a similar size and facing similar challenges to FEI. Further, while such utilities do tailor the end use modelling to address the specific challenges they are facing over the planning horizon, the FEI modelling includes the key components that are common to all of the end use modelling practices examined as part of the study. The Energitix study report is included in Appendix B-2.

FEI has improved on its End Use Annual Method for the 2022 LTGRP to enhance FEI's ability to examine the Reference Case annual demand forecast and analyse how annual demand behaves across alternate future scenarios. Improvements[138] include:

- addition of new critical uncertainties;
- updated end use studies that provide key inputs to the base year data;
- a closer tie between the Conservation Potential Review (CPR) analyses and the end use demand forecasting analyses;
- bringing new market intelligence in the transportation fuels industry to bear on the forecast of CNG and LNG demand; and

[137] While different consulting firms completed the respective demand forecasting reviews, the key individual leading the study was the same, providing consistency between the studies.

[138] In its Decision on the 2017 LTGRP, BCUC directed FEI to provide a detailed explanation of any changes to its demand forecast methodology as it evolves between now and the next LTGRP filing.

- the addition of PowerBI data analytics interface to improve the ability to display and assess forecasting results.

FEI engaged Posterity Group (Posterity) to support FEI in preparing the End Use Annual Method forecast for the 2022 LTGRP. Posterity was instrumental in preparing FEI's 2021 CPR and 2017 LTGRP end use demand forecast. Posterity prepared an updated end use forecast model for FEI based on learnings from the 2017 LTGRP.

The End Use Annual Method forecast process starts with developing a Reference Case forecast. The Reference Case is based on end use patterns observed, as well as any new changes in law or policy that will affect future demand and have been, or are quite certain of becoming, enshrined in legislation, codes, standards or bylaws in and as of the base year. The Reference Case keeps these patterns constant throughout the planning period. FEI and Posterity used the following data sources to calibrate[139] the forecast model to FEI's 2019 base year actuals and to identify Reference Case end use changes across the forecast horizon:

- FEI's 2021 Conservation Potential Review (2021 CPR);
- FEI's 2017 Residential End use Survey (REUS) which represents FEI's most recent REUS at the time the forecast modelling was undertaken;
- FEI's 2019 Commercial End use Survey (CEUS) which represents FEI's most recent study of its commercial customers; and
- Research and data analysis from the 2017 LTGRP which FEI included to utilize and build upon work that had already been completed for the 2017 LTGRP.

The impact of DSM programs up to and including 2019 are implicitly included in the end use characteristics identified for the base year, but the existing program activity is assumed not to have any incremental impact through the planning period for the purpose of demand forecasting. Section 5 separately discusses the impact of FEI's forecast future DSM programs.

4.4.1.3 *Developing a Reference Case for Annual Demand for Residential, Commercial and Industrial Demand*

The Reference Case began with the development of a base year, in this case 2019. The base year was built from customer account and weather-normalized consumption data, categorized by region, rate schedule, and, for industrial and commercial customers, industry. Gas consumption was further subcategorized by end use based on the detailed customer information in the 2021

[139] The calibration process ensures that the sum total annual gas demand of all base year end uses in the End Use Annual Method demand forecast model matches FEI's base year actuals.

CPR and 2017 LTGRP, including end use consumption, market saturation[140] and gas share.[141] As described in Section 4.4.1 above, some of this information has been derived from end use surveys commissioned by the Company, while other aspects emerged from detailed building modelling.

The resulting model, calibrated to match FEI's actual normalized sales of gas, is subdivided as follows:

- By region: Lower Mainland, Vancouver Island, Whistler, Southern Interior, Northern BC[142];
- By sector: Residential, Commercial and Industrial;
- By segment (i.e., sub-sector):
    - In residential—three dwelling types by detachment type, dominant heating fuel, and vintage;
    - In commercial—seventeen building types, by predominant use and building size (office, retail, school, hospital, etc.);
    - In industrial—thirteen plant types (mining, wood products, non-metallic minerals, etc.);
- By rate schedule: one rate schedule in residential, six rate schedules in commercial, and nine rate schedules in industrial; and
- By end use: ten residential, five commercial and seventeen industrial gas end uses.

Beginning with the calibrated base year, the Reference Case forecast was built using FEI's 20-year customer forecast (discussed in Section 4.3), with new residential dwellings and commercial floor area based on the account growth rates as identified in Section 4.3. Anticipated efficiency improvements from minimum energy performance standards that are not associated with DSM activities, such as the natural replacement of furnaces,[143] were incorporated in both existing buildings and new construction. Anticipated changes in the saturation and gas shares for specific end uses were also included. The End Use Annual Method forecast model provides the forecast consumption values for each forecast year at the same level of granularity as the base year.

---

[140] Market saturation is a percentage indicating what portion of the population of buildings has a given end use. For end uses such as space heating and water heating, this is assumed to be 100 percent of dwellings. For an end use such as clothes drying, where the logical unit of analysis is the appliance, the percentage is the number of clothes dryers divided by the number of dwellings. Market saturation in the commercial sector is based on the percentage of building floor space with a given end use, instead of percentage of dwellings. Market saturation is not employed in the industrial model, saturation is taken into account in the overall end use consumption for a given plant type.

[141] Gas share is the percentage of the energy end use that is supplied by gas. For clothes dryers, for example, this translates into the percentage of dryers that are gas-fired. Note that that gas share is based on the percentage of useful energy supplied to accomplish the end use (i.e., the tertiary load); actual energy consumption equals tertiary load divided by the efficiency of the appliance that meets this load.

[142] The region names specified in FEI's End Use Annual Method demand forecast method are independent from FEI's internal service areas that may appear in other regulatory submissions or short-term forecasts.

[143] Anticipated efficiency improvements from minimum energy performance standards are incorporated in existing buildings when old equipment is replaced and new construction when new equipment is installed.

Figures 4-5 and 4-6 below display Reference Case results using the End Use Annual Method demand forecast of annual demand by sector and by region. Overall, the Reference Case annual demand forecast shows slight growth, driven by growth in the commercial and residential sectors as shown in Figure 4-5 below.

Figure 4-5: Reference Case Annual Demand Forecast for Residential, Commercial and Industrial by Rate Schedule

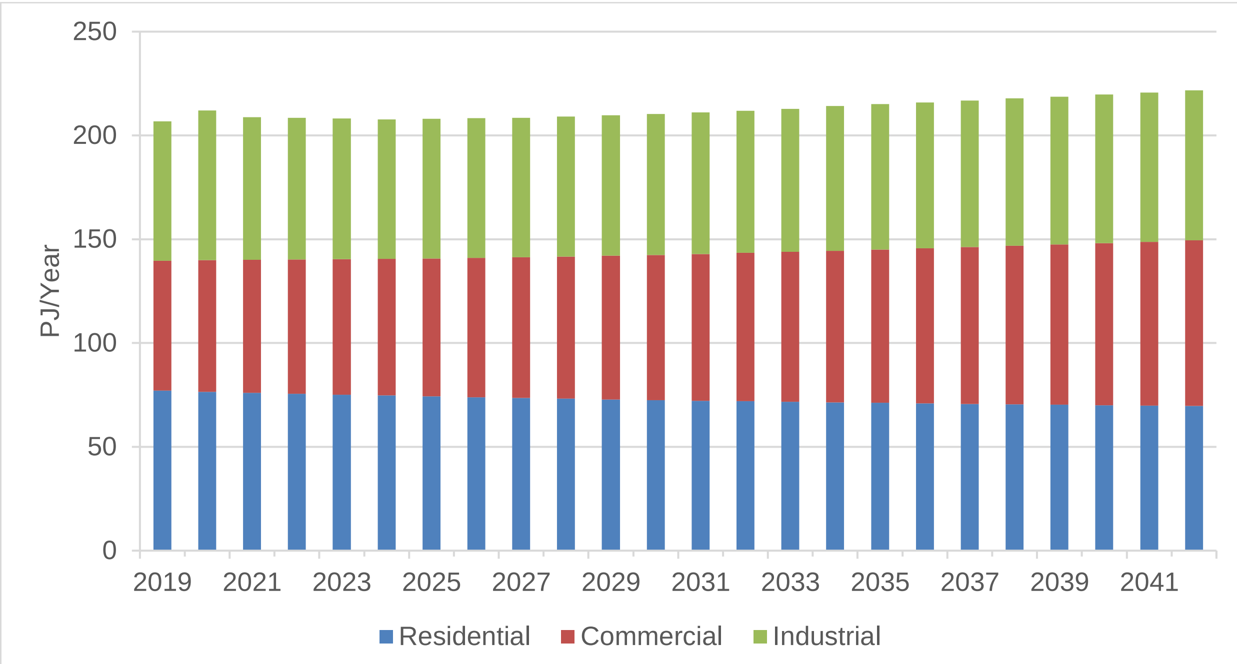


Figure 4-6: Reference Case Annual Demand Forecast for Residential, Commercial and Industrial by Region

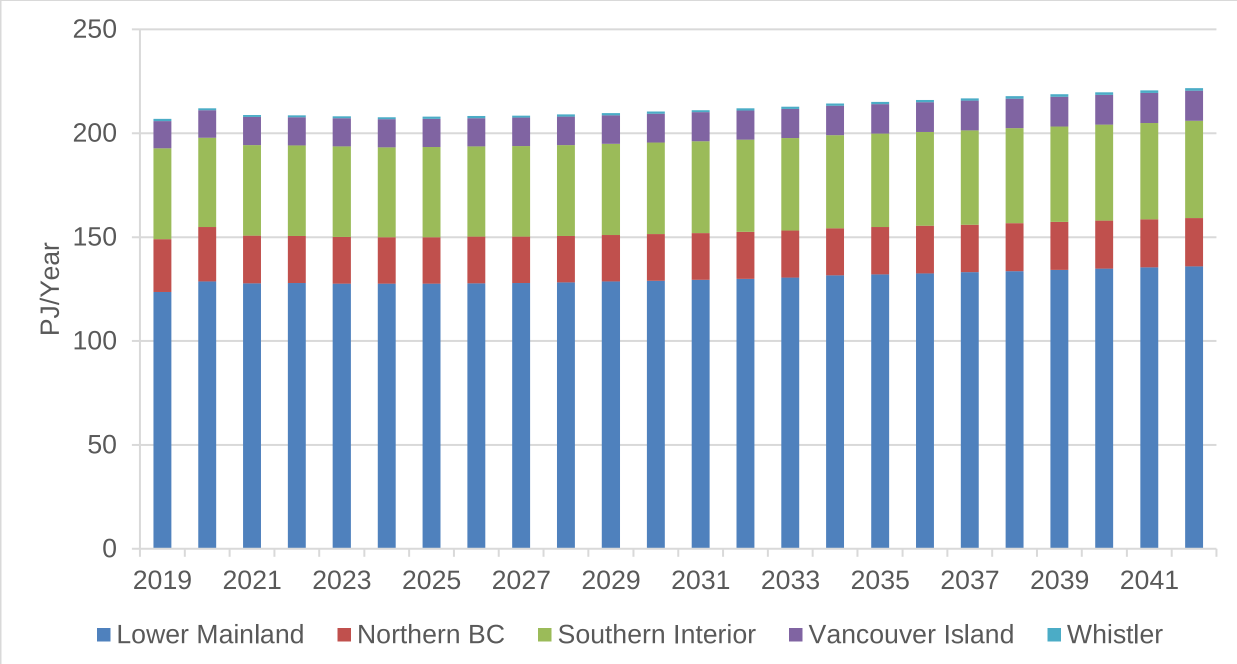


4.4.1.4 *Comparing the Traditional Annual and End Use Annual Methods for Forecasting Residential, Commercial and Industrial Annual Demand*[144]

As discussed above, FEI's End Use Annual Method, which is used to create the Reference Case, differs in a number of ways from the Traditional Annual Method, which is used to create the BAU forecast. Comparing the Reference Case forecast with the BAU forecast shows that the results of the End Use Annual Method and the Traditional Annual Method are reasonably aligned for a future that remains relatively unchanged from conditions present as of the base year. This comparison thus provides additional confidence that FEI's End Use Annual Method provides a sound approach for examining alternate future scenarios.

Figure 4-7 below compares the BAU forecast annual demand with the Reference Case forecast. By the end of the planning period, the two forecast methods differ by only five percent. This variance is due to the various differences between the two methods. One of these differences is that the BAU forecast is based on intrinsic historical end use trends, whereas the Reference Case limits itself to fully known, legally enshrined, and mandatory or highly-assured future changes[145] in trends. For example, the BAU forecast is influenced by historical trends due to changes in energy performance codes and standards, while the end use method Reference Case only accounts for such changes that are already legally enshrined and are or will be mandatory during

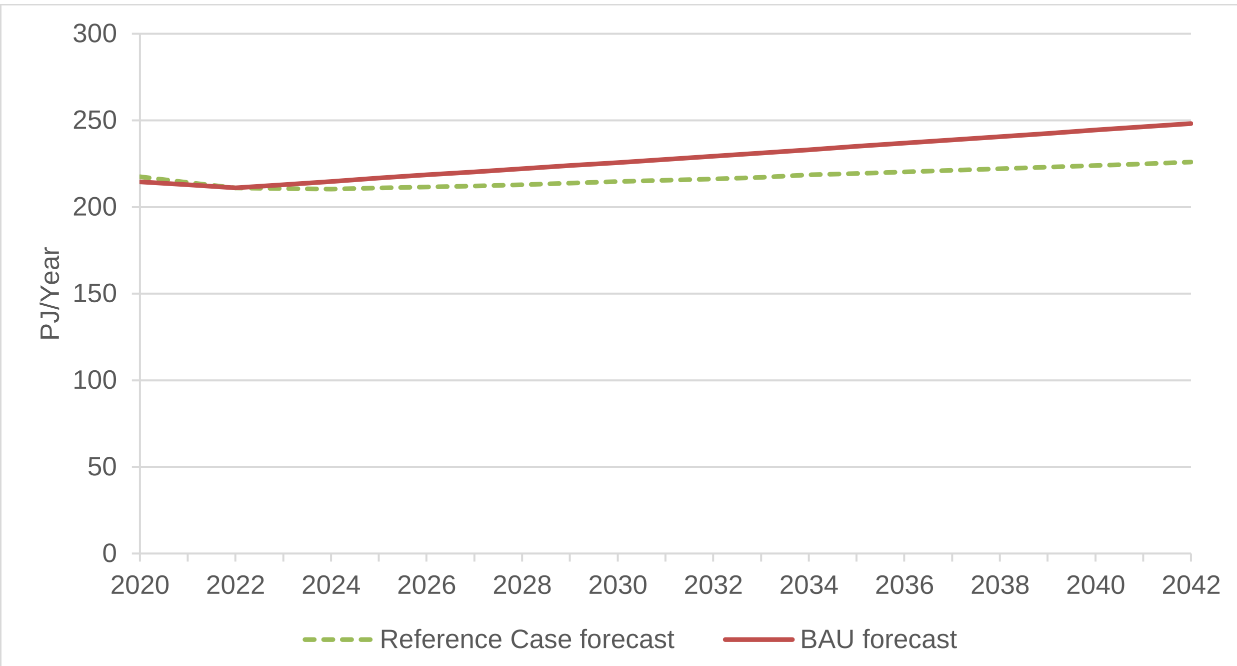
[144] BCUC Directive No.2 from the 2017 LTGRP decision directs FEI to "continue use of its Traditional Annual Method as a comparison to test its End Use Method until such time as the BCUC approves a new demand forecast methodology."

[145] By their nature, such assured future changes are limited to the near future, since the farther into the future changes are estimated to occur, the more uncertain they become.

the forecast horizon, such as a building code amendment that has been announced but not yet implemented. By the same token, the BAU forecast includes historical DSM program participation trends, whereas the End Use Annual Method Reference Case relies on specific assumptions regarding future changes in equipment characteristics and adoption but not DSM programs.

Across the LTGRP planning horizon, FEI uses the End Use Annual Method Reference Case to plan for its forecast long-term annual demand. Please refer to Appendix B-1 for more detailed results from the BAU forecast.

Figure 4-7: Comparing the End Use Reference Case and Traditional BAU Annual Demand Method Forecast Results



4.4.2 End Use Annual Method of Demand Forecasting for the Low-Carbon Transportation and Global LNG Category

This section describes FEI's forecast of annual demand for conventional natural gas as a LCT fuel, which has emerged as a growing market in BC, both for CNG and LNG customers. An important benefit of using CNG and LNG as a transportation fuel is the carbon emission reductions that result from displacing higher carbon fuels such as diesel and bunker oil. The GHG emission reductions resulting from FEI's forecast of CNG and LNG demand are discussed in Section 9.2.

4.4.2.1 *CNG Transportation Demand Forecast Method*

To derive the CNG demand forecasts, FEI formulated the CNG demand forecast settings (Reference, Planning, High, Low) by accounting for commitments that have been made by customers to take CNG supply and by forecasting the impacts of a variety of factors. These factors include inflation, discussions on new station builds, vehicle incentive applications, regulatory changes that are expected to drive conventional natural gas adoption and assumptions regarding adoption rates based on past experience. Section 1.2.1 of Appendix B-3 provides a more detailed explanation of the CNG demand settings.

To determine the percentage of BC's CNG market that will be captured in the forecasts, FEI determined the eligible market size by first quantifying the size of the diesel fuel and conventional natural gas market for transportation in BC. This data was obtained from Natural Resource Canada's (NRCan) Transportation Sector – British Columbia and Territories database, which displays the 2018 fuel consumption for the transportation sector by fuel type.[146] This fuel consumption database provided the basis for the 2018 market size, which was then escalated by a forecast growth rate fuel consumption calculated from the Canadian Energy Report Update.[147] This report is a forecast of Canada's energy supply and demand projections to 2050. The sectors included in the market size assessment were freight trucks, medium duty trucks, heavy duty trucks, school buses and urban transit and inter-city buses.

4.4.2.2 *LNG Transportation and Global LNG Demand Forecast Method*

The forecast settings developed for LNG transportation customers are the same as those for CNG transportation customers (Reference, Planning, High, Low). The forecast settings for global LNG demand are similar except that since the Reference setting assumes no global LNG demand beyond the first two years of the forecast period, there is no Low setting. Appendix B-3, Section 1.2.1 provides additional explanation of the LNG transportation and global LNG demand forecast settings.

FEI supplies LNG to customers from the Tilbury LNG facility in the Lower Mainland and the Mt. Hayes LNG facility on Vancouver Island. FEI formulated the LNG demand forecast by accounting for commitments that have been made by customers to take LNG supply, and by forecasting the impacts of a variety of factors. These factors include the availability of Original Equipment Manufacturer (OEM) technology capable of adopting conventional natural gas, regulatory changes (see Section 2.2.2.3) that are expected to drive conventional natural gas adoption and assumptions regarding adoption rates based on past experience for some of the market segments. A description of the key factors affecting the LNG market is provided below. While the key early adopters of LNG in BC were on-road heavy-duty trucking customers, conventional natural gas engines that are able to haul in excess of 80,000 pounds have recently been discontinued. On-road heavy duty trucking customers are now unable to replace or add additional 15L vehicles to their fleets, resulting in lower demand and decelerating LNG adoption for on-road trucking. LNG for the mining sector has also developed slower than expected for mine haul trucks and remote power generation. The key market that has emerged over the past years, however, is high horsepower applications for marine vessels.

---

[146] Appendix F-11: NRCan, Transportation Sector – British Columbia and Territories (2018), online at: http://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/menus/trends/comprehensive/trends_tran_bct.cfm.

[147] Appendix F-12: Canada Energy Regulator, "Canada's Energy Future 2021: Update – Energy Supply and Demand Projections to 2050 - Figure Data" (2021), online at: https://www.cer-rec.gc.ca/en/data-analysis/canada-energy-future/2021/index.html.

The two key marine segments that FEI has targeted are the short sea segment[148] and the trans-Pacific segment. FEI currently offers truck-to-ship fueling for regional ferry and small vessel operators. FEI is focused on supporting the ship-to-ship LNG fueling for trans-Pacific vessels requiring larger LNG transfer volumes. FEI expects to be able to supply ship-to-ship LNG fueling through a marine bunkering jetty connected to the Tilbury LNG facility. The jetty project is currently under development by an FEI affiliate. Final approvals for the marine jetty project are expected in 2023 with the marine jetty to be in service by the middle of 2024. FEI is also actively pursuing the LNG market for trans-Pacific exports by an International Organization for Standardization (ISO) container, using the truck loading bays at Tilbury. FEI has had some success in this market prior to the recent pandemic-related issues with international shipping and expects the market to continue to grow going forward.

4.4.3 End Use Annual Method of Demand Forecasting for the New Large Industrial Demand Category

FEI's forecast for new large industrial customer demand has evolved as a result of interest from industry that would use substantial amounts of conventional natural gas as a feedstock to locate in BC. FEI is currently developing the Eagle Mountain Woodfibre Gas Pipeline (EGP) Project that would expand the existing gas pipeline that runs between Coquitlam and a site near Squamish to provide pipeline service to Woodfibre LNG project, a new LNG processing and export facility, which has announced its intention to proceed to construction. The addition of the anticipated Woodfibre LNG project load would add significant demand, modelled for the LTGRP at 95 PJ of conventional natural gas annually.

The interest by this large industrial user of conventional natural gas in locating in BC has caused FEI to consider what impacts the potential for a second large industrial customer locating in BC's Lower Mainland could have on the conventional natural gas system in the region. While there is no firm proposal for such service, FEI believes it is important to consider this possibility in its long-term planning. FEI has based the annual demand for this second facility on that of the Woodfibre LNG project (95 PJ annually)

The forecast considerations for new large industrial customer load are limited to either zero, one or two such large industrial facilities. FEI expects the Woodfibre LNG project demand to materialize. Due to the length of time for decision making, locating and constructing such a large project, FEI does not see a need at this time to consider more than two such facilities materializing over the next 20 years.

4.5 *ALTERNATE FUTURE SCENARIOS AND CRITICAL UNCERTAINTY SETTINGS*

In order to examine different ways that the future could potentially unfold to impact the amount of demand, FEI has developed, in consultation with stakeholders, a range of six alternate future

[148] Short Sea is considered by FEI to be the segment that includes marine vessels that transit intra-provincial waterways to move goods and passengers.

scenarios (in addition to the Reference Case) within which changes in demand can be modelled using the End Use Annual Method discussed above.

This section explains the alternate future scenarios and describes how the settings for each of the Critical Uncertainties – those factors that could substantially impact future demand and which remain relatively uncertain – have been determined for each scenario and applied to the forecast modelling. Consistent with the Reference Case, 2019 formed the base year data for all six alternate future scenarios.

Section 3 of this LTGRP provides a detailed discussion of FEI's Clean Growth Pathway. FEI believes that a diversified pathway in which both the existing gas and electricity systems within BC have an important role to play in decarbonizing energy use in the province, is critical to a successful, reliable, resilient and cost-effective energy future, and that the Clean Growth Pathway plays a critical role. As such, FEI is designating the Diversified Energy (Planning) Scenario as its planning scenario for the 2022 LTGRP.

The following sections first describe the Diversified Energy (Planning) Scenario as FEI's planning scenario, followed by a discussion of how the critical uncertainties were determined and used to identify the alternate future scenarios. FEI also explains the settings for each of the critical uncertainties that apply to the three demand categories (Residential, Commercial and Industrial, LCT and Global LNG, and new large industrial demand) and cause future demand forecasts to unfold in different ways in each of the future scenarios.

4.5.1 Identifying FEI's Planning Scenario – The Diversified Energy (Planning) Scenario

The Diversified Energy (Planning) Scenario sets the planning context for FEI's 2022 LTGRP and the actions FEI will take over the next four years to ensure it can meet customers' energy needs over the planning horizon and beyond. For the residential, commercial and industrial demand category, the Diversified Energy (Planning) Scenario meets the BC GHGRS cap on carbon emissions for gas utilities. Section 9.2 presents the GHG reductions that result from the residential, commercial and industrial demand category as it relates to the GHGRS emissions cap for gas utilities.

In the Diversified Energy (Planning) Scenario, FEI models future changes needed to pursue its Clean Growth Pathway and meet decarbonization targets. The Diversified Energy (Planning) Scenario includes essential elements of the Clean Growth Pathway, such as accelerated acquisition of renewable gas supply, growth in the use of low-carbon gas as a transportation fuel, and electrification[149] initiatives in BC that impact gas demand. As these elements were not established within the trends present in 2019, they are not reflected in the Reference Case demand forecast.

[149] The Diversified Energy (Planning) Scenario is modelled with the assumption that 25% of residential and commercial gas demand, and 10% of industrial gas demand is electrified by 2050, with a straight line interpolation for each year of the forecast period.

In analysing the energy planning environment in BC, it was clear to FEI that a Diversified Energy (Planning) Scenario must be the solution to meeting the growing energy needs of British Columbians and reducing carbon emissions over the next 20 years and beyond. The Diversified Energy (Planning) Scenario depends on the utilization and improvement of both the gas and electric systems, maximizing all available energy resources. It represents a future in which the need for robust, reliable and resilient gas and electric infrastructure is embraced and promoted by government and municipal policy actions, and where customers' energy use decisions are influenced by near term signals that minimize the longer term costs of decarbonization and energy capacity challenges in BC. The integrated nature of these energy systems establishes a higher level of resiliency than relying on one system over the other and allows a multi-pronged approach to energy solutions that reduces carbon emissions in BC and globally. Working together, these systems enable the integration of a broader range of local, innovative energy solutions to meet community and customer needs and support a broader range of industry and economic development in BC.

Customer growth for both electric and gas utilities is part of the Diversified Energy (Planning) Scenario. In this scenario, FEI undertakes high levels of DSM over the planning horizon, and an aggressive transition to renewable and low-carbon gas takes place early in the planning horizon and continues. Growth in the use of gas as a transportation fuel to reduce carbon emissions in the transportation sector takes place and is larger in the Lower Mainland than in other regions of the province, particularly in the marine transportation sector.

In the following sections, FEI examines its Diversified Energy (Planning) Scenario against a number of other annual demand scenarios that represent possible other futures that could unfold. These alternate future scenarios are informed by FEI's examination of the BC energy planning environment as well as feedback from stakeholders, interveners and the BCUC as part of this and prior LTGRP processes.

4.5.2 Identifying and Developing Alternate Future Scenarios for End Use Analysis

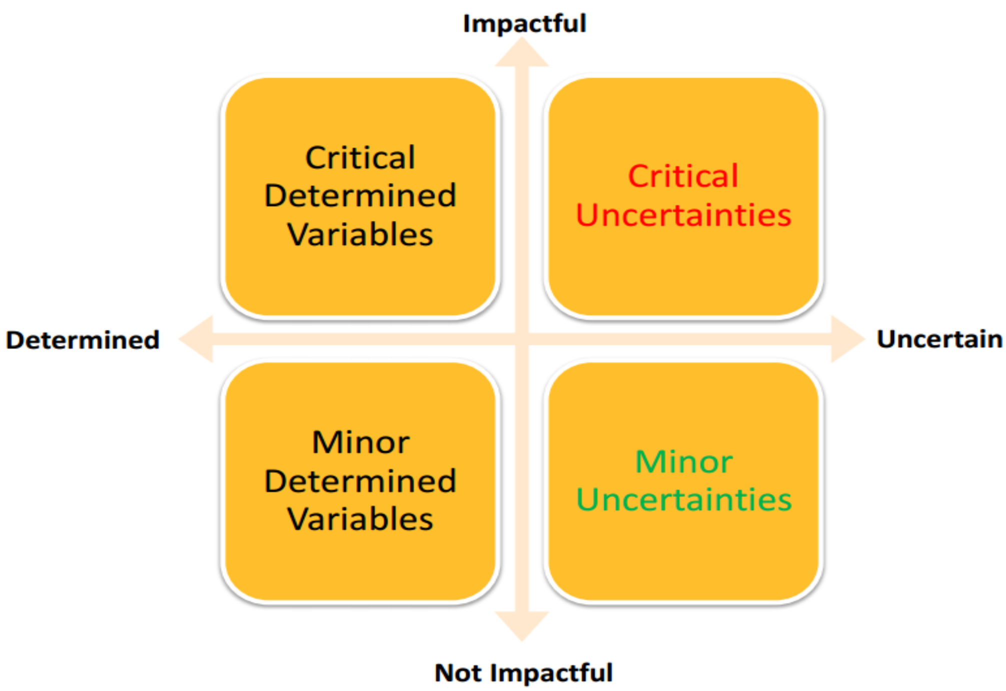
For the 2022 LTGRP, FEI developed six alternate future scenarios, including the Diversified Energy (Planning) Scenario described above, to provide insight into the impact on demand of a broader range of potential future conditions than has been examined in previous LTGRPs. FEI developed these scenarios based on critical uncertainties for annual demand, which represent future conditions that could have the biggest impact on FEI's business. FEI identified these critical uncertainties with input from the scenario analysis work for the 2017 LTGRP, and both internal FEI stakeholders and members of the external RPAG, as well as from themes that emerged from the 2022 LTGRP's community engagement workshops. The Reference Case provides a baseline against which the forecast demand under the six alternate future scenarios can be examined.

Following a standard scenario planning approach, FEI's scenario analysis proceeded in four steps:

1. Evaluating planning environment variables and identifying critical uncertainties;
2. Determining the number of outcomes (called settings) and their broad qualitative boundaries for each selected critical uncertainty;
3. Determining plausible combinations of outcomes for each critical uncertainty and creating reasonable scenario plotlines for annual demand; and
4. Populating quantitative data into the outcomes for each critical uncertainty and iterating with internal and external stakeholder feedback.

The first step in the above list intends to focus the scenario analysis by determining which of the many variables in the planning environment should be used to alter the Reference Case into alternate future scenarios. This involves selecting the most impactful and most uncertain variables. Figure 4-8 below illustrates how FEI classified planning environment variables for this first step.

Figure 4-8: Classification of Planning Environment Variables



FEI intentionally held each step separate from the other steps. Selecting critical uncertainties first, and then determining their qualitative boundaries before generating the plotlines and populating quantitative data, guards against inadvertently favoring certain visions of the future over others by presupposing scenario results rather than focusing on inputs.

FEI has grouped the critical uncertainties under demand (residential, commercial and industrial), supply (renewable and low-carbon gas supplies) and transportation (new demand for gas as a transportation fuel) uncertainties. The 2022 LTGRP's critical uncertainties break down as described below.

- Residential, Commercial and Industrial Demand:
  - Economic growth, represented by account growth values and increases in commercial and industrial floor area in the forecast model;
  - Conventional natural gas commodity price, based on a multitude of third-party forecasts (this accounts for price changes motivated by various factors, such as demand-supply balance or upstream regulatory changes);
  - Carbon price, which accounts for provincial and federal carbon pricing actions and is agnostic to the specific pricing mechanism (the forecast model simply assumes a stream of price values without identifying, for example, whether these are the result of a carbon tax or a cap and trade system);
  - Non-price policy levers, which account for changes in the building code, energy performance standards, and any requirements for switching from one fuel type to another (e.g., district energy systems[150]).
- LCT and Global LNG Demand:
  - Demand for CNG and LNG in the conventional natural gas for transportation sector and for global LNG demand. Demand for these fuels impacts FEI's system and reduces GHG emissions as CNG and LNG displace fuels that emit more GHGs.
- New Large Industrial Customer Demand
  - The potential for one or two new large industrial facilities to require substantial annual amounts of gas. As discussed in Section 1.3 of Appendix B-3, the two potential large demand industrial facilities considered within the scenarios are each either added to the system, or they are not. These demand additions each cause step change increases in demand in the year in which they are assumed to become operational within the scenarios.
- Supply and GHG emissions:
  - Renewable and low-carbon gas supply options (CCUS associated with gas use, hydrogen, RNG, syngas and lignin). While not demand uncertainties, renewable and low-carbon supply options are modelled along with demand uncertainties across the scenarios to understand how gas demand can be met while reducing GHG emissions relative to historical emissions at a point in time (i.e., 2007) or relative to a scenario where load is primarily met with conventional natural gas (i.e., the Reference Case).

[150] As noted in Section 2.3.4, some BC municipalities are pursuing goals to supply 100 percent of their energy needs via renewable and low-carbon sources by 2050. Some of these municipalities are encouraging deployment of district energy systems. In the near term, such district energy systems may rely on gas but municipalities may intend to shift these to other fuel sources in the long term.

4.5.3 Critical Uncertainty Input Settings for Each Future Scenario

Table 4-1 below summarizes the six alternate future scenarios that FEI has modelled, including the Diversified Energy (Planning) Scenario described in Section 4.5.1 as FEI's planning scenario. Scenario descriptions, input settings for each critical uncertainty, and a brief discussion of each scenario's specific attributes is included. This table does not include the Reference Case because the Reference Case sets the baseline for the scenario analysis by using the Reference setting for all critical uncertainties. The Reference setting for each of the critical uncertainties is based on the expectation of what would happen if the conditions for that uncertainty remained as they were known to be as of the base year. As such, using the Reference setting for all of the critical uncertainties results in the Reference Case forecast. Based on the Reference Case, the scenario analysis alters the outcomes of each critical uncertainty to be higher or lower, or accelerated or delayed, compared to the Reference setting. In some cases (electrification in the Diversified Energy (Planning) Scenario, for example), settings may be assumed to change moderately from the Reference setting over the panning horizon, but not to the extent the change would be considered high or low. A setting of 'Planning' indicates that the input value for that critical uncertainty is what FEI expects it to be in the Diversified Energy (Planning) Scenario. Appendix B-3 provides further explanation of the scenario analysis method and the critical uncertainty settings for each of the demand categories.

Table 4-1: Alternate Future Scenario Summary

Scenario	Description	Input Settings		Discussion
Upper Bound	The BC economy experiences higher-than-average growth. Infrastructure development in other regions, coupled with extraction infrastructure development in BC, keep regional gas supply abundant. Continued electoral strength within the right political spectrum causes governments to focus on issues other than climate policy. The BC government keeps supporting LNG exports and LCT as cost-effective existing carbon solutions.	**Residential, Commercial and Industrial Demand Category**		In general, the outcomes of the multiple critical uncertainties can offset each other's impact on annual demand but this scenario combines all outcomes that would increase annual demand. As such, this scenario represents one of two boundary scenarios that frame the scenario analysis. The Upper Bound scenario informs those conditions that FEI can monitor to understand in advance if demand is trending higher than expected, but is not the basis on which FEI plans.
		Appliance Standards	Reference	
		Carbon Price	Low	
		Customer Forecast	High	
		Fuel Switching	Reference	
		New Construction Code	Delayed	
		Retrofit Code	Reference	
		Natural Gas Price	Low	
		Low-Carbon Transportation and Global LNG Demand Category		
		LCT Demand	High	
		Global LNG Demand	High	
		New Large Industrial Demand Category		
		Industrial Demand Growth	High	

Scenario	Description	Input Settings		Discussion
Diversified Energy (Planning)	The Diversified Energy (Planning) Scenario's key planning assumptions build upon a diversified approach to energy delivery and emissions reductions to British Columbians. Under this scenario, customer growth occurs for both electric and gas utilities and the existing gas infrastructure is used to deliver low-carbon energy solutions to customers. FEI uses the Diversified Energy (Planning) Scenario as its planning scenario.	**Residential, Commercial and Industrial Demand Category**		The explanation of the Diversified Energy (Planning) Scenario and its selection as FEI's planning scenario is provided in Section 4.5.1.
		Appliance Standards	Reference	
		Carbon Price	Reference	
		Customer Forecast	Reference	
		Fuel Switching	Moderate electrification	
		Natural Gas Price	Reference	
		New Construction Code	Reference	
		Retrofit Code	Reference	
		Low-Carbon Transportation and Global LNG Demand Category		
		LCT Demand	Planning	
		Global LNG Demand	Planning	
		New Large Industrial Demand Category		
		Industrial Demand Growth	Planning	

Scenario	Description	Input Settings		Discussion
Price-Based Regulation	The BC government concludes that price signals and more ambitious upstream emissions reductions provide the best solution for carbon abatement and refrains from other forms of regulation. The price signals boost development of renewable gases, CCUS, and LCT. Upstream methane emissions regulations increase regional gas commodity costs. The policy environment has limited impacts on economic growth and LNG Exports.	**Residential, Commercial and Industrial Demand Category**		Use of price signals instead of carbon regulation within the planning environment as described in this scenario also creates favourable conditions for FEI to implement its Clean Growth Pathway. Exclusion of future demand from the Woodfibre LNG project in this scenario allows FEI to examine the unexpected, but still plausible situation in which that facility does not proceed.

Scenario	Description	Input Settings		Discussion
Deep Electrification	The BC government does not increase carbon taxes to avoid electoral backlash but uses all other policy levers to electrify the economy in order to achieve domestic carbon abatement. Government also promotes CCUS for non-electrified sectors. Such policies create constraints for the BC economy and reduce the uptake of LCT solutions and renewable gases. To support economic growth, the BC government supports LNG exports to other jurisdictions. Despite these exports, the domestic shift towards electricity causes a regional conventional natural gas supply glut, leading to low regional gas prices.	**Residential, Commercial and Industrial Demand Category**		In this scenario, electrification is the primary avenue utilized by the BC Government to decarbonize the BC economy. This in turn causes a decrease in annual gas demand. Coinciding with this decrease in annual gas demand are corresponding increases in electricity annual and peak demand that are not fully modelled in FEI's annual gas demand analysis, and which are anticipated to make a deep electrification not plausible as described in Section 4.6.1.1

Scenario	Description	Input Settings		Discussion
Lower Bound	The BC economy experiences lower-than-average growth as part of global economic stagnation. This reduces investment in regional gas supply so much that BC's demand balance becomes constricted. Global economic performance reinforces trends towards the right of the political spectrum in other jurisdictions but causes a counter-movement to the left in BC. This causes the BC government to focus on climate policy and electrification without support for renewable gases, CCUS, LNG exports, or LCT.	**Residential, Commercial and Industrial Demand Category**		This represents the second of the two boundary scenarios. This scenario is designed to represent the most extreme, low-gas-demand scenario from an annual demand perspective. In addition to deep electrification policies, all other critical uncertainties that could act to reduce gas demand do so. However, in this scenario, like the deep electrification scenario, the requirement for corresponding increases in electricity energy and peak demand requirements that are not fully modelled in FEI's annual gas demand analysis are anticipated to make the lower bound annual demand scenario not plausible as described in Section 4.6.1.1

The modelling process involved turning each of these assumptions into concrete changes to the input values for buildings in the three sectors. For example:

- In response to higher or lower gas prices, adjustments were made to the number of new buildings using gas for specific end uses, or to the number of existing buildings whose owners might opt to change fuels when equipment needs replacement.
- The policy environment affects assumptions about the number of customers who would opt to install energy-efficient equipment naturally, without influence from utility programs.
- Assumptions for developing district energy systems resulted in adjustments to the fuel shares for those options: increases in those fuel shares would generally displace the demand for gas.
- Renewable energy systems include systems such as geo-exchange, waste heat recovery, and solar thermal energy and can be stand alone or part of a district energy system. This

has the effect of displacing gas consumption, particularly for space and water heating in commercial buildings and apartments. With limited but growing market penetration of low-carbon thermal energy systems, FEI must continue to monitor this growth to gauge its impact over time on its gas infrastructure, annual and peak day demand, system capacity needs and rate design.

The model results for the six scenarios have the same level of granularity as the Reference Case. FEI does not assign probabilities to the scenarios. Rather, the six scenarios (considered together) provide a range of future demand that FEI will need to consider over the next 20 years. Please refer to Appendix B-3 for a detailed explanation of the end use demand forecast scenario parameters.

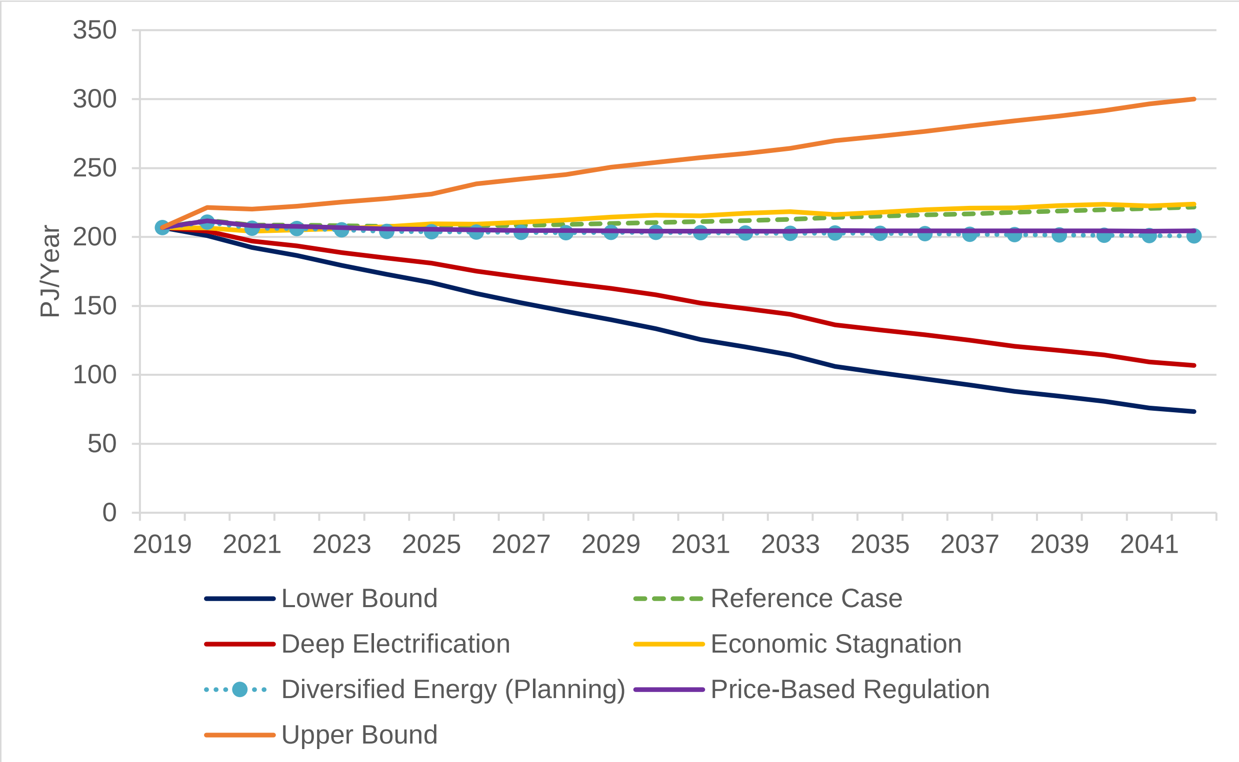
4.6 *END USE ANNUAL METHOD DEMAND FORECAST RESULTS BY SCENARIO*

This section presents the demand forecast results for each of the Residential, Commercial and Industrial, the Low-Carbon Transportation and Global LNG and the New Large Industrial Customer demand categories for all of the planning scenarios.

4.6.1 Residential, Commercial and Industrial Customer Demand Category

Figure 4-9 below displays the End Use Annual Method demand Reference Case and scenario results for the residential, commercial and industrial demand category across all regions for each of the scenarios described in Table 4-1. This figure shows that the range of annual demand forecast scenarios is sufficiently broad to ensure that FEI has examined the potential for quite different futures to unfold over the planning horizon.

Figure 4-9: Annual Demand Scenarios – Residential, Commercial and Industrial Sectors



4.6.1.1 *Lower Bound and Deep Electrification Scenarios for Residential, Commercial and Industrial Demand not Plausible*

While the Lower Bound and Deep Electrification scenarios are useful for examining a full range of possible future actions and testing the boundaries of the critical uncertainties that can change the way energy is used in the future, there are significant implications for electricity demand, particularly with regard to peak capacity requirements, system resiliency and economic implications, that cannot be reconciled for these scenarios. Both of these scenarios assume that 100 percent of residential and commercial demand for gas is switched to electricity by 2050, and that 30 percent of industrial demand is switched to electricity in the Lower Bound scenario and 20 percent in the Deep Electrification scenario over that time period.

A number of studies have shown that an electrification pathway to decarbonization is more costly and riskier than a diversified pathway, in which the existing gas infrastructure is optimized and utilized to deliver low-carbon energy to customers in combination with a strong and resilient electricity system. In Section 3.7 and Appendix A-9, FEI has presented a number of these reports, including:

- The UBC CERC report, “Clean Energy Pathways to Meet British Columbia’s Decarbonization Targets”;

- The University of Victoria's "Decarbonization of the building heating system in Metro Vancouver: comparison of two transition pathways";
- The Canadian Gas Association Report, "Implications of Policy Driven Electrification in Canada";
- The American Gas Association report, "Building a Resilient Energy Future: How the Gas System Contributes to US Energy System Resilience by Guidehouse";
- FortisBC's own report, "Pathways for British Columbia to Achieve its GHG Reduction Goals", also completed by Guidehouse; and
- A number of other studies from other jurisdictions in Canada and Europe.

These studies consider growth in energy demand and the challenges of meeting peak energy requirements under increasingly volatile weather extremes and recognize the benefits that both systems have for a more diverse, reliable and resilient overall energy system for the province. No credible alternative study has been brought forward for BC's energy system that fully examines the long-term implications and costs of full electrification of the province's entire energy infrastructure.

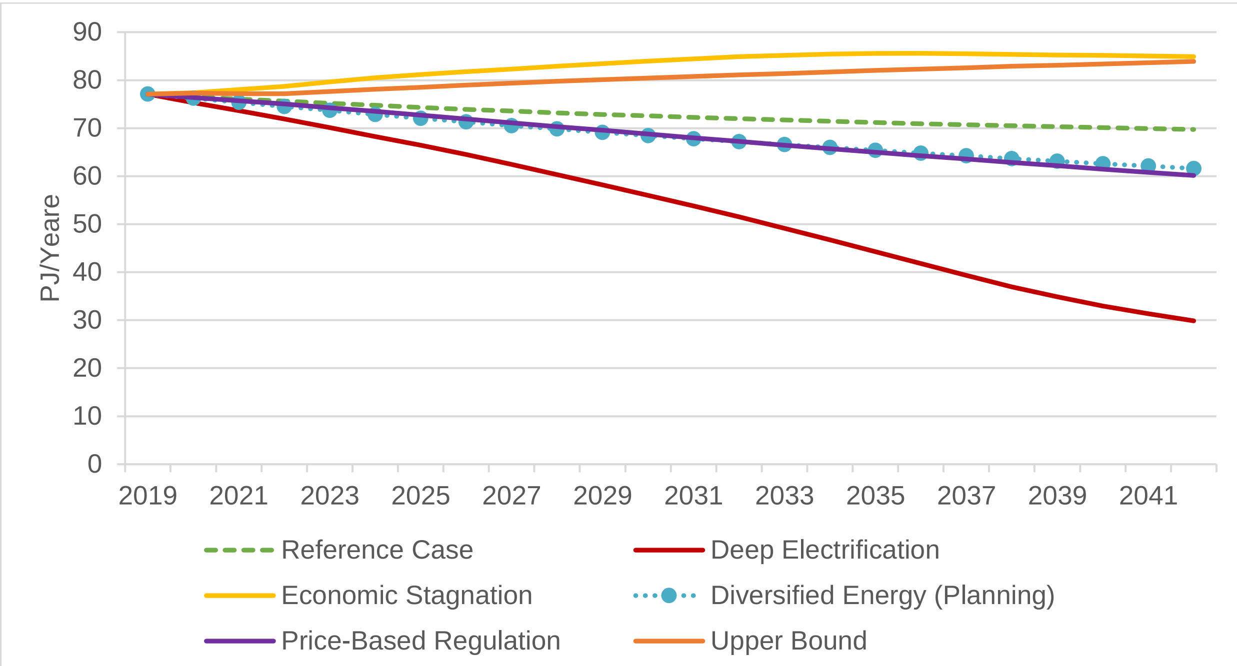
Both the Lower Bound and the Deep Electrification scenarios create technical and logistical requirements for alternative energy systems to be able to manage the scale of shifting energy resources that are not plausible, particularly to support peak energy, reliability and resiliency requirements. Since the Lower Bound scenario is a mechanical scenario that does not have a logical explanatory narrative, but simply examines what demand would look like if all settings were set to minimize demand as much as possible, it is considered untenable, and no further examination of this scenario is conducted in the 2022 LTGRP. As such, it is excluded from the remainder of this section. While the Deep Electrification scenario is also considered by FEI to be not plausible, some useful insights can be gained by examining its impact on the gas and electricity systems in BC. As such, the Deep Electrification scenario is examined through the remainder of this LTGRP to facilitate the reader's consideration of the extent of the challenge that deep electrification implies for BC's energy systems.

The majority of scenarios, including the Diversified Energy (Planning) Scenario, cluster within a narrower annual demand range since outcomes across critical uncertainties offset each other's impact on annual demand. In the Diversified Energy (Planning) Scenario, overall demand in the residential, commercial and industrial sectors declines very slightly as DSM activities and a moderate amount of electrification are largely, though not entirely, offset by new customer additions.

4.6.1.2 *End Use Annual Method Demand Forecast Results for Residential, Commercial and Industrial Customers – By Sector*

Figure 4-10 below displays the annual demand scenarios for the residential sector.

Figure 4-10: Annual Demand Scenarios – Residential Sector



Some key observations from Figure 4-10 are as follows:

- The Upper Bound and Economic Stagnation scenarios differ in their customer growth assumption only. Since new residential customers are using less gas and the difference between the high and low customer growth is modest, the difference in demand for these scenarios is not large.
- The deep electrification scenario shows a steep decline in demand for gas. As discussed in Section 4.6.1.1, the deep electrification scenario has implications for electricity supply in BC that makes such a scenario unrealistic, but is important for a full understanding of the long term implications of near term decisions on electrification.
- The remaining three scenarios are also closely aligned. The difference between the Reference Scenario and the Diversified Energy (Planning) Scenario includes a degree of electrification occurring over the planning horizon.[151]

[151] The Diversified Energy (Planning) Scenario assumes that by 2050, 25 percent of commercial and residential gas demand will be electrified.

To provide further insight into the Diversified Energy (Planning) Scenario, Figure 4-11 shows the annual demand forecast for the top three end uses in the residential sector under the Diversified Energy (Planning) Scenario.

Figure 4-11: Diversified Energy (Planning) Annual Demand – Residential Sector Top End Uses

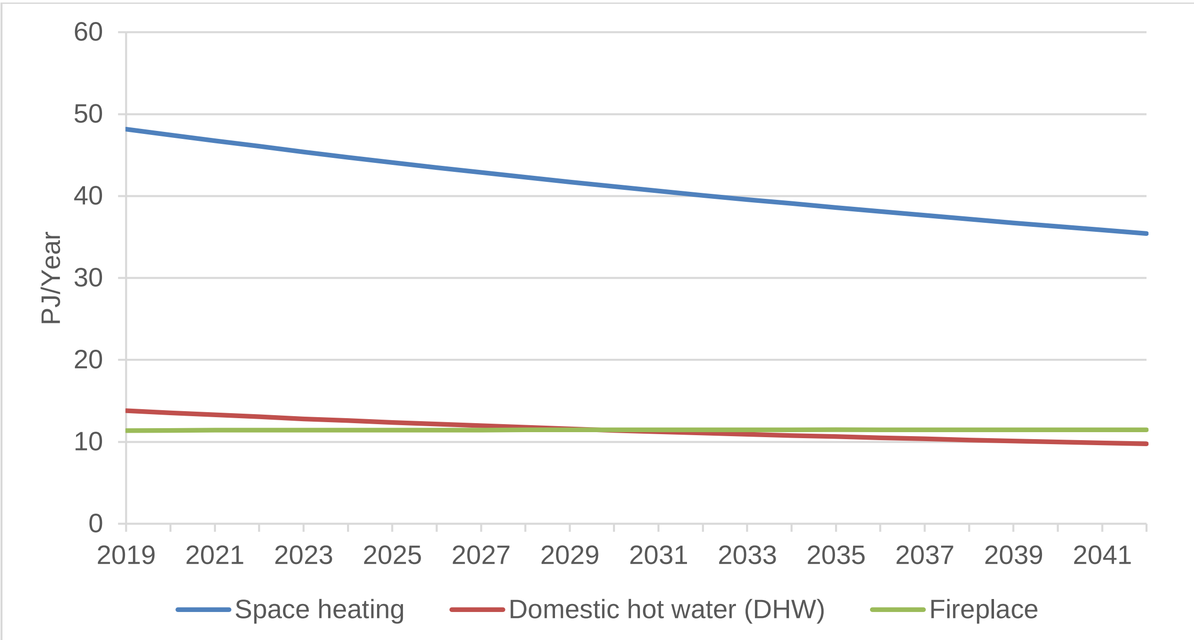


Figure 4-12 below displays the annual demand information for the commercial sector in all regions for each scenario.

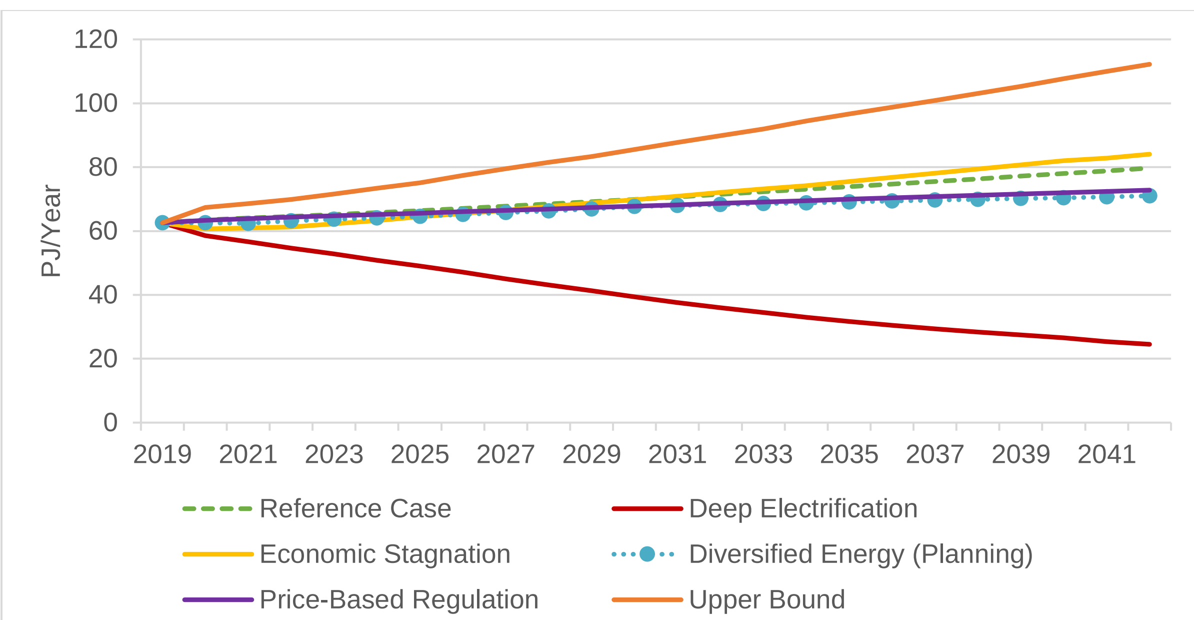
Figure 4-12: Annual Demand Scenarios – Commercial Sector

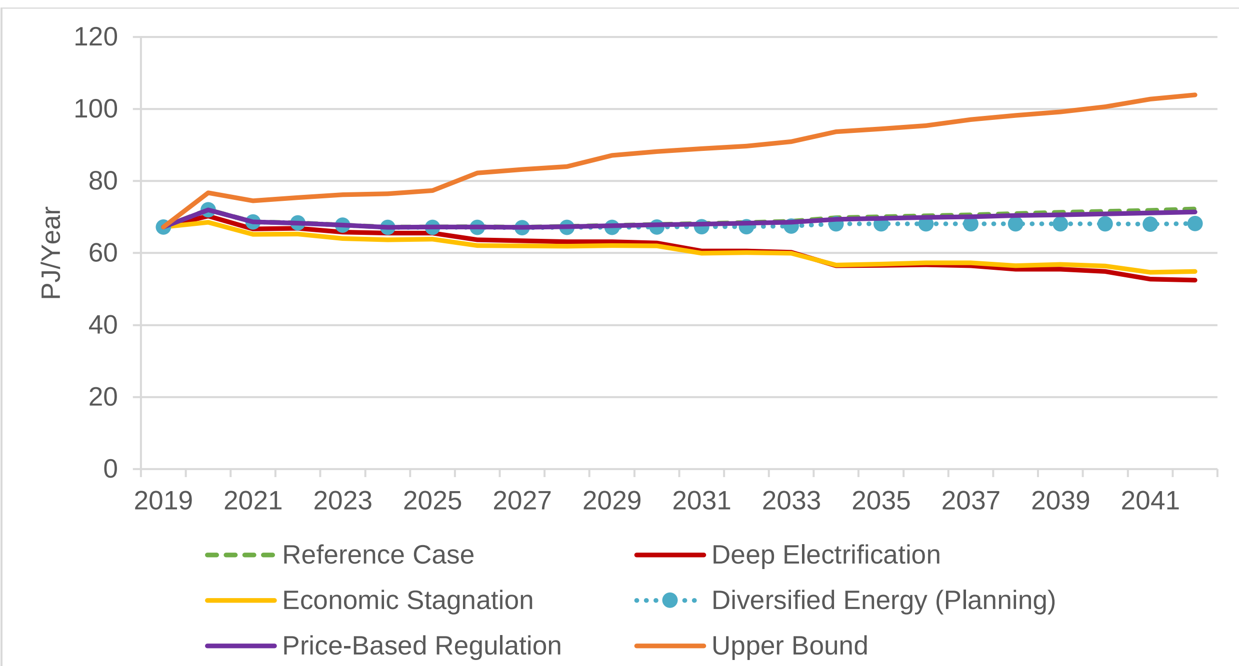


Some key observations from Figure 4-12 are as follows:

- The difference between the Upper Bound and the Economic Stagnation scenario results illustrates the impact of the differing customer growth settings on the commercial sector annual demand.
- As with residential demand, the deep electrification scenario shows a steep decline in gas demand in the commercial sector due to electrification.[152] As discussed in Section 4.6.1.1, the lack of a viable alternate energy source to take on this much demand over that time frame makes this scenario unreasonable, but important for considering near-term decision making regarding electrification to avoid future unintended consequences.
- The remaining demand scenarios are fairly narrowly clustered, with the difference between the Reference Case and Diversified Energy (Planning) Scenario again being primarily the consideration of some electrification in the Diversified Energy (Planning) Scenario and not in the Reference Case over the planning horizon[153]

Figure 4-13 below displays the annual demand scenarios for the industrial sector in all regions.

Figure 4-13: Annual Demand Scenarios – Industrial Sector



Some key observations from Figure 4-13 are as follows:

[152] Deep Electrification Scenario assumes 100 percent of gas load in the commercial sector will be electrified by 2050.
[153] In the Diversified Energy (Planning) Scenario, 25 percent of commercial load is assumed to be electrified by 2050.

- The annual demand trajectories are jagged because the customer growth critical uncertainty causes additions/removals of individual customers, and industrial customers have comparatively high annual demand.
- The Upper Bound Scenario examines the impact of high industrial customer growth and other conditions that put upward pressure on demand.
- The Deep Electrification Scenario models similar demand reductions in the industrial sector as does the Economic Stagnation Scenario. In this scenario, electrification of the industrial sector over the planning horizon is modelled to be less than that of the residential and commercial sectors as it is assumed that some industrial end uses will be too difficult to electrify in that time frame.
- The remaining scenarios are tightly clustered showing steady industrial demand throughout the planning period. The Reference Case and the Diversified Energy (Planning) Scenario are much closer than for the residential and commercial sectors since less electrification is assumed for the industrial sector in the Diversified Energy (Planning) Scenario than for residential and commercial customers due to the assumed difficulty of electrifying some industrial end uses.

4.6.2 Low-Carbon Transportation and Global LNG Demand Category

This section presents the annual demand forecasting results for CNG and LNG demand settings. In Sections 4.7 and 4.8 below, these demand setting results are mapped to the demand scenarios to arrive at the forecast of total demand for each scenario as shown in the tables below.

Table 4-2: Mapping CNG/LNG Demand Forecast Settings to the 2022 LTGRP Annual Demand Scenarios – Transportation Fuel

CNG / LNG Demand Forecast Setting	2022 LTGRP Annual Demand Scenario
Reference	Reference Case
Low	Lower Bound, Deep Electrification, Economic Stagnation
Planning	Diversified Energy (Planning)
High	Upper Bound, Priced-Base Regulation

Table 4-3: Mapping Global LNG Demand Forecast Settings to the 2022 LTGRP Annual Demand Scenarios

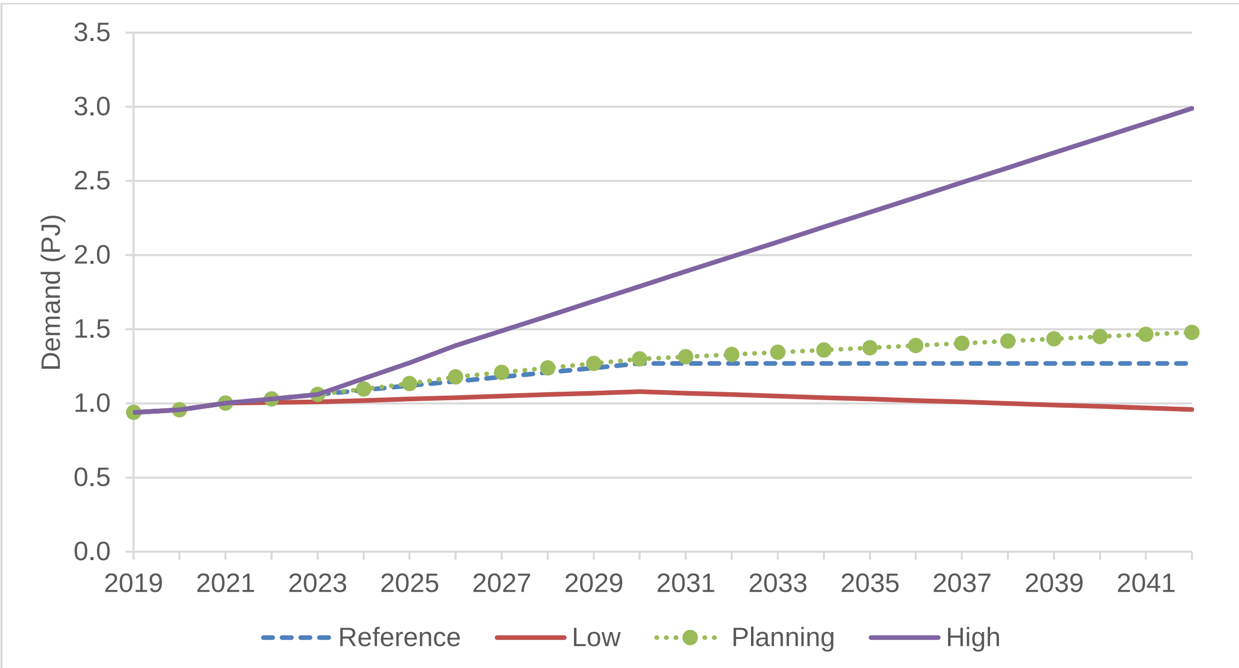
Global LNG Demand Forecast Setting	LTGRP Annual Demand Scenario
Reference	Reference Case, Price-Based Regulation, Economic Stagnation, Lower Bound
Planning	Diversified Energy (Planning), Deep Electrification
High	Upper Bound

Note: Because in the Reference Setting Global LNG Demand drops to zero, there is no "Low" setting.

4.6.2.1 *CNG Annual Demand Forecast Results*

Figure 4-14 displays a forecast of CNG demand on FEI's system over the planning period (2020 to 2042) for the four CNG demand settings.

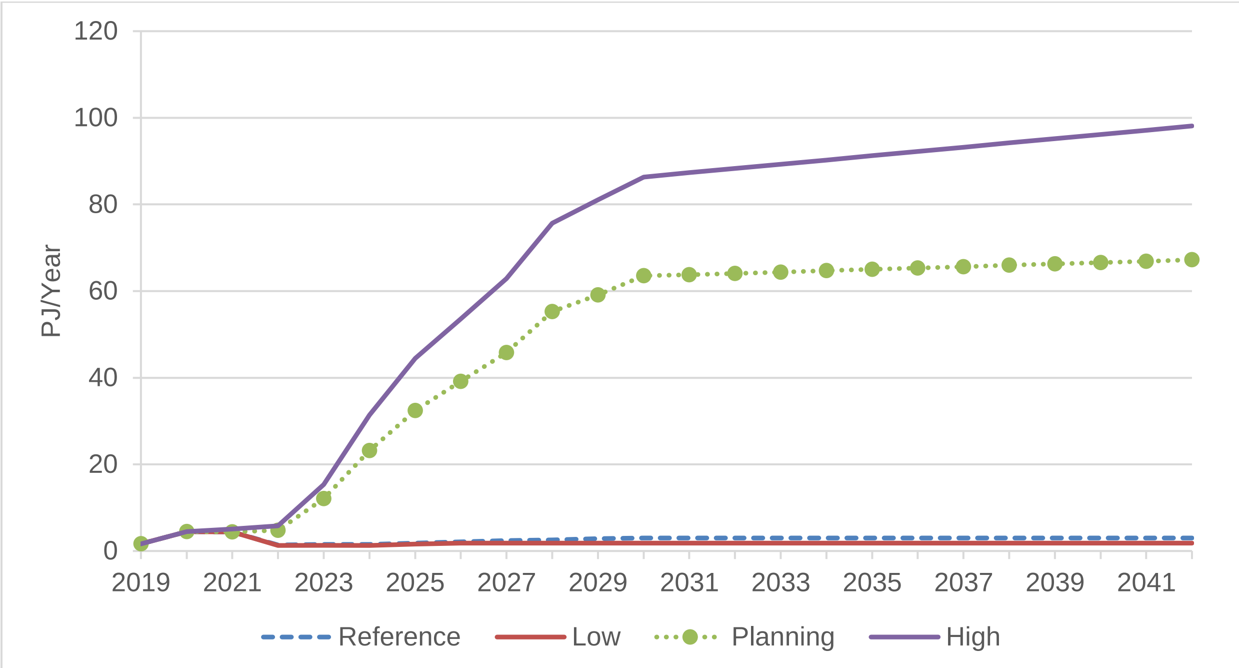
Figure 4-14: Annual Demand Forecast for the CNG Demand Settings (2020-2042)



4.6.2.2 *LNG Annual Demand Forecast Results*

Figure 4-15 below provides an illustration of the four LNG annual demand settings over the forecast period.

Figure 4-15: Annual Demand Forecast for LNG Demand Settings (2020-2042)



4.6.2.3 *Combined CNG and LNG Demand Forecast*

Figure 4-16 below illustrates the combined conventional natural gas demand forecasts by setting for both CNG and LNG, as described in the sections above. FEI combines forecast annual demand from CNG and LNG since FEI considers cumulative annual demand of FEI's customers and initiatives in its long term planning. While each fuel type has its own merit in the local and international markets, LNG accounts for a larger portion of forecast LCT annual demand than CNG and thus shapes the appearance of the combined annual demand graph.

Figure 4-16: Annual Demand Forecast for the Low-Carbon Transportation and Global LNG Demand Categories in Total (2020-2042)

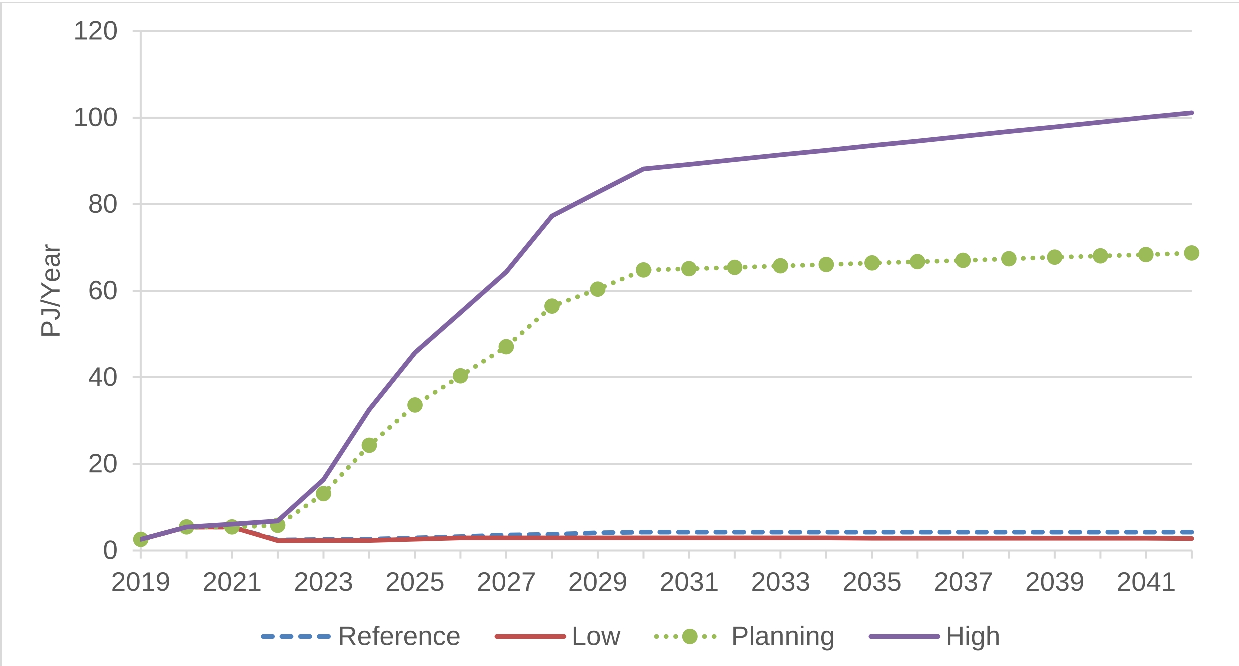


Figure 4-17 below provides a regional look at the Low-Carbon Transportation and Global LNG Demand Category for the Planning setting, which is applied to the Diversified Energy (Planning) Scenario. This graph depicts the effect of adding LCT load to the distribution system and illustrates how the majority of LCT load is expected to come onto the system in the Lower Mainland since this is where the LNG is produced and since the largest portion of LNG demand is for the marine sector. Though not shown, this locational effect is seen across the scenarios that include substantial demand growth in this category.

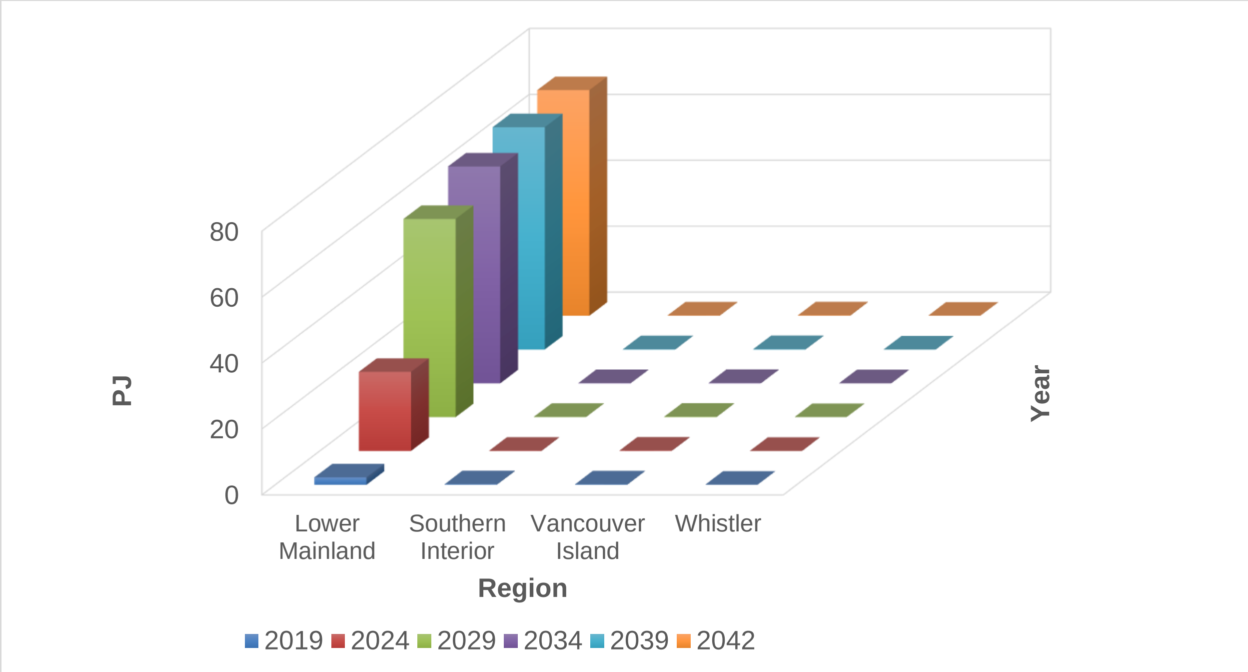
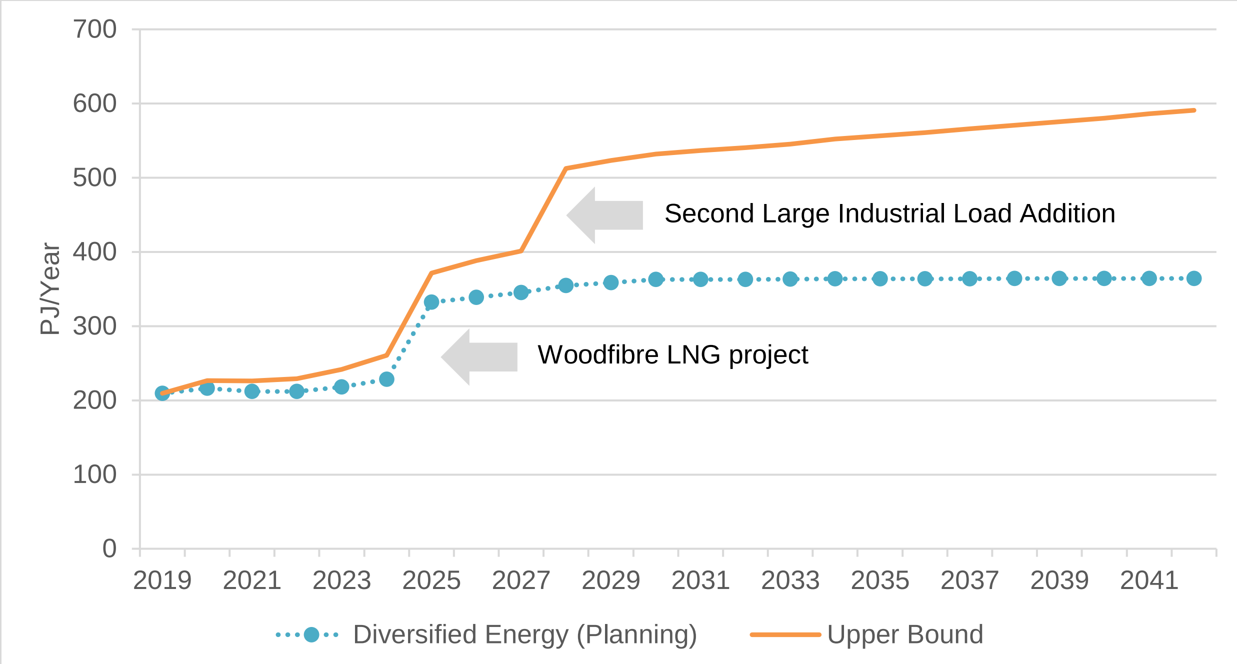
Figure 4-17: LCT and Global LNG Annual Demand Forecast for CNG and LNG Planning Setting– by Region in Select Milestone Years



4.6.3 New Large Industrial Demand Category

As discussed in Section 4.3.3, the addition of each of the two new large industrial loads would cause a large step change in demand in the scenarios in which they are applied. This effect is illustrated in Figure 4-18 which shows the total annual demand results for the Diversified Energy (Planning) and the Upper Bound Scenarios. FEI included only the Woodfibre LNG project in the Diversified Energy (Planning) Scenario, whereas FEI included both the Woodfibre LNG project and the second new large industrial facility (somewhat later) in the Upper Bound scenario. The total demand for all scenarios is presented in Section 4.8.

Figure 4-18: Total Annual Demand for the Diversified Energy (Planning) and Upper Bound Scenarios illustrating the inclusion of the New Large Industrial demand

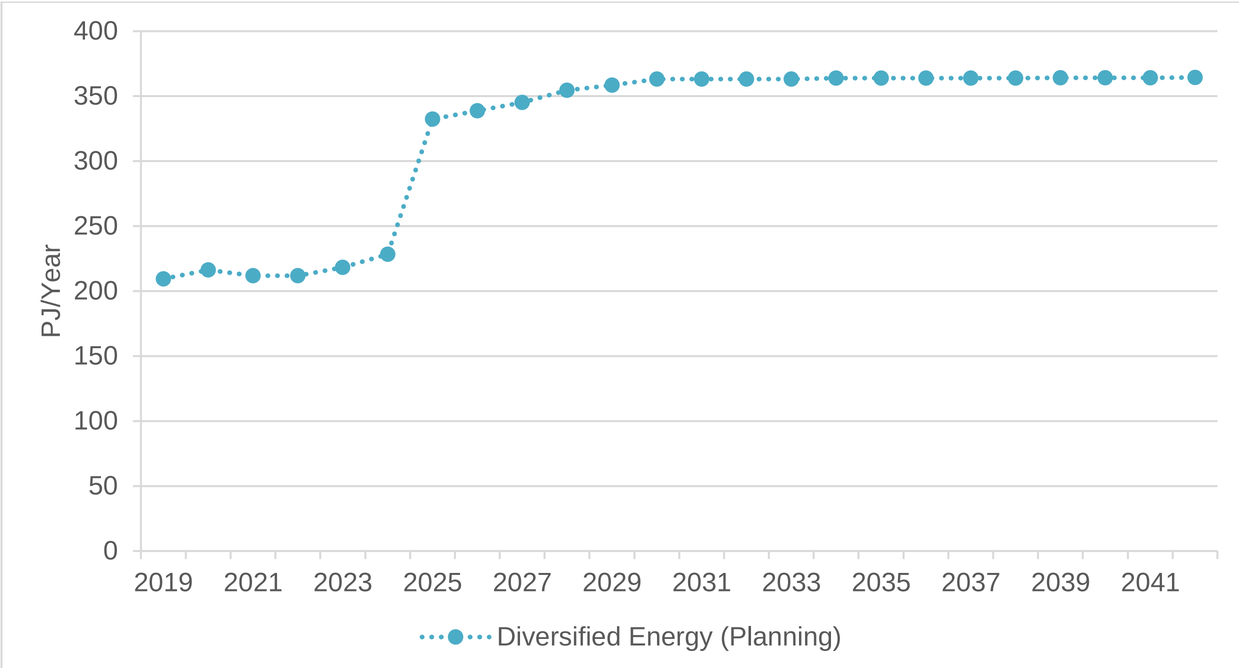


4.7 TOTAL ANNUAL DEMAND – DIVERSIFIED ENERGY (PLANNING) SCENARIO

FEI's expectation of future annual energy demand for planning purposes is represented by the outputs of the Diversified Energy (Planning) Scenario analysis illustrated in Figure 4-19 below. This planning scenario includes some electrification of gas demand captured historically by FEI in the residential, commercial and industrial sectors, though FEI continues to add customers in these sectors through the planning horizon. Observed growth in annual demand in the first half of the planning horizon is driven by load growth in the transportation sector and LNG export market, primarily with the large load step increase when the Woodfibre LNG project is modelled to begin operation in 2025[154]. Emission reductions in this scenario will result to some extent from DSM activity which is discussed in Section 5, from displacing higher carbon fuels for transportation discussed earlier in Section 4 and from FEI's transition to renewable and low-carbon gas supplies as discussed in Section 6, all of which are a part of FortisBC's Clean Growth Pathway.

[154] After the demand forecast modelling was completed, Woodfibre LNG issued a notice to proceed. Based on that notice, FEI now expects demand from Woodfibre LNG project to begin in 2027.

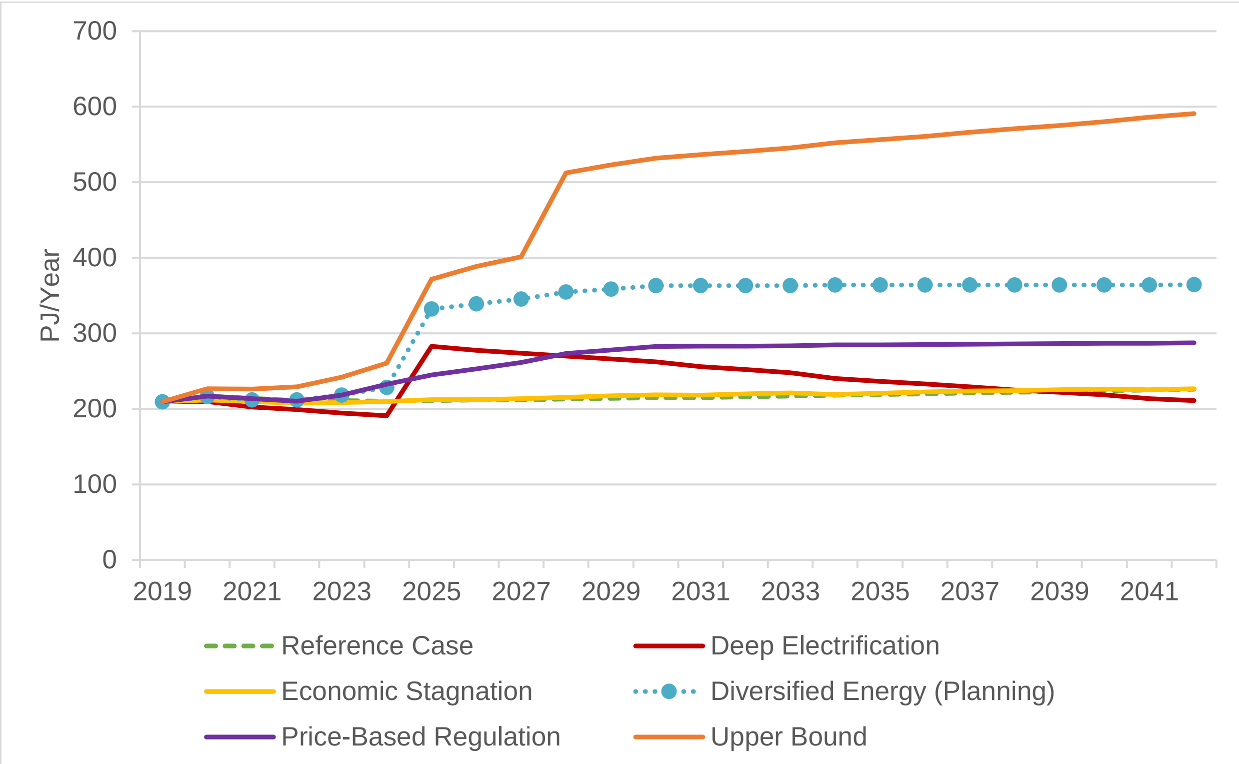
Figure 4-19: Total Annual Demand Including LCT – Diversified Energy (Planning) Scenario



4.8 *TOTAL ANNUAL DEMAND – ALL SCENARIOS*

FEI serves a growing demand for energy from residential, commercial, industrial, CNG and LNG customers. This includes demand growth in a relatively new sector to FEI, the marine transport sector, where fuel switching from higher carbon fuels to LNG will reduce global GHG emissions. FEI's demand scenarios have considered the potential for LNG export to serve carbon reduction efforts in other parts of the globe and have also considered the potential for adding new large industrial loads that can result in substantial step change increases in annual demand. The full range of demand forecast scenarios examined in developing this LTGRP is presented in Figure 4-20. Appendices B-4 and B-5, respectively, present summary tables and a working MS Excel data file of the End Use Annual Method annual demand results.

Figure 4-20: Total Annual Demand Including LCT – All Categories, All Scenarios



Consideration for electrification in the residential, commercial and industrial sectors has been considered in both the Diversified Energy (Planning) Scenario, which models the demand trajectory that reaches 25 percent electrification of residential and commercial demand and 10 percent of industrial demand by 2050, and the Deep Electrification scenario, which models the demand trajectory that reaches 100 percent electrification of the commercial and residential sectors and 20 percent of industrial demand by 2050. The Lower Bound and Deep Electrification scenarios are found to have electrification assumptions that are not plausible in that no credible fuel switching alternative has been presented that can address the peak demand requirements of this much energy demand. Both of these scenarios are shown in Figure 4-20 for completeness. However, the Lower Bound scenario is not explored further in this LTGRP and the Deep Electrification scenario is presented to facilitate the reader's consideration of the extent of the challenge that deep electrification implies for BC's energy systems.

FEI's Upper Bound scenario models all critical uncertainties set to increasing gas demand, including the highest setting for potential CNG and LNG demand growth as well as both the Woodfibre LNG project and a second generic industrial facility of similar annual demand to that of Woodfibre LNG project. These two industrial load additions cause the large step-change demand increases that can be seen in Figures 4-18 and 4-20. FEI has not assumed that it would need to acquire gas supplies to serve these industries, but uses the results of Upper Bound scenario to understand the implications of these types of demand increases and thus to monitor for indications that these types of demand increases might be unfolding. In this way, the Upper Bound scenario provides important information for consideration in planning FEI's infrastructure.

The Reference Case demand forecast models only those trends and known changes in conditions in the near term for all sectors that were in place at the time the scenario modelling began. Since it does not consider the future changes that are required to transition to lower carbon gas supplies and meet GHG reduction targets, it is no longer considered FEI's planning scenario. It is useful, however, in providing a reference point in considering a different future outcome in terms of energy demand and emissions reductions.

The broad range of demand between the alternate scenarios is dramatic, and representative of substantial change and uncertainty in the energy planning environment as discussed in Section 2. Even the range between the more moderate scenarios, Diversified Energy (Planning), Priced-Based Regulation and Economic Stagnation, is quite large at approximately 140 PJ in 2042.

The Diversified Energy (Planning) Scenario represents FEI's expectation of the way in which future demand will unfold, before DSM activities, when considering the actions that FEI is planning to take to transition to a deep decarbonization of the gas it delivers to customers. This scenario includes increased demand from sectors where conventional natural, renewable and low-carbon gases will reduce GHG emissions within BC and globally, as well as expected demand from the Woodfibre LNG project. The remainder of the 2022 LTGRP focuses on the Diversified Energy (Planning) Scenario as FEI's planning scenario.

4.9 *CONCLUSION*

FEI has provided an estimate of the annual demand for gas that it expects to serve over the 20-year planning horizon before considering the impact of new, incremental DSM activities, as required under Section 44.1(2)(a) of the UCA. This estimate is presented in Figures 4-19 and in 4-20 as a potential range of future demand that can reasonably be expected to occur under differing potential future conditions impacting residential, commercial and industrial customers, as well as customers using conventional natural gas as a transportation fuel and gas delivered on FEI's system for export to other global markets.

Since the likelihood of accurately predicting actual future conditions is low, probabilities are not assigned to the different scenario outcomes. Rather, FEI identifies and implements a set of cost-effective resources to meet the planning scenario and establishes contingency plans for meeting the scenario range of potential future annual demand.

Sections 6 and 7 of this LTGRP discuss the gas supply and physical infrastructure resources FEI requires to meet this range of demand (after DSM), including the timing of peak capacity requirements under higher or lower demand growth. These sections also discuss the implications of FEI's transition to renewable and low-carbon gas for FEI's gas supply and infrastructure planning. FEI discusses the influence of the 2022 LTGRP annual demand and supply scenarios on customer rates in Section 9.4.

DEMAND-SIDE RESOURCES

Table of Contents

5. DEMAND-SIDE RESOURCES

5.1 *INTRODUCTION*

This section describes how FEI's adequate and cost-effective portfolio of DSM activities can result in significant energy and GHG emissions reductions over the planning horizon under the range of future scenarios examined for the LTGRP. As a pillar of FEI's Clean Growth Pathway, FEI anticipates expanding its existing DSM activities over the planning horizon to reduce GHG emissions to meet provincial GHG reduction targets. In particular, FEI's future DSM expenditure plans that will be filed with the BCUC for acceptance will be guided by the High DSM Setting analysed in this LTGRP. Under the Diversified Energy (Planning) Scenario with the High DSM Setting, FEI's savings from DSM activities are forecast to be significant, at approximately 25 PJ or 13 percent of annual load in 2042.

As directed in Order G-39-19, FEI's DSM funding scenarios reflect the results of the most recent CPR (Appendix C-1), with incentive level, economic screen and budget settings applied to individual scenarios as described in Table 5-3. The Diversified Energy (Planning) Scenario (DEP) is now the equivalent to the "reference" scenario referred to in the directive, and was used as the basis for a sensitivity analysis demonstrating the effects of the Low, Medium and High DSM settings on DSM expenditures, energy savings and cost-effectiveness tests. These cost-effectiveness tests include Total Resource Cost (TRC), Modified Total Resource Cost (MTRC) and Utility Cost Test (UCT) results expressed as a ratio and the Cost of Conserved Energy (CCE) expressed as $/GJ. FEI also provides a directional view of delivery rate and bill impacts for residential customers under the Low, Medium and High DSM Settings on the Diversified Energy (Planning) Scenario.

In order to more clearly demonstrate the impacts of DSM energy savings on total demand, FEI has selected the Diversified Energy (Planning) Scenario and the Reference Case for comparative purposes throughout this section. The impact of the DSM analysis on all scenarios is presented in Appendix C-2.

Table 5-1: Overview of Reference Case and Alternate Future Scenarios in DSM Analysis and Where Addressed in the LTGRP

Scenario	DSM Setting	Section Where Addressed
Reference Case	Medium	Section 5.4 and Appendix C-2
Diversified Energy (Planning)	High (sensitivity analysis conducted with Low and Medium settings)	Section 5.4 and Appendix C-2
Deep Electrification	Taper Off	Appendix C-2
Price-Based Regulation	Medium UCT	Appendix C-2
Economic Stagnation	Medium	Appendix C-2
Upper Bound	N/A – no DSM	Appendix C-2

As FEI does not construct its own energy generation resources, FEI's DSM analysis does not weigh the cost of DSM against the need for procuring or constructing upstream energy generation resources to meet demand growth. Instead, FEI's DSM analysis primarily seeks to establish an adequate and cost-effective level of DSM activity and explore the extent to which the peak demand implications of such DSM activity may defer FEI's requirements for downstream infrastructure. To the extent that decarbonization initiatives lead FEI to produce renewable and low-carbon gas, such as for RNG and hydrogen, the benefits of DSM activities in reducing the need for additional upstream energy generation may be considered in upcoming LTGRP filings.

In prior LTGRP submissions and in more traditional DSM modelling approaches, the savings of each additional unit of energy saved would be treated equally. However, in this LTGRP, where FEI is transitioning to renewable and low-carbon gas, the software model was designed to prioritize reducing conventional natural gas. Although the ability to apply DSM savings equally to all fuel types is discussed in the 2022 LTGRP, the analysis could not be completed in time for the 2022 LTGRP submission date since such analysis will require reconfiguring the software. The decision was made early in the LTGRP planning process, that the priority for DSM in this model was to focus on energy savings to reduce GHG emissions. As an artifact of the logic in these models, the analysis may show curtailed DSM expenditures after 2030 as the proportion of renewable and low-carbon gas increases and natural gas declines. This is not demonstrated in the Reference Case due to the higher proportion of natural gas. FEI will assess updating the model for the next LTGRP, which will result in DSM savings being applied proportionally to all fuel types including renewable and low-carbon gas, so that savings will not be curtailed as the conventional gas share decreases.[155]

Section 5 is organized as follows:

- Section 5.2 describes how FEI has a cost-effective, adequate DSM portfolio.
- Section 5.3 describes the DSM analysis methodology used to develop DSM savings potential for the scenarios presented in Section 4.
- Section 5.4 provides the results of the DSM analysis for select scenarios, including:
    - a sensitivity analysis of the effects of the Low, Medium and High DSM Settings on the Diversified Energy (Planning) Scenario in terms of energy savings, expenditures, and CCE (5.4.1).
    - a directional view of delivery rate and bill impacts for residential customers under the Low, Medium and High DSM Settings on the Diversified Energy (Planning) Scenario (5.4.2).
    - the forecast long term demand after DSM savings for all sectors combined with comparisons for the Diversified Energy (Planning) Scenario – High and Medium DSM Settings, Reference Case, and Upper Bound excluding LCT (5.4.3).

[155] RPAG members were in general agreement that DSM savings could be applied proportionally to all fuel types in a future model, recognizing the value in saving an additional unit of energy whether it be natural, renewable or low-carbon gas.

  - the forecast total annual demand and the effects of projected DSM activity in reducing demand for all sectors combined (5.4.4).
  - forecast DSM expenditures for all sectors combined for the Diversified Energy (Planning) Scenario – High and Medium DSM Settings, Reference Case and Upper Bound (5.4.5).
  - cost-effectiveness test results for all sectors combined for the Diversified Energy (Planning) Scenario – High and Medium DSM Settings, Reference Case and Upper Bound for all sectors combined (5.4.6).
  - the energy savings market potential to 2030 for the top ten measures and the extent to which these measures contribute to a large proportion of total energy savings for the Diversified Energy (Planning) Scenario – High DSM Setting in comparison with the Reference Case (5.4.7).
- Section 5.5 discusses the approach FEI has taken to better understand the long-term implications of FEI's projected DSM activities on peak demand.
- Section 5.6 provides the long-term plan for implementing DSM programs.
- Section 5.7 provides the conclusion and recommended actions for the section.

5.2 FEI PLANS TO CONTINUE WITH AN ADEQUATE, COST-EFFECTIVE DSM PORTFOLIO

FEI's DSM activities consist of a portfolio of efficiency and conservation programs and activities and represents an important pillar in the Clean Growth Pathway. While supporting government energy and emissions reduction objectives, DSM activities also drive market transformation to a higher efficiency and decarbonized built environment through equipment advances, deep retrofits and innovative technologies such as gas heat pumps. Energy efficiency programs also support decarbonization in the commercial and industrial sectors by focusing on facility and process improvements. FEI's DSM activities have other customer and societal benefits, such as reducing water consumption, enhancing human health and comfort, creating jobs, and encouraging a culture of conservation throughout BC.

Over the 2022 LTGRP planning horizon, FEI's specific program offers will likely evolve to suit the evolving marketplace, legislative provisions outlined in the Roadmap, other future policy and legislative updates and FEI customer needs. In accordance with the UCA, FEI will continue to bring forward adequate, cost-effective DSM portfolios for acceptance by the BCUC.

In the subsection below, FEI provides an overview of the Program Areas that comprise its DSM portfolio and how it meets the adequacy requirements of the DSM Regulation.

5.2.1 FEI's DSM Portfolio Investment is a Key Pillar in the Clean Growth Pathway

The BCUC accepted FEI's existing DSM portfolio[156] in its decision on FEI's 2019-2022 DSM Expenditures Plan, finding that the DSM portfolio was cost-effective and in the public interest.[157] FEI's DSM portfolio assists customers in using FEI's products as efficiently as possible, contributing both to affordability and emissions reduction. The DSM current program offerings address all customer segments as outlined below.

5.2.1.1 *Residential Program Area*

Residential programs are available to over 954,000[158] customers in the FEI service territories. For DSM purposes, these customers predominantly include those living in single-family homes, row houses, townhomes or mobile homes.[159] Some in-suite measures in multi-unit residential buildings are also included in this program area. Residential programs encompass retrofit and new home applications, enabling FEI customers to reduce their energy consumption and support the building industry in improving overall home performance. The combination of rebates, policy support, customer and trades engagement offered through FEI programs is instrumental in driving a culture of conservation and fostering market transformation in the residential sector.

5.2.1.2 *Low Income Program Area*

FEI's Low Income Program Area serves individual Low Income[160] customers, Indigenous housing, co-operative housing, non-profit housing, and charities that aid Low Income customers. Low Income programs will continue to be a critical part of FEI's portfolio as these customers are anticipated to be the hardest hit by rate impacts of the clean energy transition for both gas and electrically heated homes. Affordability is a key issue that needs to be addressed for all communities in BC.

In the LTGRP scenarios, Low Income customers are modelled within the residential category, as these customers are not differentiated in FEI's customer database. FEI estimates that about 20 percent of its residential customers would be eligible for Low Income programs. According to Statistics Canada's 2016 Census data,[161] 14 to 15 percent of British Columbians are considered low income, based on Low Income cut-offs (LICO) before tax. The DSM Regulation uses LICO

159 Programs for Multifamily Dwellings served under Rate Schedule 2 or 3 are included in the commercial DSM program area.

160 As defined in DSM Regulation.

161 Appendix F-2: Low-Income Status Data tables (2016 Census), online at: statcan.gc.ca.

multiplied by a factor of 1.3 to determine low income thresholds. This suggests that, under the definition set out in the DSM Regulation, FEI's 20 percent estimate is reasonable.

5.2.1.3 *Commercial Program Area*

FEI's Commercial Program Area encourages commercial customers to reduce their overall consumption of natural gas and associated energy costs. These programs enable commercial and institutional customers to conduct both simple and comprehensive energy efficiency upgrades at their buildings. The combination of financial incentives, consultant and contractor outreach, and effective marketing in these programs is instrumental to the ongoing success of these programs in generating natural gas savings and fostering market transformation in the commercial sector.

5.2.1.4 *Industrial Program Area*

FEI's Industrial Program Area offers a number of industrial programs that encourage industrial customers to reduce their overall consumption of natural gas and associated energy costs. Industrial initiatives can be large projects with significant energy savings that span multiple years. These programs have been successful in the manufacturing, agricultural, mining and other sectors, which use large amounts of natural gas and therefore provide substantial energy savings opportunities.

5.2.1.5 *Innovative Technologies Program Area*

FEI's Innovative Technologies Program Area identifies pre-commercial and market-ready technologies that are not yet widely adopted in BC, and which are suitable for development or inclusion in the portfolio of ongoing DSM programs in other program areas. This is accomplished through pilot and demonstration projects, pre-feasibility studies and the use of industry standard evaluation, measurement and verification protocols to validate manufacturers' claims related to equipment and system performance. A number of key areas of growth for FEI's DSM portfolio have been under development in this program area. These include:

- Advancing the commercialization of gas heat pumps whereby the technologies can achieve system efficiencies of greater than 100 percent. FEI was recognized for its leadership in the evaluation and advancement of gas heat pumps across the Pacific Northwest and was the recipient of the Northwest Energy Efficiency Alliance's 2021 Leadership in Energy Efficiency Award for Innovation.
- Investigating energy consumption and technological considerations for dual fuel heating systems (hybrids) in which the gas system provides back-up to an electric system.
- Advancing FEI's understanding and implementation of Deep Energy Retrofits as the key growth area of the DSM portfolio for both Part 3 Commercial and Part 9 residential buildings.

5.2.1.6 *Conservation Education and Outreach and Enabling Activities*

FEI's conservation education and outreach initiatives continue to support DSM portfolio goals by fostering energy literacy and a culture of conservation among FEI's residential, low income, Indigenous, new Canadian, and commercial customers and educational institutions. Initiatives include programs to support behaviour change, including the My Energy Use portal through customers' online service accounts and home energy reports. FEI also continues to support training seminars and educational workshops in collaboration with such organizations as the Greater Vancouver Home Builders Association and other industry associations.

DSM-enabling activities focus on trade alliances for program support and quality installation, trades and builders' associations, building science research, advancing building codes and appliance standards, maintaining FEI's DSM tracking system, and funding to support post-secondary energy management programs.

FEI continues to focus on education, energy literacy, behavioural change and industry training to foster a culture of conservation in BC while driving program awareness and participation. These enabling and portfolio-level activities are not listed in Section 5.4.5 DSM incentives program expenditures schedules as they only report on programs with energy savings. In the past, these expenditures represented a range of about 18 to 30 percent of annual DSM portfolio expenditures.

5.2.2 DSM Portfolio Meets Adequacy Requirement of DSM Regulation

In BC, the implementation of demand-side measures is governed by the UCA, the DSM Regulation, and by the definition of "demand-side measure" found in section 1(1) of the CEA, which is as follows:

> A rate, measure, action or program undertaken (a) to conserve energy or promote energy efficiency, (b) to reduce the energy demand a public utility must serve, or (c) to shift the use of energy to periods of lower demand . . . but does not include (d) a rate, measure, action or program the main purpose of which is to encourage a switch from the use of one kind of energy to another such that the switch would increase greenhouse gas emissions in British Columbia, or (e) any rate, measure, action or program prescribed.

All of FEI's DSM activities meet the definition of "demand-side measures" in the CEA and help customers reduce their natural gas consumption, thereby reducing GHG emissions.

The DSM Regulation defines what demand-side measures must be included in a public utility's plan portfolio to be "adequate" within the meaning of section 44.1(8)(c) of the UCA. The table below lists the adequacy requirements of section 3(1) of the DSM Regulation and how FEI's DSM portfolio meets those requirements.

Table 5-2: Adequacy Requirements of the DSM Regulation

Section of the DSM Regulation	Adequacy Requirement	How FEI's DSM portfolio addresses adequacy
3 (a)	A demand-side measure intended specifically (i) to assist residents of low income households to reduce their energy consumption, or (ii) to reduce energy consumption in housing owned or operated by (A) a housing provider that is a local government, a society as defined in section 1 of the *Societies Act*, other than a member-funded society as defined in section 190 of that Act, or an association as defined in section 1 (1) of the *Cooperative Association Act*, or (B) the governing body of a first nation, if the benefits of the reduction primarily accrue to (C) the low income households occupying the housing, (D) a housing provider referred to in clause (A), or (E) a governing body referred to in clause (B) if the households in the governing body's housing are primarily low income households;	Low Income Program Area: serves individual Low Income customers, Indigenous housing, co-operative housing, non-profit housing, and charities that aid Low Income customers.
3(b)	If the plan portfolio is submitted on or after June 1, 2009, a demand-side measure intended specifically to improve the energy efficiency of rental accommodations;	Rental Apartment Efficiency Program: incentives and energy saving support for rental apartment buildings targeted for landlords, property managers, and in-suite upgrades for tenants in participating buildings.
3(c)	An education program for students enrolled in schools in the public utility's service area;	FEI's Conservation, Education and Outreach Program Area: FEI's School Education Program supports school initiatives across FEI's service area.
3(d)	If the plan portfolio is submitted on or after June 1, 2009, an education program for students enrolled in post-secondary institutions in the public utility's service area;	FEI's Conservation, Education and Outreach Program Area: FEI's School Education Program supports initiatives for post-secondary institutions across FEI's service area.

Section of the DSM Regulation	Adequacy Requirement	How FEI's DSM portfolio addresses adequacy
3(e)	One or more demand-side measures to provide resources as set out in paragraph (e) of the definition of "specified demand-side measure", representing no less than (i) An average of 1% of the public utility's plan portfolio's expenditures per year over the portfolio's period of expenditures, or (ii) An average of $2 million per year over the portfolio's period of expenditures;	FEI's Enabling Activities Program Area: provides funding and support for developing codes and performance standards at the municipal, provincial and national level for energy efficient products and codes. FEI provides resources for and collaborates with other partners and municipalities on implementation and adoption of codes and standards and adoption of the BC Energy Step Code.[162]
3(f)	One or more demand-side measures intended to result in the adoption by local governments and first nations of a step code or more stringent requirements within a step code.	FEI's New Home and Commercial New Construction Program: provides tiered incentives for BC Energy Step Code including a customized offer for Indigenous groups.

5.2.3 Summary

FEI's DSM activities are a key pillar of FEI's Clean Growth Pathway. As described in Section 3.4 FEI, through increased investments in DSM, will be expanding the Company's low- and zero-carbon solutions in buildings and commercial and industrial processes. FEI is focused on this key objective through activities managed by FEI's Conservation and Energy Management group and supporting teams throughout the organization. Over the planning horizon, FEI will maintain an adequate, cost-effective portfolio of DSM activities that will continue to contribute to energy savings, GHG emission reductions and a culture of conservation in British Columbia.

5.3 DSM POTENTIAL SAVINGS ARE ESTIMATED FOR EACH ALTERNATE FUTURE SCENARIO

5.3.1 Introduction

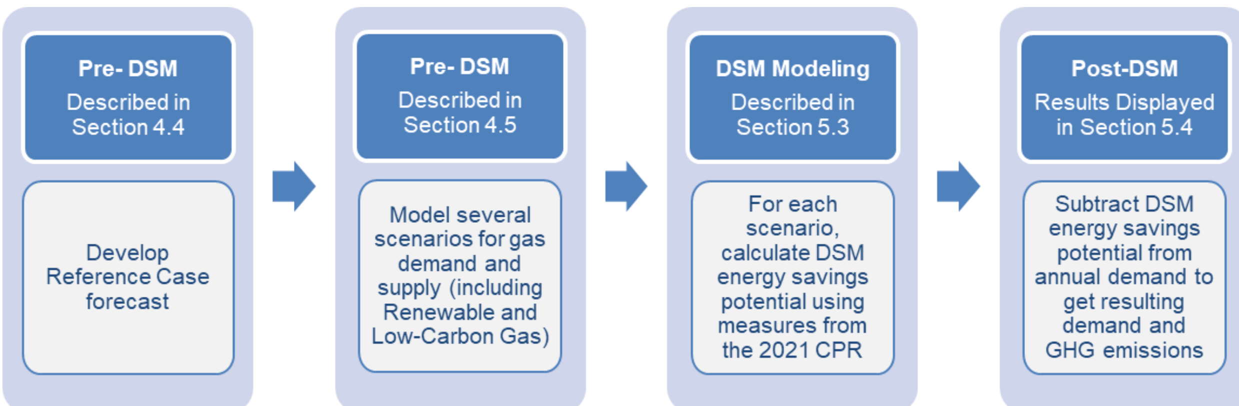
This section describes the 2022 LTGRP's DSM analysis used to develop energy savings forecasts from DSM activity for the scenarios set out in Table 5-1 above. As discussed in Section 4, the Reference Case forecast assumes that conditions that are present and legally enshrined in the planning environment when the demand forecasting exercise was undertaken prevail throughout the planning horizon. The Diversified Energy (Planning) Scenario represents FEI's planning scenario. The other scenarios (Deep Electrification, Price-Based Regulation, Economic Stagnation and Upper Bound) present a wide range of alternate futures for consideration in the

[162] BC Energy Step Code is an optional compliance path in the BC Building Code that local governments may use to incentivize or require a level of energy efficiency in new construction that goes beyond the BC Building Code requirements.

resource planning process. The impact of the DSM analysis on all scenarios is presented in Appendix C-2.

- Figure 5-1 illustrates how the modelling process used to develop DSM potential savings for each of the scenarios follows after the development of the demand forecast described in Section 4, and results in a post-DSM forecast of annual demand. DSM energy savings potential is estimated only for the built environment (residential, commercial and industrial sectors), as DSM programs do not apply to the LCT and Global LNG or New Large Industrial demand categories.

Figure 5-1: Overview of LTGRP DSM Modelling Process Conducted for Each Scenario



The modelling of the DSM impact for the Reference Case and each of the five scenarios was carried out in three key steps:

- The 2021 CPR was conducted to determine the technical, economic, and market potential for gas savings from 2020 to 2040.
- Five DSM Settings, from “Taper Off” to “High”, were developed based on incentive level, economic screen, and budget to estimate the total energy savings that could be achieved in the Reference Case and alternate future scenarios.
- The DSM potential for the Reference Case and each alternate future scenario was calculated based on the 2021 CPR, DSM Settings and the policy and economic conditions assumed in the Reference Case and each scenario.

Each of these steps is described below.

5.3.2 2021 Conservation Potential Review (CPR)

The 2021 CPR is the basis for long term DSM program analysis and reviews the energy efficiency opportunities available to FEI’s residential, commercial and industrial sectors. Using 2019 as the base year, the 2021 CPR determined the technical, economic, and market potential for gas savings from 2020 to 2040. The purpose of the 2021 CPR is not to recommend specific programs or targets to be implemented, but to examine available energy efficiency technologies, understand the inventory of energy equipment in a utility's service area, and determine the conservation potential that exists. Please refer to the 2021 CPR report included as Appendix C-1 of the Application for a description of the study approach and methods, including a summary of the study results.

The range of potential DSM measures based on the 2021 CPR results informs the 2022 LTGRP DSM analysis presented in Figure 5-1, including energy savings and expenditure estimates and projected cost-effectiveness test results. FEI's 2023 and future DSM expenditure plan applications will be informed by both the 2021 CPR and the 2022 LTGRP's DSM analysis.

The 2021 CPR and the 2022 LTGRP represent long term forecasts and do not include a request for acceptance from the BCUC for specific DSM expenditures.

5.3.3 DSM Settings Used in the Scenarios

Five DSM Settings were developed ranging from "Taper Off" to "High", to estimate the total energy savings that could be achieved in the Reference Case and alternate future scenarios. The DSM Settings are based on the following three variables:

- Incentive Level: The measure incentive levels (50 percent or 100 percent) of each measure's incremental cost. In general, higher incentives drive higher participation in DSM.
- Economic Screen: The economic screens (TRC, MTRC, or UCT) that determine which measures are included in the analysis.
- Budget Setting: Overall budget limitations, including both incentive spending and non-incentive program spending.

Table 5-3 below describes each of the five DSM Settings and the incentive level, economic screen and budget setting applied to each.

Table 5-3: DSM Settings

	Taper Off	Low	Medium UCT	Medium	High
Description	Assumes DSM spending tapers off as the province electrifies	Constrained to include only the most cost-effective measures. Only 50% incentive level is used, and measures must pass TRC > 1 (no MTRC).	Any incentive level is permitted, but measures must pass UCT > 2 and MTRC or TRC >1. This represents more efficient budget spending.	Similar to the 2021 CPR's medium market potential scenario where adoption of measures is based on incentives covering 50% of a measure's incremental cost	Similar to the 2021 CPR's high market potential scenario where adoption of measures is based on incentives covering 100% of a measure's incremental cost
Incentive Level	Any incentive level is permitted	50% of measure incremental cost	Any incentive level is permitted	50% of measure incremental cost	100% of measure incremental cost
Economic Screen	Passes either TRC>1 or MTRC>1	Passes TRC>1	Passes TRC>1 or MTRC>1 and UCT>2	Passes TRC>1 or MTRC>1	Passes TRC>1 or MTRC>1
Budget Setting	Budget limited to 50% of 2022 spending in 2023, declining to 25% of 2022 spending by 2042	No budget limit applied	No budget limit applied	No budget limit applied	No budget limit applied

Table 5-1 shows which DSM setting was applied to each scenario based on how it aligned with the scenario narrative in Section 4. FEI selected the High DSM Setting for the Diversified Energy (Planning) Scenario. Consistent with the Clean Growth Pathway, the High DSM Setting maximizes energy savings potential and therefore the potential to reduce GHG emissions by accelerating building retrofits, high performance new construction and energy efficiency in commercial and industrial processes. The choice of the High DSM Setting is also consistent with the positive support from the RPAG, Energy Efficiency Advisory Committee (EECAG) and community engagement sessions for FEI to undertake high levels of DSM.

5.3.4 Estimation of the DSM Potential for Each Scenario

The next step in the DSM analysis is to determine the potential for energy savings for each of the scenarios. As discussed in Section 4 and Appendix B-3, different combinations of settings for Critical Uncertainties were used to reflect various economic and policy conditions when developing the scenarios.

The following steps were taken to estimate the DSM savings for each scenario:

1. ***Create a DSM baseline for each scenario*** based on the scenario input assumptions, including customer account growth, the level of fuel switching (price- and policy-driven),

the stringency of codes and standards and other factors. These input assumptions affect measure potential in the following ways:

- The number of building units to which a measure is applicable varies from one scenario to another. For example, differences in the number of new building units being constructed impacts potential for measures applicable to new buildings. Differences in the fuel share of existing building units and end uses to which the measure applies impacts potential as, for example, decreased gas fuel share for an end use means less potential for applicable measures.
- The savings potential for a measure may change because the unit energy consumption (pre-DSM) may be different from one scenario to another. For example, more aggressive improvements in insulation or furnace efficiency as part of an advanced carbon policy scenario will mean less energy savings potential for advanced thermostats in the DSM estimate.

2. ***Apply DSM measures*** by incorporating the CPR's measure assumptions.
3. ***Calculate technical potential*** using applicability and Reference Case adoption rates adjusted for the avoided cost of energy in each scenario. In scenarios where more advanced codes and standards are assumed, certain measures require further adjustments to applicability and reference case adoption rates to reflect those assumptions.
4. ***Calculate economic potential*** based on the economic screen specified in the DSM Setting for the scenario and the avoided costs. These inputs affect measure potential in the following ways:
   - For scenarios in which MTRC is the economic screen, more measures will pass than for those in which TRC is the screen. Where the Medium UCT is the economic screen, measures must also pass a UCT screen.
   - The avoided cost of conventional natural gas varies from one scenario to another. Higher avoided costs for natural gas, due to commodity cost increases or higher carbon price, results in more measures passing the TRC and UCT tests. Note that this mechanism does not affect the MTRC results, as MTRC uses the Zero-Emission Energy Supply Alternative avoided cost, rather than the natural gas avoided cost.
5. ***Calculate market potential*** based on the participation rates (measure uptake) for the scenario. Measure participation rates for each incentive level are adjusted in each scenario based on the avoided costs and retail rates; avoided cost tends to drive retail rates in the long run. Therefore, in the scenarios where avoided costs change, the retail rates are assumed to change in proportion. Higher retail rates make measures more attractive to the end user, because the simple payback after incentive will be shorter. This is assumed to increase program uptake.
6. ***Incorporate program costs*** using the assumptions specified in the DSM Setting for the scenario. In the CPR, there were three incentive levels (25 percent, 50 percent, and 100

percent of measure incremental costs) and non-incentive program costs were assumed to be 15 percent of the corresponding incentive costs. The DSM Setting specifies which incentive level(s) and associated participation rates to use for the scenario.

- ***For the Deep Electrification Scenario Only: Iterate to find the optimal solutions of measures that meet the program budget.*** The process involves multiple iterations to solve for an economic screening threshold in each year that allows just enough measures to pass the screen so that the program spending is below a specified limit for that year. This capability was used for the "Taper Off" Setting which was applied only to the Deep Electrification Scenario. All other scenarios use the spending value that is calculated from implementing all the measures that pass the screening with no budget limit imposed.

7. ***Apply the energy savings potential to annual demand.*** The energy savings are subtracted from the DSM baseline to calculate the resulting annual demand for the scenario. Similarly, the GHG reductions associated with the measure savings are subtracted from the emissions baseline to calculate the resulting GHG emissions post-DSM for the scenario.

5.3.5 Summary

In short, the DSM analysis estimates the potential impact of DSM programs by tailoring the results of the 2021 CPR to the economic and policy considerations reflected in each scenario. This enables FEI to calculate post-DSM annual demand forecasts for each scenario. The results presented in Section 5.4 focus on the Diversified Energy (Planning) Scenario in comparison to the Reference Case. A chart illustrating results for all scenarios is presented in Appendix C-2.

5.4 *RESULTS OF LONG-TERM DSM ANALYSIS*

This section provides estimated DSM savings, expenditures and cost-effectiveness test results for a number of illustrative comparisons of the DSM analysis and its impact on annual demand for gas for the Diversified Energy (Planning) Scenario and Reference Case.[163] In most cases, the analysis is presented for all sectors combined, followed by the individual residential, commercial and industrial sectors.

The LTGRP DSM analysis provides the outcome of pursuing all cost-effective energy savings potential based on the economic screen used for each scenario. It is important to recognize that the CPR and the 2022 LTGRP DSM analysis display only a theoretical estimate of DSM uptake in relation to the ratio between incentive levels and measure incremental costs. These estimates take into account program experience and technology diffusion for a long-term forecast of estimated DSM potential and activity. In contrast, FEI's DSM expenditures plan takes into account

[163] A chart illustrating the results for all scenarios is presented in Appendix C-2, Figure C2-1 and C2-2.

operational program delivery factors, such as staffing levels or specific program eligibility rules, when developing a DSM expenditure plan application.

5.4.1 The Effects of the Low, Medium and High DSM Settings in the Diversified Energy (Planning) Scenario

In recognition of the key role for DSM in decarbonization and as a key pillar in the Clean Growth Pathway, and in response to positive support in RPAG, EECAG and community engagement sessions for FEI to undertake high levels of DSM, FEI selected the High DSM Setting for the Diversified Energy (Planning) Scenario. This setting maximizes GHG reduction potential and contributes to BC's objectives for accelerating building retrofits, high performance new construction and energy efficiency in commercial and industrial processes.

In its acceptance of the 2017 LTGRP (Order G-39-19) and prior resource plan submissions, the

BCUC provided a number of directives and suggestions for FEI to integrate in future resource plans. This section fulfills Directive 3 requesting that FEI provides the following information, in the next LTGRP:

- DSM funding scenarios, reflecting the results of the most recent CPR, that include a "reference" DSM funding scenario with "high DSM" and "low DSM" scenarios that are relative to the reference scenario.
- An analysis of each DSM scenario, at a portfolio level and for each DSM category (residential, low income[164], commercial etc.), including:
    - TRC and MTRC cost test results; and
    - UCT expressed as a ratio and CCE expressed as $/GJ.
- The delivery rate impact and estimated total bill impact (in dollar and percentage) demonstrated for high and low gas usage residential customers.

As directed, FEI conducted additional analysis to understand a broad range of outcomes for DSM potential under the Diversified Energy (Planning) Scenario (DEP), which is now the equivalent to the "reference" scenario referred to in the directive. The additional analysis involved applying the Low and Medium DSM Settings to vary the incentive level for measures and develop a range of outcomes in the modelling process. The Reference Case is provided for comparison. The results of this analysis are shown in Figure 5-2, Figure 5-3, and Figure 5-4 below.

[164] Refer to Section 5.2.3.2 for description of low-income program area.

Figure 5-2: Diversified Energy (Planning) or DEP Scenario DSM Savings Potential – 3 DSM Settings

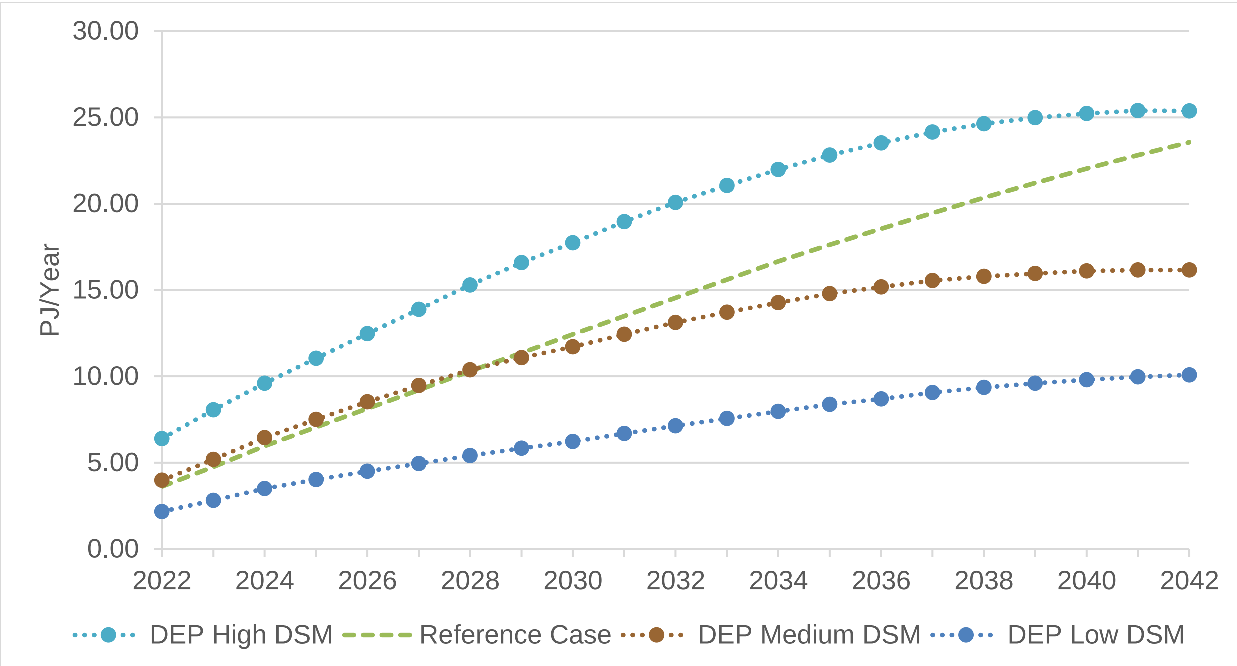


Figure 5-2 illustrates the energy savings potential of DSM activities over the long term. The PJ per year savings reflect savings from all measures providing savings in that year, including those measures where incentives were paid in prior years but the installed measure or upgrade are still operational. As shown in Figure 5-2, in 2042, DSM savings potential would be forecast as:

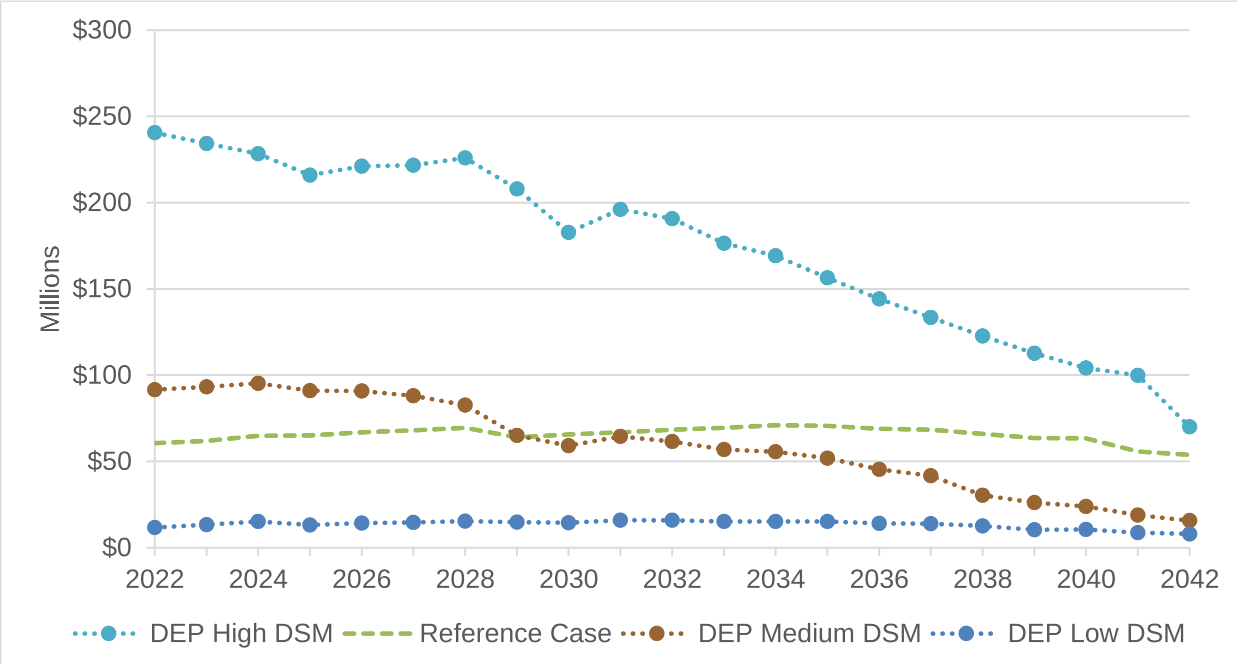
- 25 PJ for the DEP High Scenario;
- 16 PJ for the DEP Medium Scenario; and
- 10 PJ for the DEP Low Scenario.

Energy savings from the Reference Case (Medium DSM Setting) is 24 PJ which is almost equivalent to the DEP High Scenario. This is due to the high proportion of conventional natural gas and very limited electrification in this scenario and therefore there is a relatively higher potential for DSM savings.

Figure 5-3: Diversified Energy (Planning) or DEP Scenario DSM Expenditures – 3 DSM Settings

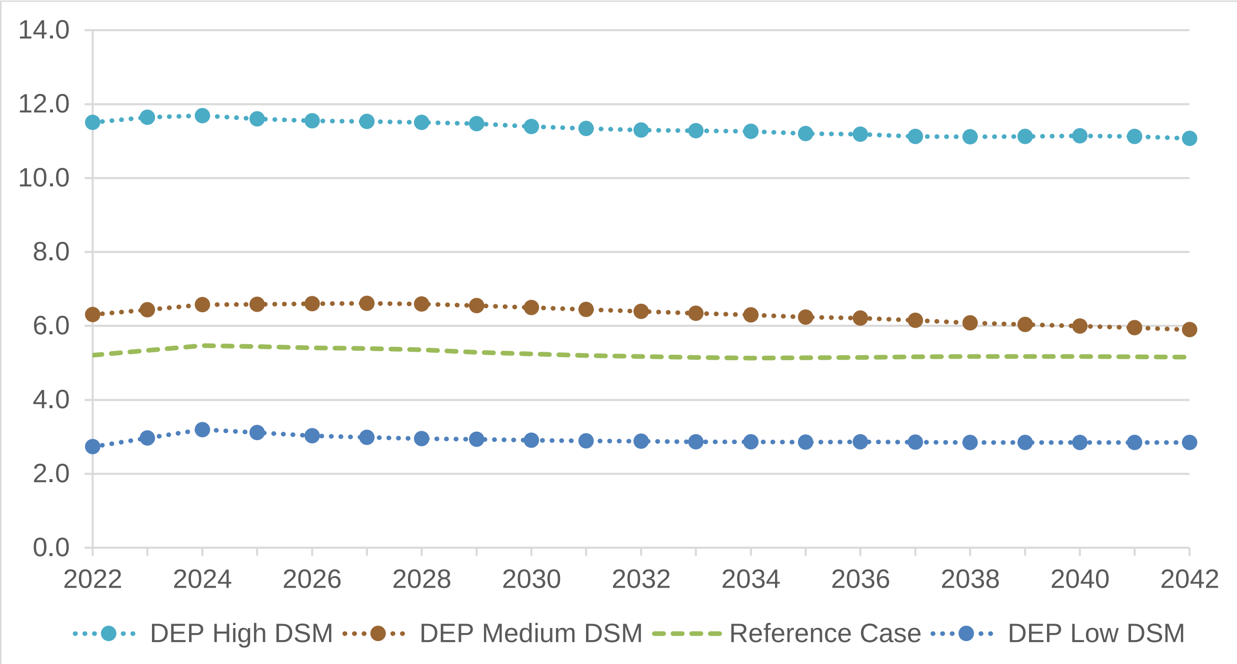


As shown in Figure 5-3, in 2042 annual DSM potential expenditures would be forecast as:

- $70 Million for the DEP High Scenario;
- $16 Million for the DEP Medium Scenario;
- $8 Million for the DEP Low Scenario; and
- $54 Million for the Reference Case.

The decline in DSM investment over the planning horizon is an artifact of the model in that DSM is allocated to conventional gas. For this reason, activity wanes by 2042 when renewable and low-carbon gas makes up a large proportion of the fuel mix. FEI will assess updating the model in the next LTGRP to include all fuel types and FEI is committed to maintaining a high level of DSM investment over the planning horizon as a key pillar in the Clean Growth Pathway.

Figure 5-4: Diversified Energy (Planning) or DEP Scenario CCE ($'s/GJ) – 3 DSM Settings



In Figure 5-4, the Cost per unit of Conserved Energy (CCE $'s/GJ) is provided and demonstrates the effect of the DSM Settings over the planning horizon. In 2042, the CCE would be forecast as:

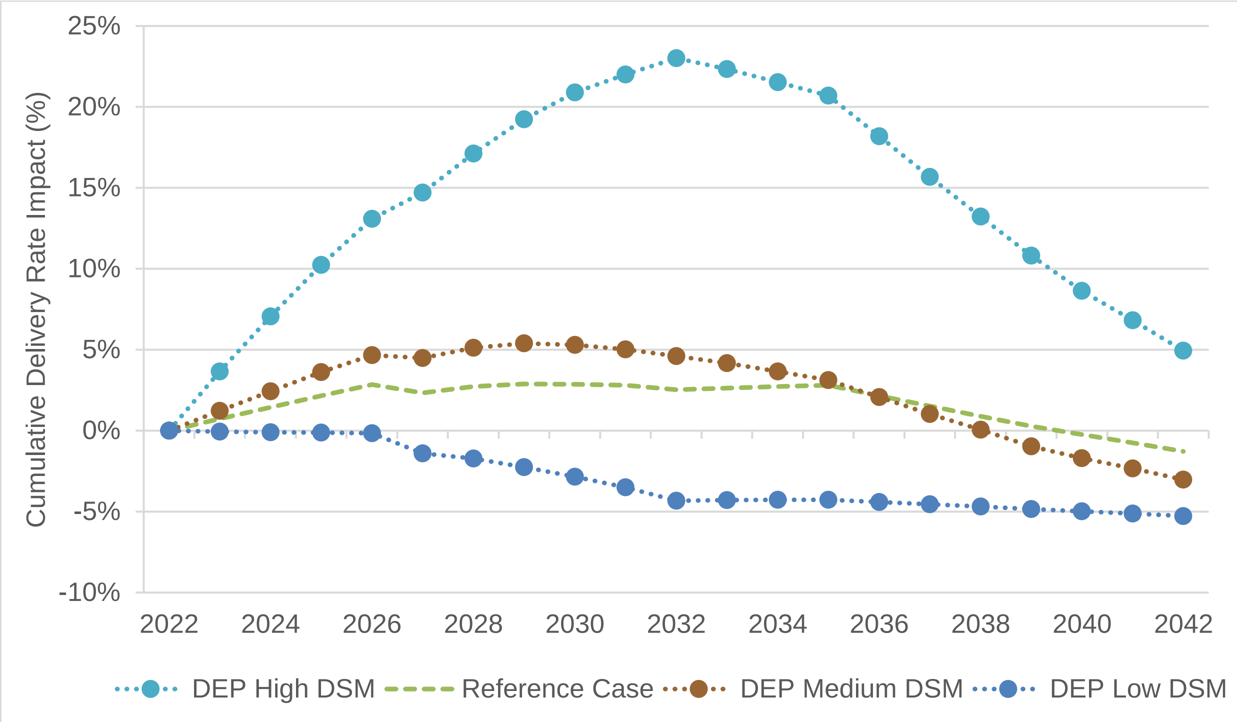
- $11.1 per GJ for the DEP High Scenario;
- $5.9 per GJ for the DEP Medium Scenario;
- $2.8 per GJ for the DEP Low Scenario; and
- $5.2 per GJ for the Reference Case

In Section 2.4, Figure 2-3, FEI forecasts that in 2042 natural gas plus carbon tax would be over $12 per GJ and renewable and low-carbon gas would be over $24 per GJ. Therefore, the CCE value of $11.1 per GJ for the DEP High Scenario will be cost effective. The CCE illustrates that DSM activities are valuable tools in GHG emission reductions, as saving one additional unit of energy (renewable, low-carbon or conventional natural gas) will be beneficial to customers over the planning horizon.

5.4.2 Delivery Rate and Bill Impact of Low, Medium and High DSM Settings

To provide further context on residential customer impact, Figure 5-5 below provides a directional look at the potential delivery rate impact (compared to the approved 2022 delivery rates) of the different DSM Settings (Low, Medium, and High) under the DEP scenarios. The delivery rate impact for the Reference Case is also included for comparison. Presenting this analysis addresses part of BCUC Directive No 3 from the 2017 LTGRP decision (see Table 1-7).

Figure 5-5: Estimated Delivery Rate Impact due to Low, Medium and High DSM Settings



Figures 5-6 to 5-8 below also provide the equivalent annual total bill impact (including commodity, delivery, carbon tax, and GST) in percentage term due to Low, Medium, and High settings of DSM under the DEP scenario from 2022 to 2042, respectively for residential customers with consumption level range from 5 to 250 GJ annually. It can be seen that the average annual bill impact due to DSM under the DEP scenario ranges in this analysis from 0.18 percent to 0.31 percent across all residential customers, depending on the DSM Settings. Furthermore, it can be seen that for residential customers that have an annual consumption of approximately 75 GJ, which is the majority of FEI's residential customers, the cumulative bill impact in 2042 due to DSM programs under the DEP scenario ranges from $8 to $15 per month average depending on the DSM Settings. FEI notes the figures do not consider future rate design changes and are not indicative of a detailed bill forecast. They simply provide a directional view of the estimated 2042 bill impact due to DSM when compared to currently approved rates in 2022[165].

[165] The analysis indicates estimated bill impacts from the perspective of a customer that does not participate in DSM programs. DSM program participants are likely to experience cost savings on their bills.

Figure 5-6: Estimated Cumulative Bill Impact for Residential Customers (5 GJ to 250 GJ) due to DSM under the Diversified Energy (Planning) Scenario – Low DSM Setting

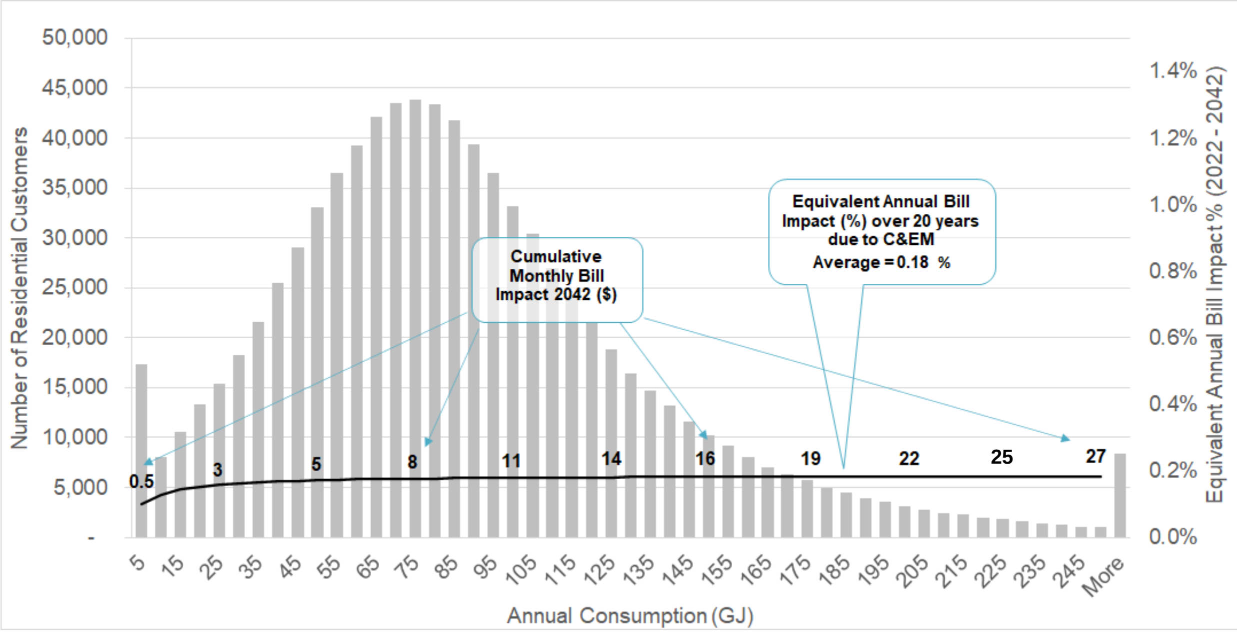


Figure 5-7: Estimated Cumulative Bill Impact for Residential Customers (5 GJ to 250 GJ) due to DSM under the Diversified Energy (Planning) Scenario – Medium DSM Setting

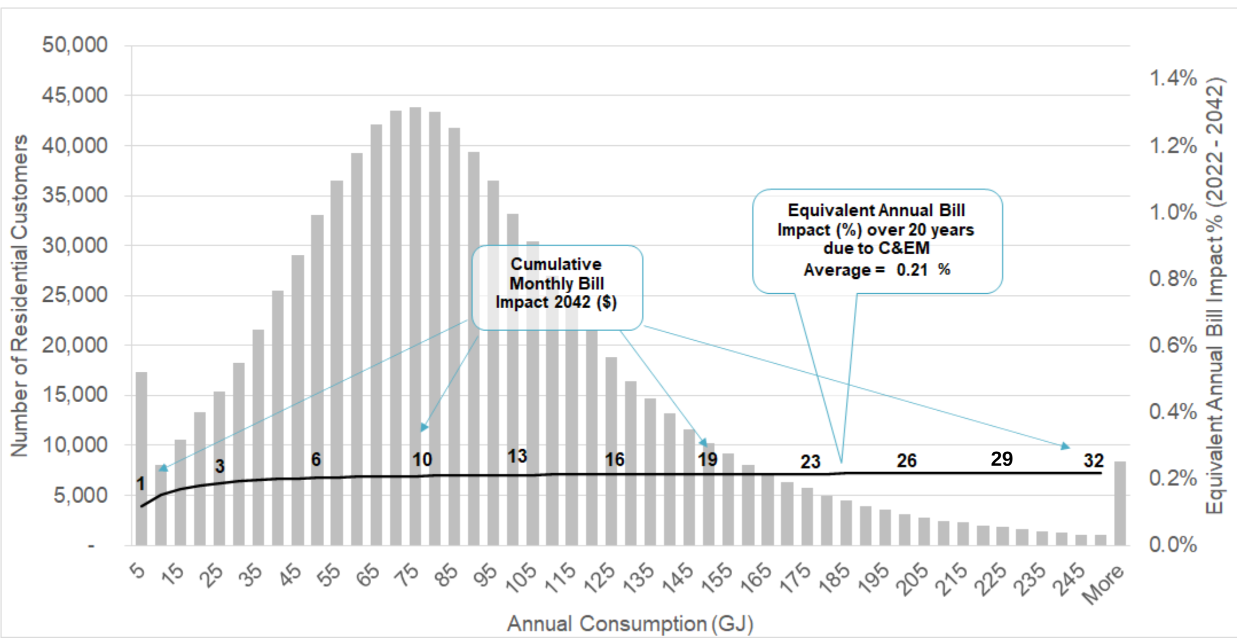

Figure 5-8: Estimated Cumulative Bill Impact for Residential Customers (5 GJ to 250 GJ) due to DSM under the Diversified Energy (Planning) Scenario – High DSM Setting

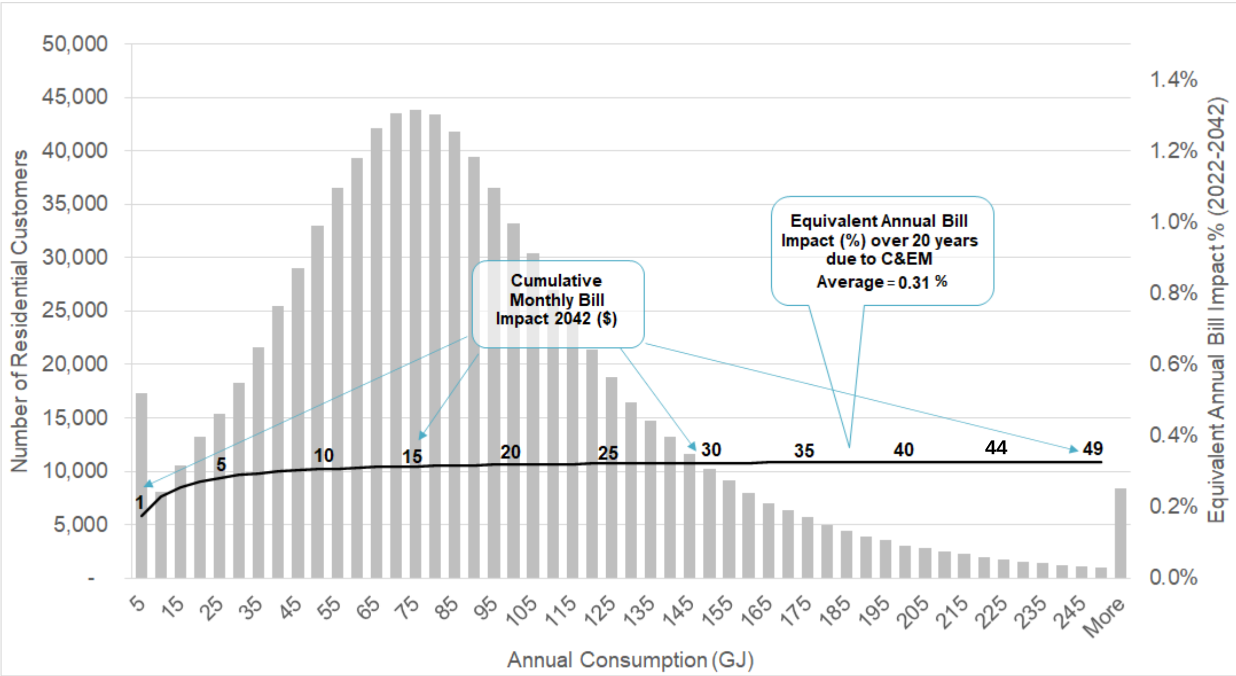

5.4.3 Total Annual Demand after DSM Savings – Excluding LCT

Figure 5-9 below illustrates annual energy demand, excluding LCT, before and after estimated DSM energy savings for all sectors combined, illustrated for the DEP and Reference Case scenarios. In terms of cumulative energy savings across the planning horizon, by 2042:

- Cumulative DEP High energy savings exceed the DEP Medium savings by 54 percent;
- Cumulative DEP High energy savings exceed the Reference Case energy savings by 31 percent;
- DEP High annual energy savings are forecast to account for a 13 percent reduction in demand in 2042 while DEP Medium are forecast to account for an 8 percent reduction; and
- Reference Case annual energy savings are forecast to account for a 11 percent reduction in Reference Case projected demand in 2042.

Figure 5-9: Annual Demand Before and After Estimated DSM Savings (Excluding LCT) – All Sectors Combined

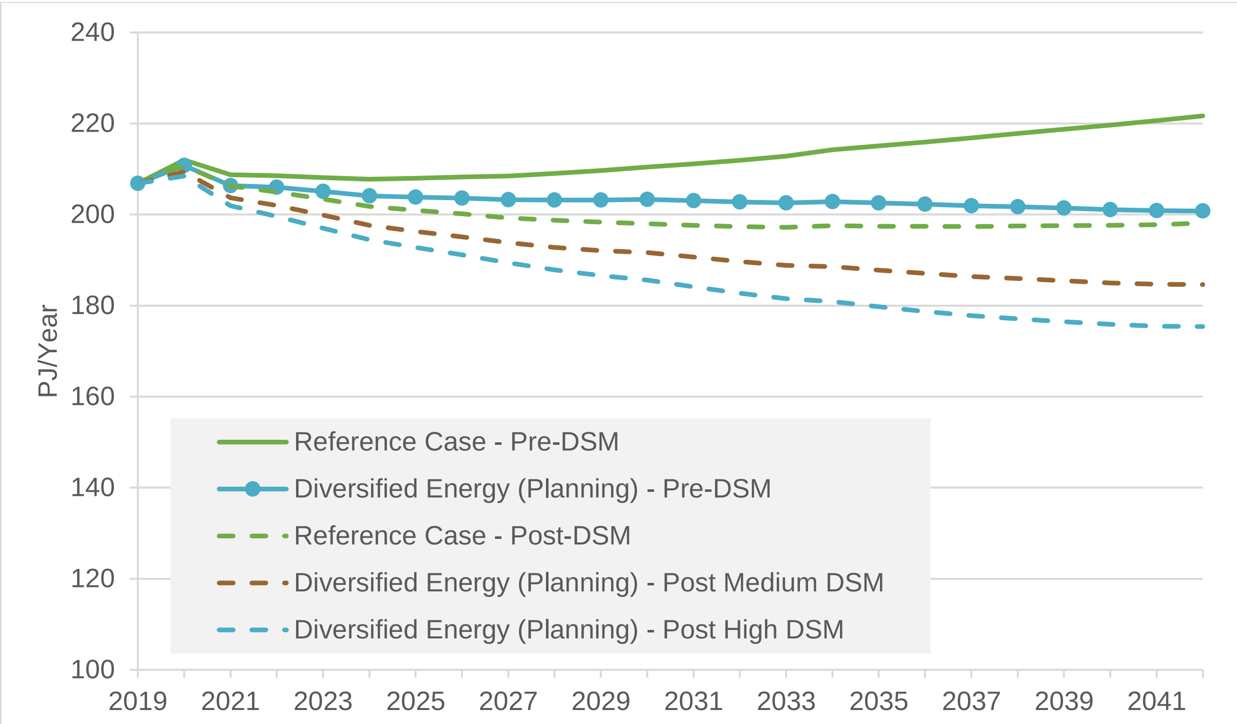

Figure 5-10 below illustrates annual energy demand, excluding LCT, before and after estimated DSM energy savings for the **residential sector**. In terms of cumulative energy savings across the planning horizon, by 2042:

- Cumulative DEP High energy savings exceed the DEP-Medium savings by 7 percent;
- Cumulative DEP High energy savings exceed the Reference Case energy savings by 5 percent;
- DEP High annual energy savings are forecast to account for a 14 percent reduction in and DEP Medium a 13 percent reduction in residential demand in 2042; and
- Reference Case annual energy savings are forecast to account for a 15 percent reduction in residential Reference Case demand in 2042.

Figure 5-10: Annual Demand Before and After Estimated DSM Savings (Excluding LCT) – Residential Sector

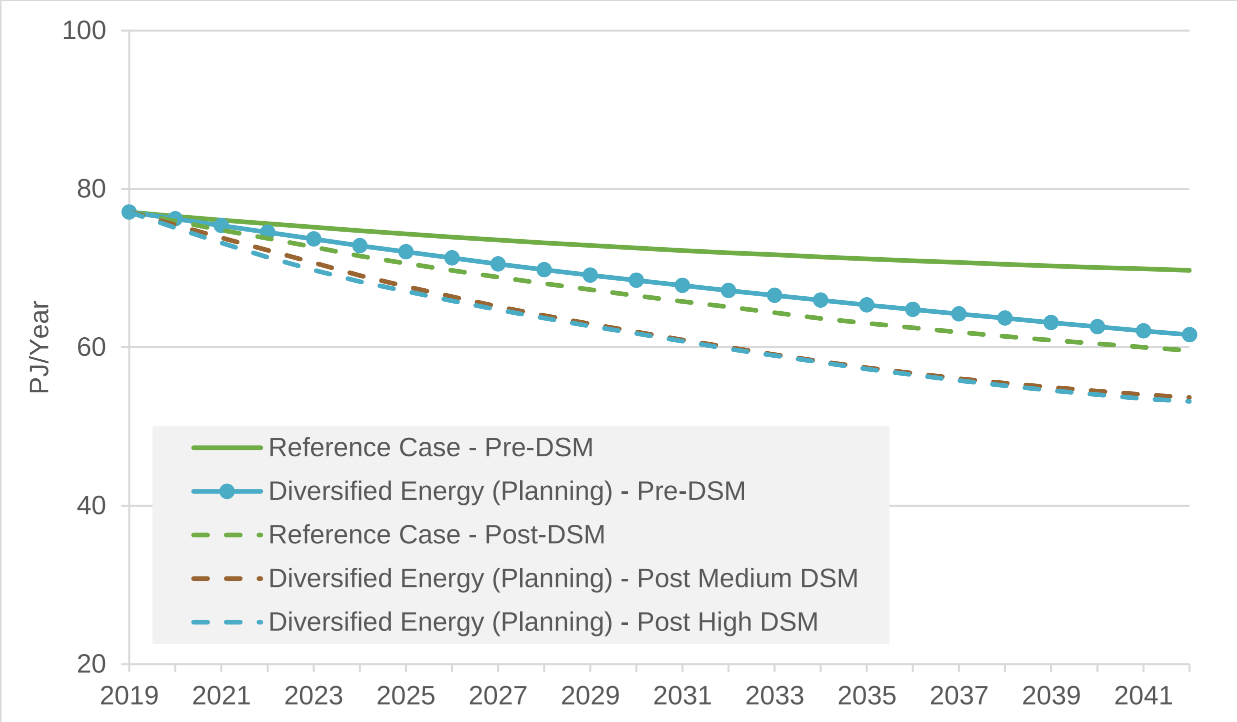

Figure 5-11 below illustrates annual energy demand, excluding LCT, before and after estimated DSM energy savings for the **commercial sector**. In terms of cumulative energy savings across the planning horizon, by 2042:

- Cumulative DEP High energy savings exceed the DEP-Medium savings by 168 percent;
- Cumulative DEP High energy savings exceed the Reference Case energy savings by 113 percent;
- DEP High annual energy savings are forecast to account for a 16 percent reduction and DEP Medium a 6 percent reduction in commercial projected demand in 2042; and
- Reference Case cumulative energy savings are forecast to account for an 8 percent reduction in commercial projected demand for the Reference Case in 2042.

Figure 5-11: Annual Demand Before and After Estimated DSM Savings (Excluding LCT) – Commercial Sector

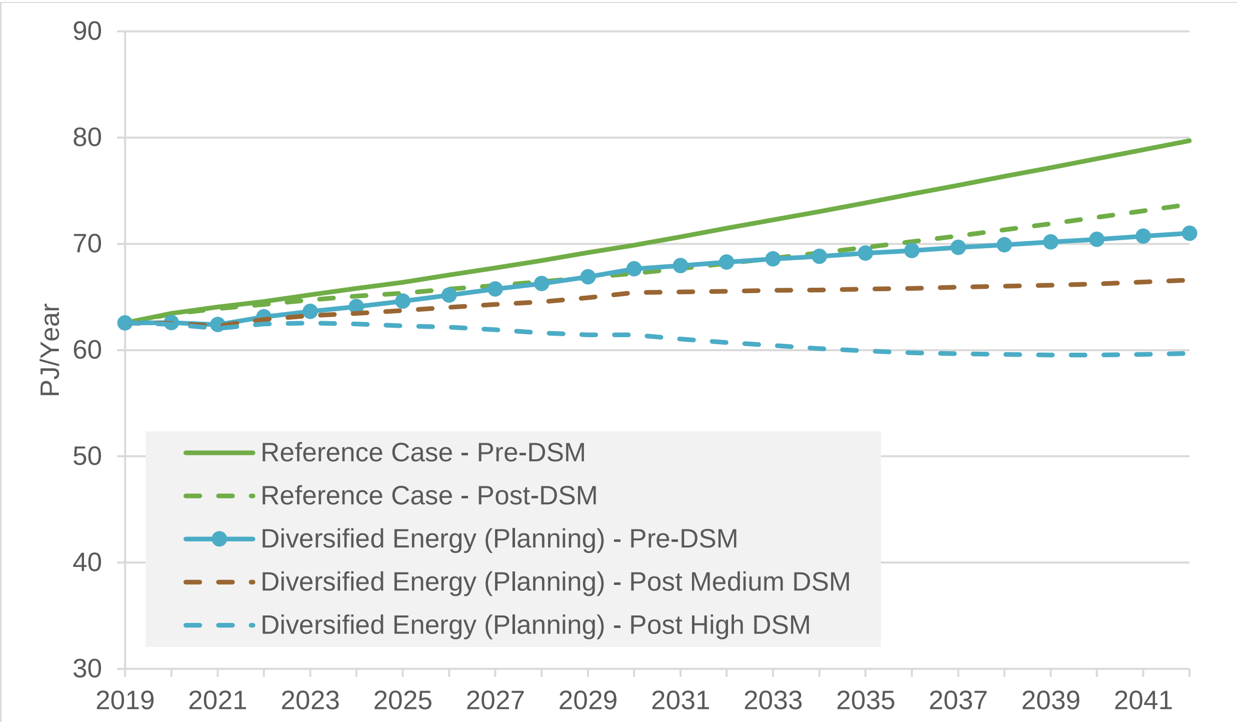

Figure 5-12 below illustrates annual energy demand, excluding LCT, before and after estimated DSM energy savings for the **industrial sector**. In terms of cumulative energy savings across the planning horizon, by 2042:

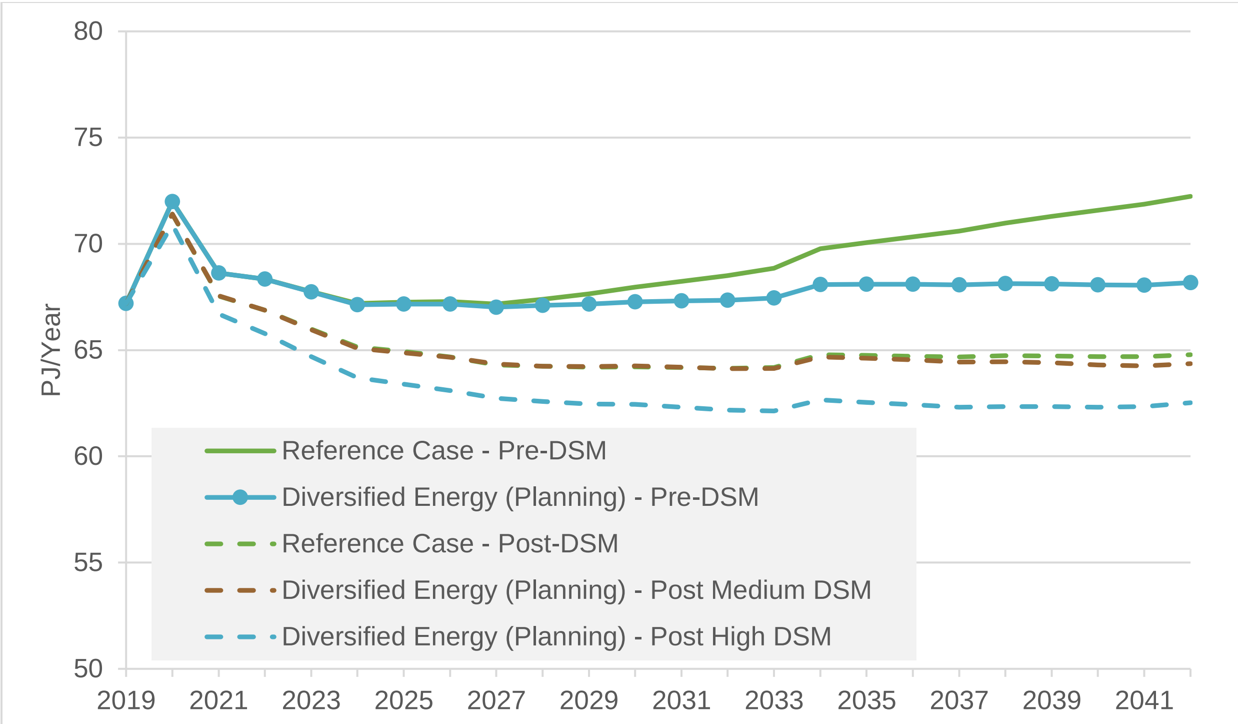
- Cumulative DEP High energy savings exceed the DEP-Medium savings by 59 percent;
- Cumulative DEP High energy savings exceed the Reference Case energy savings by 11 percent;
- DEP High annual energy savings are forecast to account for an 8 percent reduction and DEP Medium a 6 percent reduction in industrial projected demand in 2042; and
- Reference Case annual energy savings are forecast to account for a 10 percent reduction of industrial projected demand for the Reference Case in 2042.

Figure 5-12: Annual Demand Before and After Estimated DSM Savings (Excluding LCT) – Industrial Sector



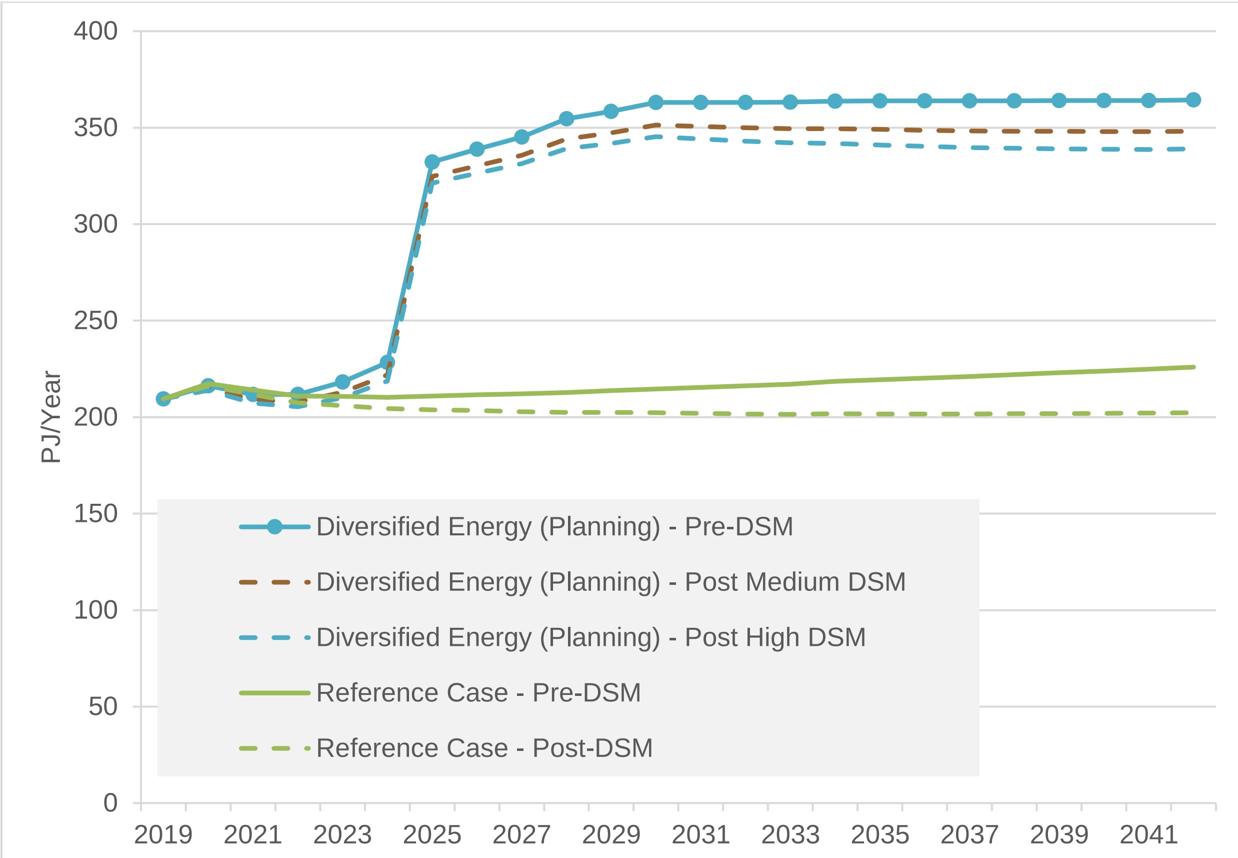
5.4.4 Total Annual Demand after DSM – Including LCT

The final step in the DSM analysis is to develop total annual demand post-DSM to demonstrate the resulting energy savings effects of projected DSM activity. Figure 5-13 below illustrates the following comparisons:

- The figure compares the Diversified Energy (Planning) Scenario pre-DSM analysis and post-DSM analysis for the High and Medium DSM Settings. A further comparison is made with the Reference Case pre-DSM analysis and post-DSM analysis (Medium DSM Setting). The demonstrated energy savings from DSM only include residential, commercial and industrial sectors. LCT demand is also included in the total annual demand forecast.
- In 2042, the DEP High is 7 percent lower, and the DEP Medium is 5 percent lower than the DEP pre-DSM Annual Demand when taking into account the impact of both forecast LCT and also DSM activity. This results in 25 PJ of annual energy savings for the High DSM Setting and 16 PJ of annual energy savings for the Medium DSM Setting.
- In 2042, the Reference case post-DSM is 12 percent lower resulting in 24 PJ of annual energy savings.

In conclusion, this Diversified Energy (Planning) Scenario total annual demand after DSM (shown as Diversified Energy (Planning) – Post High DSM in the figure below) represents the annual demand that FEI is planning to in the 2022 LTGRP.

Figure 5-13: Total Annual Demand After DSM - Including LCT



5.4.5 Long-Term DSM Expenditure Estimates

This section provides estimated DSM expenditures for a number of illustrative comparisons. First FEI presents a table of annual DSM expenditures for the DEP High DSM Setting. Then FEI presents a chart with an illustrative comparison of DEP High, DEP Medium, Reference Case and Upper Bound scenarios. These tables and charts are presented for all sectors combined, followed by the individual residential, commercial and industrial sectors.

The results presented in this section are long term expenditure estimates only and are informed by the results of the CPR and program experience.[166] The DSM expenditures and cost-effectiveness results discussed in the following sections are based on current regulation. Any future regulatory amendments that are in effect before the next LTGRP will be captured at that time.

These results do not take into account the following factors which flow into DSM expenditure plans and DSM annual reports to the BCUC:

[166] For this reason, individual DSM expenditure plans may contain higher or lower energy savings and expenditures in the short and medium term than indicated in the long term DSM analysis in the LTGRP.

- Non-incentive expenditures that support or enable DSM programs at the portfolio level, such as Enabling Activities and Conservation Education Outreach expenditures;[167]
- Operational program delivery considerations, such as changes in required DSM staffing levels or program eligibility requirements;
- Unanticipated market uptake of current technologies, emergence of new technologies more than five years into the future, or technologies which are currently unknown that may increase aggregate energy savings opportunities and thus enable greater actual DSM program expenditures and potentially savings across the planning period[168]; and
- Future DSM Regulation changes, and their impact on FEI's DSM portfolio, which could enable more DSM or result in fewer DSM program offerings.

The results shown in Table 5-4 represent the Diversified Energy (Planning) Scenario - High DSM Setting, for all sectors combined, as FEI recognizes the key role of DSM programs in the Clean Growth Pathway. There are a number of points for consideration in comparing the forecast annual expenditures for the 2022 DEP High DSM Setting ($241 million) and 2021 actual DSM portfolio level results ($107 million)[169], as follows:

- Estimated expenditures are more than double 2021 levels as a result of using the DEP High DSM Setting which may cover up to 100 percent of incentive levels to accelerate the adoption of energy efficient measures and building upgrades. In the current DSM environment, incentive levels are on average set at about 50 percent of incremental costs for the upgrade. These ratios vary per measure, per program and per program area.
- The LTGRP DSM analysis, like the CPR, also includes numerous energy efficiency measures which are not included, or have yet to be scaled, in FEI's current DSM program portfolio. For example, Deep Energy Retrofits represent significant energy savings potential. However, it will take time to establish the program and ensure a qualified workforce is available to support scaling these programs in residential, commercial and low income sectors.
- In this analysis, expenditures are estimated to be around $200 million until around 2030, when a decline in expenditures is demonstrated. This decline represents a greater proportion of renewable and low-carbon energy in the supply. As mentioned in Section 5.1, this software model was built on energy savings allocated to conventional gas taking priority as GHG reductions were emphasized at the time the model was built. The next LTGRP software modelling tool is anticipated to include DSM savings potential across all fuels.

[167] FEI expects these expenditures to continue but FEI's future DSM expenditure plans will determine to what extent.

[168] FEI does not project the actual expenditure impact of unforeseen future technologies as these depend on both their per-measure DSM expenditure and also their total DSM participation rate.

[169] 2019 was the base year for the CPR. DSM Annual Expenditures totaled $64.5 Million across the portfolio. 2021 DSM Annual Expenditures represents the most recent DSM Annual Report in which expenditures totaled approximately $107 Million.

Table 5-4: Estimated Diversified Energy (Planning) - High DSM Setting Expenditures – All Sectors Combined

	Diversified Energy (Planning) Scenario (Millions)		
Year	**Incentive Estimate**	**Non-Incentive Estimate**	**Total Estimate**
2022	$209	$31	$241
2023	$204	$31	$234
2024	$199	$30	$228
2025	$188	$28	$216
2026	$192	$29	$221
2027	$193	$29	$222
2028	$196	$29	$226
2029	$181	$27	$208
2030	$159	$24	$183
2031	$170	$26	$196
2032	$166	$25	$191
2033	$154	$23	$177
2034	$147	$22	$169
2035	$136	$20	$156
2036	$125	$19	$144
2037	$116	$17	$133
2038	$107	$16	$123
2039	$98	$15	$113
2040	$91	$14	$104
2041	$87	$13	$100
2042	$61	$9	$70

Figure 5-14 below provides comparisons of the estimated annual DSM expenditures for the DEP High, DEP Medium, and Reference Case. The DEP High DSM Setting provides the highest DSM investments, whereas the DEP Medium and Reference Case are both Medium DSM Settings and represent closely aligned expenditures. Cumulatively across the planning horizon, DEP High estimated expenditures exceed the DEP Medium estimated expenditures by 192 percent and exceed the Reference Case estimated expenditures by 166 percent. Refer to previous Section 5.4.1 to review a sensitivity analysis of the DSM Settings within the DEP (Planning) Scenario.

Figure 5-14: Estimated Annual Expenditures by Scenario – All Sectors Combined

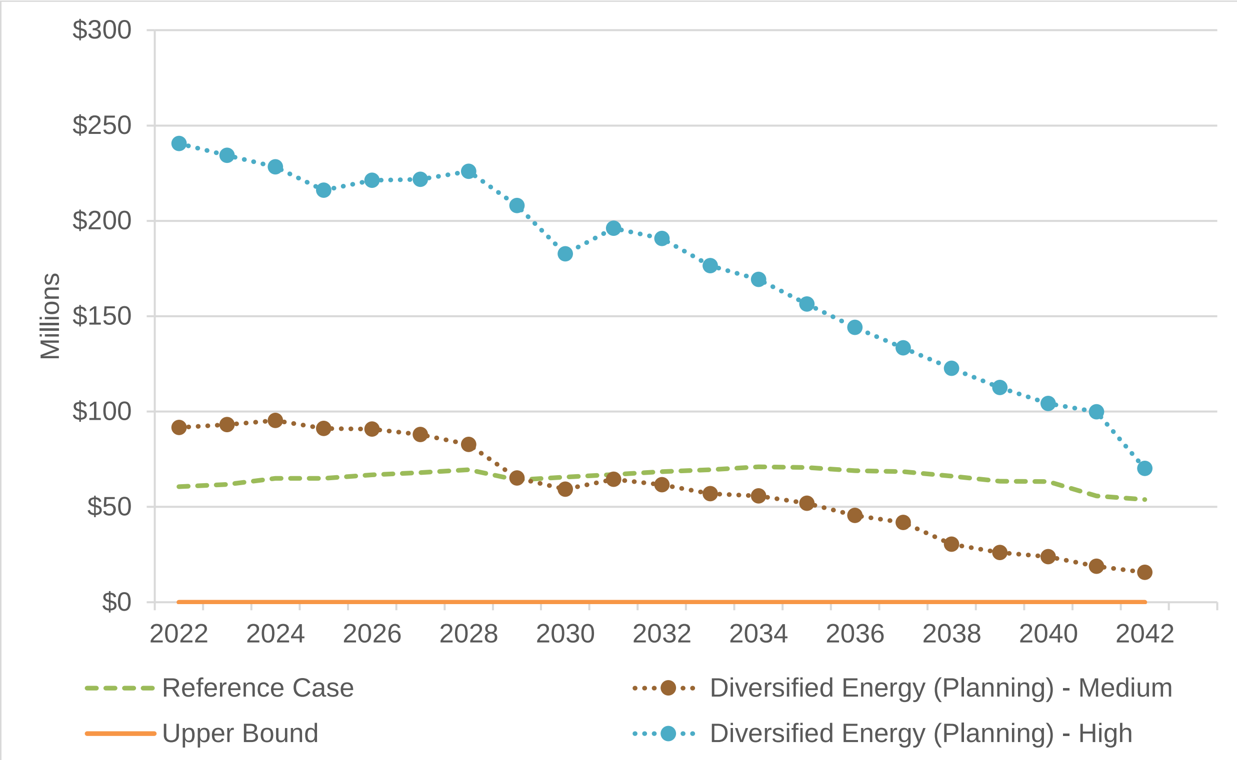


Table 5-5 below displays estimated annual DSM expenditures for the **residential sector**. Estimated expenditures are expected to decline over the years as available energy savings opportunities decline, for example through the introduction of new Minimum Efficiency Performance Standards and other codes. However, the decline in energy savings is partially an artifact of the current model where savings are based on reducing conventional natural gas, whereas after 2030 the proportion of renewable and low-carbon gas in the fuel mix grows significantly. In addition, in future DSM plans for the residential sector, technologies such as gas heat pumps, hybrid heating systems and deep energy retrofits may provide a higher energy savings opportunity than was foreseen when the CPR was being developed in 2019.

Table 5-5: Estimated Diversified Energy (Planning) Scenario - High DSM Setting Expenditures – Residential Sector

	Diversified Energy (Planning) Scenario (Millions)		
Year	Incentive Estimate	Non-Incentive Estimate	Total Estimate
2022	$156	$23	$180
2023	$142	$21	$164
2024	$125	$19	$144
2025	$103	$15	$118
2026	$96	$14	$110

	Diversified Energy (Planning) Scenario (Millions)		
Year	**Incentive Estimate**	**Non-Incentive Estimate**	**Total Estimate**
2027	$90	$14	$104
2028	$88	$13	$101
2029	$74	$11	$85
2030	$65	$10	$75
2031	$74	$11	$85
2032	$71	$11	$82
2033	$67	$10	$77
2034	$65	$10	$74
2035	$61	$9	$70
2036	$55	$8	$63
2037	$52	$8	$59
2038	$49	$7	$57
2039	$46	$7	$53
2040	$42	$6	$48
2041	$44	$7	$50
2042	$21	$3	$25

Figure 5-15 below further illustrates estimated annual DSM expenditures across the DEP High, DEP Medium and Reference Case scenarios for the **residential sector**. Cumulatively across the planning horizon, DEP High estimated expenditures exceed the DEP Medium estimated expenditures by 91 percent and exceed the Reference Case estimated expenditures by 90 percent.

Figure 5-15: Estimated Annual Expenditures by Scenario – Residential Sector

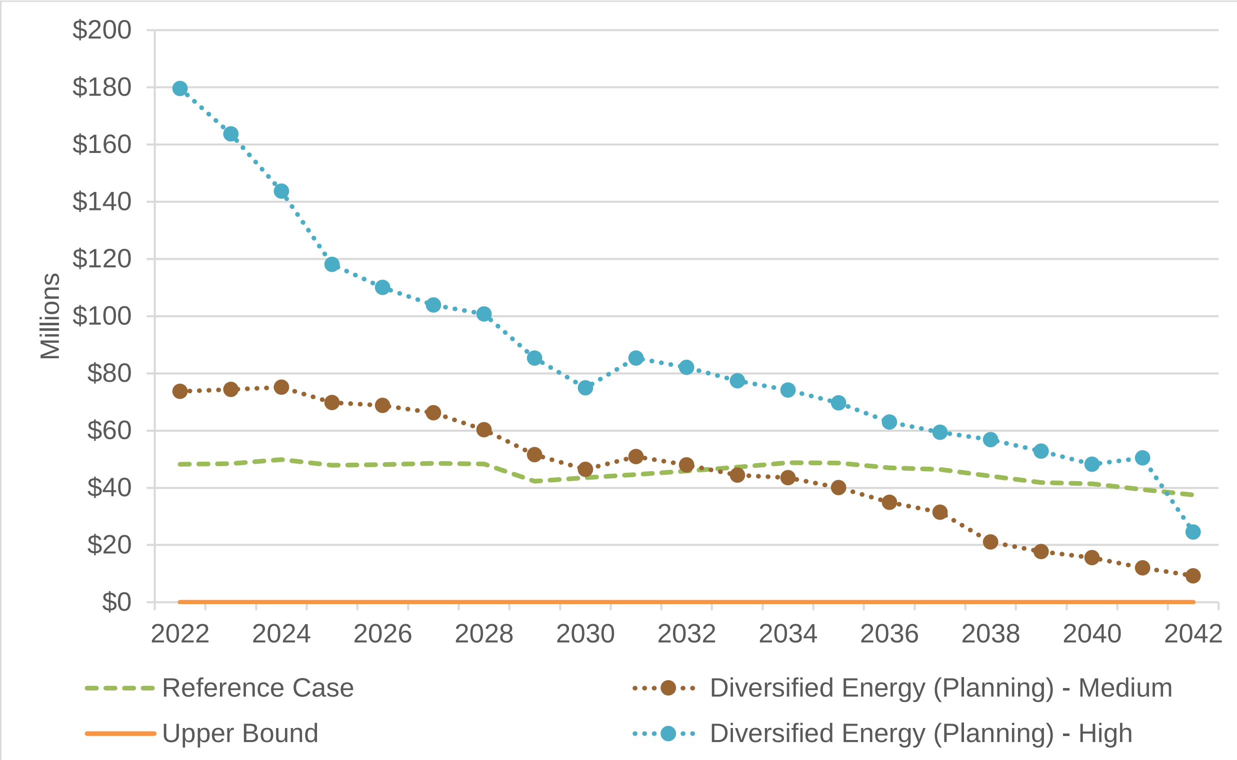

Table 5-6 below illustrates that estimated annual DSM expenditures for the **commercial sector** are expected to increase until 2031, and then decline after this year towards the end of the planning horizon. However, as discussed for the residential sector, the decline in energy savings is partially an artifact of the current model where savings are based on reducing conventional natural gas. In addition, in future DSM plans for the commercial sector, technologies such as gas heat pumps, hybrid heating systems and deep energy retrofits may provide a higher energy savings opportunity than was foreseen when the CPR was being developed in 2019.

Table 5-6: Estimated Diversified Energy (Planning) Scenario – High DSM Setting Expenditures Commercial Sector

	Diversified Energy (Planning) Scenario (Millions)		
Year	Incentive Estimate	Non-Incentive Estimate	Total Estimate
2022	$27	$4	$31
2023	$39	$6	$44
2024	$53	$8	$61
2025	$66	$10	$76
2026	$79	$12	$91
2027	$87	$13	$100
2028	$93	$14	$107

	Diversified Energy (Planning) Scenario (Millions)		
Year	Incentive Estimate	Non-Incentive Estimate	Total Estimate
2029	$93	$14	$107
2030	$89	$13	$103
2031	$91	$14	$105
2032	$89	$13	$103
2033	$82	$12	$94
2034	$78	$12	$90
2035	$71	$11	$81
2036	$66	$10	$76
2037	$60	$9	$69
2038	$54	$8	$62
2039	$50	$7	$57
2040	$46	$7	$53
2041	$41	$6	$47
2042	$38	$6	$43

Figure 5-16 below illustrates estimated annual DSM expenditures across the DEP High and DEP Medium and Reference Case scenarios for the **commercial program sector.** Cumulatively across the planning horizon, DEP High estimated expenditures exceed the DEP Medium by 753 percent and exceed the Reference Case by 559 percent.

Figure 5-16: Estimated Annual Expenditures by Scenario – Commercial Sector

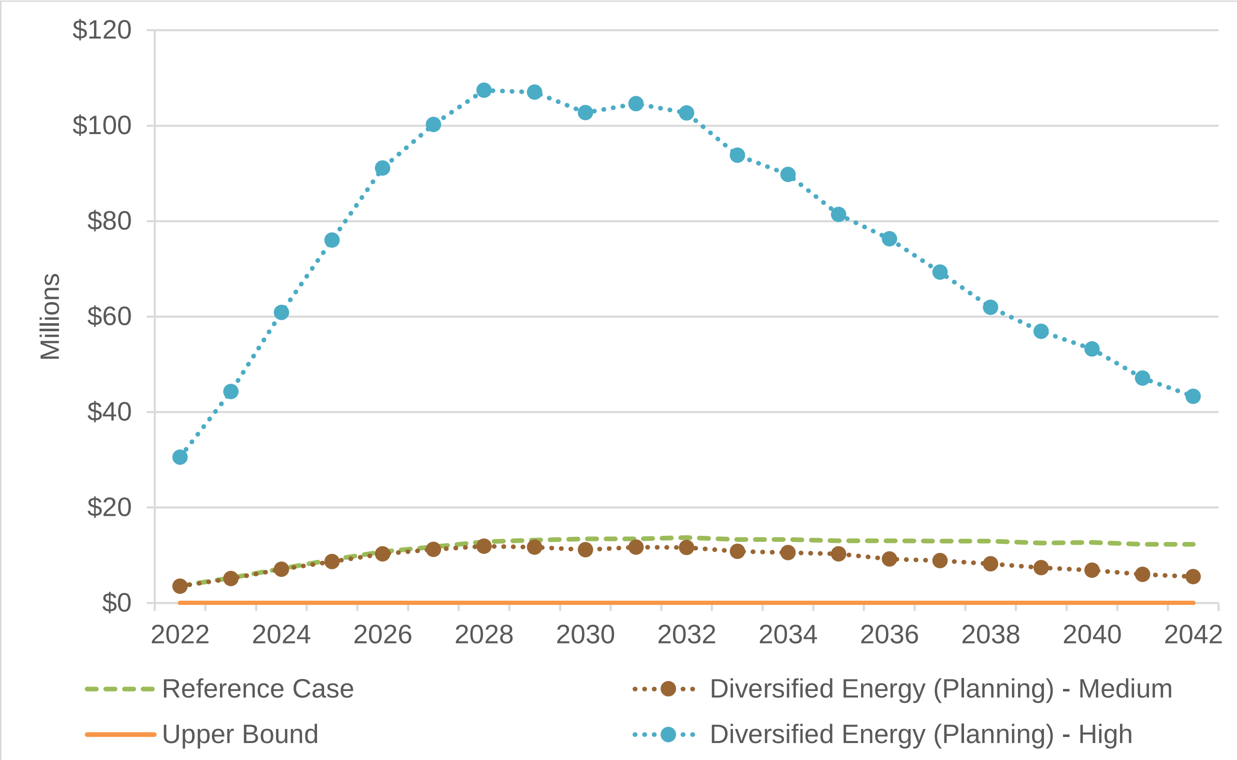

Table 5-7 below displays estimated annual DSM expenditures for the **industrial sector.** Estimated expenditures are expected to decline after 2022 towards the end of the planning horizon as available energy savings opportunities decline. However, as discussed for the residential and commercial program areas, the decline in energy savings is partially an artifact of the current model. The industrial sector can be difficult to decarbonize and poses many possibilities for direct-to-customer clean energy projects in the Clean Growth Pathway. These decarbonization priorities may not be categorized as traditional DSM energy savings opportunities but may provide significant opportunities for GHG emission reductions.

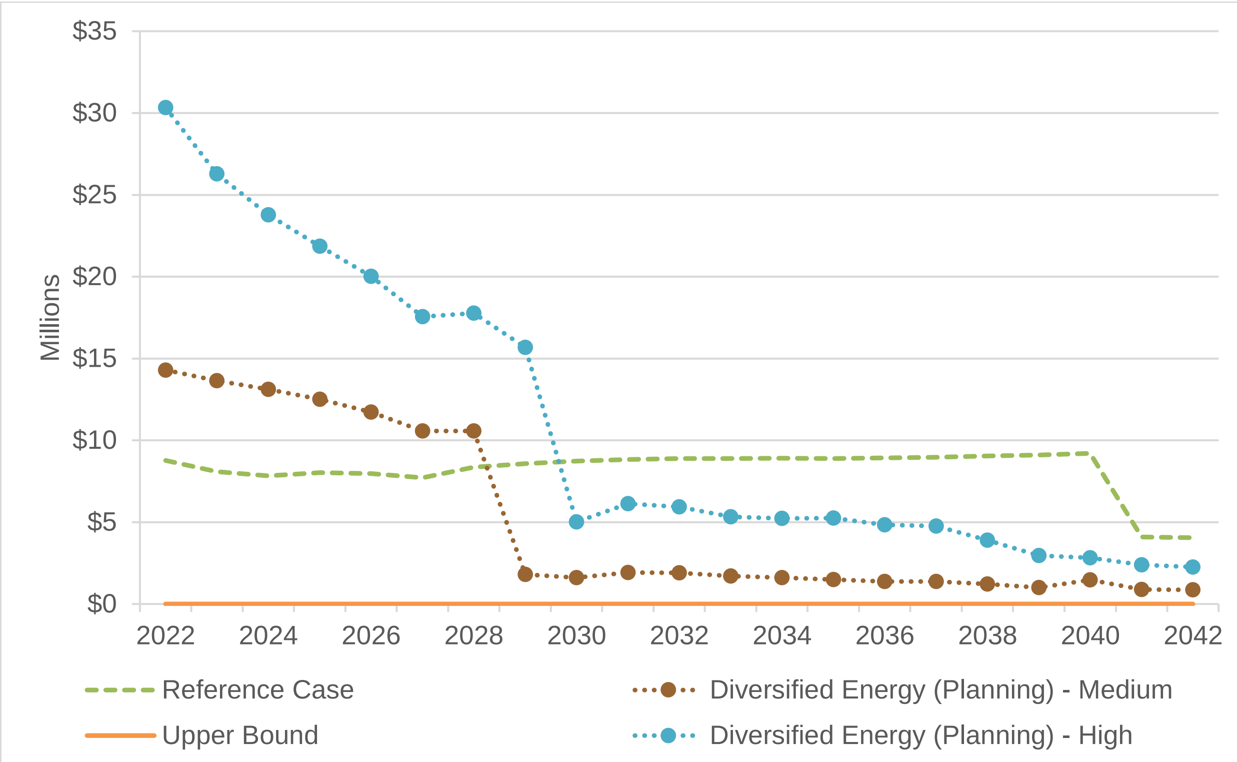
Table 5-7: Estimated Diversified Energy (Planning) Scenario – High DSM Setting Expenditures – Industrial Sector

	Diversified Energy (Planning) Scenario (Millions)		
Year	Incentive Estimate	Non-Incentive Estimate	Total Estimate
2022	$26	$4	$30
2023	$23	$3	$26
2024	$21	$3	$24
2025	$19	$3	$22
2026	$17	$3	$20
2027	$15	$2	$18

	Diversified Energy (Planning) Scenario (Millions)		
Year	Incentive Estimate	Non-Incentive Estimate	Total Estimate
2028	$15	$2	$18
2029	$14	$2	$16
2030	$4	$1	$5
2031	$5	$1	$6
2032	$5	$1	$6
2033	$5	$1	$5
2034	$5	$1	$5
2035	$5	$1	$5
2036	$4	$1	$5
2037	$4	$1	$5
2038	$3	$1	$4
2039	$3	$0	$3
2040	$2	$0	$3
2041	$2	$0	$2
2042	$2	$0	$2

Figure 5-17 below illustrates estimated annual DSM expenditures across the DEP High, DEP Medium and Reference Case scenarios for the **industrial sector**. Cumulatively across the planning horizon, DEP High estimated expenditures exceed the DEP Medium by 116 percent and exceed the Reference Case by 34 percent.

Figure 5-17: Estimated Annual Expenditures by Scenario – Industrial Sector



5.4.6 Long-Term Cost-Effectiveness Estimates for all Sectors Combined

Section 5.4.6 provides cost-effectiveness estimates for a number of illustrative comparisons. First Table 5-8 summarizes cost-effectiveness results (TRC, MTRC, UCT, and CCE) for the DEP High scenario, all sectors combined, for each year across the 20 year planning horizon. Then, Figures 5-18 to 5-21 illustrate how cost-effectiveness test results vary across DEP High and Reference Case scenarios for all sectors combined.

DSM cost-effectiveness test results presented in this section are long term estimates only and are informed by the results of the 2021 CPR and program experience.[170] The cost-effectiveness results are based on current DSM regulation. Any future regulatory amendments that are in effect before the next LTGRP will be captured at that time.

In general, cost-effectiveness test ratios decrease over time as the more easily-realized energy savings opportunities (i.e., the low-hanging fruit) are actualized. The 2022 LTGRP DSM cost-effectiveness test results also display the CCE in dollars per GJ. The CCE is an industry standard method for expressing the TRC results in dollars per GJ. Electric utilities use the CCE to express the net cost of saving one unit of utility-supplied energy. The CCE can be used to express UCT

[170] For this reason, individual DSM expenditure plans may contain higher or lower energy savings and expenditures in the short and medium term than indicated in the long term DSM analysis in the LTGRP.

1 results in dollars per GJ by applying the UCT benefit and cost inputs.[171] The aggregate portfolio
2 CCE across the planning horizon is $11.3 $/GJ as illustrated below.

3 **Table 5-8: Estimated Diversified Energy (Planning) Cost-Effectiveness Test Results – All Sectors**
4 **Combined**

Year	TRC	MTRC	UCT	CCE ($/GJ)
Aggregate	**4.1**	**14.2**	**4.0**	**11.3**
2022	6.8	25.2	6.7	11.5
2023	6.1	22.3	6.0	11.6
2024	5.5	20.1	5.4	11.7
2025	5.1	18.6	5.0	11.6
2026	4.8	17.3	4.7	11.5
2027	4.5	16.2	4.4	11.5
2028	4.3	15.3	4.2	11.5
2029	4.1	14.6	4.1	11.5
2030	4.0	14.1	4.0	11.4
2031	4.0	13.8	3.9	11.3
2032	3.9	13.6	3.9	11.3
2033	3.9	13.4	3.8	11.3
2034	3.9	13.2	3.8	11.3
2035	3.9	13.1	3.8	11.2
2036	3.8	13.0	3.8	11.2
2037	3.8	12.9	3.8	11.1
2038	3.8	12.8	3.8	11.1
2039	3.8	12.7	3.7	11.1
2040	3.8	12.6	3.7	11.1
2041	3.8	12.6	3.7	11.1
2042	3.8	12.6	3.7	11.1

5

[171] In this case, the CCE represents the annualized and, where applicable, discounted UCT net costs (i.e. sum of UCT costs minus sum of UCT benefits, excluding cost savings for utility fuel sales) divided by annual energy savings. This information fulfills BCUC Directive from the 2017 LTGRP.

Figure 5-18: Estimated TRC Results by Scenario – All Sectors Combined

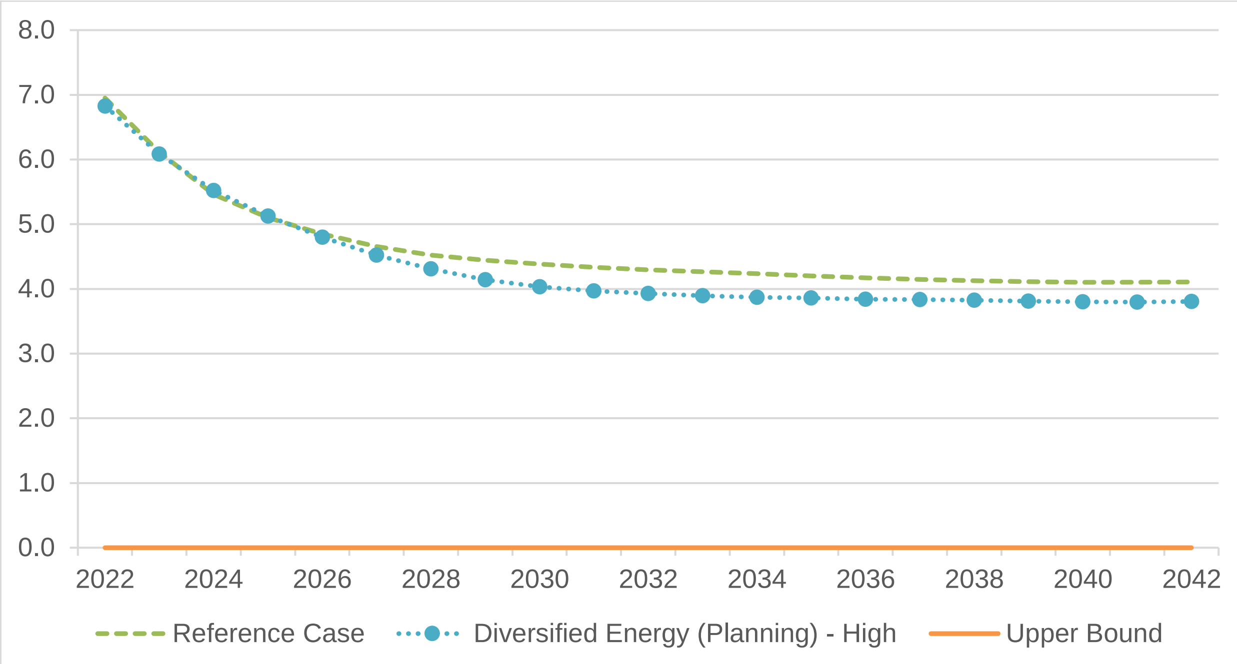


Figure 5-19: Estimated MTRC Results by Scenario – All Sectors Combined

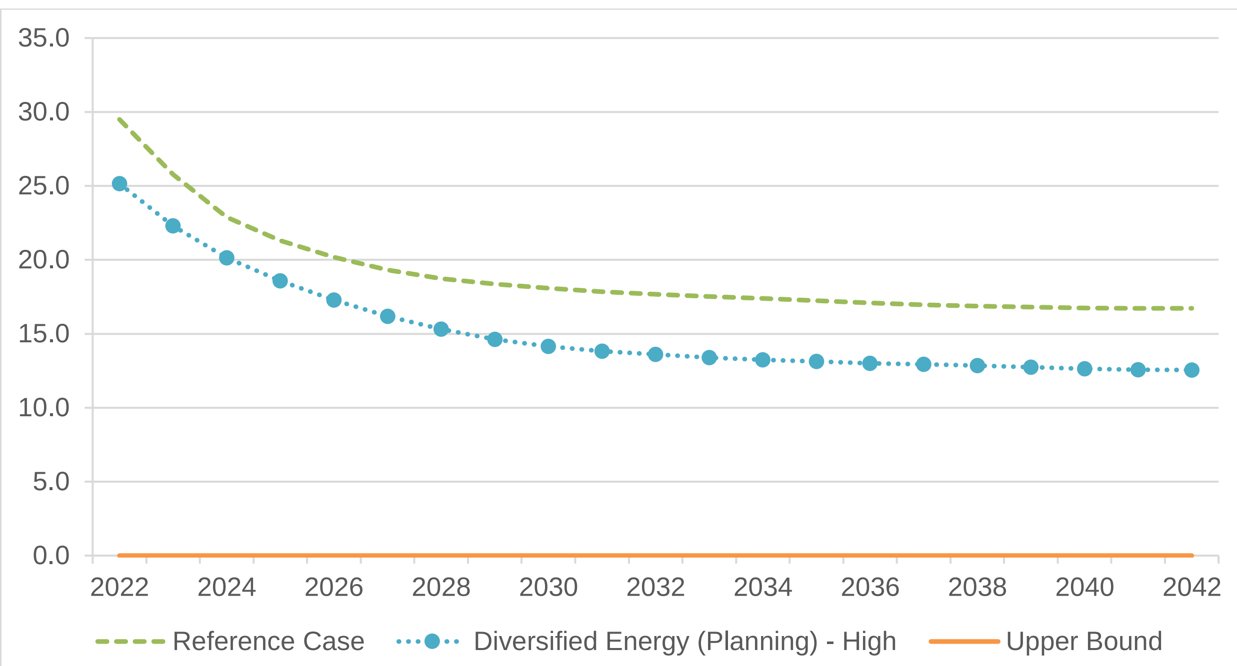

Figure 5-20: Estimated UCT Results by Scenario – All Sectors Combined

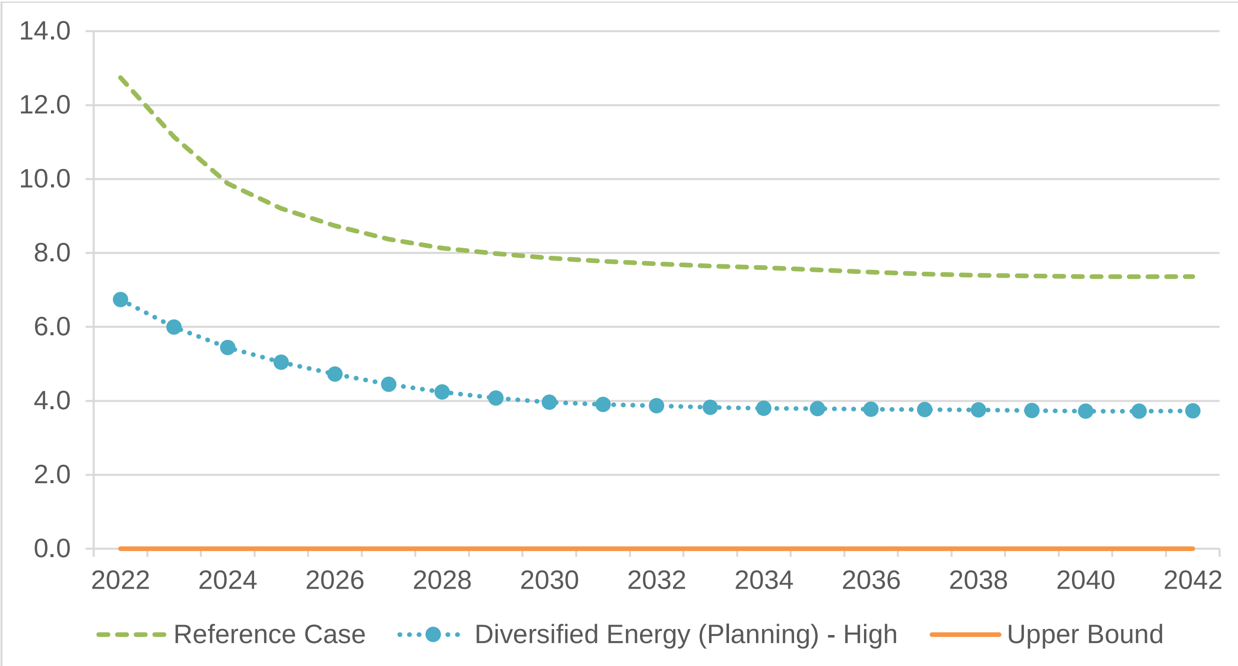

Figure 5-21: Estimated CCE Results by Scenario ($/GJ) – All Sectors Combined

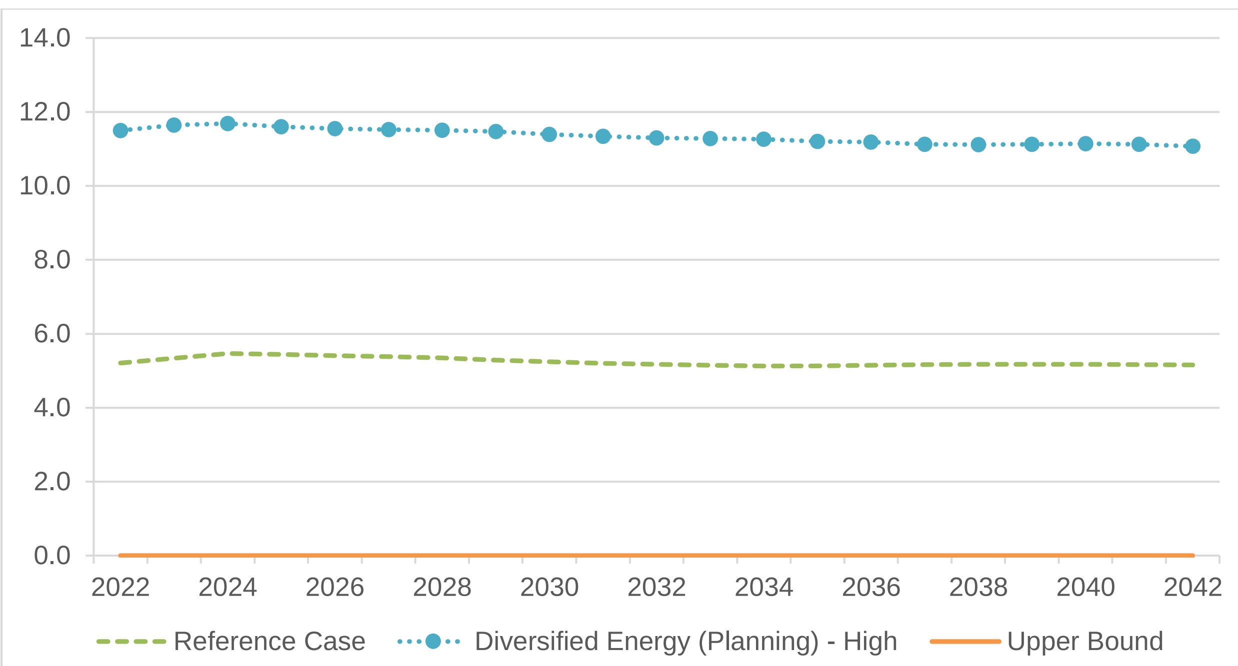

Refer to Appendix C-2 for the comparison of cost-effectiveness test results for the Diversified Energy (Planning) - High and Reference Case for individual sectors within the 2022 LTGRP DSM analysis.

5.4.7 Energy Savings Market Potential to 2030 from Top Ten Measures

Tables 5-9 to 5-12 below outline projected cumulative market potential energy savings to 2030 for the top ten measures in the DEP High DSM Scenario and illustrate how these cumulative energy savings change based on individual scenarios.

The cumulative market potential energy savings to 2030 for the top ten measures represent a significant share of total portfolio savings:

- The combined program area top ten measures account for **42** percent of DEP High DSM combined program area savings.
- The residential program area top ten measures account for **69** percent of DEP High DSM residential program area energy savings.
- The commercial program area top ten measures account for **62** percent of DEP High DSM commercial program area energy savings.
- The industrial program area top ten measures account for **73** percent of DEP High DSM industrial program area energy savings.

FEI's future DSM expenditure plans will be informed by the measure data from the 2021 CPR and 2022 LTGRP's DSM analysis and will represent program design and delivery decisions that are in accordance with changing customer needs, regulatory requirements, and technology evolution.

Table 5-9: Estimated 2030 Cumulative Savings from Top 10 Measures by Diversified Energy (Planning) – All Sectors Combined

	Diversified Energy (Planning)	Reference Case	
Measures	**Savings (GJ)**	**Savings (GJ)**	**% Change from Diversified Energy (Planning)**
Drain Water Heat Recovery (Residential)	799,597	490,145	-39%
High-Efficiency (ENERGY STAR) Condensing Gas Tankless Water Heater - Mature Market Costs (Residential)	775,356	497,415	-36%
Steam to Hot Water Conversion (District Energy) (Industrial)	748,368	446,594	-40%
Low Flow Showerhead (Residential and Commercial)	420,358	825,919	96%
HVAC Zoning (HVAC Zone Control) (Residential)	410,425	359,840	-12%
Home Energy Report (Residential)	408,430	518,459	27%
Attic Insulation (R-20 Baseline) (Residential)	405,840	170,460	-58%
High Quality Furnace Installation - ENERGY STAR Verified (Residential)	384,626	179,463	-53%
High-Efficiency Heat Recovery Ventilator (Residential)	349,440	449,954	29%
Energy Management (Industrial)	344,725	443,074	29%

Table 5-10: Estimated 2030 Cumulative Savings from Top 10 Measures by Diversified Energy (Planning) – Residential Sector

	Diversified Energy (Planning)	Reference Case	
Measures	Savings (GJ)	Savings (GJ)	% Change from Diversified Energy (Planning)
Drain Water Heat Recovery	799,597	490,145	-39%

Furnace Efficiency Retrofit	80,226	114,959	43%

5.5 ESTIMATED LONG-TERM DSM IMPACTS ON PEAK DEMAND

In its Decision on the 2014 LTRP, the BCUC requested FEI to make stronger linkages between the peak demand and the annual demand forecasts, to understand how ". . . new insights on evolving customer consumption patterns might affect time-of-day demand as well as annual demand . . . and how changes in base load annual demand under different scenarios translate into changes in base load peak demand under the same scenario assumptions."[172]

FEI commissioned Posterity to develop an exploratory process linking peak demand forecasts to the end use scenarios used in the annual demand forecasts. Section 7.2.3 further discusses this process. Overall, Posterity's approach suggests that the 2022 LTGRP's DSM forecast decreases peak demand. Section 7.3 discusses how this may impact infrastructure expansion requirements for each of FEI's regional transmission systems. FEI emphasizes that Posterity's approach currently is theoretical in nature and unsupported by direct measurement. Thus, FEI's infrastructure planning continues to rely on FEI's traditional peak demand forecast method (Traditional Peak Method).

Furthermore, in its Decision on the 2017 LTGRP, the BCUC requested that FEI "provide an update of its analysis of opportunities for DSM to be used to cost-effectively replace or defer infrastructure

[172] BCUC Decision and Order G-189-14, FortisBC Energy Utilities 2014 Long Term Resource Plan (December 3, 2014), p. 22, online at: https://www.ordersdecisions.bcuc.com/bcuc/decisions/en/111658/1/document.do.

investments in its next LTGRP."[173] To help meet this directive, FEI commissioned ICF to update its review of the state of the North American gas utility industry in exploring opportunities and implementing DSM programs that could potentially replace or defer infrastructure. ICF's report, titled Non-Pipe Solutions Status Update, is found in Appendix C-3. Non-pipe solutions are non-traditional and/or demand-side solutions that may be used to defer investment in the gas distribution system infrastructure. These non-traditional investments may include approaches such as energy efficiency, natural gas demand response, decarbonization approaches[174] and others. The report focused on demand-side non-pipe solutions, through a review of jurisdictions with relevant non-pipe solutions activity. The report highlights that there is only modest experience to date with implementing non-pipe solutions projects to address peak demand constraints, but interest is starting to grow, especially in response to decarbonization activities. FEI's AMI project, under BCUC review at this time, may provide FEI and customers the ability to more actively manage peak demand. However, the extent to which AMI can be used for Demand Response as a DSM activity, and with respect to deferred infrastructure investments, is still being explored. Further, AMI is not necessarily a requirement for undertaking non-pipe solutions and opportunities exist for FEI to further explore and perhaps pilot some non-pipe solutions initiatives.

Although not a "demand-side measure" as defined in the CEA, in Section 7.3.5.4, FEI provides an example of its first operational non-pipe solutions installed within a distribution system. In the Gibsons Distribution System, the capacity of the IP pipeline is insufficient to meet current peak demand without temporary mitigation measures. The preferred and lowest cost alternative was determined to be a local CNG peak shaving facility. This provides some insight into the use of non-pipe solutions as an alternative to address system capacity.

5.6 *LONG-TERM PLAN FOR IMPLEMENTING DSM ACTIVITIES*

In the long term, based on the 2022 LTGRP DSM analysis, FEI intends that it will design its DSM expenditures plans with the High DSM Setting in mind as DSM represents a key pillar in the Clean Growth Pathway. FEI will continue to offer residential, commercial, industrial, low income, innovative technologies, conservation education and outreach as well as DSM-enabling activities. The measures analysed in the CPR and the LTGRP DSM analysis will inform FEI's future DSM expenditure plans that will be filed with the BCUC for acceptance. In addition, FEI will continue monitoring the cost-effectiveness of its DSM activities and identifying any new measures that can be included in its activities. Over the 2022 LTGRP planning horizon, FEI will operationalize these activities through successive DSM expenditure plans. In these future expenditure plans, FEI's specific program offers will likely change to suit the evolving marketplace, legislative provisions (including future adequacy requirements), end use technologies, and FEI customer needs. FEI will continue to update its long term DSM analysis through successive future LTGRPs over the planning horizon and will continue to explore non-pipe solutions opportunities.

[173] BCUC Decision and Order G-39-19, FEI 2017 Long Term Gas Resource Plan (February 25, 2019), pp. 14-17, online at: https://www.ordersdecisions.bcuc.com/bcuc/decisions/en/363860/1/document.do.
[174] Note that impacts to the electric system were not examined in this study.

5.7 CONCLUSIONS AND RECOMMENDED ACTIONS

Expanding investment in DSM programs is a pillar of the Clean Growth Pathway and a critical contribution to FEI's efforts to meet the GHG emissions cap in the Roadmap. FEI's DSM analysis shows that significant energy and GHG emissions reduction can be achieved over the planning horizon under the range of alternate future scenarios examined for the LTGRP. Under the Diversified Energy (Planning) Scenario with the High DSM Setting, savings from DSM activities are forecast to be about 25 PJ or 13 percent of annual demand in 2042. It is important to note that the DSM measures implemented over the planning horizon will shift depending on how the future actually unfolds.

FEI will continue to examine opportunities to develop other DSM activities that offer similar benefits or to expand existing offerings and, where appropriate, seek approval for expenditures related to those offerings. Recommended actions to acquire and implement demand-side resources over the planning horizon are to:

- Develop DSM expenditure plans for the next funding period(s) reflecting an adequate and cost-effective portfolio of DSM activities guided by the High DSM Setting, and apply to the BCUC for acceptance of those expenditures.
- Assess the implications of increasing amounts of renewable and low-carbon gas over the planning horizon on FEI's DSM activities, program modelling and reporting tools. For example, FEI will assess the impact of these supplies on cost-effectiveness models to understand how these fuels impact program offerings in alignment with the Roadmap.
- Continue to examine the potential for DSM activities to reduce peak demand on FEI's transmission and distribution systems, and thus delay or avoid infrastructure investments. FEI will continue to monitor studies and advancements across the gas utility industry on DSM related non-pipe solutions as well as evaluations of the effectiveness of such initiatives. FEI will consider opportunities for studies or pilot programs for such activity on its own system.

Continue to work with federal, provincial and municipal governments and other potential partners to explore and identify ways in which FEI's DSM activities can continue to help meet government objectives while ensuring benefits for FEI and its customers. This activity will include examining and understanding the impact of any new changes to the DSM Regulation on FEI's DSM programming if and when such changes are enacted.

Section 6:

GAS SUPPLY PORTFOLIO PLANNING

Table of Contents

6. GAS SUPPLY PORTFOLIO PLANNING

In this section, FEI describes its long-term gas supply portfolio plan to meet the total forecast annual demand described in Section 4, with consideration of the transition to renewable and low-carbon gas and associated reductions to carbon emissions as FEI pursues its Clean Growth Pathway. Planning for gas supply involves accounting for FEI's DSM activities (described in Section 5), resources available to contract for gas supply, and the resources required to deliver gas to customers. This section also analyses the requirements to manage security of supply risks to FEI's gas supply portfolio and options for meeting these requirements over the planning horizon.

FEI's gas supply portfolio planning considers a subset of the total system throughput that FEI uses for system capacity planning described in Section 7. FEI's gas supply portfolio planning is responsible for appropriately planning for the forecast normal, design, and peak day demand of core market (Core) customers.[175] The gas supply requirements for the remaining portion of the total system throughput are the responsibility of customers who have elected to take service under FEI's Transportation Service model (Transportation Service customers). These Transportation Service customers arrange for their own supply that is then transported by FEI to their premises. Therefore, system capacity planning needs to consider total system throughput to ensure that sufficient capacity exists on FEI's system to reliably deliver gas supply to meet the demand of all customers.

Table 6-1 below illustrates the differences between FEI's customer service types for gas supply portfolio and system capacity planning in the LTGRP.

Table 6-1: Summary of LTGRP Customer Service Types

LTGRP Customer Service Type	Rate Schedules	FEI Gas Supply Portfolio Planning	FEI System Capacity Planning
Core	1, 2, 3, 4, 5, 6, 46	Included	Rate Schedules 1, 2, 3, 5, 6, 46 included; and Rate Schedule 4 (seasonal) excluded.
Firm Transportation	The contracted firm delivery component of 22 (including 22A and 22B), 23, 25, the transportation component of 46, and other special Rate Schedules[176]	Excluded (these customers secure their commodity supply on their own or through a shipper agent)	Included

[175] As outlined in Table 6-1, this also applies throughout Section 6 to any applicable delivery component of Interruptible customers.

[176] The special Rate Schedules are Byron Creek, BC Hydro Island Generation, and Vancouver Island Gas Joint Venture (VIGJV). These special Rate Schedules are applicable for both Firm Transportation and Interruptible customers, as they have all contracted firm delivery and interruptible components.

LTGRP Customer Service Type	Rate Schedules	FEI Gas Supply Portfolio Planning	FEI System Capacity Planning
Interruptible	7, 27, the Interruptible component of 22 (including 22A and 22B) and other special Rate Schedules	For Rate Schedule 7 and any non-transportation component of special Rate Schedules: • Included: contracted firm delivery component; • Excluded: interruptible delivery component. All other Interruptible service customers are excluded.	Interruptible components excluded (FEI can reduce gas flow to these customers during peak conditions to any firm contract amount)

FEI's gas supply portfolio planning relies on the Traditional Annual Method for deriving system-wide demand forecasts for Core customers each day through the entire year, as well as the peak design day, which is the coldest day of the design year estimated via extreme value analysis to have a return period of 20 years. In contrast, system resource planning (to be discussed in Section 7) relies on location-specific (not system-wide) peak demand. Section 7 outlines FEI's traditional peak method for deriving peak demand and also discusses FEI's exploration of an end use peak demand forecast method that may in the future provide additional insights about the impact of emerging gas use trends on peak demand.

FEI's transition to renewable and low-carbon gas supplies will continue to accelerate in order to reach carbon emissions reduction targets. While this transition is happening both within and outside of BC, it remains in early stages. In each of Sections 6.1, 6.2 and 6.3, FEI discusses the current outlook for these gas supplies and how they will impact FEI's gas supply planning moving forward. At this early stage, market information and future forecasting on renewable and low-carbon gas supplies is, as expected, less available than for conventional natural gas, and yet is developing quickly. In this LTGRP, FEI provides the information it has available about these supplies, and anticipates that evolving market intelligence for these gases will inform future LTGRPs and gas supply planning.

The remainder of this section is organized as follows:

- Section 6.1 provides background information and sets out the regulatory requirements for FEI's gas supply portfolio planning.
- Section 6.2 discusses existing gas supply portfolio planning strategies, which include managing demand uncertainty and security of supply concerns in the short-term.
- Section 6.3 describes how future supply projects will help manage security of supply concerns and enhance supply resiliency over the medium- to long-term planning horizon.

6.1 PORTFOLIO PLANNING REGULATORY REQUIREMENTS AND FILINGS

6.1.1 Regulatory Requirements for Gas Supply Planning

Section 44.1(2) of the UCA outlines the requirements for long-term resource plans. In relation to gas supply, the UCA requires long-term resource plans to provide:

> Information regarding the energy purchases from other persons that the public utility intends to make in order to serve the estimated demand referred to in paragraph (c); and

> An explanation of why the demand for energy to be served by the facilities referred to in paragraph (d) and the purchases referred to in paragraph (e) are not planned to be replaced by demand-side measures.[177]

This section meets the above UCA requirements by outlining the long-term considerations that apply to FEI's energy purchases and the impact of demand drivers, such as DSM, on such considerations. FEI's Annual Contracting Plan (ACP) operationalizes these considerations in the short and medium term, and takes into consideration the specific purchase requirements and demand driver impacts that affect FEI.[178]

As discussed in Section 1.5.5, Tables 1-7 and 1-8, the BCUC has set out two directives and one suggestion for FEI's 2022 LTGRP,[179] which are addressed in this Section:

- The Panel directs FEI to address security of supply concerns;
- The Panel directs FEI to address resiliency in a comprehensive manner; and
- The Panel suggests FEI may address pathways to zero GHG emissions by 2050.

Both the security of supply and supply resiliency items are discussed in the short, medium and long term within Sections 6.1.2, 6.2 and 6.3 below, with a discussion of the alternative supply resources available to FEI and conclusions about FEI's future supply planning. Also integrated into these sections is a discussion of how renewable and low-carbon gas resources are being integrated into FEI's gas supply portfolio considerations. To date, the majority of renewable and low-carbon gas has been acquired by FEI through direct contract negotiations and agreements with suppliers, and makes up a small, though growing, portion of the resources available to FEI to contract. Over time, as the renewable and low-carbon gas supplies in North America and the PNW grow, FEI anticipates that market participation by more players will increase and market dynamics will evolve. FEI will continue to monitor and take advantage of these developments as the market for renewable and low-carbon gas continues to develop.

[177] UCA s. 44.1.

[178] The impact of demand-side measures to date is inherently considered in the ACP since the short-term demand forecast, on which the ACP is based, captures these recent efficiency trends. Future ACPs will likewise consider future demand-side measures.

[179] BCUC Order No G-39-19 and C-2-21.

6.1.2 Relationship between FEI's Gas Supply Plans

FEI uses three different plans for its gas supply and price risk management activities: the LTGRP, ACPs, and Price Risk Management Plans (PRMP). The LTGRP, ACP and PRMP differ in the type of demand forecast on which the plans are prepared. The LTGRP is based on a broad range of long-term demand forecast scenarios and on the total system throughput of all customers. In contrast, the ACP and PRMP are based on short- and medium-term forecasts derived from trends observed in recent years (or on customer reported expectations in the case of industrial customers) and only consider the demand of Core customers, a subset of total system throughput.

The LTGRP establishes long-term planning principles, objectives, and a framework that is used to help ensure the long-term provision of safe, reliable, and cost effective service to all customers. In doing so, the LTGRP also sets out gas supply contracting and price risk management principles within the context of a 20-year outlook. The ACP and the PRMP each describe more detailed strategies and tactics for managing either the physical availability of gas supply or the impact of gas costs on rates.

The ACP is based on short- and medium-term load forecasts derived from trends observed in recent years (or on customer-reported expectations in the case of industrial customers), and also takes into account regional[180] market developments. Therefore, the ACP sets strategies and tactics for managing the availability of third-party transmission capacity, securing the physical supply of natural gas, and managing the impact of costs on customers' rates. The ACP more closely considers diversity and purchasing term supply from different supply hubs, purchasing term supply on a daily and monthly indexed basis, and using storage resources to meet peaking and seasonal demand requirements while balancing FEI's pipeline system on a daily basis.

The PRMP provides strategies and tools to enhance existing price risk management in managing the impacts of market price volatility on commodity rates and in capturing market price opportunities to help provide customers with affordable rates. The PRMP is, to a large degree, informed by the ACP since the ACP determines the physical resources required and degree of portfolio exposure to market prices.

FEI is not seeking approval of any of its gas supply portfolio or price risk management activities as part of the LTGRP, as these approvals are sought through separate applications to the BCUC. Discussion of FEI's ACPs and PRMPs is included in the LTGRP only to provide context for resource planning considerations.

6.2 *GAS SUPPLY PORTFOLIO PLANNING*

FEI's gas supply portfolio consists of natural gas commodity contracts, third-party pipeline capacity and storage resources. This section discusses the key factors that FEI considers when developing its gas supply portfolio, including marketplace developments that will affect traditional regional gas flows, and supply and demand in the region. FEI is continuing to assess the regional

[180] In this section, the term "region" broadly refers to the Pacific Northwest (PNW), which includes BC.

market for renewable and low-carbon gas volumes, and is managing the security of its supply and enhancing resiliency of its portfolio taking into account long-term supply risks, as well as managing pricing risks.

6.2.1 Overview of the Gas Supply Planning Process

FEI files an ACP with the BCUC in the spring of each year. In those plans, FEI assesses the overall North American natural gas market and evaluates the regional market with respect to supply and infrastructure. Key objectives of the ACP are:

1. To contract for resources that appropriately balance cost minimization, security, diversity and reliability of gas supply in order to meet the Core customer forecast design peak day and annual requirements; and
2. To develop a gas supply portfolio mix, which incorporates flexibility in the contracting of resources based on short- and long-term planning and evolving market dynamics.

Since the T-South incident (discussed in Appendix E), FEI has placed more emphasis on enhancing supply resiliency within its portfolio, which may increase the cost of the portfolio. Enhancing resiliency within the portfolio through the existing assets in the region is discussed in Section 6.2.4, while potential infrastructure additions to further enhance resiliency are discussed in Section 6.3.

FEI conducts portfolio planning to provide secure and reliable supply to Core customers so that system-wide forecast normal, design, and peak design day demands are met. FEI contracts the majority of its gas supply resources over the short- to medium-term,[181] and the resource cost and availability of the supply is primarily determined in the gas marketplace where FEI competes with other parties.

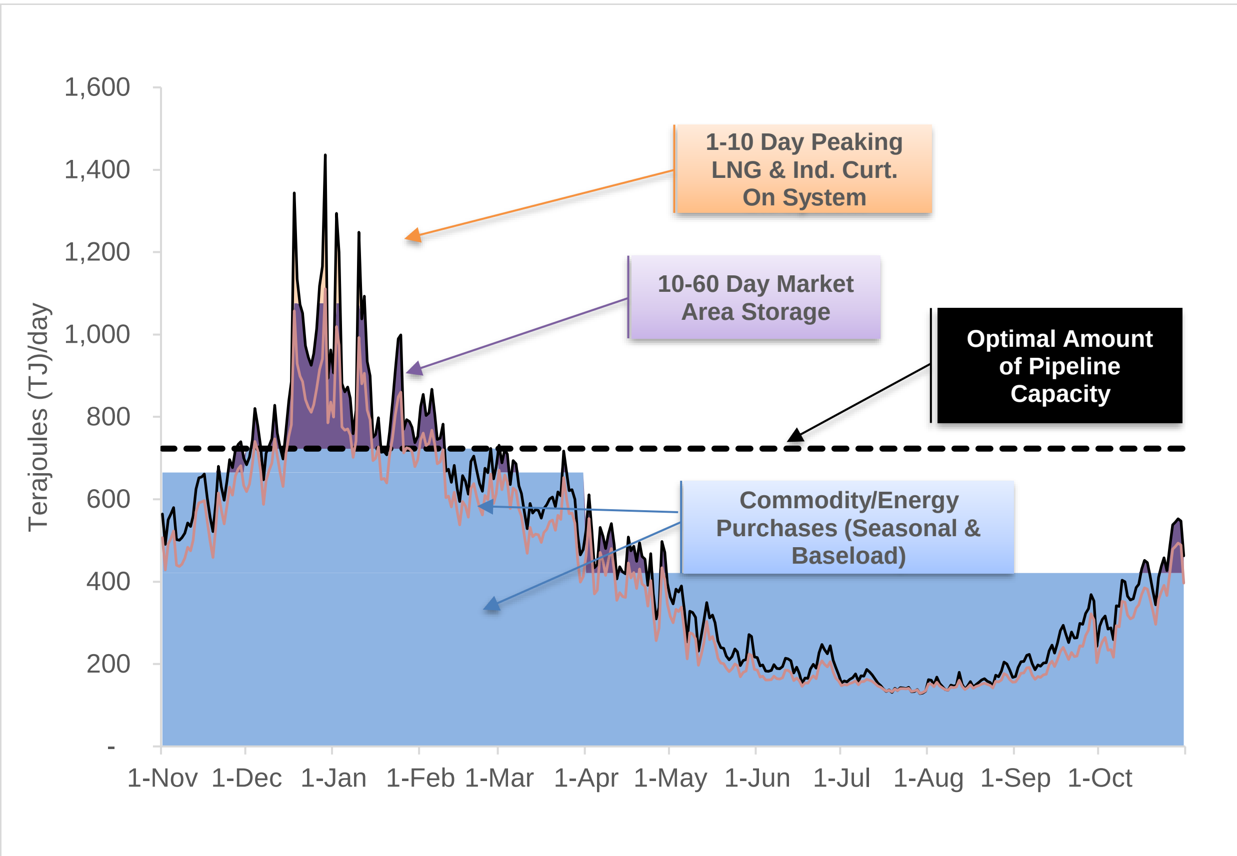
The fundamental design principle of constructing an efficient gas supply portfolio of resources, which FEI has used for many years in the ACP, is to match the resource characteristics to the demand characteristics. In broad terms, that efficient supply portfolio consists of:

- Purchasing firm natural gas commodity volumes and contracting third-party pipeline capacity to address seasonal and base load requirements (i.e., consistent demand for the 151-day winter season and annual demand);
- Shorter duration market area storage to provide short- to medium-duration seasonal supply; and
- On-system storage resources for short-duration supply to cover events such as winter demand peaks.

[181] It is not FEI's intention to specifically delineate what time periods the phrases short- and medium- term encompass for the purpose of gas supply planning throughout this section. Rather, these are general timing considerations that for short-term is approximately zero to three years and for medium-term is approximately three to seven years.

The resulting gas supply portfolio for a system such as FEI's that has pronounced demand seasonality (i.e., high load in winter and low load in summer), and therefore a low annual load factor, is illustrated in Figure 6-1 below. This figure illustrates the ACP resources that were planned to be used in the 2021/2022 gas contract year (November 1, 2021 to October 31, 2022), and how their duration fits the forecast annual normal and design load for Core customers.

Figure 6-1: 2021/2022 FEI Forecast Design and Normal Loads vs. Resources[182]



Notably, Figure 6-1 shows that the majority of this mix of resources will be used in a typical winter, when total loads can easily reach or exceed 1,000 TJ on a cold winter day. In a winter that involves several cold spells, or where these cold spells span several days, a larger portion of resources like market area storage and LNG storage will be used. This figure also illustrates that colder weather in the winter period is highly variable and can occur within any period between November 1 through March 31. Therefore, FEI must ensure that it has sufficient resources in place during the entire 151-day winter period. This weather variability also requires resources that are flexible so that they can be deployed on relatively short notice to meet changes in load requirements.

[182] This forecast is for Core requirements and does not represent total system throughput.

6.2.2 Sources of Regional Gas Supply Resources

The locations where FEI can purchase its gas supply resources and the physical gas storage and pipeline resources that FEI has access to are the foundation of FEI's gas supply planning activities. While there are various contracting and trading instruments that FEI can utilize to acquire gas supplies throughout the year, the physical resources needed to store and transport these supplies onto FEI's system for distribution to customers when needed are the bases for FEI's market planning and actions. These resources are also critical for FEI's use of displacement mechanisms that allow FEI to purchase natural, renewable and low-carbon gas supplies elsewhere in North America while ensuring the physical delivery of energy to customers in BC. As FEI moves forward on its Clean Growth Pathway, access to renewable and low-carbon gas supplies will leverage these physical resources within the PNW for the delivery of the energy customers require. Sections 6.2.2.1 and 6.2.2.2 provide an overview of the gas supply resources that FEI relies on for acquiring and delivering energy to its customers.

6.2.2.1 *Sources of Natural Gas Supply Resources*

For orientation, Figure 6-2 below provides an overview of FEI's operating region, the gas supply basins that service markets in the PNW, the transportation pipelines and storage facilities required by these markets, and the location of the trading hubs where commodity purchases are transacted.

Figure 6-2: Regional Supply Resources – Pipelines, Storage and Trading Hubs

The majority of FEI's natural gas supply is contracted at the supply hubs of Station 2 in Northeast BC, and AECO/NIT (NOVA Inventory Transfer) in Alberta. Alternative considerations when purchasing supply would be at delivered market hubs that are on the international border at Huntingdon/Sumas and Kingsgate. Purchasing supply at these market hubs allows parties to avoid contracting for pipeline resources, although at the disadvantage of increased supply and pricing risks under certain market conditions, which will be discussed next in Section 6.2.4.

Seasonal gas storage is an integral part of FEI's gas supply portfolio as it provides flexibility to meet load variations during the winter and summer months. FEI contracts the majority of seasonal storage with Aitken Creek in NEBC and a currently small portion with Rockpoint Gas Storage in

Alberta. These seasonal storage assets are available to be utilized throughout the winter season as needed. FEI also contracts for shorter duration market area storage resources, which are needed when colder-than-normal winter loads are greater than the supply available from termed gas supply and seasonal storage. FEI contracts these shorter duration assets at Jackson Prairie Storage (JPS) in Washington and Mist Storage in Oregon.

In order to facilitate the purchase of gas supply from various sources and to manage withdrawals and injections from storage facilities for delivery to FEI's transmission system, FEI contracts with third parties for transportation services (Westcoast, TC Energy's NGTL and FoothillsBC, and Williams' Northwest Pipeline (NWP)). Contracting for transportation capacity on Westcoast's T-North and T-South system provides FEI with the principal access to gas supply from NEBC, which is mainly purchased at the Station 2 market hub, and supply that is withdrawn from Aitken Creek. Contracting for capacity on TC Energy's NGTL and Foothills BC systems and utilizing FEI's own SCP allows FEI to access gas supply from the AECO/NIT and Kingsgate markets and Alberta-located storage facilities. Finally, transportation capacity on NWP provides access to redeliveries from storage facilities south of the international border in Washington and Oregon states.

FEI utilizes its own on-system LNG storage facilities at Tilbury and Mt. Hayes to provide high volume gas supply during periods of cold winter weather or during emergency situations. These are the only on-system physical storage resources that FEI has the control over to protect its system, as they are not impacted by third-party transportation or storage capacity disruptions. This is critical during an emergency situation, as on-system storage provides additional response time until the flow of gas from upstream pipelines can be partially or fully restored, or a new supply-demand balance can be achieved by shedding load.

Table 6-2 below provides a high-level summary of FEI's resource portfolio mix that was required to meet the Core customer's load forecast for the 2021/2022 gas year.

Table 6-2: FEI's 2021/2022 Planned Core Peak Day Portfolio[183]

Peak Day Portfolio	2021/2022 Portfolio-Planned (TJ/day)
Fort Nelson Supply	**5**
Alberta Baseload Supply	103
Station 2 Baseload Supply	308
Total Commodity Supply	**411**
Seasonal Supply	135
Seasonal Storage	201
Market Area Storage	211
Spot Supply	120
Mt. Hayes LNG	163
Tilbury LNG	163
Industrial Curtailment	26
Total Midstream Supply	**1020**
Total Resources	**1,436**
Peak Day Demand	**1,436**

6.2.2.2 *Sources of Renewable and Low-Carbon Gas Supply Resources*

Development of the market for producing, transporting, and trading renewable and low-carbon gas resources is relatively new but is growing quickly. At this time, the key resources that FEI anticipates acquiring over the next 20 years and beyond to increasingly displace conventional natural gas supplies are RNG, hydrogen, syngas and lignin, as discussed in Section 3. All of these supply sources will allow FEI to leverage its existing and future infrastructure to deliver low-carbon energy to customers. RNG is interchangeable with conventional sources of natural gas. Hydrogen delivery can be integrated with the existing gas infrastructure in different ways, as discussed more fully in Section 7. Syngas and lignin would utilize existing biomass waste or by-product to deliver energy to nearby industry currently served by natural gas.

By leveraging the energy trading capabilities made possible by the existing gas transportation network, discussed in Section 6.2.2.1 above, renewable and low-carbon gases can be purchased from producers across Canada and the US, with the carbon reduction benefits of that production being delivered to FEI's customers in BC. FEI expects this source of supply to be an important part of its transition to renewable and low-carbon gas supplies, particularly in the early years of the transition. Over the planning horizon, however, FEI expects to purchase or produce increasing amounts of its supplies of renewable and low-carbon gas within BC.

[183] The table is broken into two supply components: Commodity and Midstream. The Commodity supply represents the daily baseload gas required to meet the forecast annual normal load for FEI's Core customers. FEI's Midstream supply manages the variability in customer demand, including the peak day demand. It does this by providing seasonal and peaking commodity, storage services, and pipeline capacity necessary to manage swings in demand.

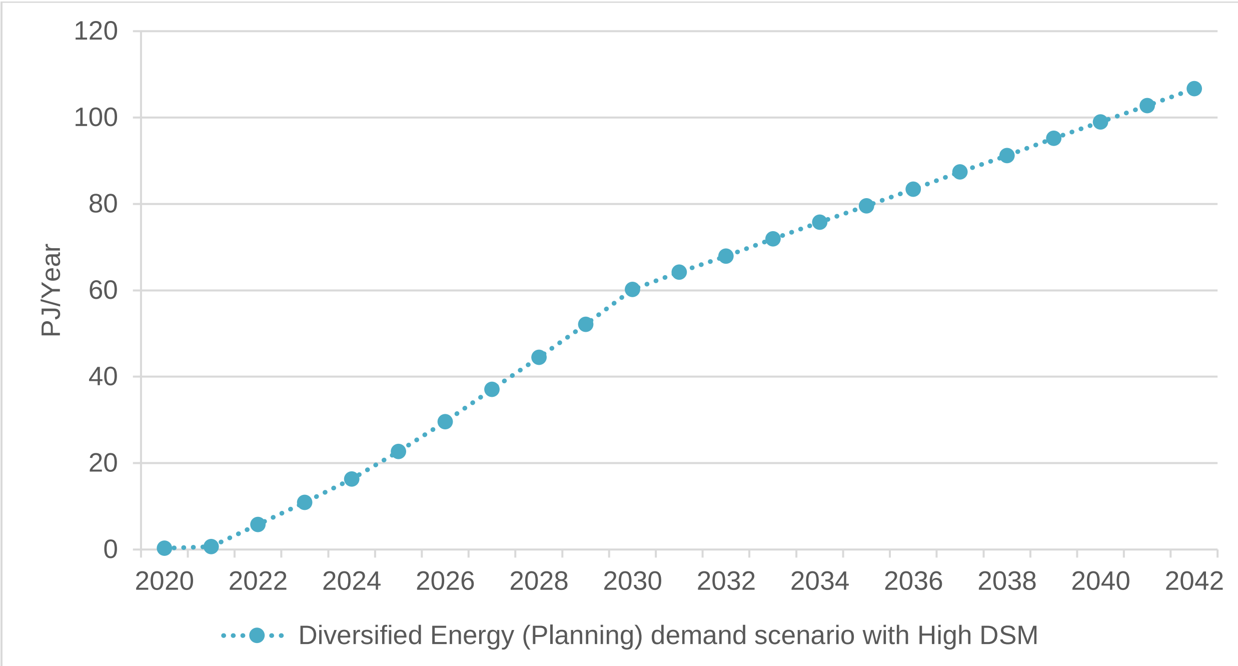
The locations within BC where new supplies will be produced are still being developed. The identified supply volumes are very large and the potential production locations are numerous as identified by the study "Renewable and Low-Carbon Gas Potential in BC and North America", commissioned in partnership with the BC Bioenergy Network and the Province of British Columbia and included in Appendix D-2. The study has assessed the costs of these resources based on information available today, and estimates that a potential of up to 444 PJ per year could be supplied within BC by 2050. This equates to approximately twice FEI's current annual energy throughput.

FEI expects the understanding of the production, supply resources, and market dynamics for these renewable and low-carbon gas supplies to evolve quickly over the coming months and years and will continue to update this information in subsequent LTGRPs. Some concern has been expressed by stakeholders about the competition for these supplies; however, increasing demand for these resources will be a catalyst for accelerating their development and decreasing costs through technology advancement and economies of scale.

6.2.3 Portfolio Integration of Renewable and Low-Carbon Gas Supply

FEI has targeted its long-term acquisition of renewable and low-carbon gas supply to meet BC provincial targets for carbon emission reductions in 2030 and 2050. Figure 6-3 below shows the forecast increase in supplies of renewable and low-carbon gas that FEI expects to acquire annually over the planning horizon. The majority of these supplies will be made up of RNG and hydrogen, with smaller amounts of syngas and lignin, and potentially conventional natural gas or RNG combined with CCUS later in the planning horizon. The amount of each of these types of renewable and low-carbon gas supplies is more difficult to forecast, although FEI expects its forecasts to evolve and be refined in future LTGRPs. Additional discussion of the renewable and low-carbon gas supply mix is provided in Section 7.4, along with a discussion of the implications for FEI's infrastructure needs.

Figure 6-3: Forecast Renewable and Low-Carbon Gas Supply



FEI's modelling of supply resources over the next 20 years has identified the following gas supply resource mix observations for annual demand for the Diversified Energy (Planning) Scenario over the planning horizon and beyond:

To 2030:

- RNG and hydrogen from off-sysem supply sources will be relied on more heavily in the early stages of FEI's carbon reduction transition. Conventional natural gas and RNG will continue to make up the majority of physical deliveries to customers during this period and will be delivered to FEI by displacement as with conventional natural gas purchases[184]. Physical flows of hydrogen on FEI's gas infrastructure are expected to rise but be limited to smaller amounts and portions of FEI's system until around 2030 as the technologies and infrastructure needed to manage larger volumes are refined and implemented.
- One or more syngas and lignin projects will displace some industrial load, though natural gas may continue to provide firm back-up service for periods when syngas or lignin production is unavailable.
- CCUS is expected to still be in development stages, perhaps available in small amounts through pilot projects, in 2030.

From 2030 to 2042:

[184] Off-system supply includes purchases that are injected into another gas system, typically out-of-province, displacing an equal unit of gas, delivered to FEI at a physical delivery point, such as Huntingdon, AECO/NIT, or Station 2.

- This is the latter part of the planning horizon for the 2022 LTGRP and as such is subject to greater uncertainty. The proportion of FEI customers using conventional methane for space and water heating as opposed to other renewable and low-carbon gas supplies will have decreased, but will still make up a majority of customers. While the development of on-system resources will have grown in the intervening years, FEI anticipates there will still be reliance on off-system supplies.

Beyond 2042:

- The steps taken earlier in the planning horizon will set FEI on a pathway to deep decarbonization by 2050 and well on its way to achieving carbon neutrality on an annual basis. RNG and hydrogen will both be an important part of FEI's resource mix.

FEI expects the mix of supply resources described above to apply to a moderate range of possible higher or lower demand forecasts based on a Diversified Energy (Planning) Scenario, in which both the electric and gas infrastructure systems are relied on to decarbonize BC's energy infrastructure.

As the supply of renewable and low-carbon gas grows, FEI will monitor whether the supply is directly connected to FEI's system (on-system) or delivered to FEI's system through displacement (off-system). FEI will also assess the firm amount of supply delivered on FEI's system, or at the Huntington/Sumas, AECO/NIT, or Station 2 market hubs. RNG purchases have different contractual obligations than FEI's conventional natural gas purchases. This is because contracted RNG projects can have either an annual or monthly supply requirement to FEI, or a minimum daily firm amount. Therefore, the volumes delivered to FEI can fluctuate during the month, based on whether the RNG plant is running and other market conditions. This will require FEI to maintain a portion of conventional natural gas within the portfolio to manage the risk of any supply variability.

Over the past several years, FEI has incorporated RNG supply into the gas supply portfolio, and expects the amount of supply will continue to grow. FEI anticipates that the majority of this supply will be secured outside of FEI's service areas (i.e., off-system supply). These supply arrangements will be delivered primarily at the AECO/NIT or Station 2 hubs by way of displacement. Therefore, FEI will still require contracts with third parties for transportation services to deliver gas (whether conventional or RNG) to FEI's customers. The impact to FEI's portfolio for this off-system RNG supply will be a reduction of conventional natural gas commodity purchases at those supply hubs. Section 6.2.4.3 discusses how FEI's contracting strategy will be flexible enough to handle these types of annual adjustments.

As RNG volumes continue to increase each year, FEI will monitor and make any adjustments that are required to the remainder of the gas supply portfolio through each ACP. Additionally, as FEI begins to integrate other low-carbon gas supply such as hydrogen, syngas or lignin, as discussed in Sections 3.3 and 6.2.2.2, FEI will annually assess the impact to the portfolio in each ACP. Although there is still uncertainty as to what the impact will be to each of FEI's service regions, many of these projects will continue to utilize the existing regional natural gas infrastructure (pipelines and storage) in a significant way.

6.2.4 Managing Long-Term Supply Risks within the Gas Supply Portfolio

Consistent with FEI's past LTGRPs, constrained pipeline and storage resources during the winter season continue to be a major concern. Over the past several years, market conditions have caused increased supply and pricing risks in the region. The following three subsections describe the major supply and demand issues that can affect the planning portfolio and how FEI will mitigate these risks with its existing portfolio of resources.

6.2.4.1 *Gas Supply Resiliency Risks*

FEI has provided safe and reliable natural gas service in the province for many years. To provide reliable service, FEI has maintained the integrity of its assets, and ensured the adequacy and security of its supply. FEI has also completed projects over the years that have enhanced resiliency, such as the SCP and the Mt. Hayes LNG facility.

While FEI has long regarded resiliency as an important system attribute, the T-South incident (discussed in Section 3.2.2.3) brought into focus the risk of supply interruption for FEI's customers. FEI obtains most of its natural gas via the Westcoast T-South system, making a disruption on the T-South system the greatest supply risk facing FEI at present. A sudden, prolonged, and wide-scale gas supply interruption could directly or indirectly affect the livelihood, health, and safety of virtually every resident of the Lower Mainland, regardless of whether they are a customer of FEI or not.

Over the past few years, FEI has, to some degree, increased resiliency within the portfolio by holding contingency resources on T-South and by taking back capacity on the SCP.[185] However, FEI has few options to further increase resiliency in the short-term given that resources in the region are fully contracted as shown in Table 6-3 below, and can be constrained during the winter.

[185] A portion of pipeline capacity on SCP was historically contracted out to regional parties. However, FEI took back this capacity effective November 1, 2020, as it was the only opportunity in the marketplace for FEI to diversify its supply portfolio.

Table 6-3: Existing Pipeline and Storage Resources in the Region

Pipeline	Daily Deliverability[1] (MMcf/day)	Total Winter Supply (Bcf)	Contract Status
Westcoast T-South (Huntingdon Deliveries)	1800	272	Fully Contracted
Westcoast T-South (Interior Division)	224	34	Fully Contracted
FortisBC SCP (Oliver North)	140	21	Fully Contracted
FortisBC SCP (Kingsvale)[2]	105	16	Fully Contracted
TC Energy (FoothillsBC)	2930	442	Fully Contracted
NWP Gorge	534	81	Fully Contracted
Market Area Storage	**Daily Deliverability (MMcf/day)**	**Storage Capacity (Bcf)**	
Jackson Prairie Storage (JPS)	1161	25	Fully Contracted
Mist	637	19	Fully Contracted
On System Storage	**Daily Deliverability (MMcf/day)**	**Storage Capacity (Bcf)**	
Mt. Hayes LNG	150	1.5	Fully Utilized on Peak Day
Tilbury LNG	150	1.6	Fully Utilized on Peak Day

Notes:

[1] Daily deliverability is the maximum amount of gas that can flow on the pipeline or the maximum amount of gas that can be withdrawn out of storage. It is important to note that the daily deliverability out of the market area storage is assuming storage inventories are full. The withdrawal rates of these resources decline as working gas volumes decline.

[2] The 105 MMcf/day is included in the 1,800 MMcf/day Huntingdon Deliveries (i.e., Kingsvale to Huntingdon).

In the past, FEI contracted pipeline capacity on third-party pipelines based on the winter design load requirements of its Core customers. Since 2019, FEI has maintained contingency resources within the ACP portfolio and FEI plans to continue this practice for the foreseeable future. Contingency resources are resources (e.g., supply, LNG, and pipeline infrastructure) above the current load forecast for Core customers that can be called on if planned resources are unexpectedly not available or insufficient to meet demand. Each year, FEI will determine a planning margin for contingency resources based on market conditions (e.g., supply risks, and fully or de-contracted regional resources).

FEI will continue to evaluate contingency resources through existing regional assets, and the resiliency of its supply portfolio, until new pipeline and storage resources are developed. Section 6.3 details the pipeline and storage projects that FEI has evaluated for its supply portfolio, and how these developments would fit into future ACPs.

6.2.4.2 *Regional Transportation and Storage Constraints*

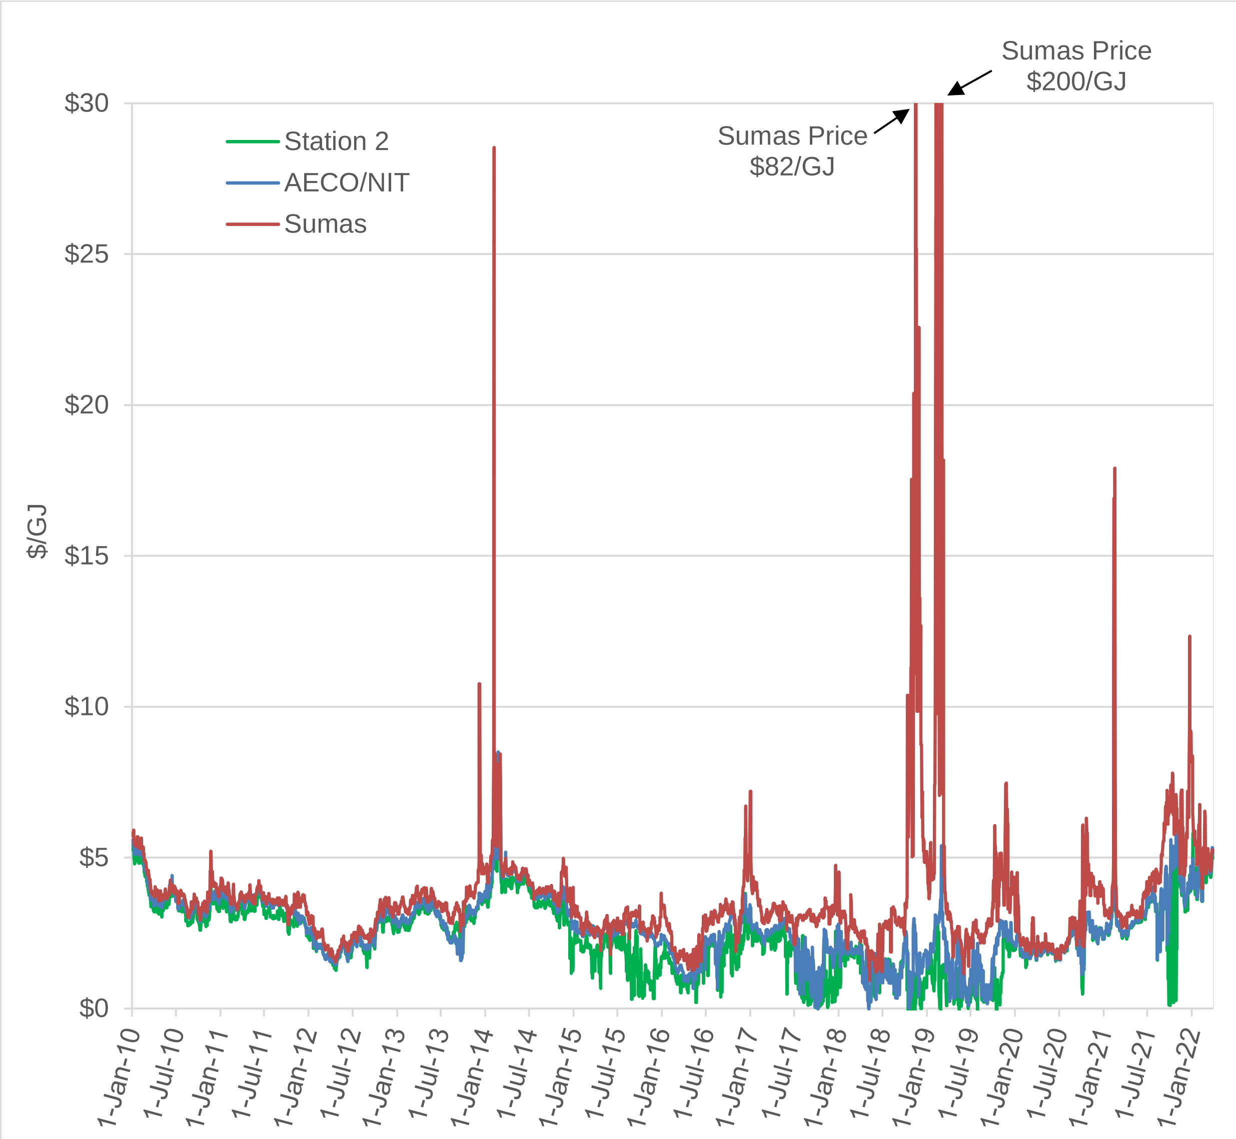
Despite the abundance of gas supply produced in the western Canadian shale gas basins (as discussed in Appendix D-1) and delivered to the AECO/NIT and Station 2 market hubs, constrained pipeline infrastructure to the Huntingdon/Sumas market results in price volatility and Sumas price spikes.

Periods of volatile pricing typically occur when increased demand in the PNW exceeds the delivery capacity of pipelines into the region, which then causes Sumas prices to rise significantly above other market hubs. This typically caused commercial and industrial users to use alternative fuel(s) if possible. Any service disruption on regional infrastructure, as occurred during the T-South incident, can also cause price spikes and sustained elevated prices.

Over the past few years there has been another growing risk to the Huntingdon/Sumas market that results from an increased reliance on natural gas-fired power generation in both the I-5 Corridor and the broader Western markets. As discussed in more detail in Appendix D-1, increased gas demand for electricity generation in the region is due in large part to recent coal-fired generation retirements across western North America that has been replaced by gas-fired generation, strengthening the relationship between gas and electricity markets in the PNW and Western markets.

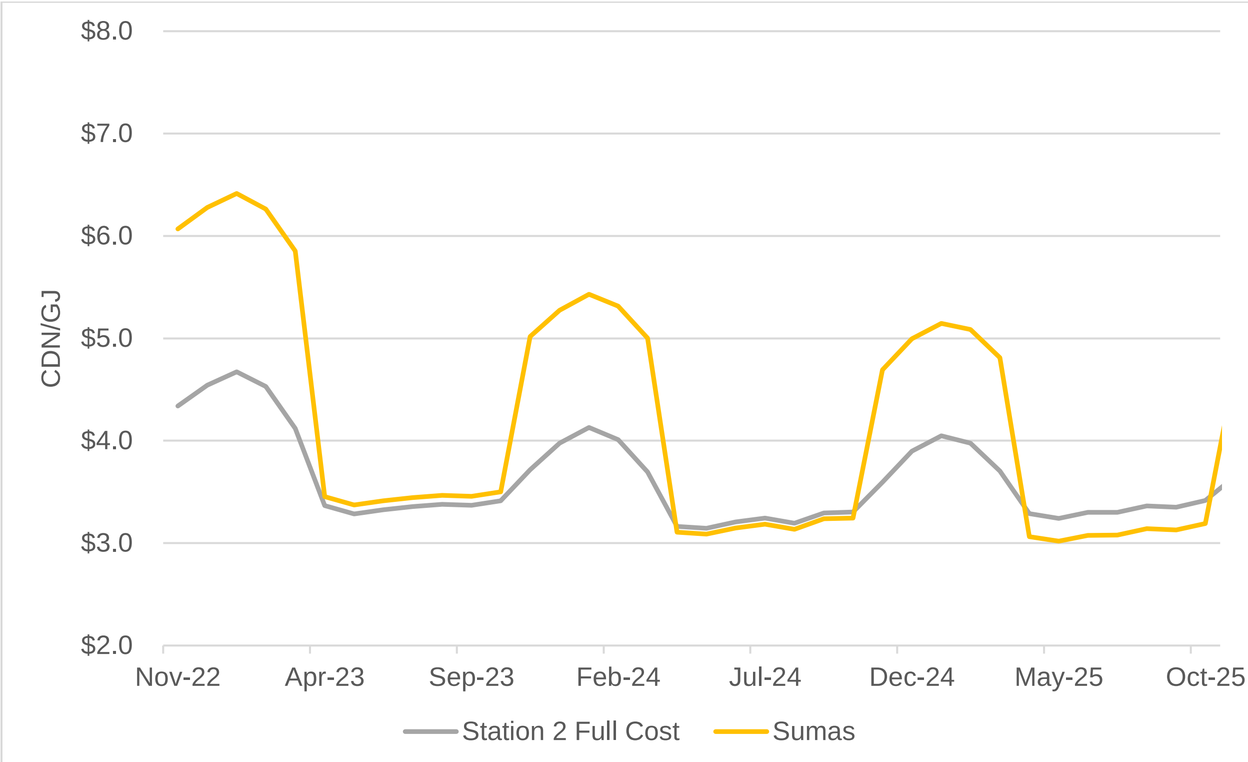
Figure 6-4 below illustrates this volatility, which includes periods of supply disruption. The figure shows historical AECO/NIT, Sumas, and Station 2 daily spot prices over the last twelve years.

Figure 6-4: Historical Daily Market Spot Prices



FEI expects that the Huntingdon/Sumas market will continue to have significant supply risks and pricing volatility going forward until pipeline resources are added to the region. The planned addition of Woodfibre LNG project demand will provide additional supply and pricing risks, as Woodfibre LNG project has already secured firm transportation capacity on the T-South system for a significant portion of their demand requirements. This continued price risk, and constrained resource environment during the winter period is demonstrated through forward prices at the Huntingdon/Sumas market hub, which are shown in Figure 6-5 below.

Figure 6-5: Station 2 Full Cost and Sumas Forward Price Comparison [186]



The forward price curve reflects the market view that there is value for regional parties to hold firm supply resources (pipeline or off-system storage) to manage their winter load requirements, instead of purchasing at the Huntingdon/Sumas market.

FEI's gas contracting strategy for its Core customers in today's marketplace has limited supply exposure to the Huntingdon/Sumas market. This is because FEI's strategy, as accepted by the BCUC in past ACPs, has been to hold firm pipeline capacity and mitigate fixed costs for holding such capacity whenever possible. FEI began to implement this strategy as far back as 2014, given the unfolding market conditions in the region. In FEI's view, this was a less risky and more prudent strategy that provided protection to customers from large price spikes, higher overall gas costs and limited availability of gas at the Huntingdon/Sumas market. However, this strategy does not insulate FEI's Core customers from cost increases, as the tolls on the T-South system have increased over the past few years, due to the restoration of the pipeline after the T-South incident, and the incremental expansion of the T-South system in 2021. These tolling costs will likely continue to increase in the future, given the greater need for maintenance and reliability on aging infrastructure in the region.

Although FEI's Core customers do not currently rely on the Huntingdon/Sumas market, many Lower Mainland customers in the Transportation Service model do, given that they do not have the credit or financial capabilities to secure long-term pipeline capacity on third-party pipelines.

[186] Graph is based off indicative forward pricing provided by Amerex on January 24, 2022. Station 2 Full Cost includes Station 2 forward monthly price, T-South fuel, Westcoast 2021 Final Tolls, Motor Fuel and Carbon Tax.

Currently, these Transportation Service customers have been able to serve their demand requirements by accessing some transportation capacity in the secondary market[187] and by purchasing gas supply at the Huntingdon/Sumas market. In the long-term, however, as new regional demand materializes, specifically from Woodfibre LNG project, much of this capacity is expected to be taken back to serve this new demand, particularly given that the Woodfibre LNG project has already secured its transportation as described above.

FEI first became concerned with these regional transportation and storage resources constraints in 2014 and secured additional T-South capacity to allow for the potential of Transportation Service customers returning to bundled service[188], as well as for future load growth.[189] This proved to be a prudent decision because the T-South to Huntingdon capacity has been fully contracted since that time. FEI began to experience an increase in Transportation Service customers moving back to the bundled service in 2017, but the most significant movement occurred after the T-South incident, when 42 percent (over 900 transportation service customers) provided notice to FEI of their intention[190] to return to bundled service as of November 1, 2019. Given FEI's proactive decision to secure additional T-South capacity for this potential development, the customer movement after the T-South incident did not have a material impact on the portfolio.

Transportation Service customer movement does pose risks to FEI's gas supply portfolio, such as not being able to secure enough incremental resources in the region to serve more Transportation Service customers moving to FEI's bundled service. As previously discussed, FEI has mitigated this risk in the past by securing contingency resources above what Core customers require within its portfolio and will continue to annually assess the planning margin for contingency resources. If additional Transportation Service customers elect to return to bundled service, the existing contingency resources could mitigate a portion, if not all, of this increased Core customer demand within FEI's supply portfolio. However, this will come at the expense of a potentially lower than recent contingency margin.

There is also a risk of having underutilized resources if customers later choose to return to Transportation Service. Despite the future risks of relying on that marketplace, this development could occur if there is a prolonged duration in which the Sumas price is lower than FEI's rate. This potential large customer movement between FEI's bundled service and the Transportation Service model creates planning uncertainty for the supply portfolio, and therefore FEI pre-emptively monitors customer movement between bundled service and transportation service.

[187] Shippers on the T-South system can temporarily release pipeline capacity on an annual or seasonal basis that is not required for their own use.

[188] Bundled service means that a customer purchases both the gas supply and delivery service from FEI. FEI's Core customers take bundled service.

[189] Approved by the BCUC on December 3, 2015 via Letter L-43-15.

[190] This was due to the volatility at the Huntingdon/Sumas market when the average Sumas daily price for the entire 2018/19 winter was approximately $15 CDN per GJ, which was approximately $12 CDN per GJ higher than FEI's cost of gas.

6.2.4.3 *Demand Uncertainties*

As discussed in Section 4, critical uncertainties could result in either increased or decreased annual demand for FEI, and this introduces planning uncertainty over the long term. While FEI's long-term supply outlook has been developed for the Diversified Energy (Planning) Scenario, FEI has also considered the potential for higher or lower demand outcomes as modelled in Section 4. Figure 4-20 shows the range of total scenario demand outcomes that have been modelled in the 2022 LTGRP. Based on this range of demand outcomes and considering the energy savings from DSM activities discussed in Section 5.4.3 and 5.4.4, the following discussion explains that FEI is prepared for managing demand outcomes either higher or lower than the Diversified Energy (Planning) Scenario demand should they arise.

As discussed in Section 2.2.2, several policies such as the Province's plan to cap carbon emissions from gas utility customers, or to transition new buildings to zero-carbon by 2030, may result in less use of conventional natural gas in the residential, commercial, and industrial sectors. There is uncertainty tied to the Diversified Energy (Planning) Scenario and FEI expects the continued development and expansion of renewable and low-carbon gas supply to address these policies. FEI expects increased gas use in the LCT sector. Reducing conventional natural gas supply, however, will not create a major risk to FEI's medium- to long-term supply portfolio planning strategy due to the contracting flexibility of FEI's portfolio:

1. Commodity Purchases – Although FEI has entered into some long-term supply commitments with counterparties, a majority of the gas supply purchased for the Core customers is negotiated on an annual basis and priced off a market index. Therefore, FEI could easily reduce or resell the amount of commodity purchases if Core demand declines or is displaced with low-carbon supply.
2. Transportation Capacity – FEI's transportation portfolio has been designed so that portions of capacity on third-party pipelines are up for renewal each year. This would allow FEI to de-contract a significant amount of its transportation capacity over a five-year period if it encounters a future with lower demand than expected in its planning scenario - the Diversified Energy (Planning) Scenario.
3. Storage Portfolio – FEI's approach to storage contracts is similar to the transportation portfolio; however, the contract terms may not necessarily expire on an annual basis but on a two or three-year period. Storage contracts are more difficult to manage because there are no renewal rights embedded in the contract terms, so FEI must balance term length versus the risk of losing access to storage supply. In any case, if the load duration curve changes over time such that less storage supply is needed, FEI will still have the ability to determine, as a long-term solution, an approach to de-contracting storage resources.

As Figure 4-20 also illustrates, the Diversified Energy (Planning) and Upper Bound demand scenarios show a large step change increase in demand in 2024. This is due to a large-scale industrial project, Woodfibre LNG project, which is discussed further in Appendix D-1. The Woodfibre LNG project would increase the region and FEI's overall load, but not FEI's gas supply portfolio as was shown in Table 6-2, since Woodfibre LNG Limited will be securing its own gas supply. However, if Woodfibre LNG project comes into service, which is likely not until 2027[191] at the earliest, the regional gas flow and prices for all customers may be impacted, and this could also elevate the supply and pricing risks at the Huntingdon/Sumas market.

As such, the risk to FEI's customers (in terms of access to sufficient and cost-effective gas supply) of demand outperforming the Diversified Energy (Planning) Scenario expectations is higher than the risk of demand underperforming the Reference Case expectations. This is due to the limited transportation and storage resources currently available in the region, and competition from other PNW utilities, such as those in Washington and Oregon, for these resources. FEI has already mitigated a portion of this risk through holding contingency resources above the Core customers' portfolio, as previously discussed, and will continue with this strategy to manage increased load until new infrastructure (pipeline and storage) is added to the gas system.

This demand uncertainty over the coming decades highlights the importance of continually assessing the demand, supply, and market conditions each year through the ACP process, and any infrastructure projects needed as part of FEI's supply portfolio.

6.2.5 Managing Pricing Risks within the Gas Supply Portfolio

FEI's gas supply portfolio includes diversified commodity, storage and transportation resources to maintain supply reliability and reduce commodity price uncertainty. While the ACPs include the portfolio of resources for each upcoming gas year, they also include resources and contracts that extend for five years and longer. This is because the natural gas marketplace is competitive and many resources cannot be acquired, or contracted for, just prior to each gas contract year but instead must be planned for and arranged ahead of time.

Volatility in natural gas prices is partially managed by maintaining access to supply hubs, utilizing a variety of storage and transportation resources, and using different pricing structures and contract terms. FEI manages price risk by accessing appropriate natural gas infrastructure, minimizing reliance on any supply that is delivered on an interruptible basis, and diversifying the gas supply portfolio, including by considering the measures discussed in Table 6-4.

Table 6-4: Price Risk Managing Mechanisms and Benefits

Measure	Benefit
Purchasing physical supply at daily and monthly index prices.	Provides pricing stability in the portfolio, as periods of high winter demand can cause daily priced supply to trade at levels much higher than monthly priced supply, and vice versa

[191] FEI notes the inclusion of a step change demand increase caused by Woodfibre LNG project in 2025, rather than 2027, within demand charts elsewhere in this LTGRP. This difference is due to the announcement of the updated in-service date coming after much of the demand modelling for the LTGRP was already complete.

Measure	Benefit
Ongoing evaluation of purchasing supply based on different pricing arrangements. This could include gas supply arrangements based on a fixed pricing structure.	Fixed-price physical purchases provide long-term security of supply as well as provide mitigation against market price volatility.
Contracting for term purchases outside the gas year (not exceeding three years) if the Station 2 monthly discount to AECO/NIT is wider than a target level laid out in the ACP.	Has allowed FEI to layer in term supply by reducing the buying exposure at Station 2 during a given contract year.
Extending the Negotiation Period[192] for when FEI purchases winter term supply at Station 2.	Provides additional pricing diversification within the portfolio, as term purchases would be layered in over a longer period of time
Procuring seasonal and market area storage capacity and deliverability from third parties.	Storage diversifies FEI's overall portfolio by not having to buy all of its winter gas requirements during the winter time. This also provides a natural physical winter hedge by locking in the value between summer and winter gas prices for gas that will be used during the heating season.
Diversifying storage resources by utilizing different storage facilities and staggered contract expiry dates.	FEI contracts for storage capacity at Aitken Creek Storage in BC, Rockpoint Gas Storage in Alberta, and JPS and Mist in the US. Storage contract terms and expiry dates are staggered to provide optionality for portfolio shaping, reduction in negotiation failure risks, and to alleviate the need to contract for large volumes of storage capacity, particularly during periods of high storage prices.
Utilizing the Tilbury and Mt. Hayes LNG facilities to balance the load in cold or extreme weather conditions, or to provide gas supply during emergency conditions.	The deliverability from these facilities helps to manage price volatility at the Huntingdon/Sumas market, while providing a secure source of on-system gas supply.

Financial hedging strategies, which are assessed through PRMPs, are another way of managing price volatility and the natural gas commodity costs. Hedging involves the use of financial derivative instruments wherein the market index-based price for gas supply purchases is converted to a fixed price or capped price (i.e., financial swap) via a transaction with a counterparty, such as a bank. The benefits of this approach include greater gas supply cost certainty and protection against rising market prices. It is important to note that hedging directly impacts the cost of gas supply for the medium or longer term while other rate smoothing mechanisms, such as the use of deferral accounts, do not directly affect gas costs but rather defer costs or surpluses over the shorter term.

[192] Term supply transactions are typically completed between one and six months prior to the gas delivery date (Negotiation Period). Since 2021, FEI has extended the Negotiation Period to ten months for winter term supply.

The last PRMP application filed to hedge prices at AECO/NIT was FEI's 2018 PRMP. This application included requests for approval of a medium-term hedging strategy at AECO/NIT, which recommended locking in up to fifty percent of the commodity supply portfolio with fixed price hedges if predefined price targets were reached, and implementing long-term hedging with terms up to five years. The 2018 PRMP was denied approval by the BCUC.[193] While the goal of FEI's price risk management is not to "beat the market", it is to capture opportunities to lock in prices and reduce rate volatility. FEI considers the development of its price risk management strategies an iterative process and continues to monitor market conditions at AECO/NIT and Station 2, and may look to bring forward another request to the BCUC for approval in the future depending on market conditions. Currently, FEI's PRMP has focused on mitigating any Sumas pricing exposure that the Core customers may have at the Huntingdon/Sumas market. Over the long term, this exposure will depend on load growth and market conditions in the region. The strategy to mitigate the Sumas pricing risk has been generally approved in the past by the BCUC. Going forward, FEI's price risk management strategies will continue to be assessed in consideration of market conditions and any underlying exposure to customers.

The price risk management tools discussed in this section have not yet been widely applied to renewable and low-carbon gases. However, with rapid industry growth and increasing supply availability expected over the planning horizon, FEI may seek to apply these tools and tactics to these renewable and low-carbon gas supplies as well. As renewable and low-carbon gas supply increases in its portfolio, FEI may look to use price risk management tools to help manage the costs for these supplies as well.

6.2.6 Short-Term Actions

FEI will continue to develop a portfolio that provides its customers secure and reliable supply for the short to medium term. FEI's efficient supply portfolio consists of natural gas commodity contracts, third-party pipeline capacity and storage resources, and FEI will continue to assess the regional market for renewable and low-carbon gas volumes and adjust the portfolio annually as needed through the ACP. Near term efforts in acquiring renewable and low-carbon gases are aimed at accelerating the transition to a low-carbon energy future to meet 2030 provincial emission reduction targets.

Until new infrastructure is added in the region, FEI's contracting strategy will continue to hold more resources than the Core customers require within its portfolio of resources. Maintaining contingency resources mitigates the risk of supply disruptions, but also benefits FEI for the next few years in ensuring sufficient resources for the expectation of continued small amounts of growth in the short-term. Further, FEI resells excess resources on the day or month if they are not required, which helps to mitigate the costs of the total portfolio. The alternative is to attempt to contract for additional resources in the future when they are forecast to be needed. However, given the current demand for these resources and their value, it would be difficult or even impossible to re-contract the resources back in the future.

[193] BCUC Decision and Order G-108-19 (May 22, 2019).

6.3 *INFRASTRUCTURE CONSIDERATIONS TO FURTHER OPTIMIZE FEI'S SUPPLY PORTFOLIO (MEDIUM TO LONG-TERM ACTIONS)*

The following subsections outline medium to long-term considerations that could further optimize FEI's gas supply portfolio planning and help mitigate the planning uncertainties discussed above. Additional infrastructure in the PNW has been a major focus for FEI, especially in light of the T-South incident, growing demand in the region, and the necessary requirements to transition to a renewable and low-carbon energy future.

6.3.1 Mist Storage Facility Capacity and Contracting Potential

The Mist storage facility is located in Oregon and owned and operated by NW Natural. FEI currently has a variety of market area storage contracts at Mist, each with different capacities, expiry dates, and injection and withdrawal capabilities. FEI's market area storage contracts at Mist are recallable, which means once these contracts expire, NW Natural may take back all or a portion of the storage capacity for their customer load requirements. This has not been an issue for FEI in the past because recalls have impacted other Mist customer contracts. NW Natural has also added less-than-firm resources in their supply portfolio which have provided additional supply resources in the near term, but are expected to be discontinued once Woodfibre LNG project is in service, since the amount of demand from Woodfibre LNG project could affect regional gas flows. If this change occurs in NW Natural's resources, it will cause a recall and could cut into the Mist capacity FEI has historically held.

The market area storage resources are essential to FEI's gas supply portfolio especially when colder than normal winter loads are greater than the supply available from seasonal storage and termed gas supply (Figure 6-1). Alternative resources in the region are evaluated by FEI on an annual basis, however, they are limited given that resources in the region are fully contracted and can be constrained during the winter, as discussed in Section 6.2.4. Further, alternative resources in the region do not have the same benefits that Mist provides in terms of helping FEI balance and meet load requirements on an intra-day basis. Given that the T-South pipeline is fully contracted and the value of holding the T-South capacity is strong, the pipeline has run at or near its maximum capacity available each winter season over the past several years. Therefore, when demand increases over the course of the day, FEI has to rely on its market area storage resources to meet the changing load requirement.

In the long-term, FEI will proactively assess the need for market area storage, as impacted by future peak demand, its winter load profile, and the daily balancing requirements of the system in normal operations. FEI has had some preliminary discussions with NW Natural regarding the potential to contract for long-term non-recallable capacity. In order for this to occur, NW Natural would have to further expand its Mist storage facility.

6.3.2 Tilbury LNG Storage Expansion (TLSE) Project

The Tilbury Base Plant[194] was built and sized to ensure that adequate natural gas supply was available to provide service to FEI's customers on the coldest days, managing the very short durations when demand during cold weather events exceeded contracted supply. Given that Tilbury is located on-system, it also provides benefits related to security of supply, reliability and flexibility to serve loads within FEI's system.

The experience of the T-South incident signalled that enhancements to gas supply resiliency are required, especially the ability of the system to withstand and recover from a no-flow[195] event. The T-South incident resulted in a two-day no-flow period, whereby commercial arrangements within FEI's gas supply portfolio were suspended. Under these types of emergency events, the physical resources that FEI has under direct control are critical. Although the Tilbury Base Plant helped during the T-South incident, ultimately its regasification capacity and storage are insufficient to support the daily load in the Lower Mainland on most days of the year, with the greatest shortfall occurring during the winter months.

Therefore, FEI applied to the BCUC for a CPCN for the TLSE project[196] on December 29, 2020, which entails constructing a new 3 Bcf LNG storage tank and 800 MMcf per day of regasification capacity. The TLSE project will significantly increase the resiliency of FEI's gas system in the event of a critical disruption of regional pipeline supply by:

- Allowing FEI to continue to serve a much larger portion of the daily system in the event of a supply emergency, including during winter periods; and
- Providing sufficient storage to meet that larger portion of the daily system load for a longer period of time (i.e., at least three days), having regard to a reasonable estimate of the time during which supply to FEI's system could be disrupted. This would allow additional time for FEI to make any necessary operational decisions so that, if needed, FEI could execute a controlled shutdown.

The LNG storage volume and regasification capacity are intended for resiliency purposes. From a planning perspective, FEI will reserve 2 Bcf in the tank at all times to meet FEI's Minimum Resiliency Planning Objective (MRPO),[197] and the incremental 1 Bcf will provide flexibility for gas supply, operational purposes, and future load growth. Further, the TLSE project will also replace the Tilbury Base Plant, which is currently part of FEI's gas supply portfolio, as shown in Table 6-2. This is important because absent the Tilbury Base Plant, FEI would have to find a replacement

[194] The Tilbury Base Plant refers to the original production and storage facility in operation since 1971.

[195] A no-flow event refers to an incident affecting regional pipeline infrastructure that results in the total interruption of gas flows on the pipeline.

[196] FortisBC, Application for a Certificate of Public Convenience and Necessity for the Tilbury Liquefied Natural Gas (LNG) Storage Expansion project (Application) (December 29, 2020), online at: https://www.cdn.fortisbc.com/libraries/docs/default-source/about-us-documents/regulatory-affairs-documents/gas-utility/201229-fei-tlse-cpcn-application-redacted-ff.pdf?sfvrsn=8aed3564_2.

[197] FEI developed a MRPO for the TLSE CPCN as a way to conceptualize or articulate the identified risk that FEI's Lower Mainland system faces from a disruption on the T-South system based on FEI's actual experience. The MRPO was defined as having the ability to withstand and recover from, a three-day no-flow event on the T-South system without having to shut down portions of FEI's distribution system or otherwise lose significant firm load.

for this storage in the open market. Contracting for the existing 150 MMcf per day peaking asset in the open market would be both challenging and costly, given that the resources in the region are fully contracted (as shown in Figure 6-4 above).

The TLSE project will also continue to be a vital resiliency resource within FEI's Clean Growth Pathway, as the transition to renewable and low-carbon gas takes place. The shorter duration peaking supply service provided by the TLSE project will continue to be utilized beyond the 20-year planning horizon of the 2022 LTGRP. RNG, which will form a large portion of the renewable and low-carbon gas supplies over the planning horizon, is methane and therefore interchangeable from a system infrastructure perspective with FEI's current natural gas supplies. Hydrogen, the other major component of the renewable and low-carbon supplies over the planning horizon, is not as interchangeable with natural gas as is RNG, but its use by FEI's customers can still benefit from the resiliency benefits of the TLSE project over time.

This project is currently before the BCUC and if approved, FEI plans to initiate the execution phase for the project in 2023, which would result in the project completion occurring in 2026.

Following an emergency, it is typical for the outage to be followed by a ramp-up to normal supply conditions. For example, after the two-day "no flow" period during the T-South incident, supply to FEI's system remained constrained for approximately 14 months. Although the TLSE project is intended to address relatively short-duration supply disruptions in the Lower Mainland, the period of time that the TLSE project will help following a ramp-up back to normal supply conditions is limited by the storage tank size. The next section discusses how additional pipeline infrastructure, such as the RGSD project, would provide further resiliency by ensuring that alternate pipeline supply is available during a T-South event that involves a sustained loss of pipeline capacity.

6.3.3 Regional Gas Supply Diversity (RGSD) Project

The need for new regional pipeline infrastructure (such as the RGSD project) is predominantly driven by the following three market conditions which are outside of FEI's control:

1. **Constrained Capacity on the T-South System:** FEI, and the PNW as a whole, rely on the T-South system for the majority of their daily gas supply. Despite nominal increases in capacity as recently as November 2021, the T-South system remains fully subscribed due to high demand in the region. As discussed in Section 6.2.4.2 above, the region has been facing several periods of market price volatility at the Huntingdon/Sumas market during the winter seasons. This pricing volatility is a reflection that the regional infrastructure is becoming more constrained. Also, as discussed above, the T-South incident highlighted the serious supply shortfall the region faces in a circumstance where pipeline capacity is either restricted or entirely interrupted for a period of time. From a resiliency perspective, the continued reliance on a single pipeline system to provide the majority of gas supply to the region is a serious risk that needs to be addressed.
2. **Forthcoming Increases in Regional Demand:** Constrained pipeline capacity and supply disruption risks will be exacerbated by both the addition of load associated with the Woodfibre LNG project and load growth in the region over time. Woodfibre LNG project

going into service will leave an immediate, significant capacity shortfall. Moreover, the demand for gas-fired electricity in the US PNW is expected to continue growing with the retirement of coal-fired generation. These developments, among others, will drive new regional pipeline infrastructure.

3. **Expansion of Renewable and Low-Carbon Gas Supply Due to Government Policy:** Government policies aimed at decarbonization drive a need for RNG and hydrogen from new supply sources, with hydrogen blending into the gas system requiring capacity increases due to its lower energy density.[198] As hydrogen emerges in the market, it will be blended into existing gas transmission and distribution systems. Additional pipeline capacity will be required to support this transition, as more volume of hydrogen will be required to deliver the same amount of energy as conventional natural gas.

To protect the interests of FEI and its customers, FEI needs to influence which regional pipeline infrastructure gets built, thereby maximizing the value obtained from it. The RGSD project would involve an expansion of SCP through construction of additional compressor stations and a new pipeline connecting SCP near Oliver, BC to the Huntingdon/Sumas market. This project will increase the capacity to the Huntingdon/Sumas market by approximately 500 TJ/day[199], and is FEI's preferred choice given that it would open valuable access to an entirely different path from the T-South system. This would provide FEI with greater access to one of the largest natural gas trading hubs in North America (AECO/NIT), and allow FEI to split its gas supply portfolio between Station 2 and AECO/NIT more evenly via the new pipeline, thereby diversifying its supply resources, improving its long-term supply security, increasing supply resiliency and further optimizing its supply portfolio.

Therefore, FEI will file an application for approval of a deferral account for the development of the RGSD project in Q2 2022.[200] This application will more fully describe how the RGSD project aligns with Section 2 of the *Clean Energy Act* and how the RGSD is needed along with other infrastructure to meet resiliency requirements, future demand forecasts in light of regional supply constraints and the transition to renewable and low-carbon gas.

Employing a mix of pipeline diversity (i.e., the RGSD project) and expanding storage resources (i.e., the TLSE project) is the most cost effective way to enhance resiliency, facilitate load growth opportunities, support the transition to renewable and low-carbon gas, while also creating flexibility within FEI's gas supply portfolio. Stated another way, it would not be efficient, or in the interest of customers, to build resiliency by holding year-round diverse pipeline resources in quantities that would only be required if a no-flow event occurred during a short duration peaking period. Conversely, it is unlikely to be feasible or economic to attempt to manage long-duration

---

[198] Hydrogen blending requires more pipeline capacity to move the same energy; compared to natural gas hydrogen has a much lower energy content partially offset by higher velocity capability.

[199] The pipeline capacity could be expanded to more than 500 TJ/day, depending on potential interest from third-party shippers. It is expected that FEI and other parties would contribute to the cost of the project.

[200] FEI anticipates filing the RGSD development cost deferral account application in Q2 2022.

supply events or exposures only with on-system LNG storage, since the amount of storage required would be too large.

6.4 CONCLUSIONS AND RECOMMENDED ACTIONS

Effective gas supply portfolio planning and price risk management on the short-, medium- and long-term basis enables FEI to secure cost effective and reliable supply and mitigate market price volatility for customers. Given the regional marketplace developments in terms of gas supply and infrastructure, FEI must continue to monitor changes and be proactive in assessing challenges and identifying opportunities in order to meet the LTGRP objectives, and may look to bring forward another price risk management application for approval in the future.

The constrained pipeline and storage resources in the region during the winter season continues to be a major concern, and market developments have caused significant supply and pricing risks. FEI has increased resiliency within the existing portfolio by holding contingency resources; however, resiliency needs to be further improved through new infrastructure projects. With the advancement and growth of renewable and low-carbon gas supplies in the region, FEI's future infrastructure is being planned to support the transition to a lower carbon future by providing increased resiliency and supporting a broader range of supply resources.

As resources in the region are limited, by monitoring potential changes in demand or market conditions, FEI maintains an evolving strategy to assess its supply portfolio annually through the ACP. FEI's portfolio does maintain contracting flexibility to mitigate security of supply risk, and is in adequate position for the short-term, but ultimately meeting increased demand over the long term will require increased storage and pipeline infrastructure.

Recommended actions that FEI will take to manage FEI's gas supply portfolio include:

- Manage supply risk and price volatility in the region by maintaining access to supply hubs (Station and AECO/NIT), hedging any supply exposure to the Huntingdon/Sumas market with financial hedges, utilizing a variety of storage and transportation resources, and using different pricing structures and contract terms;
- Continue using financial hedging strategies as approved by the BCUC in FEI's PRMPs and, where applicable, request BCUC approval for an expansion of financial hedging strategies via future PRMPs;
- Continue to support the regulatory process for the TLSE project which will significantly increase the resiliency of FEI's natural gas system in the event of a critical disruption of regional pipeline supply;
- Evaluate opportunities within FEI's own operating region to improve infrastructure resiliency and supply diversity such as the RGSD project, which will support diversity, reliability, and decarbonization over the long term;

- Evaluate opportunities to contract for long-term non-recallable capacity at Mist, which will help manage security of supply concerns in the gas supply portfolio.
- Continue to accelerate the acquisition of renewable and low-carbon gas supplies for inclusion in FEI's gas supply portfolio as part of FEI's Clean Growth Pathway; and
- Assess the firmness of renewable and low-carbon gas supplies for year-round delivery to customers and assess the evolving marketplace for opportunities to apply traditional portfolio risk mitigation mechanisms to these renewable and low-carbon supplies.

Section 7:

SYSTEM RESOURCE NEEDS AND ALTERNATIVES

Table of Contents

7. SYSTEM RESOURCE NEEDS AND ALTERNATIVES

7.1 *INTRODUCTION*

This section discusses FEI's gas delivery infrastructure and identifies any system resource needs in consideration of regional peak capacity and the energy demand of its customers, addressing the requirements of subsections 44.1(2)(d) and (f) of the UCA. While Section 6 described FEI's energy supply portfolio for deriving system-wide demand for Core customers each day through the entire year, as well as the peak design day, this Section 7 describes system resource planning for deriving location-specific (not system-wide) peak demand. Key aspects of providing a safe, reliable, and secure supply of gas to customers are identifying when and where any capacity constraints may appear, and planning for the infrastructure and system resources that FEI requires to construct over the planning horizon. When forecast peak demand exceeds available system capacity, a gas system expansion is required. FEI recognizes the rapidly emerging need for delivering renewable and low-carbon gases in increasingly larger volumes and has incorporated these discussions in relation to system planning within this section.

Planning for system resource needs includes system sustainment and renewal, integrity upgrades, and system expansion projects that together contribute to overall system resiliency. FEI's system sustainment planning process identifies important near-term and long-term system renewal requirements and projects to improve system integrity. There are traditionally three resource options to evaluate when planning system expansions: pipelines, compression and storage. As FEI continues to develop renewable and low-carbon resources, reliable on-system production will soon become a fourth alternative for consideration. To solve capacity constraints, each alternative is analysed with respect to Indigenous and public impacts, overall cost, difficulty of implementation, operational flexibility, implementation time, and other factors within the overall philosophy of system sustainment and reliability. Often, some combination of the three resource options leads to an optimal solution. Transmission infrastructure projects to address system capacity constraints are often large and take many years to plan and execute, underscoring the need for a long-term resource planning process.

Annual increases in forecast peak demand are influenced by a number of factors. The industrial sector relies on gas for existing, new, or expanded applications, as favourable pricing and a preference for lower carbon natural gas over more traditional fossil fuels such as propane, diesel or coal continues to drive demand. In addition, the LCT sector and opportunities for the LNG market continue to drive growth in demand. The location of customer demand on the system is a significant factor in determining the ability (capacity) of the system to deliver gas.

To address the specific local and regional requirements, FEI builds regional peak demand forecasts from the bottom up, assembling the peak demand from the recent consumption and regional weather history of each customer within the system. FEI conducts this analysis for each of its three main transmission systems: Vancouver Island Transmission System (VITS); Coastal Transmission System (CTS); and Interior Transmission System (ITS).

In the 2022 LTGRP, FEI's traditional peak demand forecasting method (Traditional Peak Method) is compared with a new exploratory method which links peak demand forecasts to the end use scenarios used in the annual demand forecasts. Currently, the exploratory end use method remains theoretical in nature and is unsupported by direct measurement. Until such time as more granular data from advanced metering infrastructure becomes available, FEI will continue to rely on the Traditional Peak Method for infrastructure planning which is predominantly based on current monthly consumption of FEI customers. The exploratory end use method does, however, provide a means of assessing a range of peak demand forecast possibilities and the impacts on the scope and timing of upgrade projects required for each.

FEI takes a broad outlook on system resource needs that considers long-term system capacity and sustainment plans and expansion requirements. This outlook enables an integrated approach to determining the most effective system improvements. This discussion on resource needs is organized as follows:

- Section 7.2 discusses FEI's approach to system capacity planning and describes the method for determining peak demand forecasts and infrastructure project alternatives to address forecast capacity constraints;
- Section 7.3 discusses the capacity of FEI's gas transmission infrastructure to meet current and forecast peak demand for each of FEI's major transmission service regions: VITS, CTS, and ITS. For each of the service regions, the following information and considerations are discussed:
    - Forecasts resulting from FEI's Traditional Peak Method and unique regional peak demand forecasts for LTGRP scenarios and sectors (residential, commercial and industrial and others) before and after DSM energy savings are applied;
    - Potential increases in industrial load, increasing LNG demand, and their impacts on the Traditional Peak Method forecast and system upgrade requirements where these loads are anticipated; and
    - The section further discusses forecast capacity constraints and significant projects impacting FEI's transmission laterals and distribution system networks as described in Sections 7.3.4 and 7.3.5, respectively;
- Section 7.4 introduces the considerations necessary to assess infrastructure upgrades as FEI integrates renewable and low-carbon gases into FEI systems and provides illustrative examples of the capability of FEI systems for their delivery. Further it discusses the system specific implications of renewable and low-carbon gas integration with emphasis on the unique requirements for hydrogen based on its molecular properties in relation to methane;
- Section 7.5 discusses the requirements to continue to improve FEI's systems to be more resilient in the event of supply disruptions that may occur within the regional gas infrastructure or within FEI's own systems; and

- Section 7.6 provides a description of other major system projects that are not driven by system capacity considerations and that FEI anticipates may result in CPCN applications in the next several years.

7.2 SYSTEM CAPACITY PLANNING

This section discusses FEI's approach to system capacity planning and describes the method for determining peak demand forecasts and infrastructure project alternatives to address forecast capacity constraints. Peak demand forecasts for system capacity (infrastructure) planning include considerations of demand at the local and regional level. This is a bottom-up and more granular approach than the approach used when considering system-wide peak demand use for gas supply planning (as discussed in Section 6).

Ensuring adequate capacity within the transmission and distribution systems to meet existing and forecast load is critical to the safety and reliability of gas delivery. After identifying the forecast growth in gas demand and the expected impact of DSM across FEI's service areas, FEI examines the capacity of the gas transmission systems to meet anticipated demand. When forecast demand exceeds available capacity, a gas system expansion is required. Different system expansion alternatives are then identified to determine the most effective means to address specific capacity constraints.

Gas supply resources must be designed to meet peak demand requirements of Core customers[201] (customers for whom FEI purchases gas). Further, when assessing supply resources, gas supply forecasting considers the system-wide peak. This is, in part, because on a system-wide basis, an increase in peak demand in one location can be offset by a decrease in demand in other regions and still meet the supply requirements of the whole system. As system demand changes year-over-year, supply resources can generally be adjusted in a timely and responsive manner to meet the overall peak requirement (refer to Section 6).

In contrast, infrastructure projects to address system capacity constraints on transmission systems are often large and take many years to plan and execute. As a result, securing infrastructure resources is not as expeditious as securing gas supply resources. In addition, the location of customer load within the system is a significant factor in determining the ability of the system to meet customer demand. Increasing peak demand in one region cannot necessarily be offset by a system expansion or decrease in peak demand in another region. To address the specific local and regional requirements, regional peak demand forecasts are built from the bottom up, aggregating the peak demand from the recent consumption and regional weather history of each customer within the system. For commercial or industrial loads that consume gas for process purposes and hence are not primarily driven by heating demand, either their contract demand (if they have one) or their maximum billed demand are used.

[201] Table 6-1 provides a summary of FEI customer service types for the LTGRP, and the considerations required in discussing Section 6 (Gas Supply Portfolio) and Section 7 (System Resource Needs and Alternatives).

Transmission system expansion planning is based on this regional peak forecast of demand for Core customers and also includes Firm Transportation customers not included in gas supply resource planning (as described in Table 6-1). Firm Transportation customers are those that secure their gas supply from a source other than FEI but rely on FEI's pipeline systems to transport gas to their premises for consumption. Some Transportation customers with an interruptible contract, under which FEI can curtail when necessary to control peak demand, also have a portion of their demand designated as firm which must be considered in system expansion planning.

Gas system infrastructure planning must ensure that gas system assets have sufficient capacity (in terms of size, compression requirements, and volume, for example) to meet the demand on a given system. To ensure constraints are identified and considered with sufficient lead time to plan and construct the necessary infrastructure, peak demand forecasts over a 20-year planning horizon are used.

In general, system demand growth is determined by region and applied to hydraulic models which determine resulting pressures at critical locations throughout the system. In the context of growing demand, demand will eventually exceed capacity, which typically manifests by the pressure at critical locations falling below minimum values, and a system expansion is required.

FEI's continuously monitors these factors that can impact capacity requirements to determine if there is a need to advance or delay proposed capacity expansions. Section 7.3 discusses factors that might increase peak demand and thus advance capacity requirements, as well as alternatives for addressing system constraints. Potential for lower than expected peak demand delaying the timing of system constraints is also discussed. As such, contingency planning for system capacity requirements is inherently included in FEI's regional system capacity plans.

In addition to load growth, other factors can also affect system capacity. For example, increased urban density close to existing pipeline assets can lead to a class location designation change and may result in a subsequent reduction in allowable operating pressure for that pipeline. Class location designations are defined in the Canadian Standards Association (CSA) Z662:19 *Oil and Gas Pipeline Systems* standard and used as a protective measure in pipeline design to address population density and other criteria in the vicinity of a pipeline. A reduction in operating pressure to address a class location change due to population growth in the vicinity of the pipeline will lead to a decrease in available pipeline capacity. As FEI incorporates renewable and low-carbon gases into the gas distribution and transmission systems, the physical properties of these gases, such as density and energy content per standard volume, and the ability to generate supply located on-system can have an impact on capacity. These changes in physical properties and supply options must be considered. Section 7.4 discusses the potential impacts of renewable and low-carbon gases on FEI transmission system capacity at a high level.

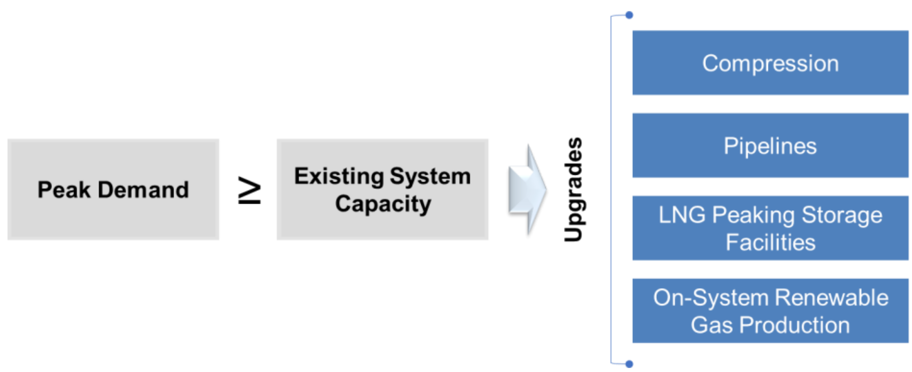
7.2.1 System Reinforcement Considerations

Pipeline capacity is determined by the quantity of gas that can be transported from a supply point at a given supply pressure to delivery points at or above required minimum delivery pressures.

The key objective of any new capacity expansion is to maintain, under peak conditions, pressures at all delivery points sufficient for the system to deliver to the consumer the contracted quantities of gas. Physically, pipeline capacity depends on the diameter and length of the pipeline, internal roughness of the pipeline, maximum operating pressure (MOP), required minimum delivery pressures and the distribution of customer demand along the system. Pipeline pressures are constrained by the MOP. The MOP is established in accordance with provincial regulations and good engineering practices in consideration of original construction specifications. To overcome friction and allow gas to flow through the pipeline, a pressure differential between the supply and delivery points is required. Compressors are used to increase this pressure differential and move large volumes of natural gas at high pressures through the transmission pipelines to major delivery points. The end pressures, which vary inversely with flow, are then controlled by pressure-regulating stations before gas enters the intermediate or distribution pressure systems for delivery to customers.

Traditionally three resource options are evaluated when planning system expansions: pipelines, compression, and storage. Each is described below. In the future a fourth, on-system renewable gas production, will become available. This fourth option is discussed in more detail in Section 7.4.

Figure 7-1: Options for Gas System Reinforcements



- **Pipelines:** To increase throughput capacity, an existing pipeline can be replaced by a larger diameter pipeline (increasing the flow area and decreasing the gas velocity) or it can be "looped" with a parallel pipeline.
- **Compression:** Adding compression helps to increase the average pipeline pressure, thereby providing a higher supply (or driving) pressure to move the gas. This higher pressure also increases the gas density leading to a reduction in gas pipeline velocity and correspondingly lower rate of pressure drop along the pipeline. Compressors can be added to existing compressor sites to provide additional station throughput capacity or new compressors can be added at intermediate locations on the pipeline.
- **On-System Storage:** Storage facilities located within a service region are considered "on-system" supply-side resources. FEI considers LNG storage to be an on-system storage facility. During low demand periods, gas is liquefied and pumped into the storage facility. Conversely, during high demand periods, stored gas is vapourized and compressed back

into the pipeline system to maintain pipeline operating pressure and increase system capacity without having to install throughput capacity from pipelines or compressors. Since FEI can call upon these resources when necessary, system security and reliability increase using these on-system storage facilities. Another benefit of FEI's LNG facilities is the ability to provide customers with the potential to buy LNG for use as a fuel in land or marine transport or for shipping internationally.

To solve capacity constraints, each resource option is analysed with respect to overall cost, difficulty of implementation, operational flexibility, implementation time, and other factors to meet system sustainment and reliability objectives. Either a single resource or some combination of the three resource options will be the optimal solution.

7.2.2 System Capacity Planning Considerations

Options to improve gas system capacity are identified through hydraulic analysis using computer models of the pipeline systems. Computer simulations allow various "what if" scenarios to be evaluated and compared against one another. In determining the need for transmission system expansions, FEI considers the following:

- Optimizing resource capacity additions to meet demand requirements over a 20-year planning period;
- Correlating actual billed consumption information against temperature to determine the expected demand under design temperature conditions;
- Planning capacity additions to meet the total Core customer and Firm Transportation customer peak demand. Interruptible demand is not considered when identifying system improvements to sustain this peak demand. System capacity upgrades identified for supporting firm peak demand provide new opportunities for interruptible customers during off-peak conditions;
- Designing transmission systems to meet peak demand. FEI's Core customer demand varies on an hourly basis and typically exhibits a morning peaking period between six and ten a.m. and an evening period between five and nine p.m. The peak hour demand for these customers can be more than 40 percent above the hourly average (daily demand/24 hours). Transmission systems are designed to meet this peak demand condition;
- The amount of line pack[202] within a transmission system, as this determines whether it should be designed to meet peak day or peak hour conditions. A pipeline system with a large relative line pack can temporarily support increased demand out of the system (to customers) that exceeds the supply into the system by drawing on some of the gas "inventory" contained in the pipeline system. As demand exceeds supply, the amount of gas "packed" in the pipeline (i.e., line pack) is reduced and pressure in the pipeline is drawn down, until such time that the demand drops below the supply into the system, at which point pressure (and line pack) can recover. Pipeline length and operating pressure

[202] Line pack is the "storage" of pressurized gas in the pipeline that can be drawn on to support short-term peaks in demand that may briefly exceed the supply into the pipeline.

determine the amount of line pack available in the system. Typically, longer, larger diameter systems operating at higher pressures with high line pack are designed to peak day conditions; conversely, systems with lower amounts of line pack (due to factors such as lower pressures and smaller volumes) are designed to meet peak hour loads; and

- Long lead times are needed for large infrastructure projects. This is due to regulatory reviews, Indigenous engagement, public consultation, conceptual design, detailed engineering, procurement, construction, and commissioning schedules.

7.2.3 Regional Peak Demand Forecasting

Traditionally, FEI has built regional peak demand forecasts based on the current peak hour use per customer (UPC_{peak}) that is held constant over the planning horizon. Since the 2017 LTGRP, FEI has worked with a consultant, Posterity, in studying a potential means of applying knowledge gained from the end use method of forecasting annual demand to forecast how UPC_{peak} might vary for each end use future scenario presented in Section 4 as well as how DSM programs may affect peak demand.

7.2.3.1 *Traditional Peak Method*

FEI has long-established methods for creating regional peak demand forecasts that have worked well in identifying system constraints and developing projects to address constraints in a timely fashion. FEI's Traditional Peak Method forecast is built from a "load gather" process that determines unique daily and hourly UPC_{peak} values for each customer. Values for most customers are based on a regression analysis of average consumption against local temperature using the most recent 24 months of consumption information extracted from monthly meter read data. Measured values are then extrapolated to the regional design temperature where the customer is located. The regional design temperature represents a one in 20-year value determined for each region. For customers where hourly consumption data is available (typically large commercial and industrial customers), UPC_{peak} is determined directly from that data. The unique hourly UPC_{peak} values for each customer are then grouped by rate and region to determine average hourly UPC_{peak} for each region and rate schedule that can then be applied to an account forecast to determine a peak demand forecast. A unique UPC_{peak} for residential, small commercial and large commercial rate schedules in 66 separate regions across the province is developed in FEI's Traditional Peak Demand Method.

For large industrial demand, the Traditional Peak Method forecast does not apply any forecast growth or decline in the demand associated with these customers. This is because the ability to forecast both the future load and location of these customers is subject to a great deal of uncertainty. UPC_{peak} for large industrial customers varies widely and can significantly impact local system capacity. Speculating on infrastructure requirements for loads of unknown magnitude and location has little value in long-term planning of facilities whose design can be greatly influenced by their location within the transmission or distribution system. However, to explore impacts to peak demand because of potential changes in industrial account forecasts, FEI has produced both high and low account forecasts that show increasing or decreasing numbers of accounts, respectively. These forecasts have been applied to the end use regional peak demand forecasts using the average peak demand for existing industrial customers in that region as an estimate of the peak demand for any new account additions or subtractions. As the location of new industrial demand is not specifically known, this increase or decrease in industrial peak demand was applied proportionally across the relevant transmission system.

UPC_{peak} values used in the Traditional Peak Method forecast are determined based on current measured consumption for customers. When applied to the 20-year account forecast to determine the peak demand forecast, these values are assumed to remain unchanged over the planning horizon. As such, there is no explicit allowance for evolving customer utilization in this approach. The estimates of UPC_{peak} and the peak demand forecasts are "point in time" forecasts, however, and are refreshed annually. Therefore, assessments of future capacity constraints and timing upgrade projects are regularly refreshed with current customer consumption patterns and end uses that reflect the presently measured impacts of energy economics, housing renewal, and DSM programs.[203]

The Traditional Peak Method forecast currently remains FEI's base forecast for determining infrastructure requirements and timing for addressing capacity constraints.

7.2.3.2 *Deriving Regional Peak Demand Forecasts from End Use Scenarios*

In its decision regarding the 2014 LTRP, the BCUC identified opportunities to make stronger linkages between the peak demand and the annual demand forecasts, to understand how "[...] new insights on evolving customer consumption patterns might affect time-of-day demand as well as annual demand [...] and how changes in base load annual demand under different scenarios translate into changes in base load peak demand under the same scenario assumptions."[204]

For this LTGRP, FEI commissioned Posterity to develop an exploratory process linking peak demand forecasts to the end use scenarios used in the annual demand forecasts. Currently the process remains theoretical in nature and unsupported by direct measurement. Until such time as data from advanced metering becomes available, FEI's infrastructure planning continues to rely on the Traditional Peak Method which is predominantly based on current monthly consumption of FEI customers. The exploratory end use method does, however, provide a means of assessing a range of peak demand forecast possibilities and the impacts on the scope and timing of upgrade projects required for each.

Posterity's approach relies on applying a series of appliance load shape profiles, developed from industry studies on appliance use, to sequentially break down annual consumption into peak monthly consumption, monthly to peak daily consumption and finally daily to peak hourly consumption. Using the base year LTGRP inputs developed for the annual demand forecast, Posterity derived a base year hourly UPC_{peak} for each rate schedule and region. The results were

[203] In the Section 6 analyses, the term DSM refers to FEI's forecast DSM activity discussed in Section 5.
[204] 2014 FEI Long-term Resource Plan (LTRP) Decision and Order G-189-14, p. 22.

corrected to peak design temperatures for each region. Posterity then determined calibration factors to match the derived UPC_{peak} values for the base year to FEI's current values of UPC_{peak} (determined from FEI's established load gather process and used in FEI's Traditional Peak Method regional peak demand forecasts). The process, using the derived calibration factors, can then be applied similarly to any year in any scenario to derive UPC_{peak} forecasts and subsequently peak demand forecasts in a format that can be easily applied to FEI's established capacity modelling methods.

The results provide a means for relating annual demand more directly to peak demand. Future effects of DSM programs and the potential impact on peak demand and infrastructure requirements can be reviewed using this approach. This exercise also provides some indication of how various end use scenarios might influence the peak hour factor (PHF), which is the ratio of peak hour consumption to peak day consumption. The results of this exploratory, end use approach are represented below in the sections discussing each regional transmission system.

Since the exploratory end use method is not based on metered FEI customer data, and the effectiveness of DSM programs on peak demand cannot be directly measured until hourly metering is deployed, the Traditional Peak Method forecast, which intrinsically reflects the current effects of DSM programs, remains FEI's base forecast for determining infrastructure requirements and timing for addressing capacity constraints. However, FEI's current application before the BCUC for its AMI project will support FEI's ability to field-validate the projections of the exploratory end use peak demand forecast method and will enable FEI to improve this method in future LTGRPs.

7.3 *REGIONAL TRANSMISSION SYSTEM CAPACITY PLANS*

For capacity planning purposes, FEI is split into three main transmission systems and several smaller transmission laterals. The three main transmission systems are described below:

- The VITS encompasses customers served on Vancouver Island, the Sunshine Coast, Squamish and Whistler;
- The CTS encompasses the Fraser Valley and surrounding cities, and Metro Vancouver; and
- The ITS encompasses the Southern Interior communities in the Kootenays, the Okanagan Valley, and the South Thompson Valley.

Each of the three main transmission systems is discussed in further detail below. For each system, FEI will discuss:

- Existing major system infrastructure;
- Demand and capacity balance, which determines approximately when demand in the region will reach the capacity of the system to deliver natural gas during peak conditions, thus identifying when system constraints will occur;

- Peak demand forecast sensitivity using the range of peak demand forecasts before and after DSM energy savings are applied;
- System expansion alternatives. These are the infrastructure options that exist for solving identified system constraints. The options for constraints that occur in the near term are more developed and are presented in more detail than those that are further out in the planning period;
- Potential increases in industrial load, increasing LNG demand, and their impacts on the Traditional Peak Method forecast and system upgrade requirements where these loads are anticipated; and
- The impact of delivering renewable gases and hydrogen on the system.

FEI examines these factors to identify the expected timing of system constraints and the action plan needed to develop formal solutions that may require further expenditure applications to the BCUC. Year after year, changes in the planning environment and new information may emerge that could impact the timing of the constraints, or the alternative solutions being considered. Such changes will be presented in future LTGRPs or in any required applications to the BCUC.

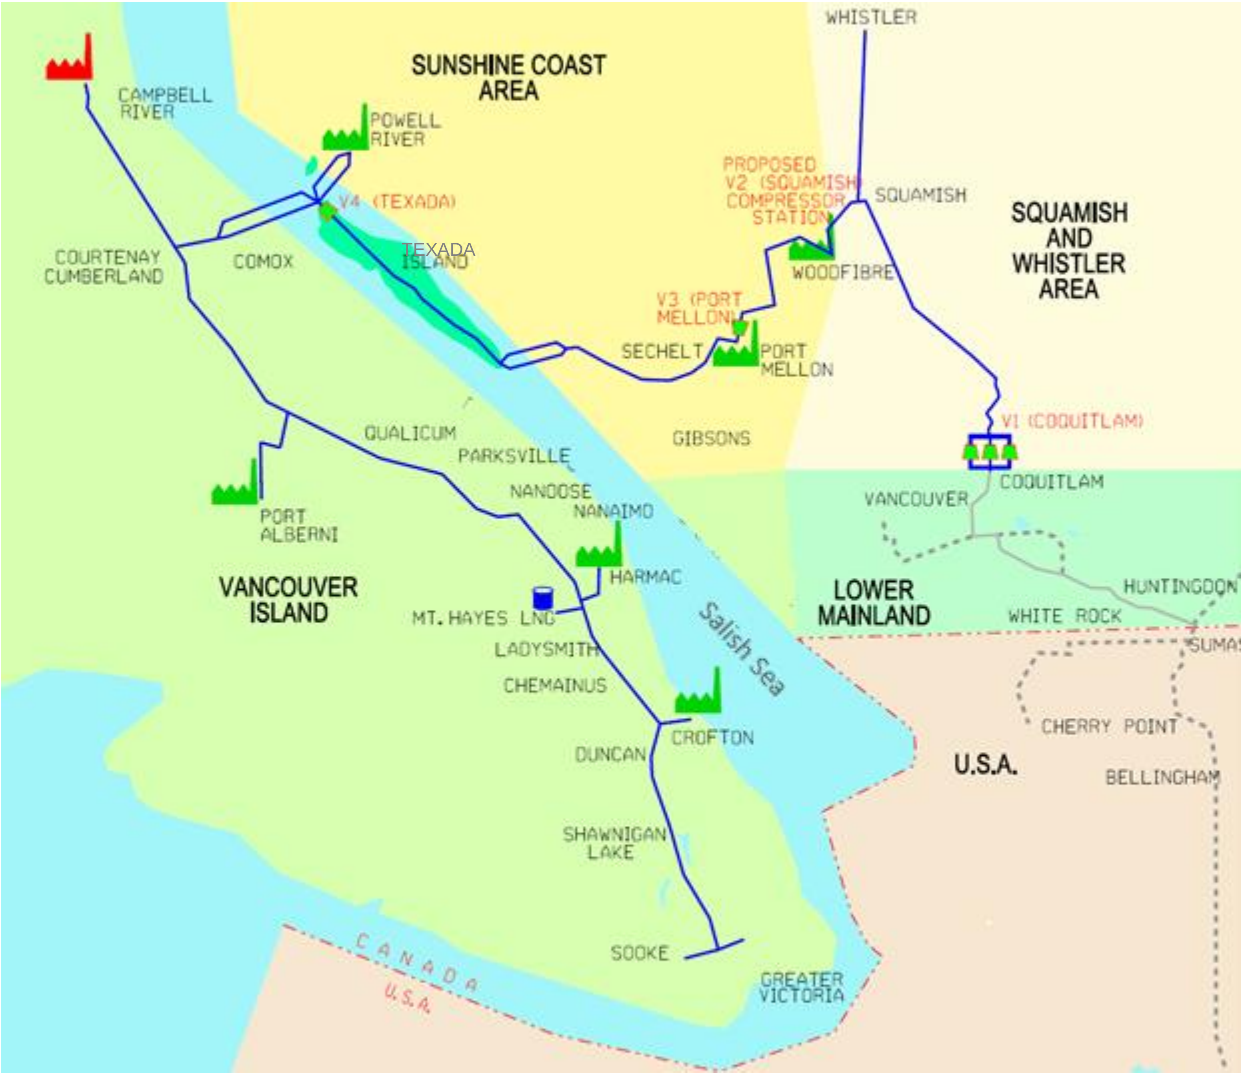
While not discussed in detail in the following sections, for peak demand associated with future CNG, FEI projected that incremental annual CNG demand of 15,000 GJ per year would result in a new fueling station constructed somewhere in the regions served by the three main transmission systems. A typical fueling station designed to deliver up to 15,000 GJ per year is estimated to exert a peak hour demand of 750 standard cubic meters per hour. These peak demands are based on fast-fill stations currently installed or being designed throughout the FEI system. The peak demand impact of CNG in all systems does not produce a significant change in peak demand or adjust the timing of any identified capacity upgrades and is not explicitly shown in the forecasts that follow.

7.3.1 Vancouver Island Transmission System

The VITS serves Vancouver Island, the Sunshine Coast and feeds the communities of Squamish and Whistler. It consists of 626 kilometres of high-pressure pipelines, including three twinned marine crossings of the Salish Sea, three compressor stations, and the Mt. Hayes LNG storage facility near Ladysmith. The system serves approximately 140,000 residential, commercial and industrial customers. Natural gas for VITS customers is delivered from upstream sources on the West Coast pipeline system to the Huntingdon-Sumas trading point. From Huntingdon, the VITS demand transits through the CTS to the start of the VITS at Eagle Mountain in Coquitlam. The Mt. Hayes LNG storage facility has improved system reliability and enabled significant operational flexibility of the combined CTS and VITS.

Figure 7-2 shows the layout of the VITS including the location of the Mt. Hayes LNG storage facility, compressor stations shown as V1 (Coquitlam), V3 (Port Mellon), V4 (Texada) and a potential future site V2 (Squamish), major industrial customers and major communities served by distribution networks.

Figure 7-2: Layout of the VITS



7.3.1.1 *VITS Configuration and Capacity*

The VITS needs to serve the natural gas capacity requirements for the following customers:

- Core residential and small commercial customers located on Vancouver Island and the Sunshine Coast, and in Squamish and Whistler;
- Pulp and paper mills represented by the Vancouver Island Gas Joint Venture (shown as the green factory symbol at various communities in Figure 7-2);
- BC Hydro for its Island Generation Plant (shown as the red factory symbol at Campbell River in Figure 7-2); and
- The proposed Woodfibre LNG project (The green factory symbol at Woodfibre in Figure 7-2).

The Peak Demand of the VITS Core and Firm Transportation customers is discussed in the following paragraphs.

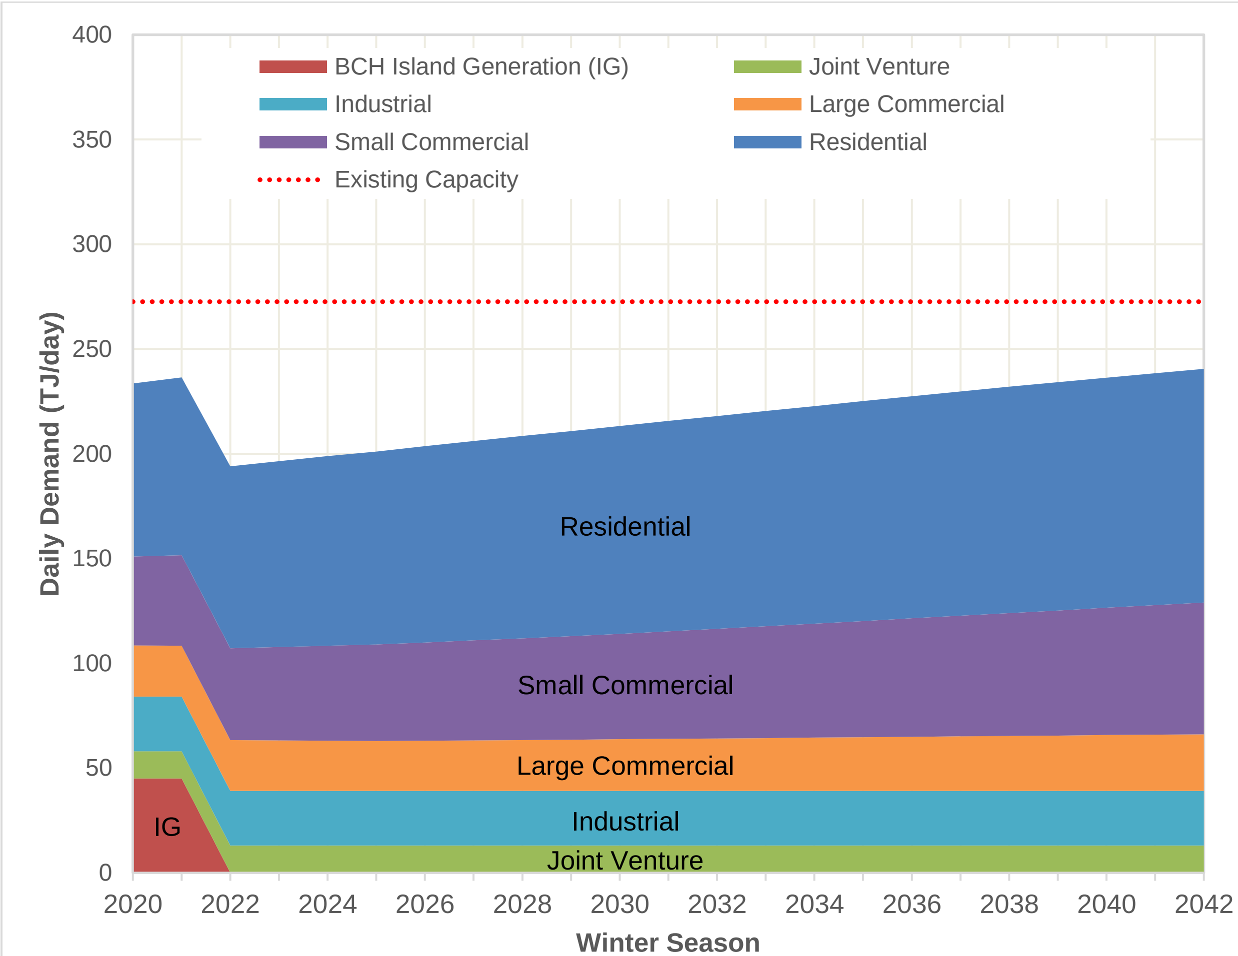
As of November 2020, the current contract demand requirement for BC Hydro Island Generation was 45 TJ per day. The agreement with BC Hydro for the Island Generation facility, the FEI-BC Hydro Transportation Service Agreement (TSA), expired in April 2022. In the next few years, there may be some seasonal demand from the facility, but no firm peak demand for winter operations at the facility has been negotiated. The forecasts shown for the VITS that follow represent the current agreement expiring in 2022 by removing 45 TJ per day from the peak demand forecasts from the winter season of 2022/2023 forward.

The Vancouver Island Gas Joint Venture currently has a firm contract demand of 13 TJ per day, which was in place beginning in the 2015/16 winter season. For demand and capacity modelling, it is assumed that the Vancouver Island Gas Joint Venture demand is fixed at 13 TJ per day throughout the forecast.

Prior to existence of the Mt. Hayes LNG storage facility, the VITS demand exceeded the pipeline capacity and the VITS relied upon a right to call back capacity from BC Hydro Island Generation during design weather events in order to serve its Core and Firm Transportation market design day (i.e., peak demand) requirements. Construction of the Mt. Hayes LNG storage facility was completed in 2011 and the facility entered service for the 2011-12 winter season. The Mt. Hayes facility has a storage capacity of 1.5 Bcf (approximately 1,614 TJ), a liquefaction capacity of 7.5 million standard cubic feet per day (MMscf/day), and a send-out deliverability of 150 MMscf/day (161 TJ per day). This on-system storage facility optimizes the existing system infrastructure by providing significant operational flexibility, regional storage resource benefits for FEI's customers, winter peak shaving capacity benefits and improved system reliability.

Further capacity constraints on the VITS are not expected within the forecast period. It is expected that the system will meet the Traditional Peak Demand forecast. Figure 7-3 shows the peak demand for the VITS with the 2020 Traditional Peak Demand forecast, and with the various customer types represented, and daily transportation requirements for Vancouver Island Gas Joint Venture mills (13 TJ per day) and BC Hydro Island Generation (45 TJ per day, until 2022).

Figure 7-3: VITS Traditional Peak Demand Forecast

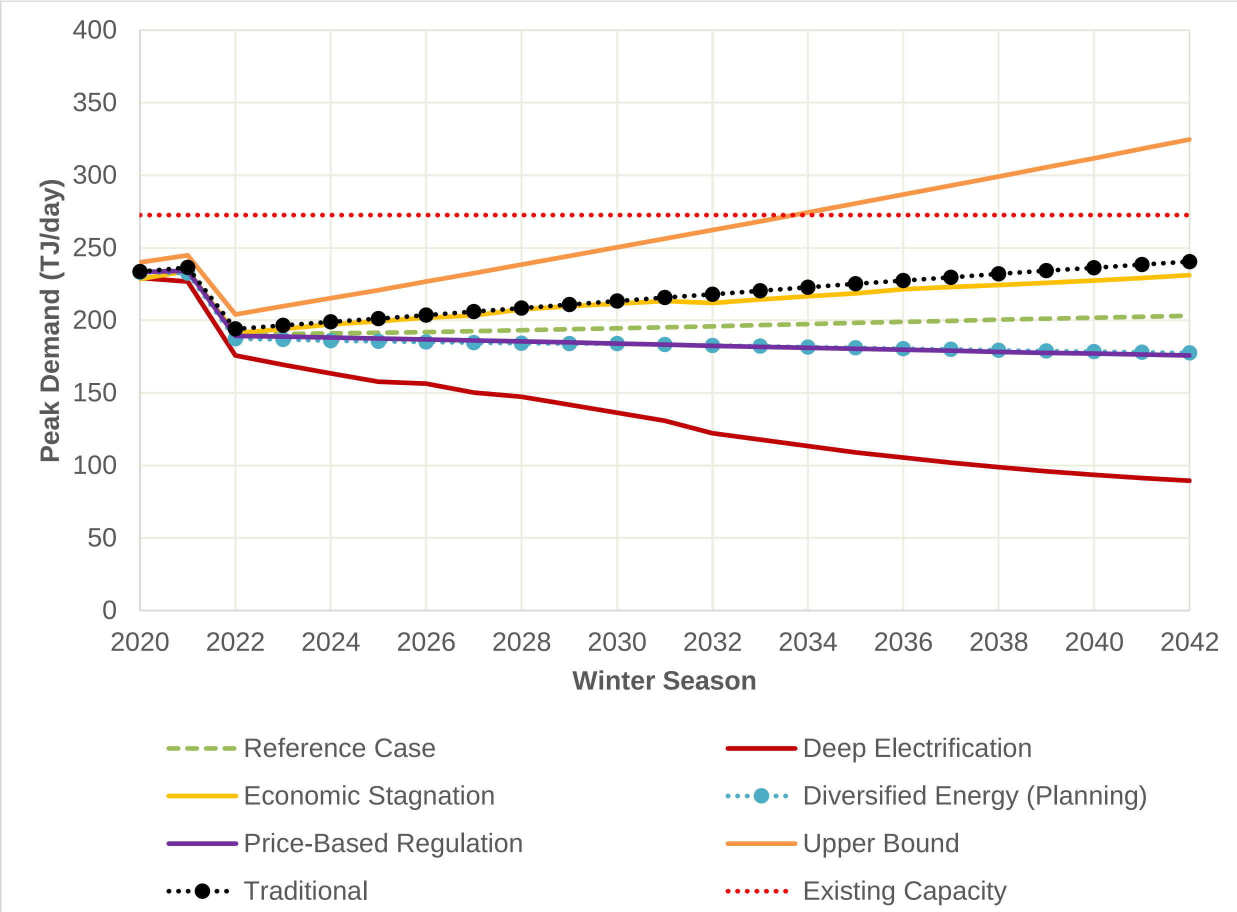


7.3.1.2 *VITS Traditional Peak Demand Forecast and End Use Peak Demand Scenarios*

The VITS regional peak demand forecast shown in Figure 7-4 below was analysed against end use peak demand scenarios. The VITS currently has sufficient facilities with the existing installed pipelines, compressors and the Mt. Hayes LNG vapourizers to meet Traditional Peak Demand excluding any proposed large industrial demand to the end of the planning horizon in 2042.

The end use method provides a wide variation in peak demand forecasts with some forecasts showing increasing and some showing decreasing system demand over time. Figure 7-4 shows: the forecasts are bounded on the high end by the Upper Bound Scenario; the Traditional Peak Demand forecast, Economic Stagnation and the Reference Case scenarios follow with lower but positive growth; the Diversified Energy (Planning) and Price-Based Regulation scenarios show very slight declining demand; and the Deep Electrification Scenario trails on the lower end with more significantly declining demand. Only the Upper Bound forecast would require facility upgrades to the VITS to increase system capacity, possibly by the winter of 2033-2034. The current capacity supports all other peak demand forecasts through the forecast period.

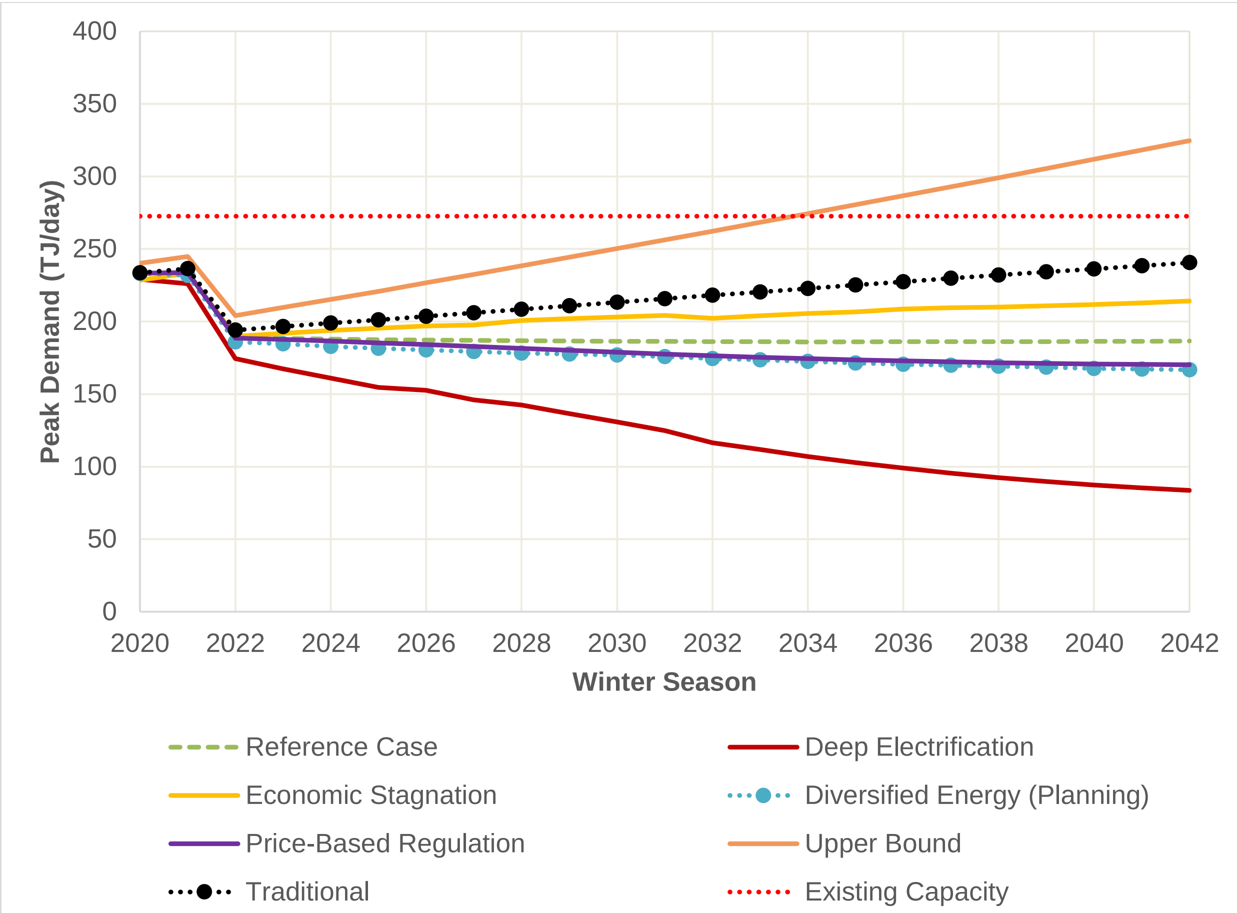
Figure 7-4: VITS Demand-Capacity Balance Using Traditional and End Use Forecasts



7.3.1.3 *VITS Peak Demand Forecast and End Use Peak Demand Scenarios with DSM*

Figure 7-5 illustrates a comparison of the traditional and end use peak demand forecasts including the impacts of DSM applied to each scenario on the same basis as it was applied to each annual demand scenario as shown in Table 5-3. Including DSM impacts causes the end use peak demand scenario forecasts to move downward, except for the traditional and Upper Bound forecasts where DSM is not applied. The Upper Bound Peak Demand Scenario continues to show a potential capacity constraint by 2033-2034. All other forecast scenarios show a decline in peak demand over time with no capacity constraint projected within the planning horizon.

Figure 7-5: VITS Demand-Capacity Balance Using Traditional and End Use Peak Demand Scenarios with DSM



7.3.1.4 *VITS System Expansion Requirements*

With the expiry of the current FEI-BC Hydro TSA for service to BC Hydro's Island Generation facility, FEI's Traditional Peak Demand forecast shows there is no need for capacity expansion on the VITS in the forecast period. Only the Upper Bound Forecast shows enough peak demand to require some system expansion.

Since the forecasts were prepared, recent customer growth on the Vancouver Island system shows that growth is currently trending well below the Upper Bound; however, if the forecast were to begin to trend towards the Upper Bound forecast, the capacity upgrade could be addressed in the future by expanding compressor horsepower (HP) on the VITS and by looping the VITS between Mt. Hayes and Duncan with a second NPS 12 or larger pipeline to support growth in the Greater Victoria area.

Although the Traditional Peak Demand forecast establishes there is no need for capacity expansion on the VITS in the forecast period, there are two pressure control station additions in the VITS that are currently proposed for installation in the next few years to serve the growing distribution systems of Greater Victoria (in the Colwood area) and Nanaimo (in the Lantzville area).

7.3.1.5 *Expanding the System for Potential New Large Industrial Demand*

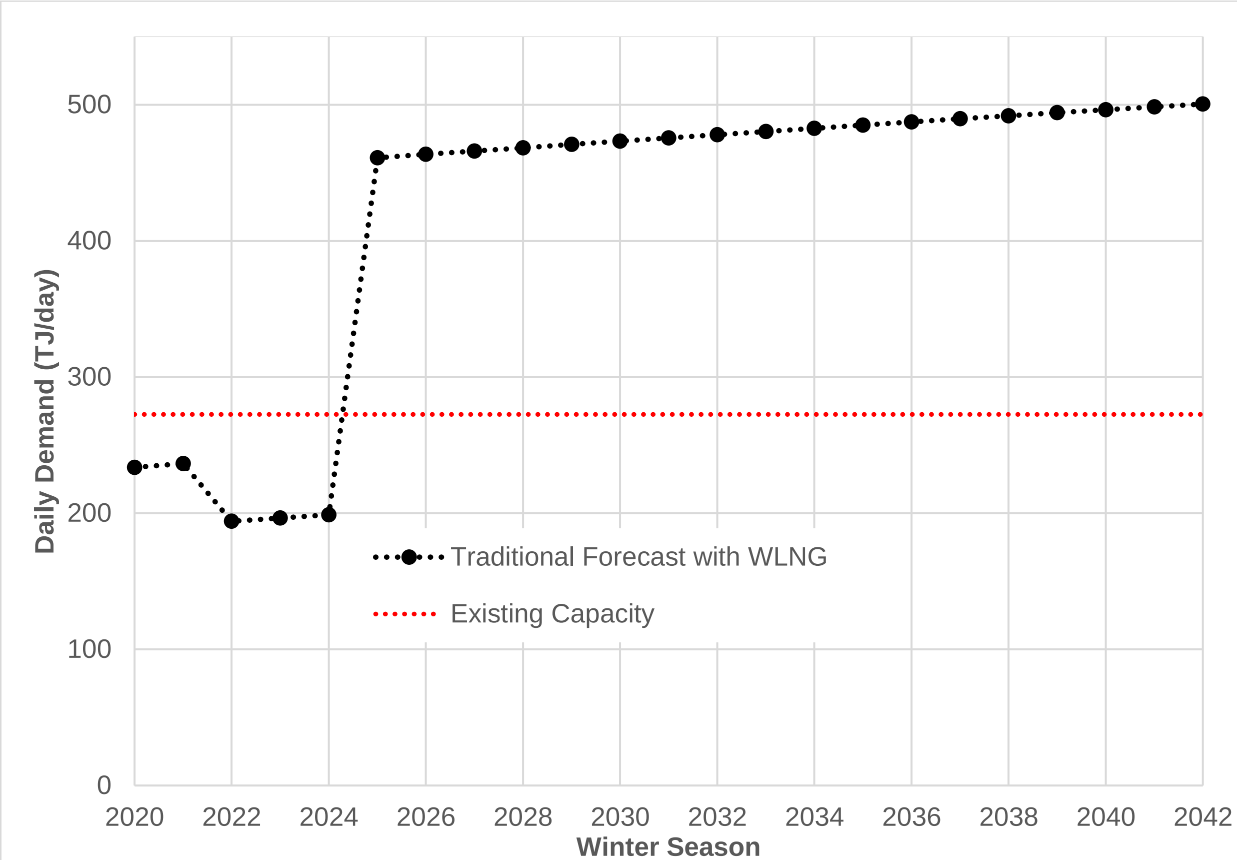
Low natural gas prices and other market dynamics in BC have spurred interest from a range of industries in locating or expanding facilities that would use large volumes of natural gas within the province. Any required major reinforcements to serve potential new industrial loads would be evaluated as part of a formal submission to the BCUC once firm agreements regarding natural gas services have been made.

One such example on the VITS is the Woodfibre LNG project, which is a small-scale LNG export and processing facility located on the VITS at the former Woodfibre pulp mill site near Squamish. Woodfibre LNG Limited, a subsidiary of Pacific Oil & Gas, and FEI entered into a Development Agreement. For several years, FEI has been carrying out development work for the Woodfibre LNG project, including a feasibility study, consultation and stakeholder engagement, engineering, and exploring the regulatory and other approvals required to expand the VITS to provide a firm natural gas transportation service to the project. Woodfibre LNG Limited has presently indicated that it expects to require Firm Transportation service from FEI of up to 237 MMscf/day on the VITS.[205] Once a final investment decision is made, the estimated in-service date of this facility is currently projected no earlier than 2025, and more likely by 2027. This project is discussed further in Section 1.4.2 of Appendix D-1.

Figure 7-6 shows the impact of the proposed Woodfibre LNG project's firm 237 MMscf/day delivery against the VITS Traditional peak demand forecast, showing that the demand exceeds the current capacity of the VITS.

[205] As a transportation service customer, the Woodfibre LNG project would not impact FEI's Vancouver Island gas supply planning as the customer would independently acquire its gas supply.

Figure 7-6: VITS Demand Using Traditional Peak Demand Forecast with Woodfibre LNG project



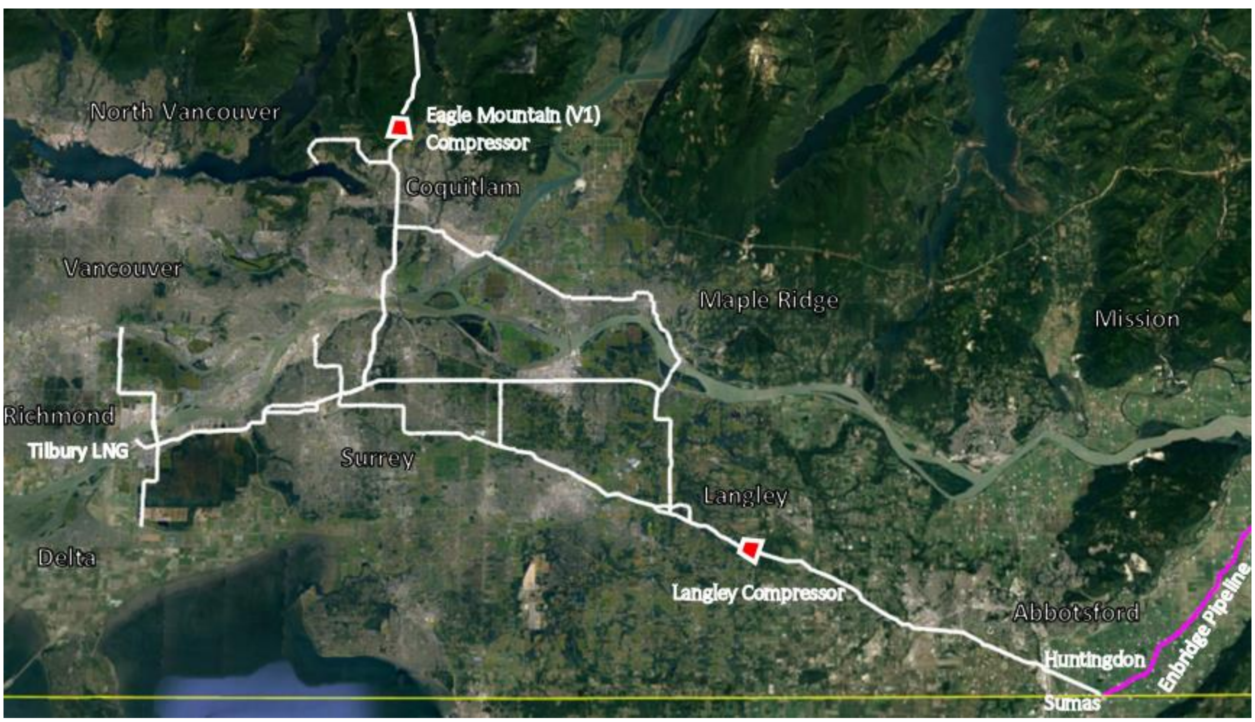
To accommodate this load addition, there is a need to reinforce the existing VITS with pipeline looping and added compression near Squamish. This infrastructure expansion would match the Firm Transportation capacity contracted by Woodfibre LNG Limited under peak demand, preserving available capacity for existing customers, but would allow large volumes of interruptible capacity to be available for much of the year. The Woodfibre LNG project will help reduce costs for firm service on FEI systems providing benefits to FEI's existing customers. Woodfibre LNG project's toll will recover the cost of the Woodfibre LNG project and provide an additional contribution to FEI's other customers over time.

The Woodfibre LNG project, while a relatively small LNG project, is an example of the impact of a large industrial load (relative to the existing system demand) on an FEI system and the challenges of forecasting and planning around such a load addition. These projects take many years of advance planning and design, and are significant in scope and impact on the pre-existing system. The projects are managed and designed to preserve existing capacity and service to customers and need to be constructed to meet FEI system requirements and the specific process and economic needs of the industrial customer. As discussed previously in Section 7.2, the upgrade requirements to support large increases in demand are very specific to the magnitude of the demand and the location of demand on the system, because of the effects of the customers' demand on flow and pressure loss across the system. As a result, the upgrades necessary to provide adequate pressure to all points in the system following a load addition cannot be forecast in advance without knowing both location and demand requirements. The solution for the Woodfibre LNG project and required system changes would look significantly different if the location of the project were at a different point on the FEI system. However, the process of managing the timing of large load additions and associated system expansion requirements without eroding service reliability to existing customers would not change.

7.3.2 FEI Coastal Transmission System

The CTS consists of a 276 km network of pipelines providing gas transportation from the Huntingdon-Sumas trading point to various metering and regulating stations in the Fraser Valley, Metro Vancouver, and Coquitlam areas. There are approximately 585,000 customers served directly by this transmission system not including the customers in the VITS who receive their gas through the CTS. There are two primary capacity-related facilities on the CTS: the Langley Compressor Station, which is used to boost pressures on the CTS during periods of high demand, and the Tilbury LNG storage facility, which is used to provide peaking gas supply during colder weather. The CTS delivers gas to the distribution networks in the Lower Mainland and to the VITS at Eagle Mountain in Coquitlam. Figure 7-7 shows the general layout of the CTS.

Figure 7-7: Layout of the Coastal Transmission System Including the Langley Compressor Station and Tilbury LNG Storage Facility



7.3.2.1 *CTS Configuration and Capacity*

Recent changes to the CTS that impact its capacity include the construction of three transmission pipeline loops that entered service in late 2017:

- A 1.5 km NPS 42 pipeline loop of an existing NPS 24 pipeline between Nichol and Roebuck Valve Stations in Surrey;
- A 4.9 km NPS 36 pipeline loop of an existing NPS 24 pipeline between Nichol and Port Mann Valve Stations in Surrey; and
- A 4.5 km NPS 36 pipeline loop of an existing NPS 20 pipeline between Cape Horn Valve Station and Coquitlam Gate Station in Coquitlam.

Approval for the construction of these loops, collectively identified as the "CTS project", was granted through BC Government Direction No. 5 under OIC 557 in 2013. The CTS project loops existing pipelines that were single points of failure on the CTS and additionally addressed the existing capacity constraints on the CTS that were identified in Section 5 of the 2014 LTRP.

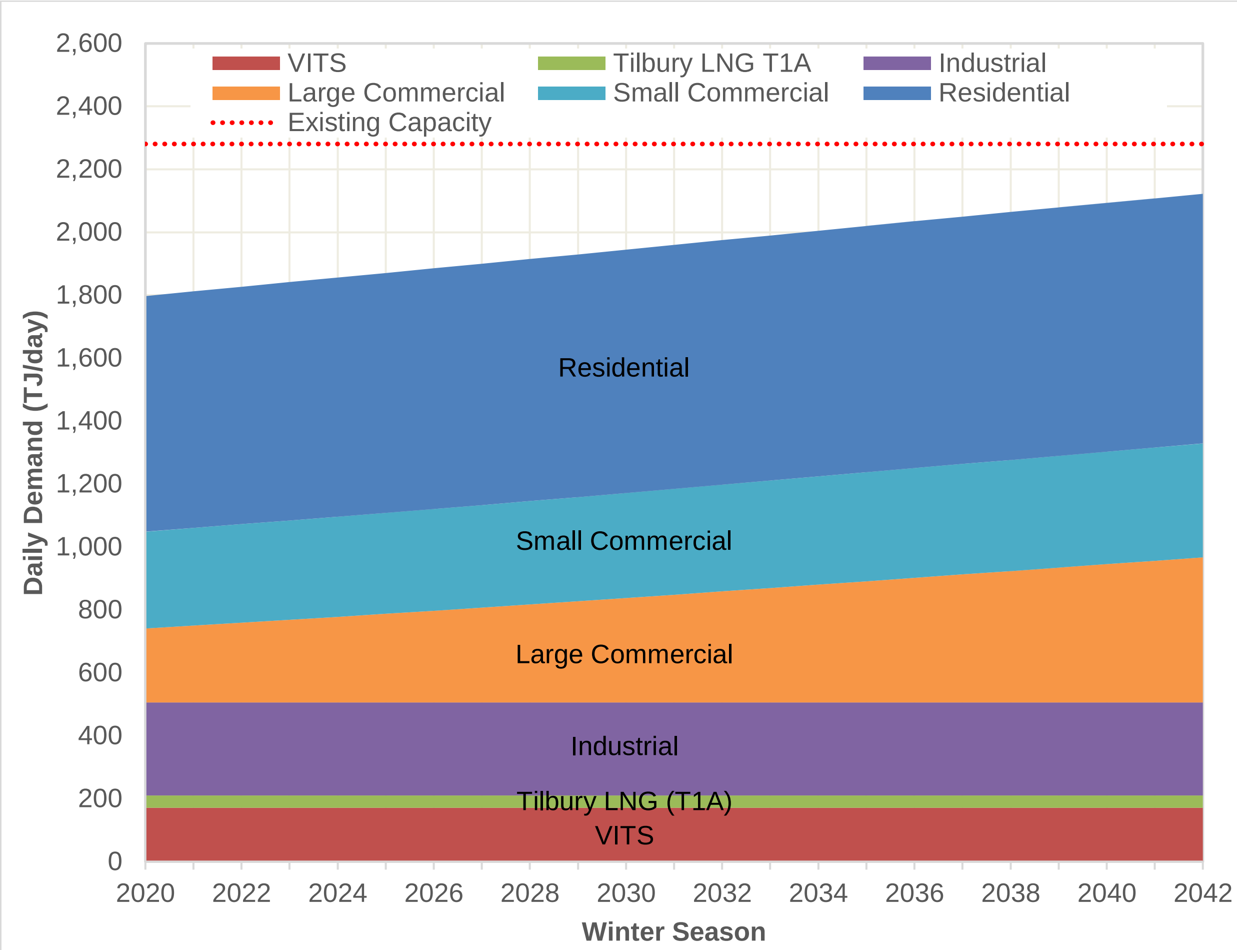
In addition to the CTS project, the Lower Mainland Intermediate Pressure System Upgrade (LMIPSU) projects (Coquitlam Gate IP project and Fraser Gate project) were complete and in service as of the fall of 2021. The Coquitlam Gate IP project replaced an existing NPS 20 pipeline nearing the end of its service life, between Coquitlam Gate Station and 2nd Avenue and Woodland Drive Station in Vancouver with a new high-capacity NPS 30 pipeline. The Fraser Gate project replaced approximately 300 metres of NPS 30 pipe with new NPS 30 pipe to upgrade the Fraser Gate IP Pipeline to current seismic design standards. The LMIPSU projects influence the CTS capacity balance through their ability to shift peak load within the transmission system from Fraser Gate to Coquitlam Gate, thereby enabling a significantly more resilient supply to the Metro Vancouver area distribution system.

In June 2021, the BCUC issued Order C-2-21 granting a CPCN for the Pattullo Gasline Replacement (PGR) project. This project will replace the supply to the Metro Vancouver area distribution system currently provided by FEI's pipeline on the Pattullo Bridge (Pattullo Gasline). The PGR project will replace the Pattullo Gasline with a new overland pipeline connecting the Coquitlam IP System to the existing system in east Burnaby currently fed by the Pattullo Gasline. The PGR project, when in service, will influence the CTS capacity by increasing the demand requirement flowing to Coquitlam to supply the PGR pipeline once the Pattullo Gasline is removed.

Since December 2018, the Tilbury 1A LNG expansion, the first of several projected increases in LNG production, has been in service at the Tilbury LNG site in Delta. This facility increases the peak demand of the CTS by 35 MMscf/day.

Figure 7-8 below shows the Traditional Peak Demand forecast for the CTS with the various customer types represented.

Figure 7-8: CTS Traditional Peak Demand Forecast



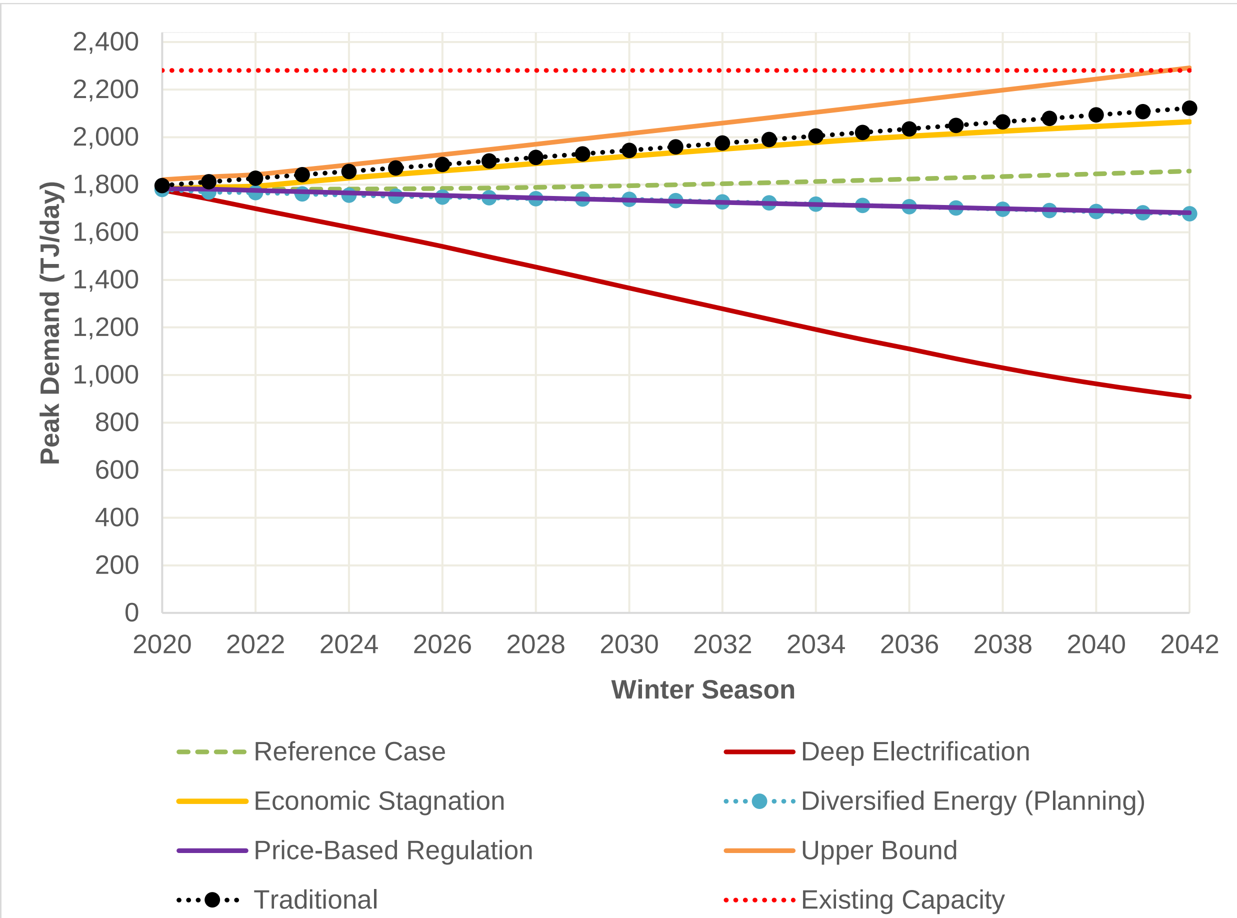
7.3.2.2 *CTS Traditional Peak Demand Forecast and End Use Peak Demand Scenarios*

The CTS currently has sufficient capacity to support peak demand throughout the 20-year planning horizon with additional capacity to support some LNG liquefaction expansion at locations like Tilbury LNG in Delta and the Woodfibre LNG project in Howe Sound. For the foreseeable future, additional expansion requirements for the CTS will be driven by LNG additions or other large industrial demand in the Lower Mainland or VITS, rather than by Core customer growth.

The regional Traditional Peak Demand forecast and end use scenarios are shown in Figure 7-9, which compares the forecast peak demand to system capacity to illustrate when system constraints may occur. FEI does not expect any capacity constraints to occur within the 2022 LTGRP planning horizon under the Traditional Peak Demand forecast.

The forecasts in Figure 7-9 show a wide range of peak demand, with the Upper Bound Scenario showing greater growth in the forecast period than the Traditional forecast and the Economic Stagnation Scenario showing slightly lower growth. The Reference Case Scenario shows a very slight increase in peak demand over the planning horizon, while the remaining scenarios show modest to more significant peak demand decline with the Deep Electrification Scenario showing the greatest peak demand decline. In the absence of large industrial loads that will be discussed later the CTS currently has capacity to meet the peak demand to the end of the planning horizon.

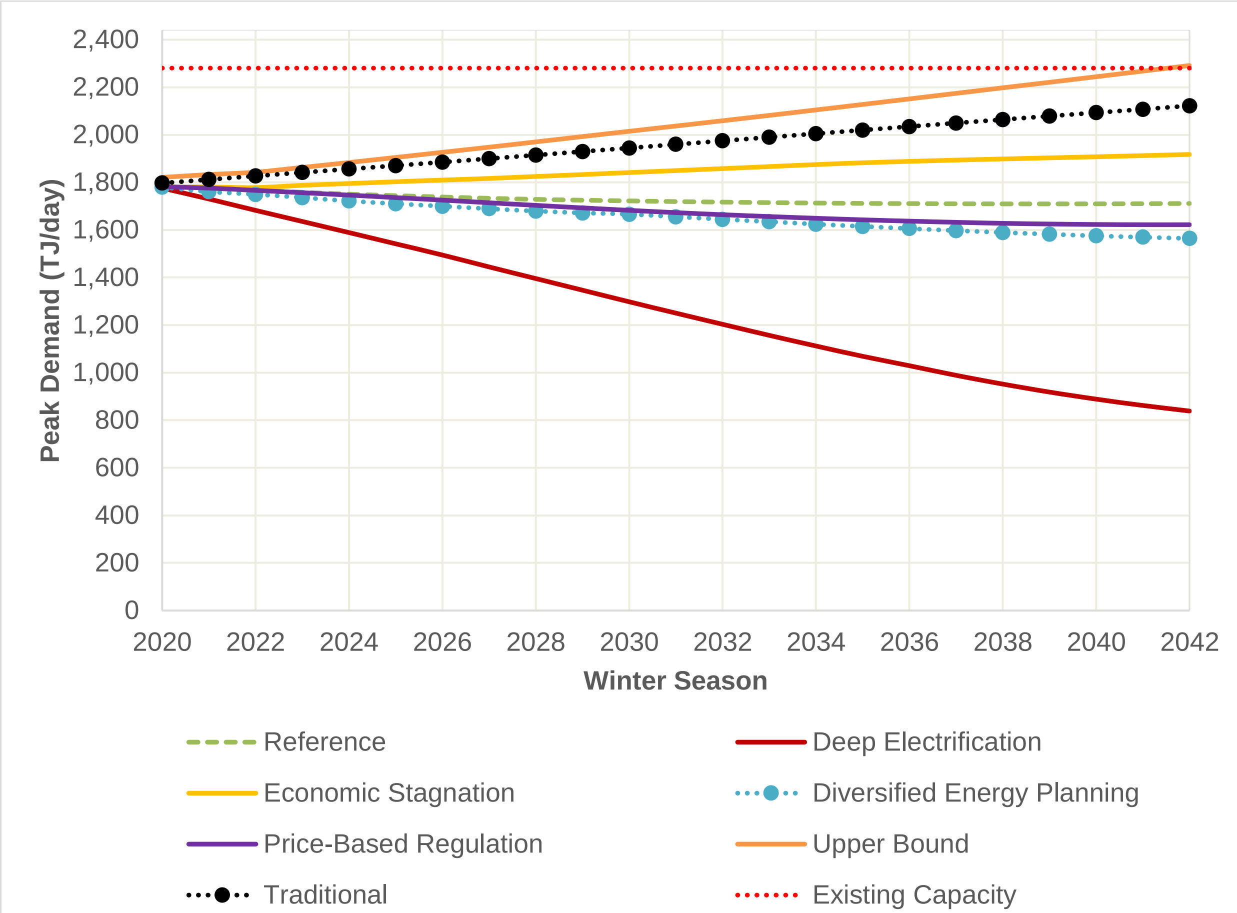
Figure 7-9: CTS Demand-Capacity Balance Using Traditional and End Use Forecasts



7.3.2.3 *CTS Peak Demand Forecast and End Use Peak Demand Scenarios with DSM*

Figure 7-10 shows the end use scenarios with DSM program impacts added (as described in Table 5-3). Applying the impacts of DSM using the end use peak demand method moves almost all end use scenario forecasts lower, apart from the Upper Bound and Traditional forecast where no DSM is applied. The Upper Bound continues to show the highest growth followed by the Traditional forecast. The Economic Stagnation Scenario shows very moderate growth through the forecast. The Reference Case Scenario shows a very slight decline in peak demand through the forecast horizon. The remaining scenarios show moderate to more significant decline in peak demand through the forecast. No forecast scenarios exceed the current capacity of the CTS.

Figure 7-10: CTS Demand-Capacity Balance Using End Use Peak Demand Forecasts with DSM



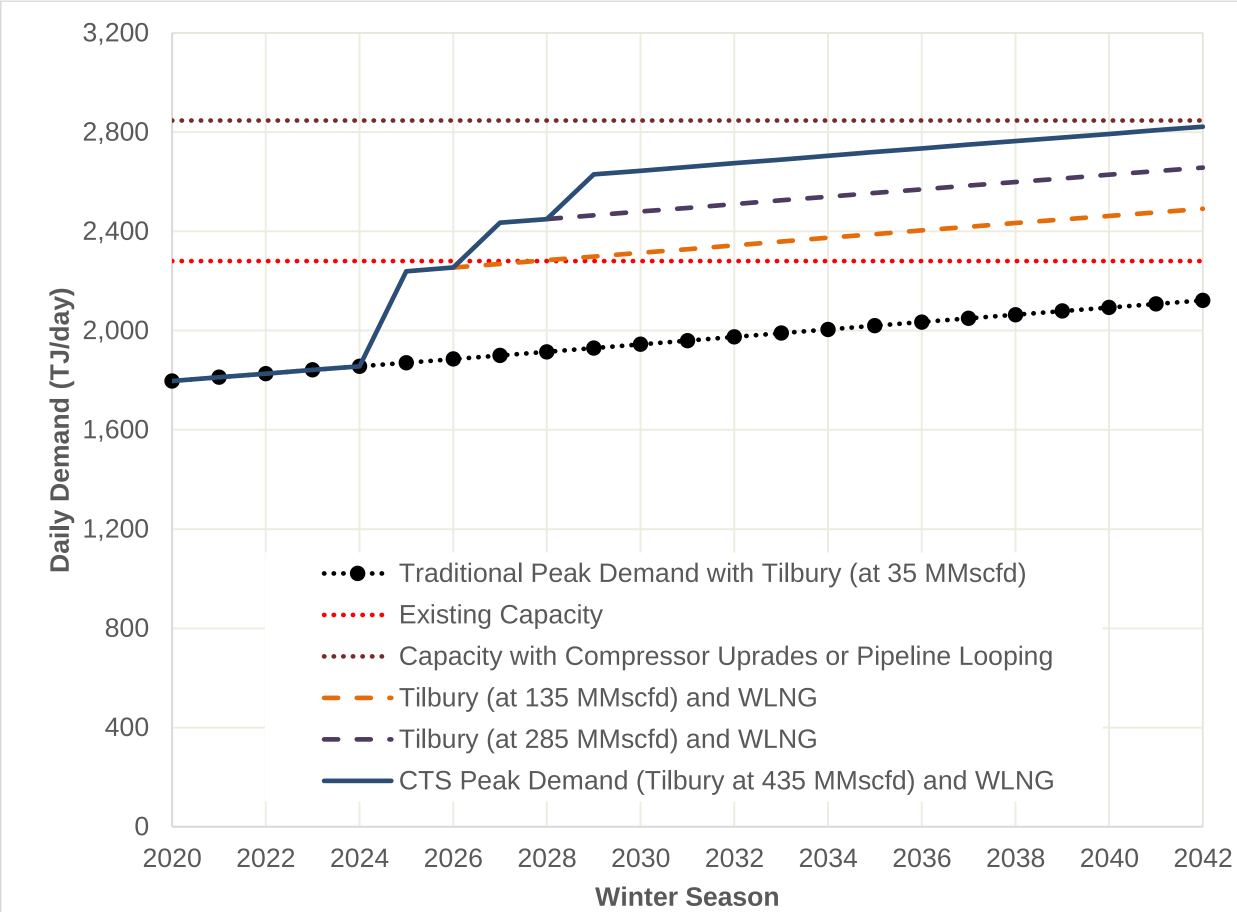
7.3.2.4 *Impact of Potential New Large Industrial Loads (Future Demand for LCT and LNG Exports)*

The demand for conventional gas from transportation sector fuel customers is forecast to continue growing over the next 20 years (as discussed in Section 4.6), and increased use of LNG as a lower intensity fuel for road and marine transport in the Lower Mainland area will likely drive LNG demand growth. The potential demand and the point-source nature of additional LNG liquefaction production in peak conditions at Tilbury may create system impacts and could trigger the need for system reinforcements of the CTS.

FEI expects demand by LNG customers across the FEI service territories to be primarily served by FEI's Tilbury LNG facilities. Based on FEI's natural gas demand forecasts for LNG, future phases of Tilbury LNG expansion beyond the current Phase 1A will need to be constructed. FEI's long-term outlook considers the system requirements for such an expansion.

Figure 7-11 shows the impact of LNG demand on the CTS Traditional Peak Demand forecast over the next 20 years.

Figure 7-11: Impact of LNG on CTS Peak Demand



The peak demand forecasts shown have a different profile from the annual demand with LNG forecasts shown in Figure 4-18. The production of LNG is consistent throughout any day of the year when the liquefying facilities are operating and has no seasonal or daily peak. In practice, the actual peak demand that may occur on the CTS in any given period would be dependent on the liquefaction capacity installed at the LNG plant to meet the forecast. LNG liquefaction trains generally operate at a fixed production rate and, for reasons of efficiency, do not vary production rates substantially when in operation. The peak demand profile on the CTS would therefore occur in a more defined stepwise fashion than is represented in an annual demand forecast, with each step corresponding to a phase of expansion in liquefying capability at the LNG facility.

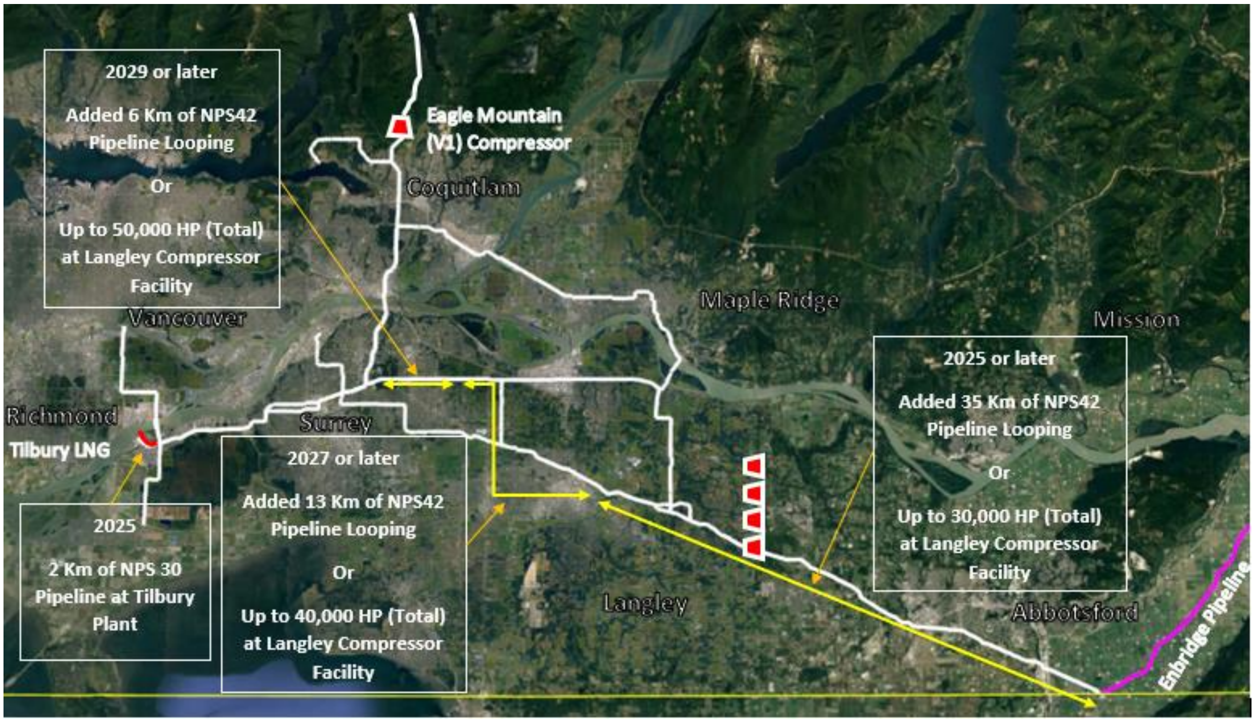
To illustrate the potential impact of LNG expansion on the CTS, some potential CTS expansion phases are described in Table 7-1, with the corresponding capacity for liquefaction that could be delivered to the Tilbury area. The next future expansion of LNG liquefaction at Tilbury will require a two kilometre NPS 30 pipeline. That pipeline will replace an NPS 6 pipeline from the plant to the CTS transmission pipelines east of the plant site. At a diameter of NPS 30, this pipeline is sufficient to accommodate any additional future anticipated LNG expansion without needing to be replaced with a larger diameter. Apart from this initial two kilometre pipeline, LNG expansion can be accommodated in the CTS though an expansion of compressor facilities in the system at the existing Langley Compressor site, or through incremental pipeline looping of the exiting NPS 42 and NPS 30 CTS pipelines between FEI's Huntingdon Control Station in Abbotsford and Nichol Valve Station. An alternative expansion scenario could also be a combination of some pipeline looping and some compression addition to meet the growth in LNG demand. The combination of upgrades selected and how they are phased to be most efficient and cost effective will be determined once the LNG demand and production requirements to meet the demand become more defined.

Table 7-1: CTS Expansion Scenarios for LNG

CTS Upgrades	LNG Expansion	Timeframe
2 km NPS 30 from Tilbury Plant and up to 15,000 HP Added (up to 30,000 HP total) or 35 km NPS 42 Pipeline Loop	Incremental 100 MMscf/day addition to Liquefaction at Tilbury Plant (up to 135 MMscf/day total) Woodfibre LNG project at 237 MMscf/day	2025 or later
Up to an Additional 10,000 HP Added (up to 40,000 HP total) or additional 13 km NPS 42 Pipeline Loop (48 km total)	Incremental 150 MMscf/day additional Liquefaction at Tilbury Plant (up to 285 MMscf/day total) Woodfibre LNG project at 237 MMscf/day	2027 or later
Up to an Additional 10,000 HP Added (up to 50,000 HP total) or additional 6 km Pipeline Loop (54 km total)	Up to 400 MMscfd additional Liquefaction at Tilbury Plant (up to 435 MMscf/day total) Woodfibre LNG project at 237 MMscf/day	2029 or later

Figure 7-12 below shows how these proposed upgrades may be laid out along the existing CTS.

Figure 7-12: CTS Expansion Scenarios to Meet Potential LNG Load Growth

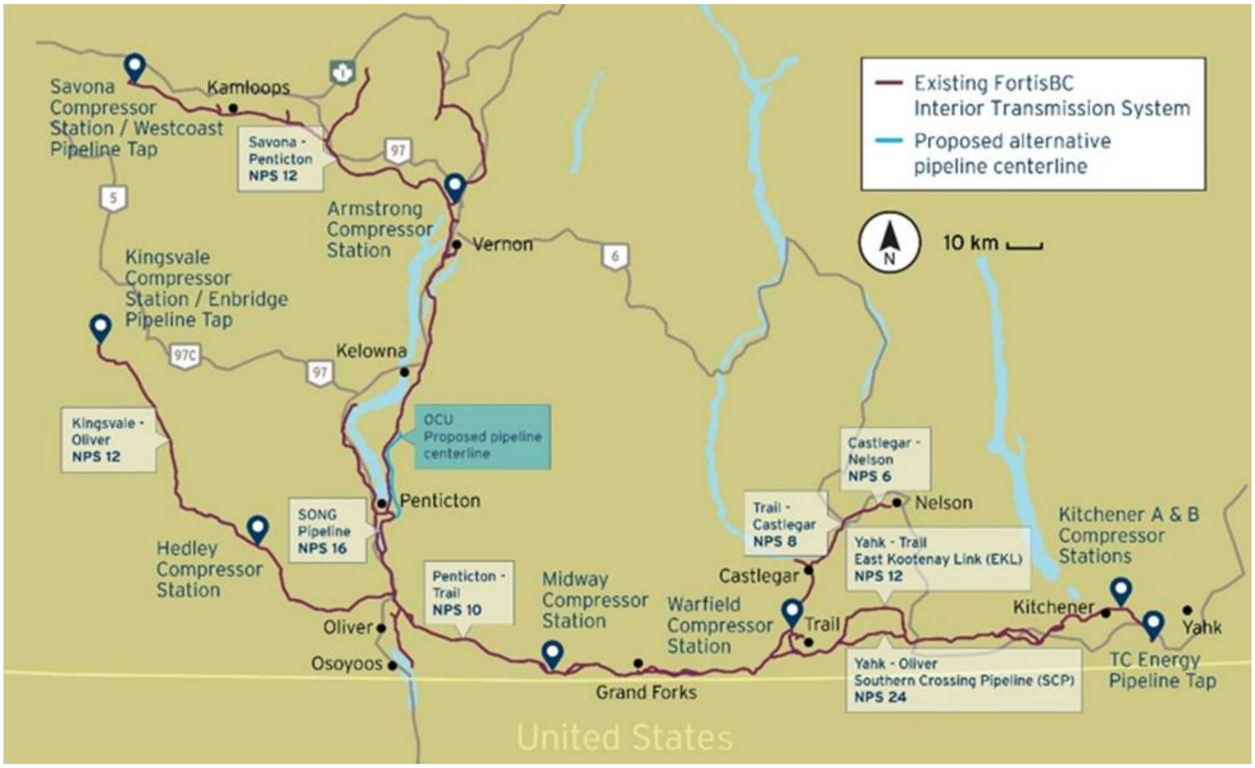


7.3.3 FEI Interior Transmission System

The ITS consists of 1,515 km of transmission pipelines operating at maximum operating pressures between 4,654 kPag[206] and 9,928 kPag. The ITS system interconnects supply from the Westcoast pipelines in the west and the TC Energy pipelines in the east. Gas received from the Westcoast pipeline at Savona typically supplies customers in the Thompson and North Okanagan regions, while gas received from the TC Energy Pipeline at Yahk supplies customers in the West Kootenay region via pipelines to Trail and Oliver. The FEI-owned SCP is a bi-directional transportation pipeline between Yahk and Oliver that in the winter moves gas needed to support peak demand in the Okanagan and Lower Mainland to Oliver. From the Oliver hub, referred to as the “Oliver-Y”, pipelines transport gas to serve customers in the South and Central Okanagan. In winter periods, the Kingsvale-Oliver pipeline transports gas from the SCP via the Oliver-Y hub to Kingsvale for redelivery to the Lower Mainland through the Westcoast Pipeline. Figure 7-13 shows the layout of the ITS system.

[206] kPag = kilopascals (gauge pressure).

Figure 7-13: FEI Interior Transmission System



7.3.3.1 *ITS Configuration and Capacity*

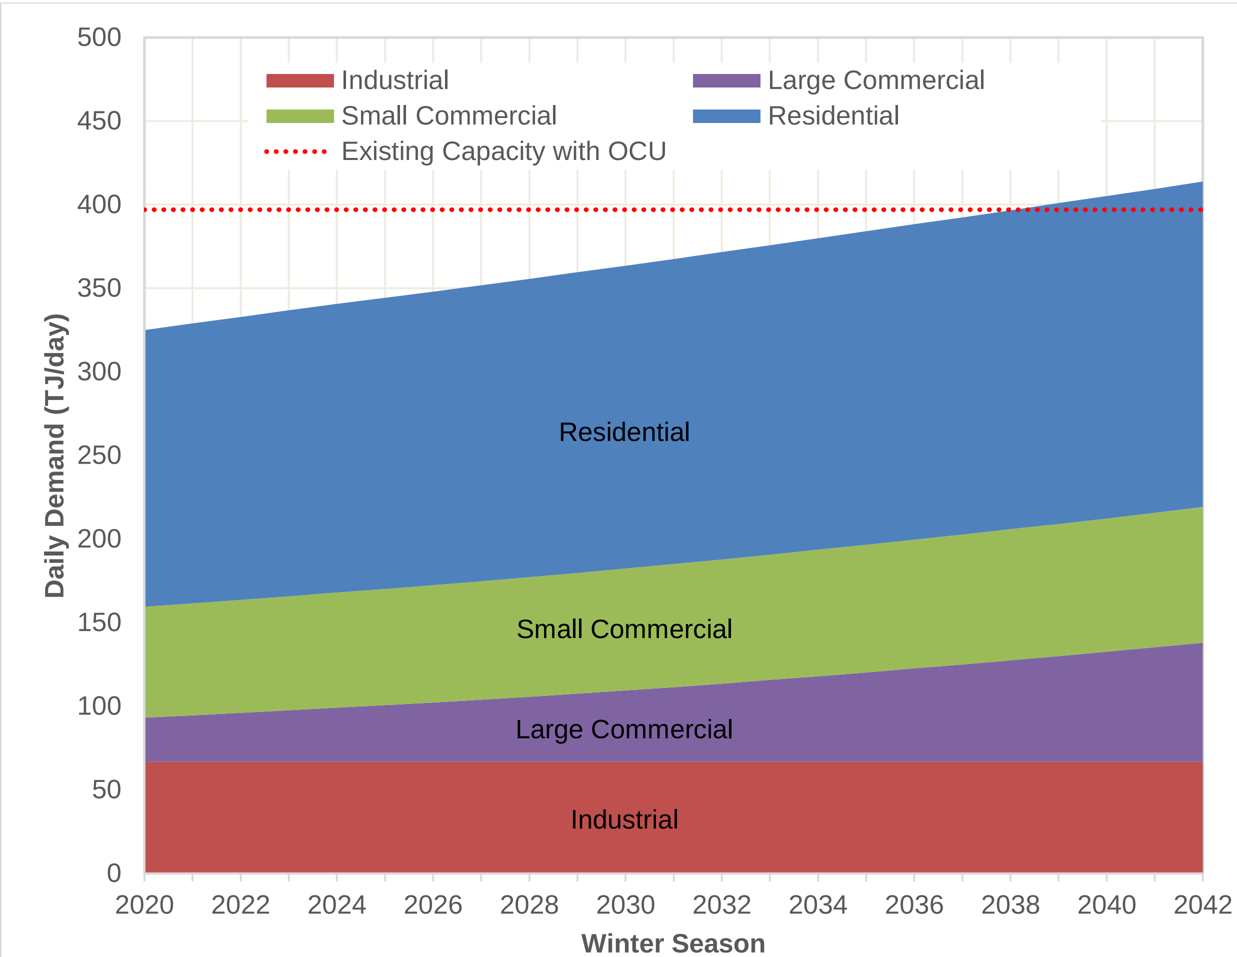
Approximately 60 percent of the current ITS Core and Firm Transportation customer demand is concentrated in the South, Central and North Okanagan regions. Growth in the Okanagan region has been, and continues to be, one of the main factors driving the location of current and future incremental capacity additions to the ITS. The ITS currently serves approximately 200,000 residential, commercial and industrial customers. Because the ITS is characterized by long pipeline lengths through several less-densely-populated areas, the system benefits from line pack effects—the "storage" of usable pressurized gas up to the pipeline MOP that can be drawn on to support short-term peak demand. The ability to draw down the gas that is stored in the ITS allows FEI to plan the ITS on a peak day, rather than a peak hour, maximum flow.

As previously described, gas is delivered to the ITS from two upstream pipelines—the Westcoast pipeline at Savona in the West and the TC Energy Pipeline at Yahk in the East. The ITS peak demand will reach pipeline capacity when the system cannot maintain minimum system pressures near the high load centres in the Central Okanagan region.

FEI currently has a CPCN Application for the Okanagan Capacity Upgrades (OCU) project in the regulatory review progress. The preferred alternative is an approximately 30-kilometre NPS 16 pipeline loop between Penticton and Kelowna reinforcing the existing NPS 12 pipeline currently in service.

The Traditional Peak Demand forecast for this region with the various customer types represented is shown in Figure 7-14

Figure 7-14: ITS Traditional Peak Demand Forecast

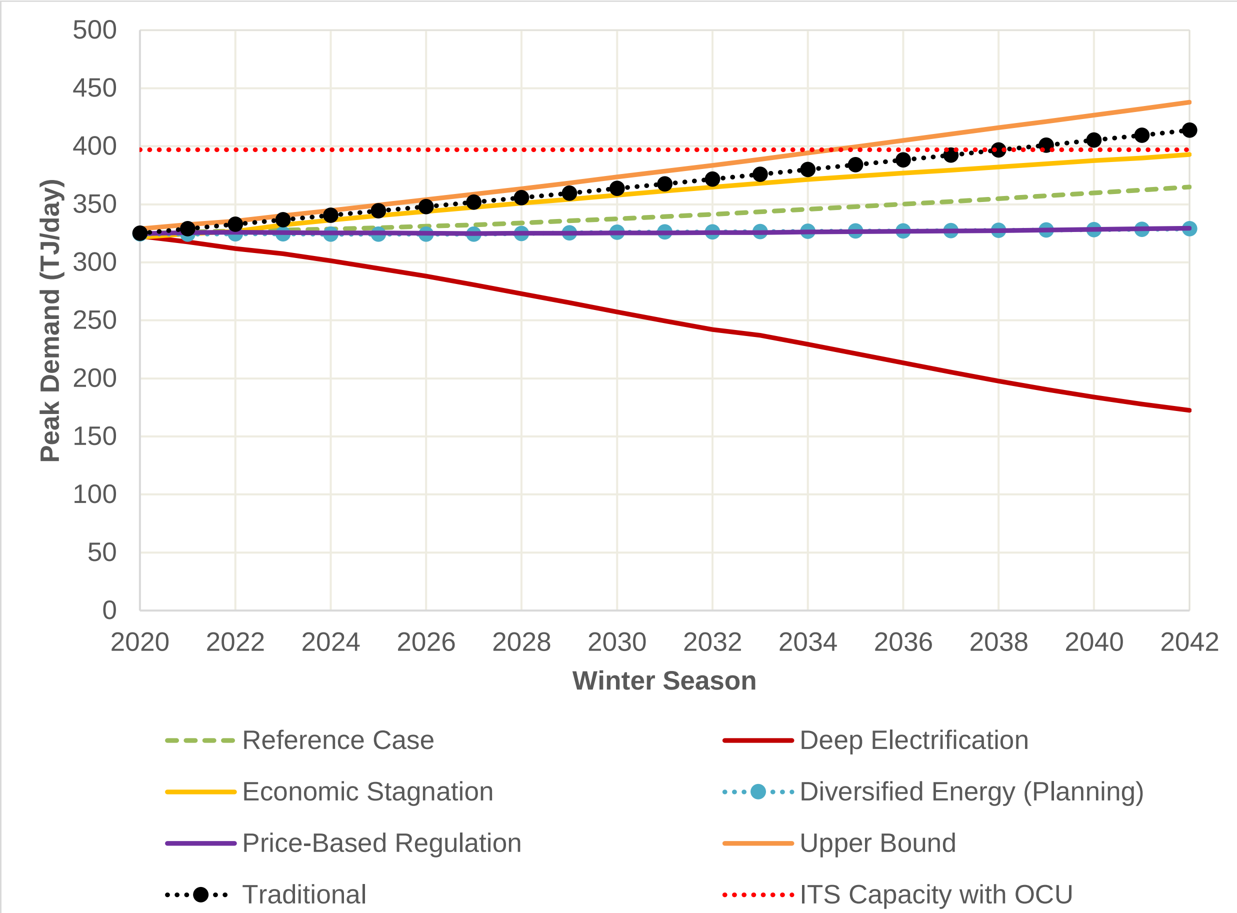


7.3.3.2 *ITS Peak Demand Forecast with End Use Peak Demand Scenarios*

Figure 7-15 shows the Traditional Peak Demand forecast and the forecasts derived from the end use scenarios for the area served by the ITS. The forecasts show a wide range of peak demand, with the Upper Bound, Traditional, and Economic Stagnation scenarios being the three highest forecasts. The Reference Case Scenario shows lesser growth in peak demand in the forecast and all other scenarios show no growth or a decline in peak demand with the Deep Electrification Scenario showing the greatest peak demand decline.

With the OCU project installed as proposed (shown as the ITS Capacity with OCU line in Figure 7-17), the current Traditional Peak Demand forecast projects that the next capacity constraint could occur by the winter of 2038- 2039. With the Upper Bound forecast, that capacity constraint might appear up to three years earlier. All other forecasts should be met with the capacity available in the ITS once the OCU project is completed.

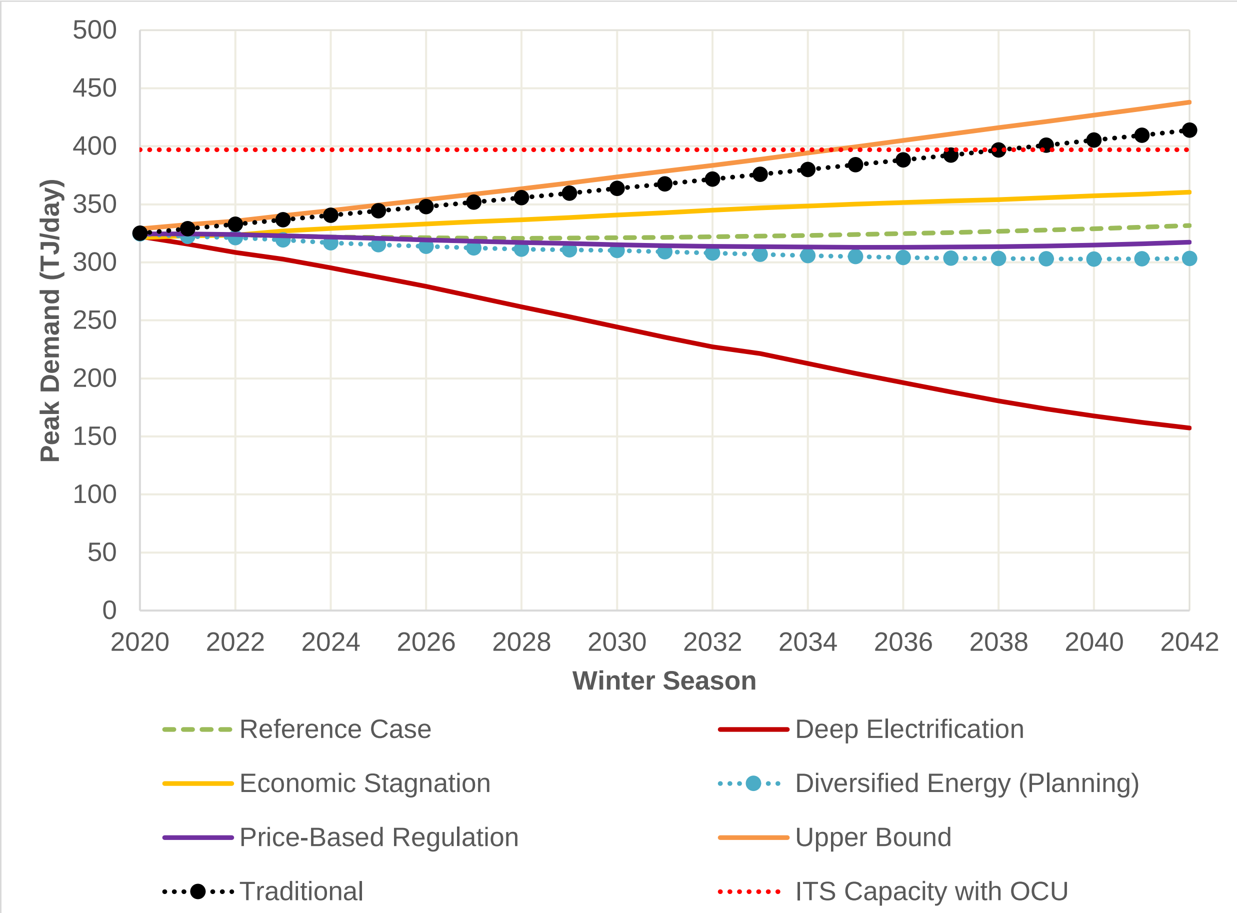
Figure 7-15: ITS Demand-Capacity Balance Using End Use Peak Demand Forecasts



7.3.3.3 *ITS Peak Demand Forecast with End Use Peak Demand Scenarios with DSM*

Figure 7-16 shows the end use scenarios with DSM program impacts added (as described in Table 5-3). Applying the impacts of DSM using the end use peak demand method moves all end use scenario forecasts lower, apart from the Upper Bound and Traditional forecasts where no DSM is applied. The Upper Bound continues to exceed the Traditional forecast. The Economic Stagnation scenario shows less growth through the forecast. The Reference case shows very slight growth in peak demand. The remaining scenarios show moderate to more significant decline in peak demand through the forecast horizon.

Figure 7-16: ITS Demand-Capacity Balance Using End Use Peak Demand Forecasts with DSM



7.3.3.4 *ITS System Expansion Alternatives*

The three reinforcement alternatives described below have been identified to meet the demand forecast and would be required, in addition to completion of the OCU project, by the winter of 2038-2039 for the Traditional forecast and could be required for the winter of 2035-2036 to meet the Upper Bound forecast. The proposed OCU project provides sufficient capacity to meet the capacity requirements of all other peak demand forecasts though the forecast period.

Alternative 1 one would be the most moderate capital expansion that could meet the future peak demand requirements within the ITS. Alternative 3, if built to support resiliency, would provide better security of supply to customers in the Okanagan communities.

7.3.3.4.1 ALTERNATIVE 1 – COMPLETION OF THE OCU PROJECT WITH ADDITIONAL COMPRESSION

The first alternative solution to address the capacity constraint in 2038 requires additional compression to be added to the Savona Compressor Facility, increasing the compressor horsepower (HP) there by at least 1000 HP. This solution would also include an upgrade to the four-kilometre Coldstream lateral pipeline in addition to the completion of the preferred alternative of the OCU project (a 30-kilometre pipeline loop between Penticton and Kelowna). These additional upgrades can move the capacity constraint to beyond 2042.

7.3.3.4.2 ALTERNATIVE 2 – PIPELINE EXTENSION TO THE OCU PROJECT

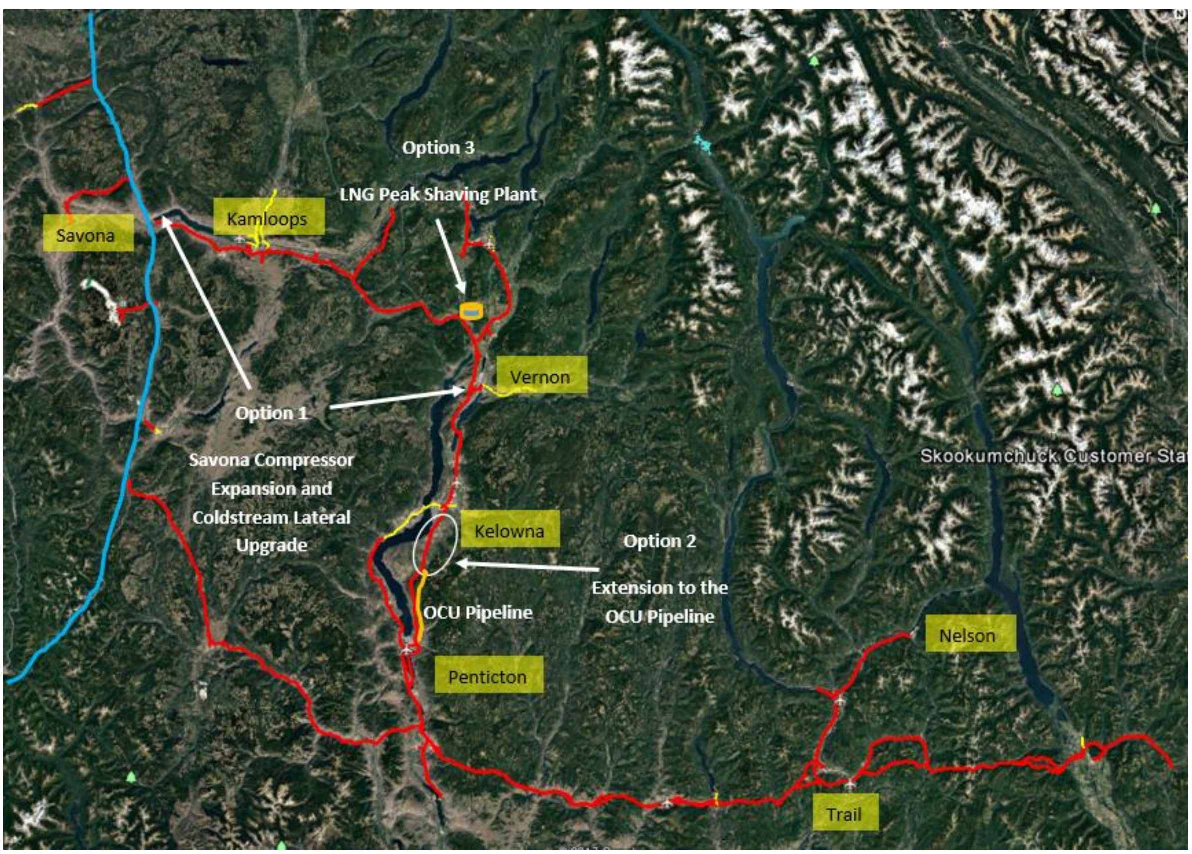
The second alternative is an extension of the OCU project further north by installing approximately 13 kilometres of NPS 16 pipeline towards Kelowna from its currently-proposed termination point between Penticton and Kelowna.

7.3.3.4.3 ALTERNATIVE 3 – LNG STORAGE FACILITY

The third alternative is an LNG storage facility located close to Vernon. An LNG facility located closer to the load centre allows natural gas to be moved into storage in times of low gas demand when excess pipeline capacity is available, and provides on-system delivery to the region during periods of high demand. Sized appropriately, this alternative could also provide a higher level of resiliency for the Thompson-Okanagan region like what the TLSE can provide in the Lower Mainland system to protect against short duration upstream supply interruptions or shortages to the ITS in the Thompson-Okanagan region.

Figure 7-17 below shows the potential locations of the three system resource expansion alternatives on the ITS.

Figure 7-17: Location of Possible ITS Reinforcement Alternatives



7.3.3.5 *Potential New Industrial Load*

Based on the FBC 2021 LTERP filed with the BCUC in August 2021, a simple cycle gas-fired turbine (SCGT) power generating plant was identified as one of the preferred long-term options in the Okanagan area to meet growing peak electricity demand. Such a plant could be installed in two phases between 2031 and 2035. The potential to add a 100 MW SCGT, expanding to 148 MW by 2035, proposed to be fuelled by RNG, would drive additional expansion of the ITS. The upgrade options would depend on the future location of the facility in the Kelowna area. Adding this load would impact the preferred ITS expansion options and would support an extension of the OCU project much further north into the Kelowna area than is previously described in Option 2. For the Traditional forecast, a future SCGT would require an OCU pipeline extension just before the generating station's proposed in-service date of 2031.

7.3.4 Transmission Laterals

FEI operates transmission laterals that connect the Westcoast and TC Energy pipelines to supply industrial users and to supply distribution systems serving communities in north-central and southeastern BC. The Cache Creek/Ashcroft Lateral has been identified as the only lateral to have insufficient capacity to meet the forecast demand throughout the 20-year planning horizon.

The Cache Creek/Ashcroft Lateral is served by the Westcoast pipeline in the Thompson region. The lateral delivers gas to Cache Creek and Ashcroft, which are located approximately 70 km west of Kamloops. The lateral consists of a combination of two pipelines and has been at its capacity to meet peak demand for several years; however, there is no forecast growth in customer accounts or demand in this system. Reductions in available supply pressure from the Westcoast pipeline are increasing the possibility of curtailment to an industrial customer on the lateral. An addition of a 19-22 km pipeline loop would be required to meet current Firm Transportation service to the industrial customer. FEI continues to work cooperatively with this customer to manage demand under peak conditions to avoid the need for the pipeline loop.

7.3.5 Distribution System Capacity

By convention, FEI has reported on infrastructure operating at or below 3100 kPag as distribution assets, which are further divided into:

- IP systems operating above 700 kPag and up to 3100 kPag; and
- Distribution pressure systems operating at or below 700 kPag.

For ease of operation and maintenance, safety to the public and reliable service, distribution networks operate at a relatively low pressure. In general, FEI operates its distribution networks at a MOP of 420 kPag; on Vancouver Island and the Sunshine Coast, FEI typically operates its distribution networks at a MOP of 550 kPag. Supply resources for distribution systems include:

- *Pressure regulating stations* – the capacity of a distribution network can be reinforced by the addition of a new regulating station; and

- *Distribution pipelines* – the capacity of a distribution network can be reinforced by increasing the cross-sectional area of a distribution pipe section. Distribution pipelines operate at a lower pressure, and can be installed by replacing an existing pipe with a larger diameter pipe, adding a parallel pipe (a loop) or by introducing gas into the network from an alternate source (a back feed).

Since distribution systems operate at a low pressure through relatively small diameter pipes, there is little line-pack capability for managing hourly demand fluctuations. Therefore, capacity requirements for distribution systems are based on peak hourly demand rather than peak daily demand.

Distribution system improvement projects generally occur more frequently and are smaller in scale than transmission system projects. Distribution system improvement projects are routinely identified as part of the capital planning process and are not discussed in any detail here.

The 2017 LGTRP identified systems where some significant changes were being assessed. The following is an update on the status of those projects as well as other significant work proposed or underway in the distribution systems that have been identified since the 2017 LTGRP.

7.3.5.1 *Metro Vancouver DP and IP Systems*

Construction on the LMIPSU projects referred to previously in Section 7.3.2 was fully completed and in the fall of 2021, when the projects entered into service. The LMIPSU projects replaced an existing 20 km NPS 20 IP pipeline between Coquitlam Gate Station in Coquitlam and 2nd Avenue and Woodland Drive Station in Vancouver with a new high capacity NPS 30 pipeline. This new pipeline significantly improves the capacity and security of supply to more than 250,000 gas customers in the region. A 300 metre replacement of a portion of the NPS 30 IP pipeline was also completed in the fall of 2021, just east of Fraser Gate Station in South Vancouver. The project upgraded the seismic resiliency of this pipeline to meet current seismic design requirements.

As mentioned in Section 7.3.2, the BCUC approved a CPCN for the PGR project in June 2021. The Pattullo Gasline is scheduled for replacement before the existing Pattullo Bridge is demolished following the planned construction of a new bridge. The PGR project will construct a replacement for the Pattullo Gasline via a new overland NPS 20 IP pipeline connecting the new Coquitlam IP NPS 30 pipeline to the existing NPS 20 (700 kPa) pipeline in east Burnaby.

7.3.5.2 *Revelstoke Propane System*

FEI operates a satellite, off-grid propane distribution system that serves residential and commercial customers in the Revelstoke area. Due to its geographic location, Revelstoke is located too far away to economically connect to the natural gas grid. Consequently, propane is transported by railcar and tanker truck to Revelstoke where it is then off-loaded into storage tanks, vapourized as needed and distributed to customers through an underground pipeline system. As a result of growth in demand, FEI replaced and increased the capacity of Revelstoke's second propane vapourizer in 2018 to provide full redundancy in meeting peak demand on the system.

In October 2020, FEI received approval for the Revelstoke Propane Portfolio Cost Amalgamation Application that provided a favourable reduction in energy costs for FEI's propane customers in Revelstoke. Core demand growth in Revelstoke is forecast to increase and FEI continues to assess the impact of the amalgamation on Core and Industrial demand. FEI expects to expand the propane system with additional storage tanks and some pipeline looping when increased demand warrants the expansion.

7.3.5.3 *Whistler Distribution System*

The Whistler distribution system is supplied by the VI Transmission System at Squamish. From Squamish, an NPS 8 pipeline with an operating pressure of 2069 kPag follows the Highway 99 corridor north to Whistler. The pipeline was commissioned in 2009 and the Whistler distribution system was converted from propane to natural gas that summer, prior to the 2010 Winter Olympics.

Since the commissioning of the pipeline in 2009, there has been sustained growth in the community. In late 2014, a series of phased system improvements were proposed to be installed between 2015 and 2020 that would result in extending the pipeline approximately 5 km further north into the community, along with another Gate Station facility to address growth.

In 2016, BC Transit announced its intention to convert the Whistler transit fleet to CNG and construct a CNG fueling facility at its existing transit site on the north side of Whistler. The facility began operating in late 2017. As a result of this substantial load near the northern extremity of the system, the need arose to advance the future system improvement phases from future years to the present. For the winters of 2017-2018 and 2018-2019, while FEI worked on completion of the IP pipeline extension and the new gate station, FEI installed and operated a portable small-scale LNG peak shaving unit in the northern part of the Whistler system. This temporary installation provided support for peak demand requirements for surrounding gas customers as well as the initial needs of the BC Transit CNG fueling compressors. FEI completed the required pipeline and station facilities in July 2019.

7.3.5.4 *Gibsons Distribution System*

The community of Gibsons is supplied with natural gas by a 19 kilometre IP pipeline from Sechelt Gate Station which is in turn served by the VITS. The capacity of the IP pipeline is insufficient to meet current peak demand without temporary mitigation measures. These temporary mitigation measures will be insufficient beyond 2023, thus requiring additional upgrades. FEI has completed the project scope and cost estimate development for a local peak shaving CNG unit in the Gibsons distribution system area to offset the peak demand support required of the IP pipeline supplying the distribution system. Several alternatives were considered for this project (including IP pipe installation), and a local CNG peak shaving facility was determined to be the preferred and lowest cost alternative. This project was included in the FEI FBC 2024-2024 MRP application as a Major

Project: the FEI Sunshine Coast Capacity Upgrade (Section C.3.3.3.7). Through the development of the preliminary project cost estimate, it was determined that this project no longer meets FEI's CPCN materiality threshold of $15 million. The Gibsons Capacity Upgrade project will be identified in FEI's Annual Review for 2023 Delivery Rates application. This project would become FEI's first operational non-pipe solution installed within a distribution system and will provide valuable information on using non-pipe solutions as alternatives to address system capacity.

7.4 INTEGRATION OF RENEWABLE AND LOW-CARBON GAS

FEI's framework to transition to a low-carbon energy future is its Clean Growth Pathway, discussed in Section 3. The Clean Growth Pathway is a diversified approach that is technology agnostic. At this point in the energy transition, it is important to maximize the number of decarbonization pathways available and explore business models that meet energy demands and maximize the use of existing assets, thereby avoiding the costs that would come with the complete reengineering of BC's energy sector. In the 2022 LTGRP, the Clean Growth Pathway is represented by the Diversified Energy (Planning) Scenario.

FEI is planning for gas supply resources made up of increasing amounts of renewable and low-carbon gas over the next 20 years and beyond. The components of this resource mix are expected to include RNG, hydrogen, natural gas, and smaller amounts of syngas and lignin, supplemented later in the planning period by CCUS. The amount of each resource to be acquired and delivered to customers throughout the planning period will ultimately be predicated by several variables, including:

- **Quantity and Timing of Resource Availability**: Although FEI has modelled the mix of renewable and low-carbon gas in certain proportions over time in the LTGRP planning scenario, the actual amount of each component that is acquired and delivered to customers could vary from the forecast amounts over the planning horizon based on a number of important factors, including resource costs and supply project opportunities and development. Renewable and low-carbon gases with the highest volume potential over the planning horizon are RNG and hydrogen. In particular, RNG is interchangeable[207] with natural gas and has wider availability so will make up a greater proportion of the resource mix in the near term. RNG will continue to be a large part of the resource mix throughout the planning horizon and beyond. While hydrogen resource development is underway, it is expected to become more widely available and make up an increasing proportion of the resource mix later in the planning horizon beyond 2030.
- **Resource Development and Delivery:** Many pathways exist for bringing the benefits of renewable and low-carbon gas to FEI's customers; however, there are several ways in which these resources can be developed and delivered to customers which will ultimately

[207] The physical properties of renewable natural gas, such as specific gravity, viscosity and heating value, etc., falls within the range of the physical properties of FEI's conventional sources of natural gas. The capacity impacts and gas supply resource needs are comparable, and both sources of methane can utilize the same upstream and on-system infrastructure.

determine the capacity impact and the overall system upgrade scope and timing. The following discusses the various modes of production and delivery and explains some of the capacity impacts associated with each.

i. **Off-System Supply and Off System Delivery:** Off-system supply is where FEI acquires renewable and low-carbon gases in other regions and the gas transportation and consumption is conducted completely outside of FEI systems. This process achieves carbon reduction and credit for FEI customers with the environmental attributes associated with renewable and low-carbon gas. However since FEI customers continue to physically receive conventional natural gas through FEI infrastructure the capacity requirements to meet peak demand forecasts remain the same on the FEI system. This capacity impact of off-system supply and delivery has the same neutral effect regardless of the form of the off-system energy delivered. The incorporation of these types of off-system supplies will play an important role while the transition to renewable and low-carbon gas occurs over the planning horizon until more on- or near-system resources that flow directly through FEI systems are developed.

ii. **CCUS:** processes for carbon capture at the customer location will not change the system capacity required to meet the peak demand. The process does not change the amount of conventional natural gas that would be flowing through the system to support customers using these processes.

iii. **On-System Hubs:** Local production and supply of renewable low-carbon gas will be developed. These local hubs, whether they produce RNG, or hydrogen or syngas and lignin will have some ability to free up pipeline capacity as the local demand served by this production no longer needs to be transported through the upstream transmission pipeline. For hubs that in addition to serving local demand inject RNG or electrolytic hydrogen (known as green production) into the transmission system as well there can be an additional capacity benefit on the system, however with hydrogen there can also be some offsetting capacity reduction where hydrogen blends are present in the transmission system or if conventional natural gas delivered through the upstream transmission pipeline is used as a feedstock for hydrogen production, by reformation or pyrolysis (known as blue or turquoise production respectively). The impacts of hydrogen blends on capacity are discussed further in Appendix D-3.

iv. **Off-System Supply and On-System Delivery:** Off-system supply of RNG and hydrogen physically delivered into FEI transmission systems from upstream pipelines will produce no net change in FEI transmission system capacity to meet peak demand forecasts if the supply is RNG. If the supply is a blend of hydrogen, there will be some capacity reduction for the reasons discussed below and in Appendix D-3.

- **Location:** Given the length of the planning horizon, the geographic location where renewable and low-carbon supply production is physically delivered to FEI's customers is not yet known in detail. Production facilities for RNG and hydrogen supplies are expected to be developed both on FEI's system and, over time, in locations where these low-carbon gases can be injected into the existing upstream gas infrastructure. While many potential projects are in the concept and development stages, the location of all those that will proceed during the next 20 years is uncertain. In particular, the extent to which such resources are developed and delivered to customers on one portion of FEI's system will impact the amount of RNG and natural gas that will still need to be delivered on other portions of the system over the planning horizon.

Although FEI is securing about as many contracts for supply within BC as outside of BC, the larger producers, in the near term, are outside of the province. Therefore, in the early years of the planning horizon, FEI's supply will predominantly be acquired and used outside of FEI's service territory. As a result, during this early part of the planning horizon, the system capacity impacts will remain largely unchanged from what FEI would have otherwise anticipated without renewable gases, as the transmission and distribution systems continue to predominantly move conventional natural gas. By 2030 and through the end of the planning horizon, on-system delivery of renewable gases supplied within FEI systems or by upstream pipeline systems will expand.

As FEI incorporates renewable gases into the gas distribution and transmission systems, the physical properties of these gases, such as density and energy content per standard volume, can have an impact on capacity. Gases with physical properties within the range of conventional gas, such as RNG, will have no net impact on delivery capacity. Delivering hydrogen or a blend of hydrogen and natural gas or hydrogen and RNG, where the gas density and energy content are different from traditional natural gas supply, will change the energy delivery capacity. The following sections provide some additional detail and examples of the impacts on system capacity and infrastructure requirements of introducing hydrogen gas blends.

Refer to Appendix D-3 for additional discussion on system planning considerations regarding hydrogen and hydrogen / natural gas or RNG blends

7.4.1 Integration of Renewable and Low-Carbon Gas in FEI Systems

7.4.1.1 *Overview of System Planning Considerations in Integrating Renewable and Low-Carbon Gas*

Each of FEI's regional pipeline systems have unique considerations with regards to the potential opportunities to bring on renewable and low-carbon gas to displace the need for pipeline delivery of conventional gas. From now until 2030, FEI expects a larger share of on-system renewable and low-carbon gas contribution will come from on-system RNG, syngas and lignin production, and CCUS. By 2042, as technology advances to produce hydrogen electrolytically, by pyrolysis or reformation, hydrogen is expected to be a larger share of FEI's fuel mix. By 2030 and through the rest of the planning horizon FEI's on system supplies will be increasingly enhanced by off-system production of renewable gases that is delivered into and through FEI systems.

Existing end use equipment such as furnaces, boiler and other residential and commercial appliances can burn a blended mix of methane and low concentrations of hydrogen. In its approach to delivering hydrogen, FEI assumes that (1) gas equipment will evolve to be able to utilize higher concentrations of hydrogen mixed with methane, and (2) some gas equipment (industrial process equipment, for example) could be able to fuel switch between hydrogen and methane when necessary. Some customers may also choose to install equipment that will be hydrogen dedicated. The eventual mix of these types of equipment throughout FEI's service territory is yet to be determined and would influence how adoption and distribution of renewable and low-carbon gases progress in each system.

As it is still early in the development of the production and delivery of hydrogen along with other renewable gases, FEI does not yet have sufficient definition to provide projections on their specific impact to the capacity of the system. Hydrogen has the most complex requirements from a system planning perspective. Considerations for hydrogen distribution is a likely and flexible way that the system can be expanded later in the forecast period considering the number of factors, yet to be fully determined, that may need to be defined and managed.

Table 7-2 provides an overview of FEI's system planning considerations for integrating renewable and low-carbon gas into regional transmission systems. Sections 7.4.1.2 to 7.4.1.4 then discuss further details regarding specifics within each regional transmission system.

Table 7-2: Overview of Considerations for Integrating Renewable and Low-Carbon Gas in FEI Systems

Fuel Type / Other Considerations	Regional Transmission and Distribution Line Considerations		
	VITS	CTS	ITS
RNG (on-system)	• Supply potential • No detrimental impact on transmission system capacity • Reliable supply from local on-system hubs will reduce upstream supply requirements and improve available capacity	• Supply potential • No detrimental impact on transmission system capacity • Reliable supply from local on-system hubs will reduce upstream supply requirements and improve available capacity	• Supply potential • No detrimental impact on transmission system capacity • Reliable supply from local on-system hubs will reduce upstream supply requirements and improve available capacity

Fuel Type / Other Considerations	Regional Transmission and Distribution Line Considerations		
	VITS	CTS	ITS
Hydrogen	• Supply potential from blue or turquoise production potential may require system upgrades • Green hydrogen hub will reduce upstream supply requirements and improve available capacity, but reduce available capacity downstream	• By 2030, hydrogen production anticipated with hydrogen and RNG in similar proportions. • By 2042, hydrogen supplied from upstream of Huntington Control Station and comprises a much larger portion of the fuel mix • With upstream supply, hydrogen separation facility at Huntingdon anticipated • Dedicated hydrogen “backbone” pipeline likely	• Supply potential from blue or turquoise production potential may require system upgrades • Green hydrogen hubs will reduce upstream supply requirements and improve available capacity, but reduce available capacity downstream
Syngas and Lignin	• Supply potential	• No supply potential currently identified	• Supply potential
LNG and Industrial Project Impacts	• Woodfibre LNG project may preclude hydrogen blending upstream (at Eagle Mountain) • Management of hydrogen at FEI’s Mount Hayes LNG facility would be required	• Flow of hydrogen likely to be separated from transmission system at Huntingdon control station due to large scale LNG production at Tilbury and Woodfibre LNG project	• Management of hydrogen at any future LNG facilities would be required •
System Upgrade Requirements	• Scope and location of system upgrades not yet feasible to determine as supply volumes and locations are currently in early stages of development	• Local supply hubs and small dedicated systems eventually connected to upstream by dedicated hydrogen “backbone” • Scope and location of system upgrades not yet feasible to determine as supply volumes and locations are currently in early stages of development	• Renewable and low-carbon projects could offset the need for upgrades • RGSD project under development could provide significant support for delivery of hydrogen and other renewable gas • Scope and location of system upgrades not yet feasible to determine as supply volumes and locations are currently in early stages of development

7.4.1.2 *The VITS*

For the VITS, there is opportunity to develop supply from on-system local RNG hubs. The RNG production can be blended in the transmission or distribution systems at the point of production. As described above in Section 7.4, RNG supply hubs, once reliable production has been developed, could offset some need for future pipeline capacity to support peak demand because of the reduced need to move the gas from upstream of the local hub. The VITS could also accept any RNG that is produced and injected in upstream transmission systems (such as the CTS, Westcoast, TC Energy and possibly the RGSD). RNG entering the VITS from upstream would not offset future capacity upgrades as the physical properties of the gas that determine the capacity requirements are the same as if conventional natural gas were supplied.

There are also several existing industrial locations where syngas and lignin production could meet local needs and displace the need for pipeline delivery (and capacity) of conventional gas to those locations.

To integrate hydrogen into the VITS, with the possibility of the Woodfibre LNG project entering service within the next few years and given the impacts of hydrogen blends on pipeline capacity and larger scale LNG production, FEI is not currently considering allowing hydrogen blends into the system at Eagle Mountain (the start of the VITS). FEI would achieve this by controlling the flow of hydrogen in the upstream CTS. However, downstream of the Woodfibre LNG plant there is potential to produce hydrogen in local hubs to be used locally or to be blended into the transmission or distribution system. This integration of hydrogen would require some means of removing hydrogen at FEI's Mount Hayes LNG facility when the plant in liquefying. As described in Sections 7.4 and Appendix D-3 green hydrogen supplied by these local hubs can provide a capacity benefit by offsetting the upstream gas supply otherwise required, but also reduce the existing capacity in the downstream system where hydrogen blends would flow. Blue or turquoise hydrogen production on system (produced from conventional natural gas supplied from upstream) may not provide any upstream benefit. As a result, these hubs could drive some future system upgrades in portions of the VITS.

At present, FEI expects a larger share of the renewable and low-carbon gas contribution will come from on-system RNG, syngas and lignin production, and some CCUS, with hydrogen forming a lesser part of the blend early in the forecast period until processes to produce hydrogen are in a more advanced stage of development. Until hydrogen and other renewable and low-carbon projects on the VITS are developed further and production rates and locations are more clearly defined, it is not yet feasible to identify and develop any specific system upgrades to support these energy supplies.

7.4.1.3 *The CTS*

FEI expects that as RNG supplies in the CTS develop, they will be blended in both the distribution system and the transmission system. These local hubs as the production becomes sufficiently reliable to support peak demand will provide some offset to upstream pipeline delivery (and capacity) of conventional natural gas to those location. Most of the supply will be produced within the CTS until later in the forecast period when off-system RNG production becomes available and can be delivered into the upstream pipeline systems supplying the CTS. At present there is potential for any significant syngas and lignin production identified within the CTS.

For hydrogen supplies, as with the VITS, the development of large scale LNG production in the CTS and the capacity impacts of hydrogen blends entering the VITS at Eagle Mountain need to be considered when addressing the distribution and blending of hydrogen in the system. Hydrogen at locations like Tilbury and Eagle Mountain, and possibly other industrial locations using methane as a feedstock would require hydrogen to be removed to accommodate production. By 2030, FEI expects to have developed hydrogen production within portions of the CTS at various locations and will be developing upstream supply. FEI is also expecting the potential for some, but not large quantities of hydrogen delivered from pipelines upstream of Huntingdon Control Station by that time. The proportions of hydrogen and RNG delivered in the system by 2030 may be similar. By 2042, however, FEI expects that most of the hydrogen used in the CTS will be supplied from the pipelines upstream of Huntingdon, and hydrogen will comprise a much larger portion of the renewable and low-carbon gas delivered.

To keep the blended hydrogen from the upstream pipelines out of the CTS as it begins to arrive in more significant quantities after 2030 would require a hydrogen separation facility at Huntingdon and a dedicated hydrogen pipeline that would ultimately connect to FEI's initial hubs. This pipeline would share a common alignment with FEI's existing CTS pipelines so that hydrogen could be blended directly into the distribution systems at the gate stations served by the CTS. This would allow the distribution system to receive a controlled blend of conventional gas, hydrogen and RNG, while leaving the CTS to deliver natural gas and RNG to the LNG production at Tilbury and the VITS-supplying Woodfibre LNG project via the Eagle Mountain Compressor facility in Coquitlam. This approach to introducing hydrogen along a dedicated "backbone" that connects earlier established local hubs allows some flexibility to control the increasing delivery of hydrogen in the system.

An alternate approach would be to accept increasingly higher blends at Huntingdon into the CTS directly as the supply increases and install multiple separation facilities throughout the CTS at locations like Tilbury LNG where it is necessary to separate the hydrogen. This requires re-blending the hydrogen collected at these locations back into the CTS downstream of the facility and adds a greater level of complexity to the system required for the delivery of hydrogen. Another concern with this approach is that directly blending hydrogen into the CTS would increasingly reduce the capacity of the CTS, which may expand upgrade requirements to support LNG expansion by increasing the capacity upgrades necessary for LNG as well as increasing the scale of hydrogen separation (and downstream re-blending of hydrogen) at the Tilbury LNG facility if future phases of LNG expansion occur.

As it is still early in the development of the production and delivery of hydrogen along with other renewable gases in the CTS, FEI does not yet have sufficient definition to provide projections on their specific impact to the capacity of the system. The hydrogen "backbone" described earlier is a likely and flexible way that the system can be expanded later in the forecast period considering the number of factors, yet be fully determined, that may need to be defined and managed.

7.4.1.4 *The ITS*

The ITS presents a variety of potential future options to meet FEI's carbon reduction goals including RNG, syngas and lignin and hydrogen that could all be produced and consumed directly by industrial customers and other local consumers. There are a variety of potential future off-system supply options as well, for each renewable and low-carbon gas, from the Westcoast system in the west at Savona and Kingsvale and the TC Energy system in the east at Yahk to help meet carbon reduction goals.

There is opportunity to develop supply from on-system local RNG hubs. RNG supply hubs, once reliable production has been developed, could offset some need for future pipeline capacity to support peak demand because of the reduced need to move the gas from upstream of the local hub. The ITS could also accept any off-system RNG that is produced and injected in upstream transmission systems. RNG entering the ITS upstream at Savona, Kingsvale or Yahk would not offset future capacity upgrades as the physical properties of the gas that determine the capacity requirements are the same as if conventional natural gas were supplied.

Similar to the VITS, in the ITS there are also several existing industrial locations where syngas and lignin production could meet local needs and displace the need for pipeline delivery (and capacity) of conventional gas to those locations.

Hydrogen sources, supply could also be produced and injected on-system into nearby distribution systems or injected into the ITS for wider consumption at local supply hubs. Green hydrogen supplied by these local hubs can provide a capacity benefit by offsetting the upstream gas supply otherwise required, but also reduce the existing capacity in the downstream system where hydrogen blends would flow. Blue or turquoise hydrogen production on system (produced from conventional natural gas supplied from upstream) may not provide any upstream benefit. As a result, these hubs could drive some future system upgrades in portions of the ITS. The ITS could also accept any off-system hydrogen that is produced and injected in upstream transmission systems hydrogen entering the ITS upstream at Savona, Kingsvale or Yahk. As described earlier and as discussed in Appendix D-3 introducing hydrogen blends at the source of the system will reduce some of the available capacity and could drive some additional future upgrades requirements than would be required with conventional natural gas supplies. The upgrade requirements and system capacity will look different depending on the range of hydrogen supplied into the system from each upstream source.

Currently FEI is developing the RGSD pipeline. Should the potential project proceed, the pipeline and system upgrades which include additional compressor facilities along FEI's SCP. The RGSD would allow FEI to receive and deliver off-system hydrogen production from TC Energy and on-system supplies along the ITS and SCP to other locations along the ITS, but also as envisioned will have the capacity to move additional hydrogen and conventional gas required for the CTS via a new NPS 30 hydrogen ready pipeline between Oliver and the Lower Mainland.

As mentioned previously there are a significant number of other combinations of supply from Westcoast and TC Energy that could ultimately occur in the ITS. As these opportunities are developed into defined projects and specific sources of supply for each renewable gas, the specific capacity upgrade requirements required within the ITS to accommodate delivery of renewable gases will become more clearly defined.

7.5 SYSTEM RESILIENCY

Broadly speaking, gas system resiliency depends on a combination of pipeline diversity, ample storage, and the ability to manage load. Establishing system resiliency enables the gas transmission and distribution systems to effectively respond to system disruptions and avoid or minimize impacts of those disruptions. FEI applies and leverages two of the three key elements, storage and pipeline diversity, in both the transmission and distribution systems to build infrastructure that along with the third element, load management support, provide end to end resiliency while connecting FEI consumers with the region's gas supplies.

FEI has provided safe and reliable natural gas service in the province for many years. To provide reliable service, FEI has maintained the integrity of its assets, and ensured the adequacy and security of gas supply. FEI has also completed a number of projects that have significantly enhanced the resiliency of its system, such as the SCP and Mt. Hayes LNG facility. FEI's system exhibits a high level of reliability and has to date proven resilient to system failures and unforeseen events in the region. While FEI has long regarded resiliency as an important system attribute, the T-South incident (discussed in Section 3.2.2.3) underscored the benefits that would come from new investments in system resiliency.

FEI provides a comprehensive discussion of system resiliency across all FEI systems and the PNW in Appendix E. This section summarizes the resiliency of each of the transmission systems and the distribution system and TP lateral system infrastructure projects FEI is currently developing, or considering, to enhance resiliency

7.5.1 Transmission System Resiliency

In order for the gas system to avoid and effectively respond to disruptions, FEI must establish a resilient system. The high-level resiliency considerations for each transmission system are:

- ***The Vancouver Island Transmission* System:** The Mt. Hayes LNG facility supports VITS resiliency by providing LNG inventory and vapourization capacity, which can support the system for several winter days in the event of a supply disruption and can indirectly support supply disruptions upstream of the CTS through displacement of load requirement from the CTS. As it is connected to the Mt. Hayes LNG facility the VITS has a high level of resiliency in meeting peak winter demand and supply disruptions. FEI has therefore not presently identified or considered projects to increase resiliency for the VITS.
- ***The Coastal Transmission System*:** To enhance resiliency in the CTS, as discussed in Section 6.3.2 and 6.3.3, since the T-South incident, FEI has filed an application with the BCUC for the TLSE project to address resiliency for FEI's Lower Mainland systems. FEI is also considering new regional pipeline infrastructure to build on the resiliency provided

by the TLSE project and add pipeline diversity to the CTS and broader region. The RGSD project would expand the SCP from Oliver to the Lower Mainland to increase the CTS's supply diversity. In the medium term, FEI's AMI project will be beneficial in enhancing FEI's CTS load management capabilities. These projects will add key components to FEI's portfolio approach to resiliency while providing other benefits for customers.

- ***The Interior Transmission System*:** The ITS is dependent, in the Okanagan region, on supply from both the Westcoast system supplying the ITS at Savona, west of Kamloops, and the supply from TC Energy supplying the ITS and SCP near Yahk in the Kootenays and entering the Okanagan region at Oliver. Although the ITS has some diversity of supply, interruption of one of the two supplies in a period of higher demand could result in loss of supply to customers in portions of the ITS. As a result, FEI is looking at the need to improve resiliency in the ITS. FEI is examining options to improve resiliency in this area of the Interior, which are discussed below.

The infrastructure projects FEI is currently developing, or considering, to enhance resiliency are described below.

7.5.1.1 *Regional Gas Supply Diversity (RGSD) Pipeline*

As described earlier in Section 6.3.3 the RGSD project is being developed to add resiliency to the Lower Mainland system and enhance the resiliency and supply diversity of the broader regional pipeline infrastructure in BC and the PNW. As part of the project approximately 238 km of NPS 30 pipeline would extend FEI's Southern Crossing pipeline from Oliver to the Lower Mainland. Four new compressor stations would be installed between Yahk and Oliver on the existing Southern Crossing pipeline. With the upgrades the project will have the capacity to increase FEI's existing supply along the Southern Crossing pipeline and into the Lower Mainland at Sumas from 115 TJ per day to approximately 500 TJ per day and is planned to have the metallurgical capability to support FEI's plans to deliver hydrogen across BC and the PNW.

7.5.1.2 *Interior Transmission System (ITS) Resiliency*

Increased resiliency and supply diversity within the high-population centres in the Thompson Okanagan region of the ITS can be accomplished through either extensive pipeline looping and compression or through a centrally located LNG supply that could provide short-term supply like that proposed by the TLSE project in the Lower Mainland.

Option 1 – LNG Storage

As described in Section 7.3.3, an LNG storage facility close to Vernon could, if suitably sized, provide a higher level of resiliency to protect against upstream supply interruptions or shortages to the ITS in the Thompson-Okanagan region, in addition to addressing future capacity needs in the latter part of the forecast period.

Option 2 – Pipeline Looping and Compression

Pipeline looping from both the northwest (Savona) and from the South (extending the OCU pipeline) is another option to increase resiliency. Looping from Savona would extend east past Kamloops towards Vernon, along with additional pipeline looping from the south extending the OCU project pipeline from its terminus near Chute Lake north around Kelowna and past Vernon. Additional compressor units would also be installed at Savona to accommodate a higher flow rate if the gas supply from Yahk is interrupted. Pipeline upgrades and compressor power upgrades at FEI's Armstrong compressor would also be undertaken to allow discharge towards Kamloops in the event supply from Savona is interrupted.

7.5.2 Distribution System and TP Lateral System Resiliency

FEI distribution systems are inherently resilient in that they have evolved as communities have expanded. As such, there is a high degree of interconnection within the systems allows the continuation of service to the majority of customers in the system, and results in outages caused by system damage to be limited in scope compared to transmission system incidents and supply disruptions. In addition, the duration of outages while repairs are completed can be much less extensive, most often a few hours or less. This is due to the pipeline's low operating pressures, smaller pipeline sizes, and more routine and less incident-specific regulatory system requirements. There are very few locations within FEI distribution systems where many customers would be at risk of extended outages in winter conditions. As a result, FEI gas customers enjoy a high degree of reliability and most never experience an unplanned outage. Nevertheless, FEI is reviewing distribution system resiliency options in locations where large numbers of customers are vulnerable to pipeline failure and where the ability to restore service in the event of an outage may extend to several weeks or months.

7.5.2.1 *Major DP, IP and TP Lateral Pipeline Crossings*

The risk of prolonged service interruptions in distribution pipelines is almost exclusively limited to single feed gas lines at major water crossings where the line is inaccessible or otherwise extremely difficult to repair. FEI is examining options to improve resiliency at select points of the distribution systems, including at the Ironworkers Memorial Bridge in the Lower Mainland and at Okanagan Lake between Kelowna and West Kelowna.

A NPS 24 IP pipeline located on the Ironworkers Memorial Bridge provides the only gas supply to more than 45,000 customers in North Vancouver and West Vancouver. Loss of this crossing would result is an extensive outage for these customers. Providing a second redundant crossing to the Northshore communities would significantly improve the resilience of this portion of the Metro Vancouver distribution system.

In the Interior region, West Kelowna is supplied by an NPS 8 IP pipeline that crosses Okanagan Lake between Kelowna and West Kelowna. While the system may require capacity upgrades later in the forecast period that could entail looping the lake crossing, looping the crossing would address capacity constraints but would not improve resiliency. In anticipation of future resiliency needs, FEI is studying alternatives for the crossing that would improve the resiliency of supply to West Kelowna, Summerland and Peachland.

Other than service to the communities mentioned above, there is a limited number of similar water crossings in FEI's distribution systems where large numbers of customers are at risk of extended supply outages because of crossing failures.

Despite the inherent resiliency of distribution systems, FEI is in the process of developing criteria to more clearly define projects where single points of failure would cause disruption to significant numbers of customers and where service would be unable to be restored in a timely manner. Such failures would result in a risk of customers being without supply for extended periods in winter conditions and thus would be prioritized in planning analyses for resiliency. In some cases, small transmission lateral bridge and water crossings provide the sole source of gas supply to communities, and therefore present similar risks in the event of a supply failure. To develop the criteria to identify these projects, FEI is reviewing the maximum capability of temporary "non-pipe" solutions such as a CNG or LNG "virtual pipeline" arrangement to support communities in a sustained manner through a winter period in the rare circumstance that a failure of the single supply occurs. Defining this capability and establishing the feasibility, timeliness of mobilization, and cost of implementation will help define how many new projects should be considered to improve resiliency for systems too large to be supported by non-pipe solutions. Additionally, not all single-feed crossings will have the same probability of failure, so criteria to establish the risk associated with each location will provide a basis of establishing the priority of identified resiliency projects. As mentioned previously, FEI's DP, IP and TP lateral systems are generally highly resilient, and the criteria developed are not expected to produce many projects of significant scope or cost.

7.5.2.2 *Metro Vancouver LMIPSU System Resiliency*

In Section 3.6 of the PGR project CPCN Application[208], FEI described the impact of its preferred alternative on system resiliency. While the PGR project would erode the resiliency provided by the recently completed LMIPSU project to be fully resilient under the coldest design conditions, the LMIPSU nonetheless remains a substantial improvement to the Metro Vancouver distribution system. It continues to support system resiliency in the event of a failure of supply at either of the two major gate stations serving the region by preventing service interruptions up to nearly the coldest day in a typical winter. However, for FEI to recover the incremental resiliency eroded by the PGR project, an approximately 5100 m long 508 mm (20") IP pipeline loop in South Vancouver would be required. This would be a significant project very similar to the scope of the current PGR Project.

In the process described above of developing criteria to identify other resiliency projects, FEI expects to identify and prioritize other proposed projects that would address more urgent locations where a failure of a single feed would result in customers being without gas at any time of year.

[208] Application for a Certificate of Public Convenience and Necessity for the Pattullo Gas Line Replacement project Decision and Order C-2-21.

As a result, at this time, FEI is not intending to file an application for a project to restore the eroded distribution system resiliency resulting from the PGR project prior to the submission of its next LTGRP. In the interim the installation of enhanced metering with the AMI project, if approved, may provide additional information to FEI useful in evaluating the need to recover resiliency. Further consideration for the potential need and timing for this project will be provided in a subsequent LTGRP application.

7.6 *OTHER MAJOR SYSTEM PROJECTS*

FEI has several other significant system projects either in progress, before the BCUC, or in development. These are described below.

7.6.1 The Okanagan Capacity Upgrade (OCU) Project

FEI continues to forecast a capacity deficit in the Okanagan region of the ITS. At present, the CPCN Application[209] for the project is adjourned. In the interim, FEI continues to prepare contingency plans for temporarily addressing the capacity deficit until a permanent capacity upgrade solution is approved and installed.

7.6.2 Transmission System Laterals In-Line Inspection (ILI) Capability

FEI operates transmission pressure laterals across the province served from FEI-operated transmission systems or the Westcoast and TC Energy pipelines. These laterals range from several hundred metres to several tens of kilometres in length. A total of more than 400 km of these pipeline laterals are between NPS 6 and NPS 10 and currently are not configured to allow ILI tools to be used as part of FEI's pipeline integrity management programs. ILI technology is an effective tool for detecting and subsequently repairing pipeline corrosion and defects prior to leaking or rupture.

In January 2020, FEI received approval to move forward with the Inland Gas Upgrade (IGU) project[210] and is currently in progress on this multi-year project to upgrade transmission laterals for ILI capability or install pressure control station to reduce pressure sufficiently to avoid the need for ILI activities on some lateral systems.

[209] Application for a Certificate of Public Convenience and Necessity for the Okanagan Capacity Upgrade project (Application): https://www.cdn.fortisbc.com/libraries/docs/default-source/about-us-documents/regulatory-affairs-documents/gas-utility/201116-fei-okanagan-capacity-upgrade-cpcn-ff.pdf?sfvrsn=adf84903_2.

[210] Application for a Certificate of Public Convenience and Necessity for Approval of the Inland Gas Upgrade project (IGU project or the project): https://fbcdotcomprod.blob.core.windows.net/libraries/docs/default-source/about-us-documents/regulatory-affairs-documents/gas-utility/181217-fei-igu-cpcn-application-ff.pdf.

7.6.3 Southern Crossing Pipeline Class Location Project

Urban development around existing pipelines can drive changes in pipeline class location as defined in CSA Z662[211] and necessitate changes to increase pipeline safety factors. Pipeline safety factors can be increased by either:

- Decreasing pipeline operating pressures at existing or new pressure control stations; or alternatively
- Replacing the identified pipeline segment in populated areas with higher grade and or thicker walled pipe.

Installing additional mainline valves may also be necessary in either case. Decreasing pipeline operating pressure to increase the safety factor will reduce the capacity of the pipeline and is not a viable option given the capacity this pipeline currently requires and would need in the future to deliver FEI requirements for renewable and low-carbon gas. Replacing the pipeline segments with higher grade or thicker walled pipe can maintain or increase operating pressures and capacity. The SCP is an NPS 24 pipeline operating between Yahk and Oliver in the BC Southern Interior. The Class Location project will address the installation of six kilometres of pipe replacement and one new mainline valve between 2024 and 2028 to sustain established pipeline operating pressure and pipeline safety factors.

7.6.4 Advanced ILI on Pipelines Currently Inspected with ILI

Advanced Electro-Magnetic Acoustic Transducer (EMAT) ILI capability for pipelines that are already ILI-capable is currently being proposed by FEI. FEI's CPCN Application for the Coastal Transmission System Transmission Integrity Management Capabilities project is currently before the BCUC and FEI is developing a similar application for the ITS. EMAT technology can detect Stress Corrosion Cracking (SCC) and cracks in alignments currently not detected by traditional ILI tools. The implementation of this technology includes upgrades such as:

- Alterations of the sending and receiving barrels to accept the newer tools;
- Alterations to the transmission pipelines so that the new tools can traverse them without hindrance or interruption to ensure successful data collection;
- The installation of flow control equipment or transmission loops to facilitate the control (i.e., reduction) of the gas flow velocity to ensure successful data collection; and
- Capacity upgrades to facilitate operation at reduced pressures when SCC features are detected and subsequently investigated and corrected.

7.6.5 Reliability Upgrade to Langley Compressor Facility (Existing Units)

The Langley compressor facility consists of two 7,500 HP units. With large industrial load additions like the Woodfibre LNG project, the Langley compressor units would need to run for

211 https://www.csagroup.org/store/oil-gas-pipeline-systems/.

periods of several days to weeks in winter periods. The current units are undergoing some upgrades, and to support increased service hours would require the installation of a cold recycle loop in the facility and a fuel condition system that are scheduled to be completed in 2023 and will be funded by FEI's sustaining capital budget. With increased operation, compliance with air quality permit and requirements to ensure compliance are currently under way. The Vancouver airshed environmental regulations continue to change and the Canadian Ambient Air Quality Standard is expected to become more stringent in terms of emission requirements. At this time, it is unclear if changes will necessitate premature replacement of the units to meet a more stringent emission criterion. If the current units are not able to meet new emission requirements, it is expected that they will be upgraded to address both the environmental requirements and the long-term availability concerns with Original Equipment Manufacturer (OEM) model support. As indicated in Section 7.3.2.4, additional phases of LNG expansion could drive the need for an additional compressor unit at Langley in addition to the units currently installed.

7.7 RECOMMENDATIONS FOR SYSTEM REQUIREMENTS TO MEET GROWTH AND THE DIVERSIFIED ENERGY (PLANNING) SCENARIO

FEI's gas system must be improved to meet future demand growth and optimize operation of the whole system. With annual increases in forecast peak demand, potential new sources of demand from LCT and industrial sources, and the introduction of renewable and low-carbon gas in significantly increasing quantities, the VITS, CTS and ITS could all require capacity-enhancing projects to meet peak demand forecasts while enabling FEI's Clean Growth Pathway. To address system capacity, FEI plans to:

- Accelerate efforts to study and develop solutions for understanding the system's capacity to support increasing production and delivery of renewable and low-carbon gas;
- Refine reinforcements that would be required to maintain system reliability and resilience for Core customers as LNG expansion occurs on the CTS and VITS;
- Refine criteria to identify and prioritize projects to address system resiliency in all FEI systems;
- Refine and implement mitigation plans to address the capacity shortfall in the Okanagan region of the ITS until an OCU project solution is approved and implemented; and
- Continue evaluating other major system projects outlined in Section 7.6 and submit CPCN applications for these projects if required.

FortisBC Energy Inc.
2022 LTGRP

Section 8:

STAKEHOLDER, INDIGENOUS AND COMMUNITY ENGAGEMENT

Table of Contents

8. STAKEHOLDER, INDIGENOUS AND COMMUNITY ENGAGEMENT

8.1 *INTRODUCTION*

In this section, FEI provides details of its engagement activities, including the process, the stakeholders and Indigenous groups with whom FEI engaged through this process, common themes that emerged, and FEI's responses to some of the feedback raised. Connecting with customers, Indigenous groups, communities, and other stakeholders on long-range planning issues is of critical importance to FEI. Effective stakeholder and rights holder engagement provides valuable insights for incorporation into the long-range planning process, including demand and supply forecasting analysis, the transition to renewable and low-carbon gases, DSM program development, and the development of an Action Plan for implementing FEI's preferred resource solutions to meet the future energy needs of customers. The feedback and input provided during the LTGRP process also supports FEI's continued commitment to evolving and continually improving its engagement process for future FEI energy planning initiatives.

When seeking input and feedback during the resource planning process, the BCUC's Resource Planning Guidelines encourage utilities to "focus such efforts on areas of the planning process where it will prove most useful and to choose methods that best fit their needs."[212] For this 2022 LTGRP, FEI undertook a number of initiatives to offer customers, stakeholders, and Indigenous groups the opportunity to participate in discussions to inform the planning process. These activities continued until the first quarter of 2022. FEI has an external website for its resource planning and stakeholder engagement, which includes all of FEI's presentation materials and meeting notes from its engagement sessions: https://www.fortisbc.com/about-us/projects-planning/natural-gas-projects-planning/natural-gas-planning-stakeholder-engagement.[213]

FEI has adjusted how it has consulted and engaged with stakeholders and Indigenous groups due to the COVID-19 pandemic. Prior to 2020 and the start of the COVID-19 pandemic, FEI had been consulting with stakeholders and engaging with Indigenous groups in person through the RPAG and community engagement workshops. However, since the start of the pandemic in March 2020, engagement has been conducted by virtual meetings. While in-person engagement is preferred, virtual meetings have continued to promote stakeholder and rights holder engagement and enabled them to provide valuable feedback and input into the 2022 LTGRP development process.

The remainder of this Section is organized as follows:

- Section 8.1 describes the feedback received from Resource Planning Advisory Group (RPAG) workshops and how the feedback is addressed in the LTGRP;

[212] Issued December 2003, p. 5, online at: http://www.bcuc.com/Documents/Guidelines/RPGuidelines_12-2003.pdf.
[213] FEI confirms that, by providing this link, it considers the webpage and the documents linked on the webpage to be part of the record of this proceeding.

- Section 8.2 describes the feedback received from engagement workshops with First Nations community representatives and how the feedback is addressed in the LTGRP or other FEI initiatives;
- Section 8.3 describes the feedback received from consultation workshops with representatives from communities served by FEI and how the feedback is addressed in the LTGRP; and
- Section 8.4 describes other FEI consultation and engagement activities that directly or indirectly inform the resource planning process, such as discussions with advisory groups, government, industry associations, and other stakeholders.
- Section 8.5 provides a summary of other engagement activities not directly related to, but which helped inform, the 2022 LTGRP and the development of the Clean Growth Pathway.

8.2 THE RESOURCE PLANNING ADVISORY GROUP (RPAG) PROVIDED KEY INSIGHTS AND FEEDBACK TO FEI

8.2.1 FEI Held Six Workshops with the RPAG

The RPAG is a technical working group that engages representatives of municipalities, provincial government, customers, public interest associations, environmental organizations and intervener groups in the development of the LTGRP. RPAG members bring significant knowledge and experience to the process and provide key insight and feedback to FEI. The table below provides an overview of the organizations represented in the RPAG.

Table 8-1: RPAG Members

Organizations Represented at RPAG Meetings
Avista Utilities
BC Business Council
BC Hydro
BC Ministry of Energy, Mines and Low Carbon Innovation
BC Public Interest Advocacy Centre
BC Sustainable Energy Association
BC Utilities Commission (as an information provider and observer)
Building Owners and Managers Association
Canadian Biogas Association
Canadian Institute of Plumbing and Heating
City of Abbotsford
City of Burnaby
City of Campbell River
City of Kamloops
City of Kelowna

Union of BC Municipalities
University of Victoria
Village of Keremeos

FEI held six RPAG workshops between 2021 and 2022 to review key steps in the LTGRP process, discuss plan inputs, gather feedback on the results of the LTGRP process to date, and provide input into FEI's decision to use the Diversified Energy (Planning) Scenario as the planning scenario in the LTGRP. Attendees participated by asking questions and providing discussion throughout each presentation. An overview of presentation content is outlined in Table 8-2. An interactive tool (discussed in Section 8.2.3) was also utilized to gather crowd-sourced feedback regarding demand drivers and scenarios.

The first two RPAG sessions were held in early 2021. Members of the RPAG and the Energy Efficiency and Conservation Advisory Group (EECAG), FEI's consultant Guidehouse, and FEI staff attended the sessions. FEI and Guidehouse presented the findings from the Pathways Report.[214] FEI provided background information on the long-term resource planning process and objectives, an overview of the Pathways Report regarding the comparisons of the Diversified and

[214] Appendix A-2: Pathways for British Columbia to achieve its GHG reduction goals.

Electrification Pathways for BC to achieve its GHG reduction goals, and the implications of the pathways for resource planning purposes. Discussion included how various components of the Pathways Report and FortisBC's Clean Growth Pathways pillars were included within the LTGRP demand forecasts and scenarios. RPAG members expressed a strong commitment to reducing GHG emissions and in that context, there was general support for ensuring a long life for gas infrastructure, addressing the costs of decarbonization and impacts of climate change, and providing affordable energy and a resilient energy system for all customers. There was also general support for FEI to use the Diversified Energy (Planning) Scenario as FEI's planning scenario for the 2022 LTGRP.

In the subsequent four RPAG meetings, topics of discussion were key initiatives such as accelerating the procurement of renewable and low-carbon gas, evolving the hydrogen future, supporting and expanding a resilient gas infrastructure, developing innovative DSM approaches, and FEI's response to the Roadmap. Table 8-2 below outlines meeting dates and major topics discussed and Section 8.2.2 discusses feedback received through the RPAG sessions.

Table 8-2: Overview of RPAG Meetings and Major Discussion Topics

RPAG Meeting	Topics Discussed
January 25, 2021 2022 LTGRP Kick-off	• Resource planning process and objectives • BC's energy planning landscape • Presented Pathways Report • FortisBC's 30BY30 target as an important step in the low-carbon transition • The LTGRP engagement plan for 2021
February 12, 2021 FortisBC: Joint Gas and Electric BC's GHG Reduction Pathways and Implications for the LTGRP and Long-term Electric Resource Plan (LTERP)	• Background on LTGRP and demand side planning • Presentation of *Pathways for BC to achieve 80 percent GHG reduction through comparison of the Electrification and the Diversified Energy Future* • Feedback on the Pathways Report • Illustrative demand forecast scenarios and drivers
June 17, 2021 Demand Forecast and Renewable Supply Scenario	• LTGRP update on Traditional Annual Method and BAU forecast • FortisBC outlook and considerations for renewable gas supply • Critical uncertainties and renewable supply alternatives modelling • Reference case demand forecast and alternate scenarios • Crowd forecasting activity
November 3, 2021 Demand-side Management Scenarios	• DSM scenarios • System planning and gas supply

RPAG Meeting	Topics Discussed

December 1, 2021
System Planning and Gas Supply
	• Renewable gas – FEI's comprehensive review filing
	• System planning overview:
	  ○ Annual and daily peak demand
	  ○ Capacity impacts of renewable and low-carbon gas
	  ○ Regional forecasts and infrastructure upgrades
	• Gas supply – market conditions and portfolio planning
	• Infrastructure transition to renewables and resiliency

February 10, 2022 Overview of 2022 LTGRP submission	• Status of the 2022 LTGRP submission and overview of RPAG feedback received to date • The Diversified Energy (Planning) Scenario – FEI's planning scenario • Regional Gas Supply Diversity (RGSD) project and its role in the Clean Growth Pathway • Development of the LTGRP Action Plan

8.2.2 FEI Received and Addressed Feedback from the RPAG

The feedback received from the RPAG has been useful in developing the 2022 LTGRP. Through the RPAG workshop sessions, stakeholders have been able to provide FEI with input on many areas including scenario development for demand forecasting, system planning, gas supply and DSM. This feedback is particularly critical at this pivotal time as FEI transitions to a low-carbon future.

Some of the feedback received during these sessions related to the opportunities and risks for customers and stakeholders under the different pathways. For example, there was mention by some stakeholders of the economic development potential relating to the Diversified Pathway for communities, such as through the development of RNG and hydrogen production. Some members expressed their concern for urgent climate action and advocated for more intense electrification and allocation of renewables to "hard to decarbonize sectors". Some members highlighted the benefits of maintaining the gas system in providing an affordable, reliable, and resilient complementary energy system that optimizes the use of both the gas and electric systems to deliver energy in BC. Some members were interested in system capacity planning, the impacts of renewables, and how to make the system hydrogen-enabled. There was general support for developing BC clean energy projects. The costs of decarbonization were highlighted in most sessions, but it was acknowledged that any pathway to deep decarbonization will result in significant costs.

Table 8-3 below outlines examples of feedback FEI received from the RPAG and where the feedback was incorporated into the LTGRP.

1 **Table 8-3: Overview of General Feedback Received and Where it is Addressed in the Plan**

Feedback	2022 LTGRP sections where feedback topics are addressed
FEI should respond to the CleanBC Roadmap to 2030 targets in the Diversified Energy (Planning) Scenario (although it was acknowledged that the October 25, 2021 announcement came late into the LTGRP process).	Section 2.2.2.2 explains the Road Map in the context of the Planning Environment. Section 4.5.1 provides background on the development of the Diversified Energy (Planning) Scenario and Section 9 provides an overview of GHG emissions in relation to the provincial cap.
FEI should review its provincial carbon accounting methods and approach in presenting lifecycle carbon accounting. This is especially relevant for LNG, LNG exports and potential double counting of, for example, industrial customers.	Section 4 describes LCT, Global LNG and new Large Industrial Demand. Section 9 describes analysis of FEI's GHG emissions.
FEI, BC Hydro and the Province should work together in resource planning to ensure alignment of demand, supply and cost scenarios in developing long-term energy scenarios to meet the needs of British Columbians.	FEI is continuing its work to collaborate where it makes sense and each utility sits on the others external advisory group.
Discussion was raised regarding the potential allocation of RNG specifically to "hard to decarbonize" end users such as industrial, Heavy Duty Road, marine and others.	Sections 6 and 7 discuss the allocation of renewable and low-carbon gas to sectors and regions. Section 9 discusses GHG reductions for FEI's Clean Growth Pathway.
FEI should provide a consolidated resiliency plan and explain why LNG storage is required as part of the resiliency plan.	Section 3.2.2.3 introduces Appendix E – Gas System Resiliency Plan which includes an overview of where resiliency is discussed in the LTGRP.
FEI should explain the breakout of transportation demand (CNG and LNG) and where it fits in demand curves and GHG emission reduction results. FEI should provide this information for LNG projects and provide an overview of how much of total demand will be allocated to the LNG export market.	Sections 4.4.2 and 4.6.2 provides an overview of the demand forecasts for LCT. Section 9 provides an overview GHG emissions pertaining to transportation. The LNG export market is not discussed in the LTGRP.
FEI should demonstrate how BC communities, including Indigenous groups, can develop clean energy projects that can feed into gas infrastructure as part of the Clean Growth Pathway.	Section 3.2.2.5 discusses economic development opportunities for the Clean Growth Pathway.
FEI should project the costs of decarbonization at customer group levels (residential, commercial and industrial).	Section 9 provides rate impacts at the customer group level.
FEI should provide clarity on the highest performing DSM measures in the CPR and provide access to the CPR.	Section 5.4.7 provides an overview of highest performing DSM measures in DSM analysis. The CPR is available in Appendix C-1.

Feedback	2022 LTGRP sections where feedback topics are addressed
FEI should provide annual demand and daily peak demand comparisons for sectors and regions.	Section 4 provides annual demand by customer group and Section 7 provides peak demand for customer groups and regional transmission systems.
The longevity of DSM and energy efficiency programs is going to be critical. There is a need to be focused on building envelope insulation in addition to mechanical systems. FEI should ensure DSM models incorporate all gaseous fuels including natural gas, RNG and hydrogen as each unit of energy saved benefits customers overall.	Section 5 provides the DSM analysis, program area descriptions, and long-term plan for implementation, including consideration for these measures and fuels. FEI anticipates that new information on these measures and continued modelling improvements for the next LTGRP will further enhance understanding of their impact on energy use and emissions.
FEI should explain the benefits of the Regional Gas Supply Diversity (RGSD) project over the Westcoast T–South expansion, especially as compared to the ability of electrification to significantly reduce demand for gas.	The RGSD project is discussed in Sections 6.3.3 and 7.5.1.1 and other sections of the LTGRP.

As resource planning is an iterative and ongoing process, some of the feedback and recommendations received from the RPAG during this planning period may be considered by FEI in the next iteration of the resource planning process, to the extent they remain relevant. Examples of forward-thinking feedback for consideration in the next resource plan include recommendations that FEI:

- Provide more information on renewable and hydrogen/low-carbon gas pricing and long-term market pricing models. FEI should compare the Diversified Pathway with a plan that involves other renewables such as solar and wind.
- Provide economic outlooks on the full costs over the long term, to all ratepayers resulting from the electrification pathway, as these will ultimately be borne by ratepayers.
- Expand the crowd-sourced “slider tool” for the next LTGRP consultation so FEI can gather a range of feedback to support the development of unique scenarios.
- Apply DSM savings equally to all fuels (natural gas, renewable and low-carbon gas).[215]
- Examine the cost per tonne of emissions reductions for electrification, as the costs may or may not be higher than for gas DSM initiatives, although consider that some measures perform better than others. Air Source Heat Pumps are not the only answer for GHG emission reduction initiatives. FEI should consider how to run GHG emission reduction scenarios to determine the best options for BC.

[215] Although the ability to apply DSM savings equally to all fuel types is discussed in the 2022 LTGRP, this analysis cannot be completed in time for the March 31 submission date since such analysis will require reconfiguring the software.

FEI will consider each of these recommendations and, if feasible and useful, include them in the next LTGRP filing.

8.2.3 Stakeholder Expert (Crowd) Opinion Forecast

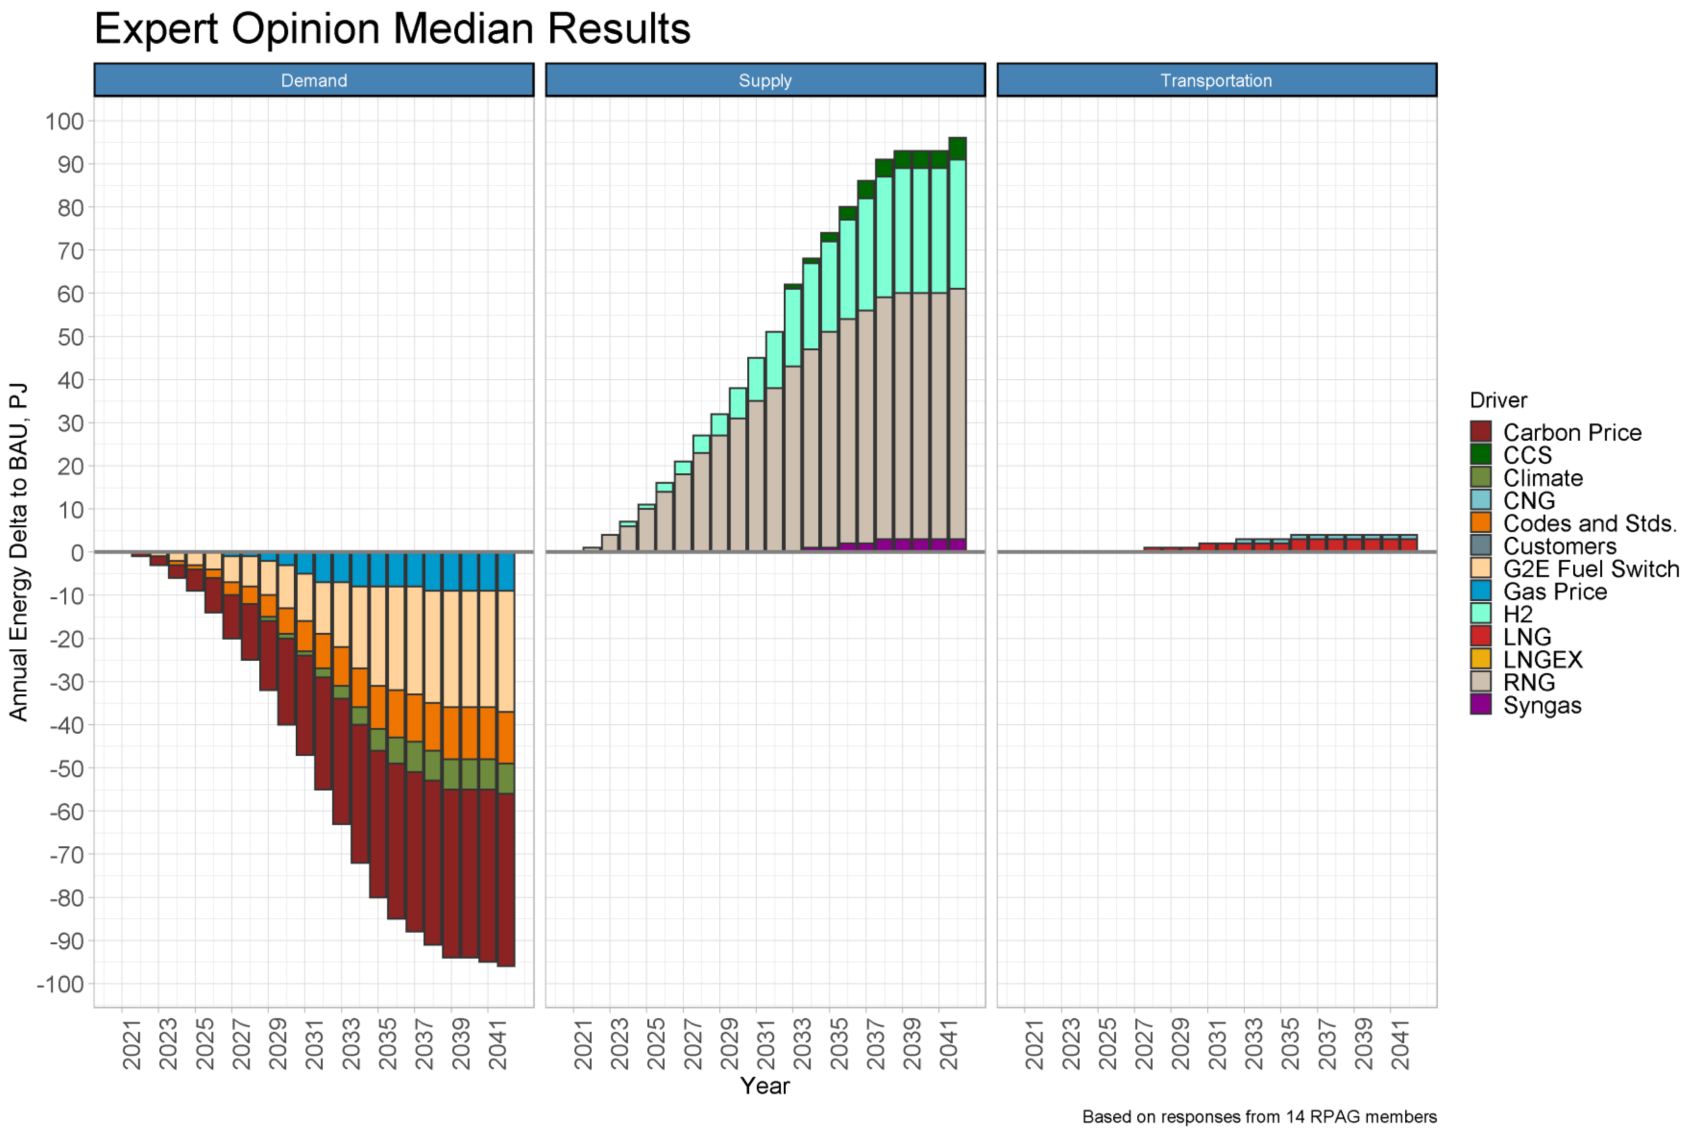
At the June 21, 2021 RPAG meeting, FEI introduced the Expert (Crowd) Opinion Forecast and "Slider" forecasting tool (Expert Opinion Tool). Stakeholders were given an introduction to the exercise and a website link via email after the session. Stakeholders were invited to use the tool to develop their own forecast scenario and to then submit the results to FEI. The exercise was anonymous, but an option was made available for participants to identify their affiliation. The invitation was sent to 31 stakeholders. FEI received responses from 14 RPAG members.

The exercise asked participants to estimate the impact of a number of drivers[216] over the 20-year period of the LTGRP. FEI selected those drivers that were not reflected in the historical data used to develop the BAU forecast at the level that would likely be experienced in the future. Drivers were provided to explore the impacts of variations in demand, supply, transportation and the Woodfibre LNG project.

Once the data was collected, FEI prepared the following figure using the median of each of the 14 responses.

[216] Drivers in the Expert (Crowd) Opinion Tool analysis and shown in Figure 8-1 legend: 1. Carbon Price 2. CCS – Carbon Capture and Storage 3. Climate 4. CNG – Compressed Natural Gas 5.Codes and Stds.- Codes and Standards. 6. Customers 7. G2E Fuel Switch – Gas to Electric Fuel Switch 8.Gas Price 9. H2 – Hydrogen 10. LNG – Liquified Natural Gas 11.LNGEX – LNG Export 12. RNG – Renewable Natural Gas 13. Syngas.

1 **Figure 8-1: Median Results from the Expert (Crowd) Opinion Forecast**



2

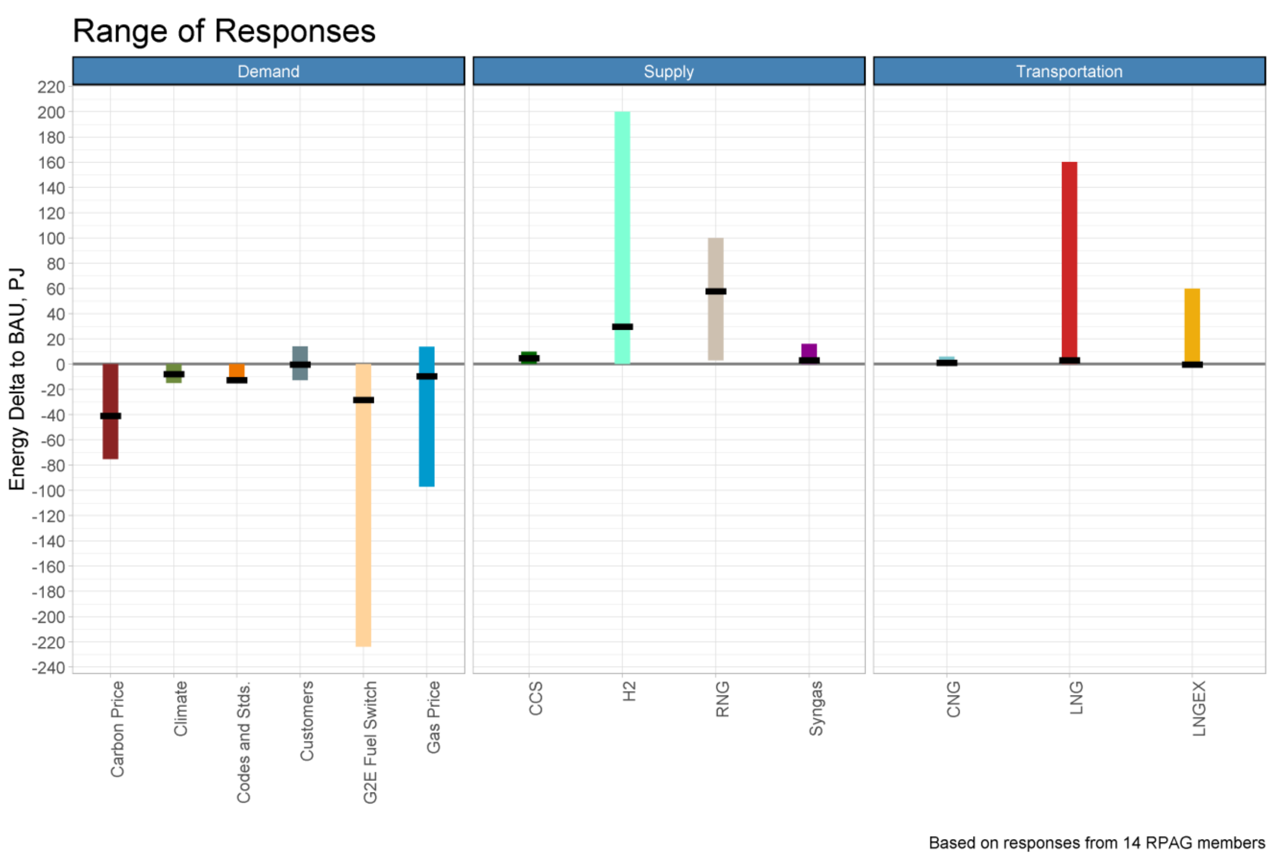
FEI makes the following observations from the Expert (Crowd) Opinion Tool Median Results:

- From the Demand plot, the largest impact in 2042 is expected to come from increased carbon prices at 40 PJ, and gas-to-electricity fuel switching at 28 PJ;
- By 2041, the median aggregate reduction in demand is forecast to be 96 PJ, relative to the BAU forecast;
- From the Supply plot, the largest contributors are RNG at 58 PJ, and Hydrogen at 30 PJ;
- By 2042, the median aggregate supply from non-traditional sources is forecast to be 96 PJ; and
- The median impact from transportation is 4 PJ. In the LTGRP, this demand category is referred to as ‘Low-carbon Transportation and Global LNG’ and in this analysis includes CNG, LNG and LNG export from FEI.

Of the 14 responses, eight felt that the Woodfibre LNG project would not go ahead and therefore the median demand from the Woodfibre LNG project driver is 0 (and not shown on the chart).

The following figure shows the ranges of the responses for each driver. This plot indicates where there is both uncertainty and agreement across the drivers. The black “tick” indicates the median response for each driver.

Figure 8-2: Range of Responses from the Expert (Crowd) Opinion Forecast



The key observations from the Range of Responses include the following:

- The responses for gas to electric fuel switching showed the widest range of all the drivers, ranging from no impact up to a reduction of 225 PJ. The median response was lower at 28 PJ;
- The impact from adding hydrogen to the supply also showed a very wide range of responses, topping out at 200 PJ. Once again, the median response was a more modest 30 PJ, and less impactful than the median response from RNG at 58 PJ; and
- Finally, the LNG driver also showed a significant range, from zero to 160 PJ. For this driver, the median response was close to zero at just 3.5 PJ.

The crowd forecast exercise seemed to be effective in providing RPAG members with a better understanding of the critical inputs that can impact the demand forecast versus those that have little to no impact. For the 2022 LTGRP, the sample size (i.e., the number of crowd participants) was small and so likely contains a level of bias. Therefore, FEI did not create a crowd opinion forecast scenario for analysis in the demand forecast Section 4. However, the results clearly indicate that the stakeholders who responded shared the view that decarbonization is of great importance to them. Support from some RPAG members and FEI's experience suggests the exercise is worth continuing and building upon for the next LTGRP as a means of engaging those outside of FEI in these important discussions.

8.3 *DIALOGUE AND ENGAGEMENT WITH INDIGENOUS GROUPS*

8.3.1 FEI Recognizes and Respects the Constitutional Rights of Indigenous Peoples

FEI recognizes and respects the constitutional rights of Indigenous Peoples. FEI's Statement of Indigenous Principles[217] aims to ensure the Company's business operations are conducted with respect for Indigenous people's social, economic and cultural interests. To support meeting this objective, FEI establishes an open dialogue with First Nations communities at the earliest opportunity during its planning stages so that expectations for Indigenous engagement are understood and addressed in the process and that Indigenous input is incorporated. FEI coordinated engagement with the FBC resource planning team in the shared service territory to ensure First Nations community representatives were able to provide meaningful input into both FBC's LTERP application and FEI's LTGRP application.

FEI is committed to developing and maintaining relationships with First Nations communities within whose territories FEI works and operates within. Understanding, respect, open communication and trust continue to be FEI's aim when working with Indigenous peoples and

[217] Appendix A-8: FEI's Statement of Indigenous Principles, online at: https://www.fortisbc.com/in-your-community/indigenous-relationships-and-reconciliation/our-statement-of-indigenous-principles.

First Nations communities throughout the province. FEI, in keeping with it's Statement of Indigenous principles:

- Upholds a high standard of engagement, through clear and open communication on an ongoing and timely basis;
- Promotes awareness and understanding of Indigenous issues within its workforce, industry and communities where FEI operates; and
- Works to better understand Indigenous culture, values and world views through ongoing community engagement on matters including FEI's resource planning process.

8.3.2 FEI Supports Implementation of the United Nations Declaration for the Rights of Indigenous Peoples

FEI supports the implementation of the UN Declaration into law in BC under the provincial Declaration Act.[218] FEI also recognizes the elevated status of the UN Declaration at the federal level, where the UNDRIP Act[219] was assented to on June 21, 2021. This legislation mirrors and builds upon the legislative framework developed in BC.

FEI continues to learn from the UN Declaration and is committed to actions that move towards reconciliation with Indigenous peoples. FEI acknowledges the principles of the UN Declaration, and the Declaration Act will play a significant role in energy policy and the regulatory environment over the twenty-year planning horizon of this LTGRP. FEI is committed to aligning its resource plans with provincial policy, and will continually review its engagement process to ensure that FEI is engaging in meaningful dialogue with Indigenous groups regarding its resource plans as reflected in FEI's Action Item 4 in Section 10.

8.3.3 Engagement Process

FEI works to meaningfully engage with First Nations communities and Indigenous groups to gather input and feedback on the Company's various planning initiatives. Throughout the preparation of this LTGRP, First Nations communities from across the gas and electric service areas were invited to attend either regionally focused community engagement meetings or Indigenous-specific engagement workshops. This section details the feedback and input provided by First Nations and Indigenous groups during this engagement process.

While FEI invited several communities to participate in the process, not every community responded to FEI regarding LTGRP engagement opportunities. FEI also invited First Nations communities to discuss alternative engagement options, such as individual community meetings. Accordingly, FEI engaged directly with community representatives who confirmed their interest in participating in the LTGRP engagement sessions and planned workshops directly with these communities. FEI appreciates the engagement of First Nations and acknowledges that many communities are managing multiple priorities and may not have the available capacity to

[218] Declaration on the Rights of Indigenous People's Act, S.B.C. 2019, c. 44.
[219] United Nations Declaration on the Rights of Indigenous Peoples Act, S.C. 2021, c.14.

participate in LTGRP engagement workshops. Regardless, FEI will continue to engage with First Nations communities in its service area to identify opportunities for dialogue on long-term energy planning initiatives.

8.3.4 FEI Held Five Engagement Sessions

Throughout 2021 and into early 2022, FEI planned five virtual engagement workshops directly with First Nations community representatives and Indigenous groups across the FEI service area. This included two workshops within the shared service territory, which focused on both FBC's LTERP process and a high-level overview of FEI's LTGRP process. These workshops were held on February 4, 2021 and March 3, 2021 and were attended by community representatives from the Ktunaxa Nation and the Okanagan Nation Alliance. Two additional virtual engagement workshops were held with First Nations located in the Lower Mainland and Fraser Valley regions of the province on January 13, 2022 and January 18, 2022. Another engagement workshop was planned for First Nations community representatives in the North-Central Interior region of the province, but was ultimately cancelled due to low interest. Various external factors including the COVID-19 pandemic, and severe weather events (e.g., wildfire evacuation alerts and orders), may have impacted the capacity of communities to participate in LTGRP engagement sessions throughout 2021 and 2022.

First Nations community representatives were also invited to the various regional community engagement workshops discussed in Section 8.3, for Vancouver Island, the Sunshine Coast, and the North-Central Interior regions. Multiple community representatives from the Treaty 8 and Secwe̓pemc Nations participated in the May 20, 2021 regional community engagement workshop for the North-Central Interior.

8.3.4.1 *FortisBC Shared Services Territory Engagement*

During the February 4, 2021 and March 3, 2021 workshop sessions, FEI provided an overview of the Pathways Report and key aspects of FBC's LTERP and FEI's LTGRP. Given the timing of the engagement, aspects of the FEI LTGRP were discussed at a high level during these engagement workshops as further work was required by FEI to complete key aspects of the LTGRP, such as a final analysis of demand scenarios, resource options, and system needs. FEI provided an overview of its preliminary outlook for customer demand, including the Reference Case, potential load drivers and scenarios, and supply-side resource options available to meet future energy demands.

FEI sought feedback from First Nations community representatives in attendance on their energy priorities for the future. Some key themes and areas of interest that were identified as important to community representatives in the February 4, 2021 and March 3, 2021 meetings, specific to the LTGRP or FEI's broader energy planning process, included:

- Ensuring the UN Declaration and energy priorities of Indigenous groups are considered in the development of the LTGRP;

- How the LTGRP informs the planning process for specific capital projects;
- Cost and affordability are key priorities, as many community members deal with high electricity and natural gas bills;
- Opportunities for additional energy efficiency collaboration with local communities as a means to reduce high energy bills, and support local housing improvements and community development projects; and
- Interest in expanding natural gas service to communities not currently served by FEI.

Other key energy priorities identified during the February 4, 2021 meeting included cost effectiveness, energy resiliency, environmental protection, and economic growth. One group indicated that economic growth and partnership opportunities help community development and therefore indirectly foster energy affordability. Multiple representatives also identified interest in FEI's involvement in hydrogen development and potential future partnership opportunities as these technologies develop.

During the March 3, 2021 meeting, community representatives expressed their main priority as having access to cost effective energy. Economic growth for the community is also an important consideration. One representative asked FEI about its discussions on environmental reclamation activities and GHG reduction initiatives with industrial partners in the region. FEI described its ongoing relationships with customers, including industrial ones, to continue to explore opportunities for decarbonizing the natural gas system and enhancing the local environment where FEI operates.

Discussions during these sessions reinforced FEI's understanding of the importance of the UN Declaration and FortisBC will continue to assess its resource planning process to ensure that Indigenous energy objectives and the UN Declaration are considered in both FBC and FEI's future project plans. FortisBC shared its commitment to acting on the key principles of the UN Declaration and ensuring that FortisBC's engagement is conducted in alignment with the values of its Statement of Indigenous Principles. FortisBC clarified that any capital projects that may result from the findings of FBC's LTERP and FEI's LTGRP would require separate BCUC approval, including future engagement related to those applications. FortisBC also confirmed that its resource plan objectives are aligned with current BC energy policy and the *Clean Energy Act*, which encourage the development of clean and renewable resources and support the development of First Nations communities (discussed in Section 1.5).

8.3.4.2 *FEI Service Territory Engagement*

For the May 20, 2021, January 13, 2022 and January 18, 2022 engagement sessions, an overview of the Pathways Report and key aspects of the FEI LTGRP were provided. This included a high-level overview of system considerations and DSM scenarios for the FEI LTGRP. FEI sought feedback from First Nations communities on the LTGRP and on their energy priorities for the future.

During the May 20, 2021 community engagement workshop session, one community representative raised concern over the engagement process and felt that FEI had not provided enough notice for the individual to actively participate in the process. FEI acknowledged this concern and FEI will continue to work closely with communities going forward to ensure invitations to engagement sessions on resource planning and other FEI initiatives are delivered to where known, the representatives directly responsible for those initiatives in the community.

Another community representative inquired about Canadian LNG and potential leverage foreign investors may have on Canada's LNG projects. They raised concerns about the potential implications of foreign investment on the cost of domestic natural gas supply and inquired about protections in place from foreign investment associated with Canadian LNG export projects. FEI clarified that it is not in a position to speak to any government protections that may or may not be under consideration when it comes to LNG exports internationally. FEI highlighted the review of market conditions for natural gas production and supply in the region, which was conducted for the 2017 LTGRP, and provided a link to this review. FEI also clarified that it includes any necessary actions to safeguard its customers from these type of risks in the Action Plan contained within the LTGRP.

One community that was invited to the May 20, 2021 session did not attend but provided written correspondence to FEI in July, 2021, in response to the FEI invitation for this session. A community representative identified to FEI that formal terms for engagement identifying process and capacity support would be required for the community to provide a comprehensive review of FEI's LTGRP. The representative communicated that engagement on planning activities, including the LTGRP, in their territories requires capacity of their experts, leadership and territorial authorities. FEI responded and committed to holding a direct meeting with the community to review the engagement process and specific aspects of FEI's LTGRP. FEI also offered the community an opportunity to participate on FEI's RPAG and to discuss capacity support options for engagement on the LTGRP process. Capacity support was offered to other communities on an as-required basis throughout the engagement process on the LTGRP. FEI held further meetings with community representatives outside of the LTGRP process to discuss engagement on utility planning along with a range of other FEI initiatives that were of mutual interest to the community and FEI. FEI is continuing engagement with the community on a range of opportunities and energy issues, such as long-term energy planning. The feedback provided by the community on FEI's engagement process has been integrated and considered in the development of Action Item 4 within Section 10 of this filing.

Key themes relating to the LTGRP identified during the January 13, 2022 and January 18, 2022 engagement sessions with First Nations communities in the Lower Mainland and Fraser Valley included:

- Discussion on the regulatory review process of the LTGRP and how FEI will continue to engage First Nations communities on the LTGRP after it is filed with the BCUC;
- Interest in the transition towards renewable energy supply and trade-offs associated with the electrification and diversified energy pathways identified in the LTGRP;

- Clarification on the steps FEI and the Province are taking to encourage renewable energy collaborations with First Nations communities and to navigate the challenges associated with the transition to low-carbon energy solutions, such as rate impacts and affordable energy supply over the twenty-year planning horizon;
- FEI providing greater transfer of its energy expertise and knowledge to communities through local, low-carbon project partnerships;
- Further information on the process for First Nations communities to access FEI energy efficiency programs, such as ECAP;
- Feedback to FEI on the value energy efficiency programs have in improving housing conditions for community members and contributing to more affordable energy service; and
- Opportunities and best practises that FEI should consider for future LTGRP engagement, such as early engagement, in-person meetings, capacity funding, open forums between communities and direct engagement with Chief and Council or community leadership.

During the January 13 and 18, 2022 sessions, community representatives also inquired about multiple FEI major projects. One representative inquired about FEI's Advanced Metering Infrastructure (AMI) project and asked if FEI could provide further information on the potential rate impacts to community members and workforce impacts associated with the project. FEI clarified that workforce impacts resulting from the AMI project are still being assessed and reiterated its commitment to continued support for those whose jobs may be affected by the project. Regarding rates, FEI clarified that rate impacts from the AMI project are expected to be minimal for individual customers and FEI provided all attendees in the session a website link to the project application, which is currently under regulatory review with the BCUC. Another representative requested that FEI provide additional notifications to their community regarding permitting amendments on the Eagle Mountain Woodfibre LNG project. FEI acknowledged this feedback and the complexity of specific permit amendment applications through the BC Oil and Gas Commission's project permitting process. The representative identified earlier notifications from FEI, with greater detail on the purpose of the upcoming permitting amendments, as a practise that would further support the engagement process with the community. FEI noted this feedback and provided this information to the Woodfibre LNG project team to support ongoing and future project engagement with the Community.

Additional feedback was provided during these sessions for FEI to consider in both its resource planning process and its broader business operations. One representative inquired about FEI's plans for long-term economic partnerships with First Nations communities. They identified target setting on contracting opportunities and connecting First Nations communities to the local gas system as two areas where they would like to see more action from FEI moving forward. FEI acknowledged their concerns and outlined the continued work taking place through FEI's Progressive Aboriginal Relations (PAR) certification process, to assess key areas of business development including how we support procurement and employment opportunities for First Nations Indigenous groups. After the session, FEI committed to following up with the Community on opportunities or challenges associated with extending natural gas service to community members. The representative also asked FEI about Indigenous awareness training for employees, and FEI outlined its internal training program, which includes a commitment to have at least 85 percent of all employees complete Indigenous awareness training by the end of 2022.

A key theme of discussion in the January 18, 2022 workshop revolved around Reconciliation and the varying perspectives community representatives had on this term and its meaning. One representative stated that FEI should not use the term "Reconciliation" given how much further we have to go collectively to understand the "Truth" that precedes "Reconciliation". Another community representative saw Reconciliation as a much broader discussion that needs to be started. Given that Reconciliation may be understood differently to each individual, the representative stated that further discussion is needed to define its meaning and we need to give one another a chance to work together as we share opportunities along the road to Reconciliation. The representative also identified multiple actions FEI should consider in its business operations within the context of Reconciliation. These actions include:

- Continued engagement with community leadership;
- Providing access to career development opportunities for community members;
- An active presence in schools to educate youth on employment opportunities in the energy sector;
- Continued information sharing through culturally appropriate and/or community networks; and
- Offering equity partnership opportunities to First Nations communities, such as through co-ownership of development projects.

FEI acknowledged this feedback and thanked the participants for sharing their perspectives on Reconciliation and broader actions FEI can take to build stronger relationships and partnerships with First Nations communities moving forward. FEI sees much of the feedback provided on Reconciliation as consistent with its Statement of Indigenous Principles and consistent with FEI's ongoing activities to provide greater access to business development and employment opportunities for Indigenous peoples, such as through PAR certification. This reinforces the importance of FEI taking action on feedback provided and continuing to engage with First Nations communities early and often on a wide range of utility planning processes. This continual engagement is critical to creating strong relationships and identifying strategies that create meaningful business development and employment opportunities for Indigenous peoples through FEI's business operations. Within the context of this LTGRP, continued and evolving engagement is reflected in an Action Plan described in Section 10 of the Application.

8.4 COMMUNITY ENGAGEMENT WORKSHOPS

8.4.1 FEI Held Online and In-Person Community Engagement Workshops

In recognition of the importance of considering diverse community perspectives, FEI relied on community engagement workshops for its development of the LTGRP. When planning for the future, FEI informs participants about the resource planning process and considerations, while gathering feedback from representatives throughout FEI's service territory. Community participants in the resource planning process bring significant local knowledge and perspectives to the process and provide key insights and feedback to FEI. FEI views consultation as an ongoing process, just as resource planning is an ongoing activity.

Table 8-4 below provides an overview of the variety of organizations that were invited to participate in these events for the 2022 LTGRP development.

Table 8-4: Community Engagement Participants Represented a Variety of Organizations

Types of Organizations Represented at Community Engagement Sessions
Community planners/developers/operations managers
Energy and sustainability managers and professionals
First Nations community representatives
Municipal community leaders and elected officials
Energy and sustainability non-profit organizations
Real estate builders and developers
Large businesses/manufacturers
Industrial customers
Local businesses and business associations
Economic development representatives, including Chamber of Commerce and Board of Trade members

Multiple community engagement workshops were held in regions across BC from 2019 through to 2022. Three community engagement workshops were held in person within FortisBC's shared services territory in the fall of 2019, and eleven online workshops were held in 2020 and 2021, involving a total of 117 registered participants.

Meetings in FortisBC's shared services territory were conducted in collaboration with the FBC electric resource planning group and therefore included presentations and discussions regarding FBC electricity resource planning as well as FEI gas resource planning. This made for the most efficient use of time for those within the combined gas and electric services areas and provided a comprehensive point of view on the diversified pathway where electrification and gas decarbonisation items were considered.

In these workshops, FEI provided background information on the long-term resource planning process and objectives, an overview of the Pathways Report regarding the comparisons of the Diversified and Electrification Pathways for BC to achieve its GHG reduction goals, and their implications for resource planning. Discussion included how various components of the Pathways Report and how climate action pillars in FortisBC's Clean Growth Pathway were included within FEI's LTGRP demand forecasts and scenarios. The impact of accelerating renewable and low-carbon gas supply and emerging energy and emissions policy were key topics of discussion. FEI presented plans to meet the future needs of customers and communities, and discussed issues affecting energy supply and demand, DSM, renewable and low-carbon gases, and LCT. FEI's resiliency plans were also discussed, including its plan to expand LNG storage facilities to provide safe, reliable and affordable energy to meet the demands of British Columbians.

8.4.2 FEI Received Feedback from Communities

Table 8-5 lists FEI's engagement sessions and summarizes the feedback that was given to FEI in support of resource planning and other FEI initiatives.

Table 8-5: Overview of Community Engagement Sessions – Feedback on Key Discussion Topics

Meeting Date and Location	Themes and Feedback
FEI / FBC Combined in-person sessions in the FortisBC shared services territory (SST) October 8, 2019 – Kelowna October 9, 2019 – Osoyoos October 10, 2019 – Rossland – natural gas and electric long-term resource planning was discussed although feedback presented pertains to LTGRP	• Continue to provide reliable energy supply. • Continue to provide programs to help customers and communities manage the need to balance energy costs and reduce GHG emissions. • Coordinate initiatives with municipalities and enable municipalities to work together on energy plans. • Support opportunities for community development and economic growth for clean energy projects such as wood waste into renewables. • Provide more educational resources for customers and communities regarding energy savings and new technologies. • Suggest increased data sharing and collaboration to improve stakeholder planning processes and support regional growth and development. • GHG emission reduction opportunities are critical, but affordability and carbon tax impacts need to be considered. Will need to monitor both electricity, natural gas and renewable costs over time through the energy transition. • Transportation, EVs, LCT discussed from a cost and GHG reduction perspective, noting that transportation provides a huge opportunity for GHG reductions. • Highlighted the benefits of integrating gas and electric energy systems to increase reliability and optimize costs. • Emphasized unique requirements in rural communities including energy costs, operations practicalities, capital costs generally and new construction specifically. Signalled energy advisor shortage for Home Renovation programs. • One attendee noted that BC Housing was favoring electric heat pumps (since these are viewed as 'greener' than natural gas) but wondered if renewable gases could provide a balance of being cheaper and "green."

Meeting Date and Location	Themes and Feedback
December 2 and 3, 2020 (SST)	• Provide incentives for customers to hit lower consumption targets as an opportunity to educate about conservation. A change in culture and behavior is needed to impact GHG reduction. • Discussed approaches FortisBC is taking to balance affordability and GHG reduction in presenting the Pathways Report and FortisBC's 30BY30 initiative. • Emphasized unique requirements in rural communities and need for increased funding for clean energy projects including for individual homes. • Discussed the unknowns surrounding the upcoming building retrofit code which will have big impact but implementation may be delayed. Encouraged FortisBC to engage with government to ensure building retrofit visions align with SST communities. • Discussed how FEI/FBC reconcile fuel switching programs and the opportunity for customers to choose the right fuel for the right application.
October 14 and 16, 2021 – Lower Mainland/ and South Coast	• Urgent need for FEI to be part of the solution for climate action and reducing the need for conventional natural gas, especially in light of fracking practices. • Some attendees are concerned about LNG export and GHG emissions while others noted the global competition for natural gas as a risk to BC energy supply. • Concern that FEI continues to advertise and promote natural gas use and connections when gas consumption needs to be reduced with FEI replying that maintaining and growing the gas system is vital for decarbonisation as costs are shared across customers. • Diversified Energy (Planning) Scenario with complementary and robust gas and electric systems will be more resilient in the long-term. • Requested FEI to provide more gas consumption information to local governments including percentage of renewable and percentage of fracked conventional gas. FEI responded that it is exploring enhancements to Community Energy and Emissions Inventories reporting with the Climate Action Secretariat. • Encouraged FEI/FBC and BC Hydro to work together on long-term resource planning to serve British Columbians. • Discussed supply concerns in the long-term, including conventional, renewable and low-carbon sources and cost implications. • The requirements for FEI to enable hydrogen distribution and concern expressed for the environmental impacts of blue hydrogen. • Support for decentralized energy systems and ways for trading and interacting with energy distribution at a local and even neighbourhood level. • Support for expanding FortisBC's activity in renewable projects for gas and electricity generation. • Suggestion for FortisBC to connect customers in projects that support waste heat recovery and energy redistribution. • An attendee shared their community's experience during the 2018 T-South incident in terms of high costs and risks associated with relying on one energy system. • An attendee provided innovative approaches to expanding DSM program eligibility and noted need for removing DSM regulatory constraints to expand project opportunities.

Meeting Date and Location	Themes and Feedback
November 9, 2021 – Vancouver Island South November 18, 2021 - Vancouver Island North	• Urgent need for FEI to be part of the solution for action on climate change. • Local energy sources on Vancouver Island of paramount interest to diversify the supply in order to promote resiliency and mitigate the impacts of extreme weather events. • Diversified Energy (Planning) Scenario with complementary and robust gas and electric systems will be more resilient in the long-term. • Requested information on how local governments can access RNG. • Extend gas service to rapidly growing developments on Vancouver Island. • Resource planning needs to account for all costs of externalities and risks when planning for the energy transition and account for the full life cycle of GHG emissions. • Support for development of hydrogen projects but indicated a desire for more information about the environmental safety of all kinds of hydrogen (blue, green, etc.). • Bring together economic alliance associations for a larger voice in regional planning of BC's energy future.
November 23, 2021 – Southern Interior	• Energy affordability and housing affordability is a top priority for the region and low income segments are already struggling to manage utility bills. • Discussed how FEI will incorporate the CleanBC Roadmap to 2030 in LTGRP in terms of reaching GHG reduction targets. • Interest in locally-sourced renewable projects. • Diversified Energy (Planning) Scenario with complementary and robust gas and electric systems will be more resilient in the long-term. This pathway is even more critical in rural and colder parts of the province where electric outages are more common. • Attendee noted the need for energy storage including battery in a decarbonized energy system.

The feedback received from these sessions as outlined in Table 8-5 above has been highly useful in developing the 2022 LTGRP. Through the community engagement sessions, attendees were able to provide FEI with input on climate action initiatives and balancing affordability with the costs of electrification and decarbonization. A broad range of recurring themes were of particular interest to community representatives and these resulted in extensive discussion and feedback. Examples of these key themes include:

- The need for urgent climate action and FEI's need to transition to clean energy by increasing access to a supply of renewable and low-carbon gas. Incorporating climate change and local adaptation considerations was viewed as central to developing a resilient and reliable low-carbon system;
- General agreement that the Diversified Energy (Planning) Scenario with complementary and robust gas and electric systems will be more resilient in the long-term and with the need to balance affordability with decarbonization initiatives;
- Energy affordability was top of mind, especially for low income customer segments;

- Economic development regarding clean energy projects was seen as a large opportunity;
- Support for FEI to continue to work with communities on DSM programs, providing funding, incentives and educational resources to help customers and communities manage energy costs and reduce emissions; and
- Support for FEI and BC Hydro to work together in resource planning to ensure the alignment of demand, supply and cost scenarios in meeting BC's energy needs into the future.

Overall feedback from these sessions highlighted the urgent need to respond to climate change while balancing the need for reliable, resilient and diverse energy systems. A number of sessions took place during the extreme weather events of November 2021 and communities highlighted the need for resilient systems while responding to the urgent call for action on decarbonization. Some attendees noted the economic development potential for clean energy projects in communities, such as the development of RNG and hydrogen production. Some participants were proponents for more intense electrification and the allocation of renewables to "hard to decarbonize sectors". Many highlighted the benefits of maintaining the gas system in providing an affordable, reliable, and resilient complementary energy system that optimizes the use of both the gas and electric systems to deliver energy in BC. Some sessions highlighted the unique requirements needed to serve rural communities. The cost of decarbonization was highlighted, but it was acknowledged that the low-carbon transition, either through electrification or decarbonization of the gas supply, will result in significant costs to British Columbians.

There were a number of specific examples of feedback received in LTGRP community sessions that were forwarded to appropriate FEI project teams. Examples include:

- An attendee wanted to know the solicitation process to develop an RNG project in their region and was connected with an FEI representative to explore the opportunity.
- Several attendees wanted to know how they could procure more RNG for their communities.
- One attendee had ideas for DSM program development and identified a need to reassess program and regulatory limitations in light of the urgency of responding to climate change.
- An attendee highlighted the need for a greater understanding of embedded emissions and full lifecycle costs in construction projects. This could lead to partnerships or new ideas on information exchange on renewable and low-carbon gas projects. Their organization is looking at its own construction in terms of embodied carbon. Their approach is to assess net reduction in carbon emissions over the project life on a full construction and operational level. However, cost is still an issue so wondered if FEI could help through incentive programs.
- One attendee shared an idea for demonstrating GHG consumption on utility bills which was forwarded on to the billing redesign team.

- A number of attendees requested enhanced gas consumption data in Community Energy and Emissions Inventories distributed through the Climate Action Secretariat for community energy plans. At this time, gas consumption is primarily fossil fuel, but FEI is determining the best way to designate the percentage of renewables and low-carbon gas for future reporting needs.
- A number of attendees were concerned about the use of fracked gas.
- A number of attendees supported opportunities for decentralized energy systems, the opportunity for FEI to assist with energy distribution at a neighbourhood level, and the development of renewable projects outside of gas distribution. Some of these types of initiatives are currently supported by FortisBC Alternative Energy Services and are not covered in the current LTGRP scope.
- An attendee highlighted FEI's competence in transactional services and customer end uses and proposed that FEI could address opportunities to connect separate organizations in joint waste heat recovery projects.
- A number of attendees asked about opportunities to extend FEI's service into new developments and rural communities.
- An attendee commented that there are broader environmental impacts, beyond GHG emissions reductions as the obvious cost, associated with all energy transition scenarios that sometimes get missed in climate action discussions. Knowing that GHG emissions are critical, FEI continues to try to understand and will consider addressing these other aspects in future resource plans.

8.5 *FEI UNDERTOOK OTHER ENGAGEMENT ACTIVITIES*

FEI undertakes engagement activities associated with its customer service initiatives, project applications and other undertakings that can also provide an important avenue for input into the LTGRP. The sections below summarize other engagement activities that FEI has undertaken that have provided feedback for the evolution of the Clean Growth Pathway and the LTGRP. Although these activities were undertaken in support of initiatives other than the LTGRP, the provide important insights for consideration in the LTGRP.

8.5.1 Discussions with the BCUC

The BCUC's Resource Planning Guidelines encourage utilities to seek regulatory input from BCUC staff during resource plan preparation. To that end, a representative of the BCUC attends RPAG meetings in an observer capacity. FEI receives feedback from the BCUC through other filings and regulatory processes that inform the LTGRP and, in some cases, resulted in directions to FEI regarding content to be included in the LTGRP. The BCUC has also engaged FEI and BC Hydro in a separate project to share data and collaborate on building a number of resource planning scenarios to better understand the implications of decarbonization pathways.

8.5.2 FEI's Consultation on the Clean Growth Pathway and Low-Carbon Transition Initiatives

In 2018, FortisBC released its plan to reduce emissions, the Clean Growth Pathway, as part of the consultation surrounding the Province's CleanBC strategy. In 2020, FEI released the Pathways Report illustrating the benefits of the Clean Growth Pathway in relation to a deep electrification pathway as two alternative pathways BC can take for a low-carbon energy future.

Throughout the development of the Pathways Report, FEI engaged with all levels of government, including local government officials. FEI was able to present the findings from the Pathways Report as one of the first studies that provides British Columbians with a long-term view of the costs of energy planning in the low-carbon transition. FEI continues to conduct consultation with all three levels of government about the importance of the gas system in a clean energy future.

8.5.3 FEI's Consultation on Decarbonizing the Built Environment

In response to climate action goals, FEI conducted research about how best to reach CleanBC's 2050 decarbonization goals through consultation on approaches to be taken in decarbonizing the built environment. From April through June 2021, FEI engaged with 41 organizations including 21 industry stakeholders, 5 departments in the provincial government and 15 local government advisors. This engagement was undertaken for the purposes of receiving general feedback from stakeholders on the clean energy transition, and to understand stakeholders' current knowledge on FEI's solutions to achieving the province's GHG reduction objectives.

Some of the key themes and questions resulting from these discussions that FEI has addressed and will continue to address include:

- The need for more education on renewable and low-carbon gas including how they are generated, their ecological footprint, air quality impacts, and supply potential from BC sources;
- How low-income customers could be supported through the low-carbon transition; and
- The Climate Solutions Council[220] emphasized the need for urgent climate action and proposed the need for a pathway to zero-emissions, not 80 percent. Short/mid-term actions should consider the net-zero goal and avoid underutilized assets if new projects do not get used in the longer term.

8.5.4 FEI's Consultation on the Comprehensive Review and Revised Renewable Gas Program Application (RG Program Application)

The RG Program Application, filed with the BCUC in December 2021, provided opportunities to continue to educate a broad range of stakeholders on renewable gas considerations, and to

[220] Climate Solutions Council. Online at: https://www2.gov.bc.ca/gov/content/environment/climate-change/planning-and-action/advisory-council.

exchange information on how FEI can support local community climate action strategies. FEI engaged with 176 individual stakeholders, including interveners and interested parties, industry, associations, an environmental non-governmental organization, community associations, local and provincial governments, and RPAG. The subset of industry engaged included: builder/developers, energy consultants, trades, building and trades associations, manufacturers and a renewable gas supplier. The proceeding has received a large number of letters of comment from stakeholders; 94 expressed support while 18 were not in support of all or parts of the RG Program Application.

Consultation was generally consistent with previous discussions, including scepticism related to the amount of renewable and low-carbon gas supply. The majority of participants generally were in favour of the 100 percent renewable and low-carbon gas service offering to all new residential buildings. Local governments, such as the City of Burnaby, City of Prince George and the City of Delta, expressed appreciation for the plans to provide all new residential buildings with 100 percent renewable and low-carbon gas. There was also general interest in how FEI would address decarbonization of the existing building stock which will continue to be an ongoing topic of discussion and concern for the impact on cost of RNG for customers as a transportation fuel. These topics are important as FEI increases the supply of renewable and low-carbon gas, and proposes to decarbonize the gas supply for all sales customers. Overall, many stakeholders expressed support for FEI's direction in addressing decarbonization and their corollary support for the RG Program Application.

8.5.5 2021 Conservation Potential Review Technical Advisory Committee (TAC)

The 2021 CPR informed the 2022 LTGRP's DSM analysis. FEI established a Technical Advisory Committee (TAC) consisting of a group of knowledgeable members of the public with significant interest, stake, and experience in determining energy conservation potential in BC. They provided technical advice and feedback throughout the development of the 2021 CPR, holding 6 workshops at key deliverable milestones and completing reviews of the initial measure list and of the 2021 CPR draft report.

8.5.6 DSM Plan Development for 2023 and Future Years

A key input in the development of the next DSM expenditures application is feedback from various program stakeholders, trade and industry representatives, and interested parties. Entities that have been consulted to date include communities, customers, contractors, manufacturers, trade associations, government, First Nations, vendors, interest groups, and the EECAG. Consultation has taken place through virtual workshops, surveys, interviews, and conference calls. Directional feedback to date has included the following:

- Continue to support Energy Advisors
- More education, training and resources for customers, contractors and consultants
- Broaden the collaboration within the value chain

- Energy concierge and financing support needed for deep energy retrofits
- Support hybrid systems and gas heat pump adoption
- Expand eligible measure set

8.6 SUMMARY OF STAKEHOLDER CONSULTATION AND COMMUNITY ENGAGEMENT ACTIVITIES

FEI has a strong record of conducting effective stakeholder and community engagement. Continuing its practice from the 2017 LTGRP, FEI has consulted a dedicated RPAG and hosted a number of Indigenous group and Community Engagement workshops to receive diverse perspectives on FEI's planning activities across the communities that FEI serves. Workshops in the Southern Interior provided the opportunity for FBC and FEI to receive feedback on long-range planning topics for both utilities.

These initiatives adhere to the BCUC stakeholder input guidelines contained in the BCUC's Resource Planning Guidelines and have been beneficial to the development of this plan. The information gained through these activities informs FEI's market research and analysis and assists with the identification of long-term planning issues of concern to a number of stakeholder and rights holder groups and of interested stakeholders who may become more engaged in the LTGRP process.

RPAG workshops provided valuable feedback and inputs on long-term planning from a diverse and knowledgeable stakeholder group. In particular, the workshops assisted FEI in updating and solidifying its demand scenarios and in providing instructive feedback on FEI's decarbonization strategy. Much of the discussion focused on receiving feedback on FEI's analysis of the gas utility's long-term role as a key component of the critical infrastructure required to meet BC's long-term clean energy needs. FEI has taken the RPAG feedback into consideration in developing the LTGRP (as illustrated in Table 8.3), and in developing the Outcomes of FEI's Clean Growth Pathway (Section 9) and the Action Plan (Section 10).

Indigenous engagement sessions provided a critical forum for FEI to receive input on long-term resource planning and to learn more about the key energy priorities of local First Nations communities within its service territory. Multiple representatives expressed gratitude to FEI for the opportunity to participate in these sessions underscoring the value of ongoing dialogue. Upon completion of these sessions, FEI followed up directly with community representatives to answer any outstanding questions and to explore potential opportunities identified during the sessions. FEI continues to engage with community representatives from First Nations across the province to explore options to help meet their energy needs.

FEI is committed to evolving its engagement processes, integrating First Nations community feedback into the energy planning process, and continuing action on FEI's Statement of Indigenous Principles and the key principles of the UN Declaration. Based on the feedback received during these engagement sessions, FEI has developed an Action Plan item in Section

10 of the LTGRP which outlines future actions FEI will take to engage with First Nations community representatives on energy planning. This Action Item will support future FEI resource plans and will ensure FEI is engaging meaningfully with First Nations communities on long-term energy planning initiatives.

Community engagement workshops facilitated the sharing of valuable long-term planning information and provided opportunities for feedback from attendees. In particular, the workshops assisted FEI in identifying energy issues and planning opportunities in local governments and local organizations. Attendees appreciated the opportunity to learn about FEI's initiatives and energy issues in BC, make direct connections with FEI staff in an open and consultative format, and offered feedback on FEI's long-term plans. Some attendees stressed the importance of GHG emission reduction initiatives in light of the extreme weather events being experienced in BC. FEI was able to share the Clean Growth Pathway, which envisions the decarbonization of the gas system as being key to BC's clean energy transition. The workshop discussions were robust and customer-focused, and they demonstrated that FEI's long-term planning considerations align with stakeholder expectations. FEI has taken feedback received from the community session participants into consideration in the development of the 2022 LTGRP.

The information gathered through these activities is incorporated into the LTGRP process in a number of ways, such as by informing FEI's planning and analysis, helping to determine the inputs in the Diversified Energy (Planning) Scenario, the Action Plan and general feedback that may help inform FEI's long-term corporate vision. As FEI's resource planning process is ongoing, FEI recommends continuing with the RPAG, Indigenous group and community engagement activities as part of its next long-term resource planning process in order to build on the interest and feedback gained through these initiatives. This process is even more critical as FEI responds to the need for urgent climate action in developing its low-carbon transition plan over the planning horizon.

FortisBC Energy Inc.
2022 LTGRP

Section 9:

OUTCOMES OF FEI'S CLEAN GROWTH PATHWAY

Table of Contents

9. OUTCOMES OF THE CLEAN GROWTH PATHWAY

9.1 INTRODUCTION

FEI's vision for the future of energy in BC is that of a diverse, integrated and resilient network of energy infrastructure and services, building on the strength and benefits of both the existing gas and electric energy delivery networks in the province. FEI's role in this future is to utilize, grow and strengthen its gas transmission and distribution systems for the continued delivery of safe, secure and reliable energy to customers, while reducing carbon emissions for customers through the four pillars of its Clean Growth Pathway. As FEI proceeds down this pathway, the continued commercialization of existing technologies, advancements in new technology and innovation will enable deeper carbon emission reductions, while putting BC at the forefront of emerging industries such as those that will drive BC's future hydrogen economy.

This section presents some of the key outcomes of FEI's 2022 LTGRP based on planning for its Clean Growth Pathway, and is organized as follows:

- Section 9.2 provides an overview of the estimated GHG emission reductions associated with the initiatives and recommendations set out in the 2022 LTGRP;
- Section 9.3 describes the influence that FEI's plans will have on markets for the various energy services and initiatives described in the 2022 LTGRP;
- Section 9.4 discusses the rate impacts of the Diversified Energy (Planning) Scenario, on both customer rates and average bills; and
- Section 9.5 discusses key drivers that could impact the need for infrastructure and gas supply resources for FEI's customers over the 20-year planning horizon.

9.2 GHG EMISSION REDUCTIONS IN THE DIVERSIFIED ENERGY (PLANNING) SCENARIO

FEI's Diversified Energy (Planning) Scenario, in which FEI models future changes needed to pursue its Clean Growth Pathway, is projected to meet the emissions reductions required by the GHGRS cap on natural gas utility emissions in the CleanBC Roadmap for the Buildings and Industrial Sectors. This scenario also helps BC achieve substantial emission reductions in the transportation sector by providing low-carbon transportation fuels. Although the LTGRP planning horizon extends 20 years to 2042, the emission reductions discussed in this section are presented for 2030 and 2040 to allow for comparison against the provincial emission reduction targets at these carbon reduction milestone years established by the BC Government.

9.2.1 Residential, Commercial and Industrial Demand

GHG emissions from FEI's residential, commercial and industrial customers will be subject to the GHGRS cap on emissions from buildings and industry. This section presents the emissions and emission reductions for these customers (categorized in Section 4 as the Residential, Commercial and Industrial Demand Category) as a result of FEI's Clean Growth Pathway initiatives as modelled in the Diversified Energy (Planning) Scenario. Emission reductions for these customer groups come from changes in demand (before DSM), reductions in demand as a result of DSM, the transition to renewable and low-carbon gas supply and additional actions that are not yet modelled in the LTGRP demand forecast modelling as discussed in Sections 9.2.1.1 through 9.2.1.4. Section 9.2.1.5 provides the GHG emission reduction results for other future scenarios modelled by FEI.

In this section, FEI presents emission reductions using the end use emission factor in order to align with the GHGRS. Section 9.2.2.3 presents emission reductions for all four pillars of FEI's Clean Growth Pathway using life cycle emission factors. A complete listing and explanation of the emission factors used is presented in Table 1-2 of this LTGRP.

9.2.1.1 *Demand Reduction (pre-DSM)*

The impact of natural efficiency[221] and some electrification of end use demand in the Diversified Energy (Planning) Scenario results in slightly reduced overall demand in these customer groups over the planning horizon as shown in Figure 4-9. This demand reduction corresponds to GHG emission reductions of 0.3 Mt CO_2e per year in 2030 and 0.4 Mt CO_2e per year in 2040.

9.2.1.2 *DSM*

Section 5 of the 2022 LTGRP recommends that FEI pursue the High DSM Setting with the resulting gas savings presented in Figure 5-5. In the Diversified Energy (Planning) Scenario, this high level of energy savings results in 0.9 Mt CO_2e reductions in 2030 and 1.3 Mt CO_2e reductions in 2040.

9.2.1.3 *Renewable and Low-Carbon Gas Supply*

FEI's transition to renewable and low-carbon gas supplies has the largest impact on GHG emission reductions for residential, commercial and industrial customers. Acquiring and allocating 60.2 PJ of renewable and low-carbon gas supply by 2030 to these customer groups results in emission reductions of 3.0 Mt CO_2e. In 2040, the allocation of 99 PJ of renewable and low-carbon gas to these customer groups results in 4.9 Mt CO_2e of GHG emission reductions.

9.2.1.4 *Additional Reductions*

After completing the demand and supply modelling for the 2022 LTGRP, FEI identified further opportunities for additional emission reductions which FEI expects to incorporate into its Clean Growth Pathway. These additional emission reduction opportunities, which have not yet been modelled, consist of:

[221] Efficiency improvements that occur through the natural replacement of older, less efficient equipment with newer, more efficient equipment without the influence of DSM incentives.

- **Additional demand-side measures not modelled in the 2021 CPR**: Three promising energy efficiency technologies have emerged in recent months as having a higher potential impact on gas demand than was modelled in the 2021 CPR or in the 2022 LTGRP. These are deep energy retrofits, gas heat pumps and hybrid heating systems. As discussed in Section 5.4.4, FEI expects that these technologies will provide additional energy savings to those modelled in the 2021 CPR and the 2022 LTGRP DSM Analysis.
- **Additional reductions from FEI's transition to renewable and low-carbon gas supplies – particularly from higher than modelled CCUS implementation**: Interest in and expectations for the role of CCUS in reducing carbon emissions globally have continued to accelerate as exemplified in the federal government's investment tax credit for CCUS technologies announced in the April, 2022 Federal Budget[222]. As the technology advances, there are many opportunities for implementing CCUS at industrial sites that use natural gas or other fossil fuels for process applications. Employing CCUS along with RNG production is garnering a lot of interest and has the potential to remove additional carbon from the natural carbon cycle[223].

FEI expects these opportunities to result in a further 0.9 Mt CO_2e reductions or more by 2030. FEI is still considering how these additional opportunities feed into the emissions reductions later in the planning horizon and so has not included them in its assessment of 2040 emission reductions at this time. FEI will formally include these additional opportunities in its demand and GHG emission modelling for the next LTGRP.

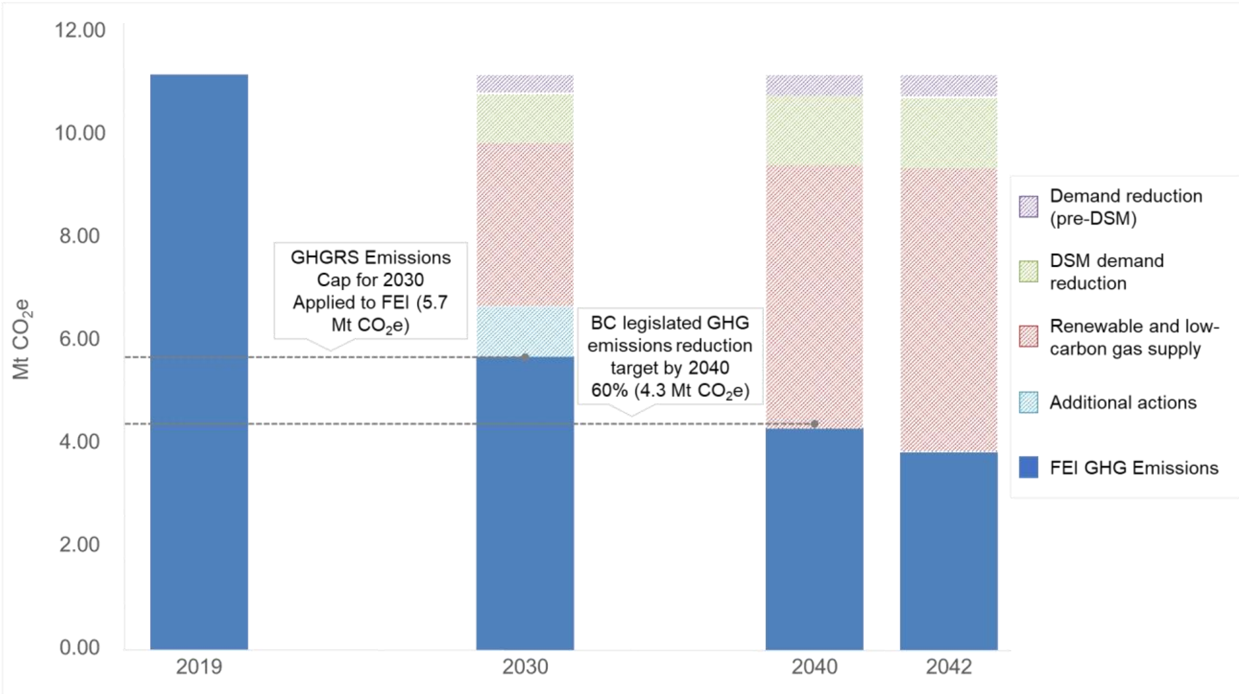
FEI anticipates that as it proceeds along its Clean Growth Pathway, additional new opportunities and information will continue to arise for further potential GHG emission reductions for residential, commercial and industrial customers.

9.2.1.5 *Meeting the Greenhouse Gas Reduction Standard for Gas Utilities*

The Province's Clean BC Roadmap states that the GHGRS emissions cap on gas utilities will be approximately 6 Mt CO_2e in 2030. Accounting for the fact that FEI is not the only gas utility in BC, the portion of the cap that applies to FEI is estimated to be 5.7 Mt CO_2e. Figure 9-1 shows that, when summed, the GHG emission reductions discussed in Sections 9.2.1.1 through 9.2.1.4 meet the GHGRS cap for gas utilities. Further, FEI's modelling of GHG emissions reductions for the Diversified Energy (Planning) Scenario meets the Province's 2040 target emission reductions and makes net-zero GHG emissions by 2050 for these customer groups plausible.

[222] Online at: https://budget.gc.ca/2022/report-rapport/tm-mf-en.html#a3_2.
[223] CCUS employed in conjunction with RNG production is considered carbon negative because it sequesters carbon from the natural carbon cycle. It is considered separately from industrial CCS or direct air CCS because the implementation of bioenergy with carbon capture and storage is directly tied to RNG production.

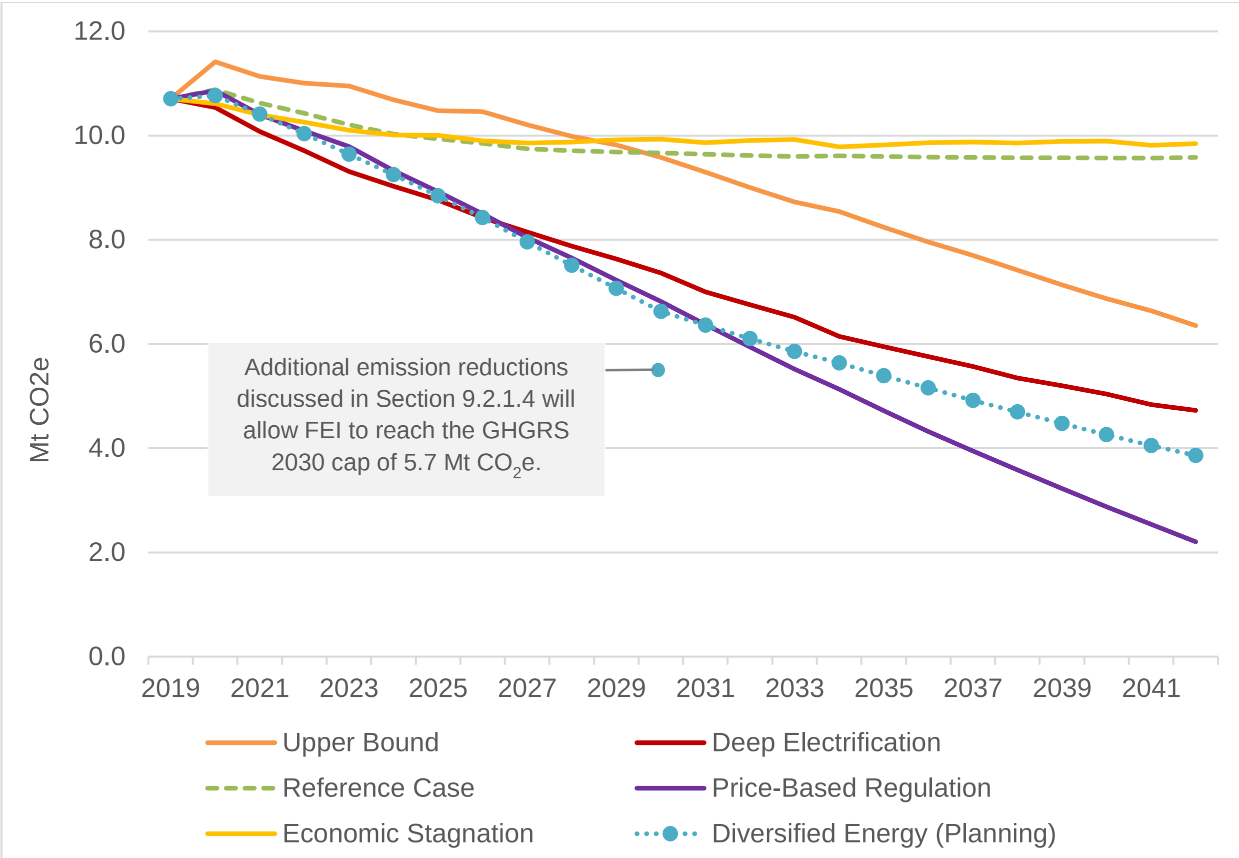
Figure 9-1: GHG Emission Reductions for Residential, Commercial and Industrial Customers Meets the GHGRS for the Diversified Energy (Planning) Scenario



9.2.1.6 *GHG Emission Reduction Comparison for Other Future Scenarios*

FEI modelled emission reductions for the Reference Case demand and for the demand and supply modelled for the alternate future scenarios described in Section 4, including the Diversified Energy (Planning) Scenario. The results are presented in Figure 9-2. The GHG emissions in this figure are shown using end use emission factors consistent with Figure 9-1. In Figure 9-2, the Diversified Energy (Planning) Scenario does not include the additional reductions discussed in Section 9.2.1.4 since they were identified after the demand and supply modelling for the 2022 LTGRP was completed. With these additional reductions, FEI reaches the GHGRS 2030 cap on emissions. Figure 9-2, therefore, provides a comparison of the different demand and supply inputs modelled for each scenario in terms of GHG emissions reductions. Note that the additional reductions discussed in Section 9.2.1.4 are not included in these results as they have not yet been added to the modelling.

Figure 9-2: GHG Emission Reductions (End Use) Modelled for the Reference Case and Alternate Scenarios – Residential, Commercial and Industrial Customers

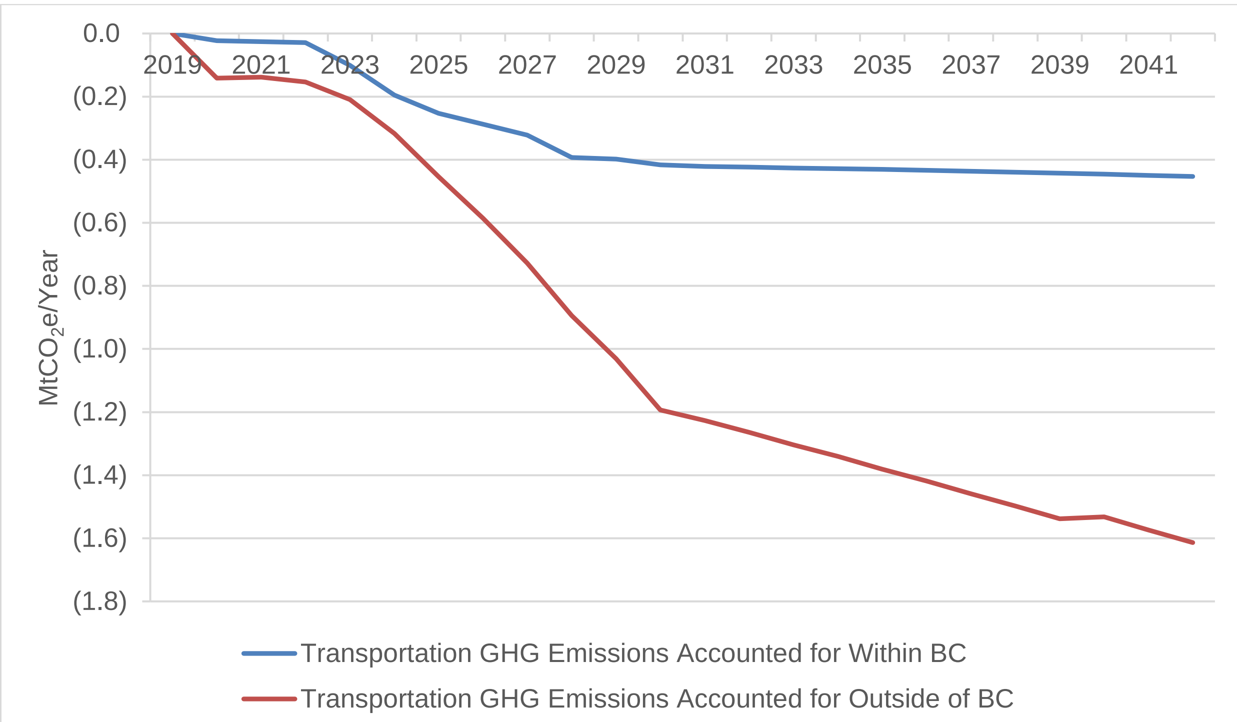


Over the long term, the Diversified Energy (Planning) Scenario has similar emission reductions to the Deep Electrification Scenario, with somewhat deeper reduction in the Diversified Energy (Planning) Scenario driven by growth in the supply of renewable and low-carbon gases. The Price-Based Regulation Scenario also has similar emission reductions since the use of price signals rather than regulation drive high levels of investment in energy conservation and in renewable and low-carbon gas production in BC. These trends accelerate later in the forecast period more than in the Diversified Energy (Planning) Scenario. The Upper Bound Scenario also shows substantial GHG emission reductions. However, since in this scenario all relevant factors that can influence growth in gas demand are doing so and there is little electrification taking place, the production and use of renewable and low-carbon gas, though still high, do not displace as large a proportion of natural gas use as in the Diversified Energy (Planning) Scenario. The Economic Stagnation Scenario has similar emission reductions to Reference Case since in that scenario, energy and carbon policy is less of a focus for government, stalling the low-carbon transition. As discussed in Section 4, the Reference Case by definition considers that conditions in place or sure to be implemented as of the base year (2019) extend over the forecast period.

9.2.2 Low-Carbon Transportation and Global LNG

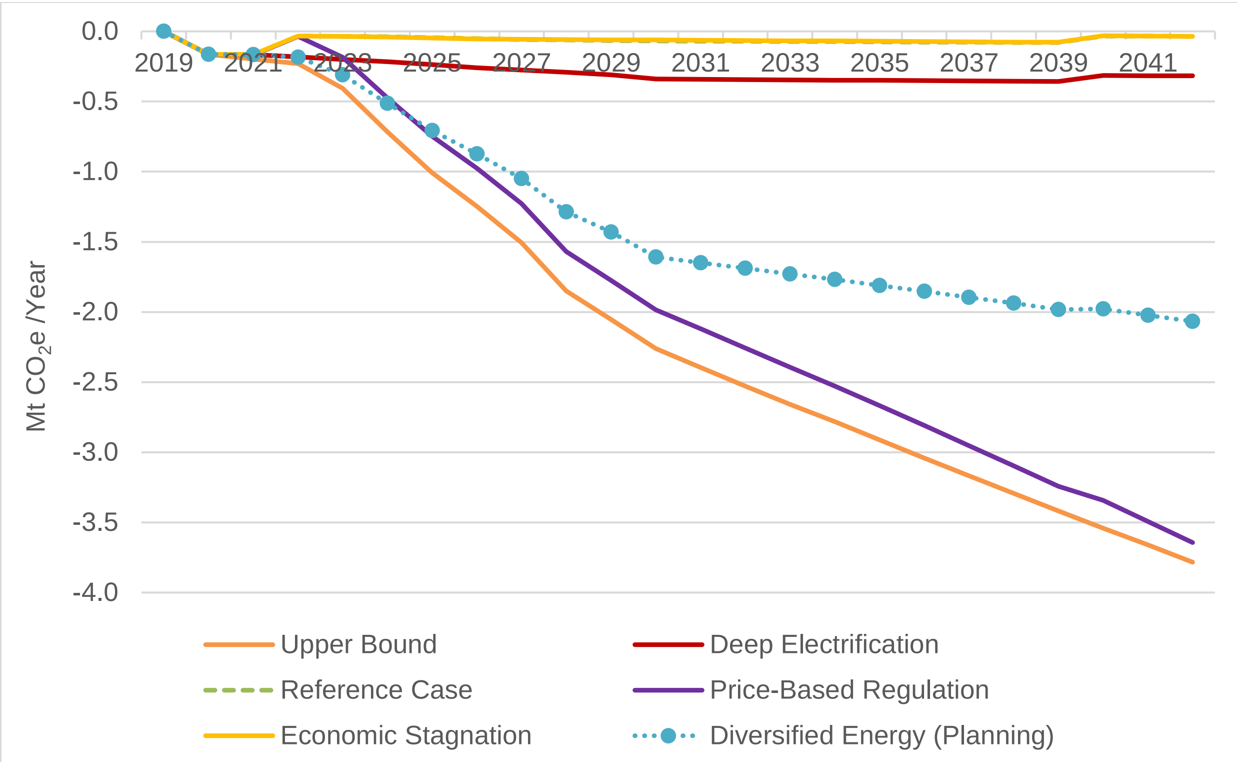
Figure 9-3 presents the emissions reductions that result from growth in FEI serving low-carbon transportation fuels and global LNG exports in the Diversified Energy (Planning) Scenario. These emission reductions are separated into those that would occur within BC, and so would contribute to reductions in BC's GHG emissions inventory, and those that are either in other inventories other than BC or, though occurring, are not captured in any inventory. FEI is not inferring ownership of any carbon credits with regard to Figure 9-3, but simply stating the emission reductions that will occur when natural gas displaces higher-carbon fuels for these uses. The total potential for carbon reductions as a result of serving this demand is much greater than FEI has modelled in the Diversified Energy (Planning) Scenario and shown in Figure 9-3.

Figure 9-3: BC and Global Emission Reductions (Life Cycle) in the Diversified Energy (Planning) Scenario from Serving the Transportation and Global LNG Markets



To provide a comparison of emission reduction results across the Reference Case demand and alternate future scenarios, Figure 9-4 shows total life cycle emission reductions that occur as a result of demand from low-carbon transportation and global LNG customers. The planning environment conditions present in the Upper Bound and Price-Based Regulation encourage higher investment in low-carbon transportation infrastructure, logistics and gas delivered by FEI than is expected to occur in the Diversified Energy (Planning) Scenario. On the other hand, the conditions present in the Deep Electrification and Economic Stagnation Scenarios do not encourage diversified energy solutions, hindering such investments and resulting in minimal carbon reductions for these high energy users that are difficult to decarbonize.

Figure 9-4: Total Emissions (Life Cycle) for Serving Low-Carbon Transportation and Global LNG Demand for the Reference Case and Alternate Scenarios



9.2.3 Total GHG Emission Reductions for FEI's Clean Growth Pathway

GHG emission reductions from FEI's Clean Growth Pathway are transformational. In order to provide a complete picture, the reductions from serving both the residential, commercial and industrial, and the low-carbon transportation and global LNG customers throughout the planning horizon are shown in Figures 9-5 and 9-6 based on life cycle emission factors (those discussed in Section 9.2.1 are based on end use emission factors to be consistent with the GHGRS). Figure 9.5 shows the Diversified Energy (Planning) Scenario total emission reductions broken out into reductions that are accounted for by BC and those that are accounted for outside of BC.

Figure 9-5: Total GHG Emission (Life Cycle) Reductions for the Diversified Energy (Planning) Scenario – BC and Outside of BC

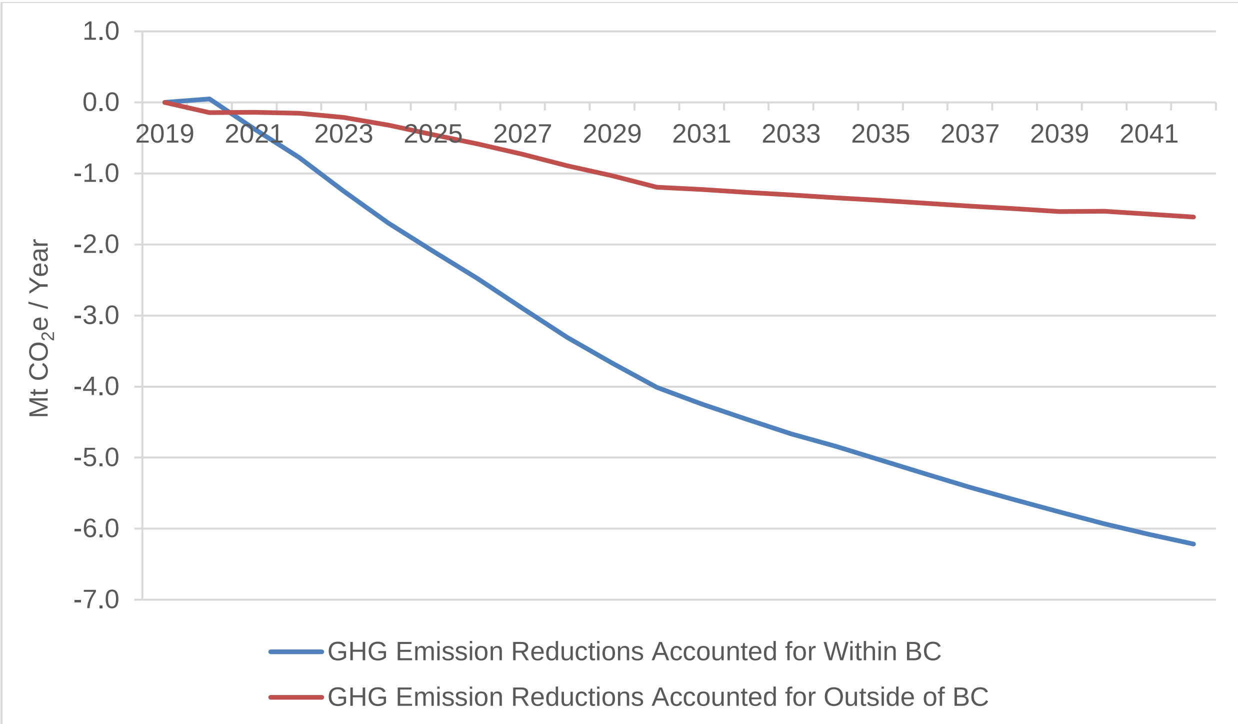


Figure 9-6 shows total emission reductions from the DEP Scenario in 2030 and in 2042 (the final year of the LTGRP planning horizon), compared to the 2019 base year emissions from FEI's customers and to 2019 emissions included in the BC inventory. The purpose of this figure is only to provide a comparison of total GHG emission reductions associated with FEI's Diversified Energy (Planning) Scenario next to base year (2019) emissions for FEI's customers and for total BC emissions for context and comparison purposes. There is no intent to infer ownership of carbon reduction benefits or allocation to BC or other emission inventories within this figure.

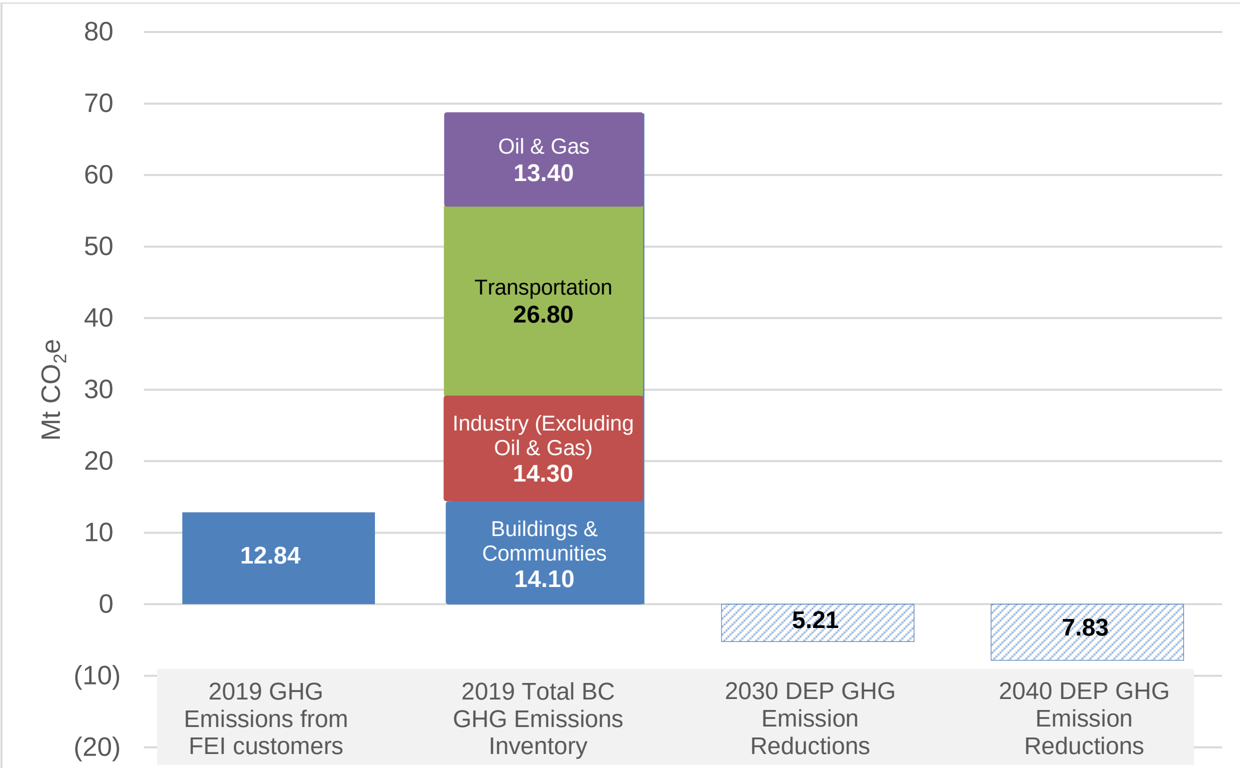
Figure 9-6: Comparison of Total Emission (Life Cycle) Reductions for FEI's Diversified Energy (Planning) Scenario[224] in 2030 and 2042 to FEI 2019 Customers and to 2019 Total BC GHG Emissions Inventory



9.3 *FEI'S CLEAN GROWTH PATHWAY WILL TRANSFORM CERTAIN MARKETS AND INFLUENCE OTHERS*

FEI's Clean Growth Pathway involves maintaining both the gas and electric infrastructure as part of BC's future energy system, leveraging FEI's existing infrastructure to reduce risks associated with the low-carbon transition. This foundation allows for more flexible and innovative solutions to be more easily developed and deployed. Through ongoing innovation, decarbonization is accelerated, contributing to provincial GHG emission reduction targets at a more rapid pace. In this pathway, the gas infrastructure continues to grow and thrive by adding new customers, communities, and commercial and industrial processing activities in order to maintain a viable infrastructure where rates continue to be shared across a diverse set of customer segments that can support the additional costs incurred through the clean energy transition. The industrial sector, in particular, is the most difficult to decarbonize and direct-to-customer clean energy projects may be one of the most viable solutions.

Table 9-1 illustrates how FEI's investments in decarbonization will support ongoing market transformation across the energy services supply chain.

[224] Diversified Energy (Planning) Scenario is referred to as DEP in this figure

Table 9-1: FEI's Investments in Decarbonization Initiatives Support Market Transformation Over the 20-Year Planning Horizon

Market Being Influenced	Anticipated Outcome in 2042
Decarbonization of fuel types through transitioning to renewable and low-carbon gases	
Renewable and low-carbon gases transition	By 2042, FEI's forecast annual demand will be increasingly supplied by renewable or low-carbon gases in the form of hydrogen, RNG, syngas and lignin, and some CCUS associated with gas production or consumption. By 2030 and through the rest of the planning horizon FEI's renewable and low-carbon gas will be increasingly supplied by BC based production. This initiative represents a transformational change within traditional gas supply markets.
Hydrogen production and distribution	Hydrogen will make up an increasingly large portion of the renewable and low-carbon gas supplies that FEI will rely on over the planning horizon. This demand for hydrogen will catalyse the development of BC's hydrogen economy and the development of innovative energy solutions in BC that use hydrogen as the key, low-carbon fuel. FEI's existing gas delivery system will enable this transition from natural gas to renewable and low-carbon gas in a number of different ways as outlined in Section 7, including the development of hydrogen hubs, the potential repurposing and upgrading sections of the existing gas grid to reliably supply clean, low-carbon hydrogen and the potential for dedicated hydrogen infrastructure.
Industrial decarbonization	The renewable and low-carbon gases that FEI will leverage to implement its Clean Growth Pathway offer some of the best opportunities for decarbonizing industrial processes within BC. FEI anticipates being a catalyst in the transformation of industrial energy use through its future supplies of RNG, hydrogen, syngas and lignin, and the use of CCUS in association with energy generation and/or use.
Carbon Capture, Utilization and Storage	Since the time that FEI undertook its modelling for the supply of renewable and low-carbon gas, the role that FEI expects CCUS to play in the Clean Growth Pathway has grown. FEI anticipates that CCUS will become increasingly commercially available and contribute to GHG emission reductions in FEI's fuel mix earlier in the planning horizon.
Electrification	The electrification of a degree of current gas load is expected to happen over the planning horizon as one of the solutions to reduce carbon emissions in the Diversified Energy (Planning) Scenario. Total electrification of FEI's existing gas demand, however, creates challenges for electricity capacity requirements that FEI considers are not plausible. FEI's Clean Growth Pathway is based on using the right energy, for the right purpose at the right time.
Low-Carbon Transportation and LNG	
Low-Carbon Transportation	FEI is not anticipating a complete transformation of the transportation sectors it is targeting with its low-carbon fueling supply and services. FEI's Clean Growth Pathway will, however, substantially reduce GHG emissions from one of the hardest to decarbonize sectors and catalyse the development of a marine bunkering industry in BC.

Market Being Influenced	Anticipated Outcome in 2042
DSM Reduces Energy Consumption in Residential, Commercial and Industrial Sectors	
Demand-side Management and high efficiency equipment	Heat pumps (gas and electric), dual-fuel heating systems, deep energy retrofits, building envelope upgrades and HVAC control systems will reduce energy requirements as BC's building stock is transformed to high performance. Waste heat recovery and integrated community energy systems offer some of the emerging innovations that will allow FEI to reach the GHGRS emissions cap for gas utilities.
Decarbonization in Commercial and Industrial Processes	Innovative technologies, process improvements and waste heat recovery will be implemented to help transform commercial and industrial processes toward higher efficiency and low-carbon emissions.
Enabling Activities to Support Market Transformation	
Clean energy workforce capacity	Workforce training and capacity building across the clean energy supply chain ensures decarbonization success.
Utility, government, rightsholder and stakeholder collaboration on climate action	All stakeholders collaborating on an approach to BC's energy system, understanding that there needs to be a multi-faceted approach to decarbonization.
Policy and regulatory environment supportive of decarbonization	Policy and regulatory environment are supportive of a diversified, complementary approach to meeting BC's energy needs.

9.4 RATE IMPACT IMPLICATIONS OF THE DIVERSIFIED ENERGY (PLANNING) SCENARIO

To provide context for FEI's long-term volume forecasts Figures 9-7 through 9-10 provide a 20-year directional view at the potential impact on customer rates under the Reference Case, Diversified Energy (Planning), Deep Electrification, and the Upper Bound Scenarios for Residential (RS 1), Small Commercial (RS 2), Large Commercial (RS 3), and Industrial General Firm Service (RS 5) customers, respectively.

Considering the volume of information presented, FEI has only included the results for these four scenarios since they provide a representative overview of the implications for rates that different futures will have. The figures below do not consider future rate design changes and are not indicative of a detailed rate forecast; rather, they simply provide a directional, 20-year view of how FEI's rates are influenced by these scenarios over time.

The analysis on effective rate impacts compares the changes in rates to the current 2022 approved rates with the following assumptions:

- The 20-year annual demand for each scenario includes DSM and low-carbon transportation;

- The long-term DSM expenditures for each scenario are under the High DSM setting discussed in Section 5.4.1;
- Commodity costs are based on a mix of supply of conventional natural gas and renewable gas, and midstream (i.e., storage and transport charges) costs assumed an escalation of by inflation;
- Carbon tax under the Diversified Energy (Planning) and Deep Electrification scenarios assumes annual escalation until it reaches $170 per tonne in 2030 as discussed in Section 2.2.1.4.2. For the Reference scenario, carbon tax is assumed to remain at $50 per tonne while for the Upper Bound scenario, carbon tax is assumed to be eliminated. For all scenarios, the bill impact analysis includes the avoided carbon tax resulting from the mix of renewable and low carbon gas in the commodity costs. For example, assuming FEI's gas supply includes 5 percent mix of renewable and low carbon gas in 2023, then the carbon tax is applied to the 95 percent of conventional natural gas only with no carbon tax on the remaining 5 percent;
- The 2022 approved delivery margin as the baseline cost of service plus annual escalation by inflation as well as the incremental cost of service for the capital expenditures on FEI's major transmission systems (VITS, CTS, and ITS) related to capacity upgrades, integrity, and resiliency depending on the peak demand forecast in each scenario;
- The incremental cost of service (including any offsetting revenue) related to FEI's major capital projects recently filed (or expected to be filed) or approved by BCUC, including:
  - Inland Gas Upgrades (IGU) CPCN;
  - Pattullo Gas Line Replacement (PGR) CPCN;
  - Tilbury LNG Storage Expansion (TLSE) CPCN;
  - Advanced Metering Infrastructure (AMI) CPCN;
  - CTS and ITS Transmission Integrity Management (TIMC) CPCNs;
  - OIC Tilbury Phase 1B; and
  - Woodfibre Gas Pipeline.
- The effective rate impacts are based on the average use per customer (UPC) between 2022 and 2042 under the Diversified Energy (Planning) Scenario:
  - Residential (RS 1): 60 GJ per year
  - Small Commercial (RS 2): 293 GJ per year
  - Large Commercial (RS 3): 3,253 GJ per year
  - Industrial General Firm Service (RS 5): 18,542 GJ per year

Figure 9-7: Cumulative Effective Rate Impact (2022 – 2042) – Residential RS 1, Avg. UPC 60 GJ

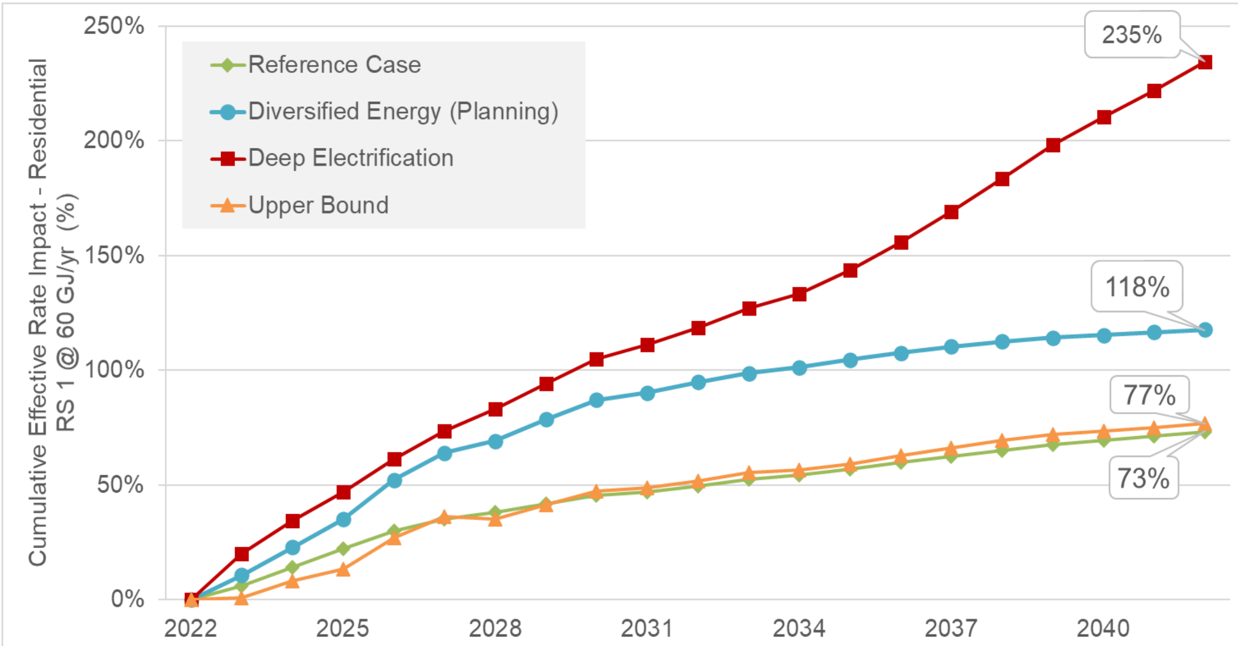


Figure 9-8: Cumulative Effective Rate Impact (2022 – 2042) – Small Commercial RS 2, Avg. UPC 293 GJ

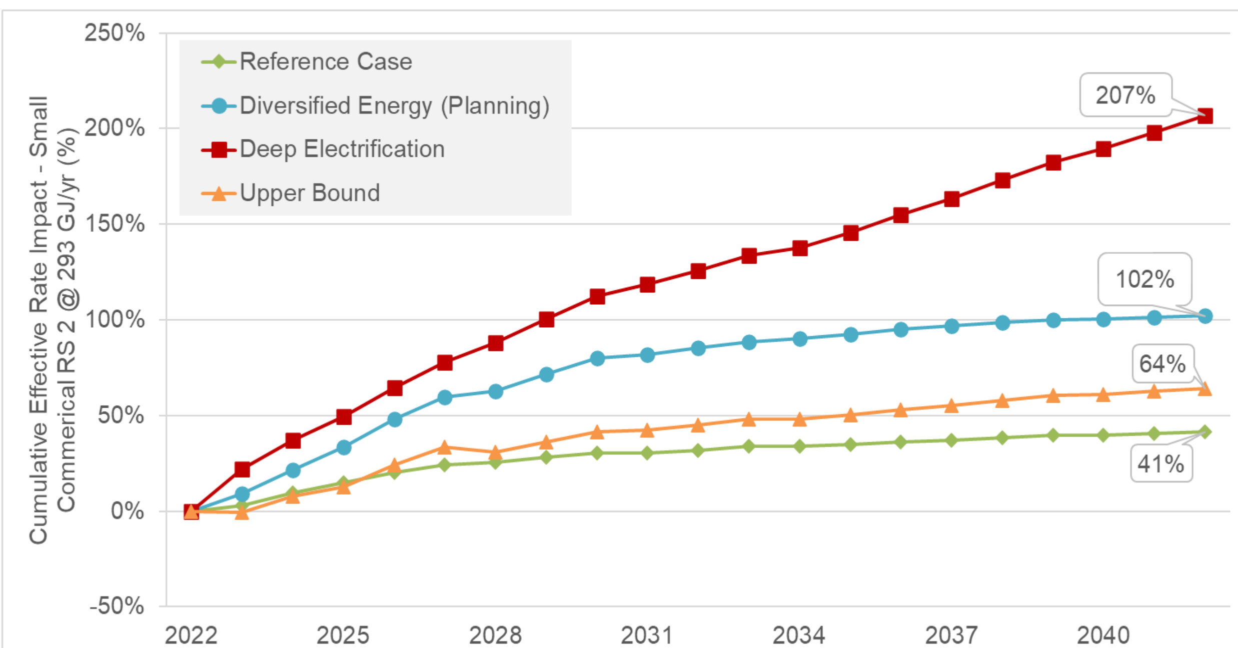

Figure 9-9: Cumulative Effective Rate Impact (2022 – 2042) – Large Commercial RS 3, Avg. UPC 3,253 GJ

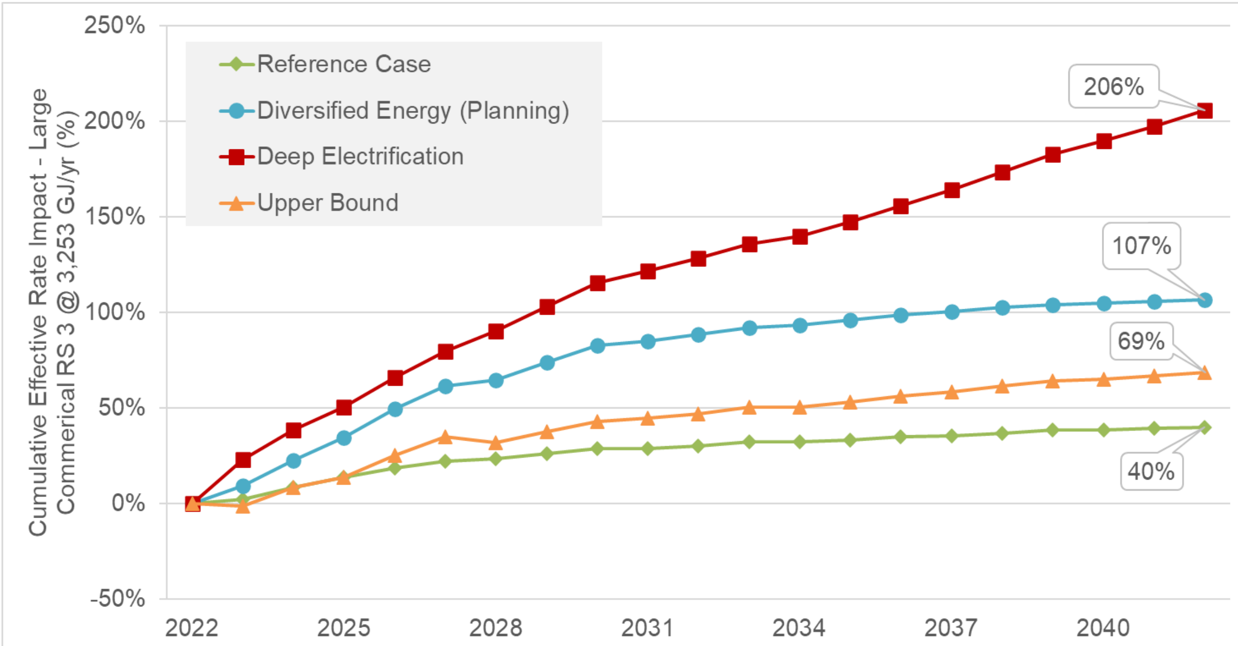

Figure 9-10: Cumulative Effective Rate Impact (2022 – 2042) – General Firm Service RS 5, Avg. UPC 18,542 GJ

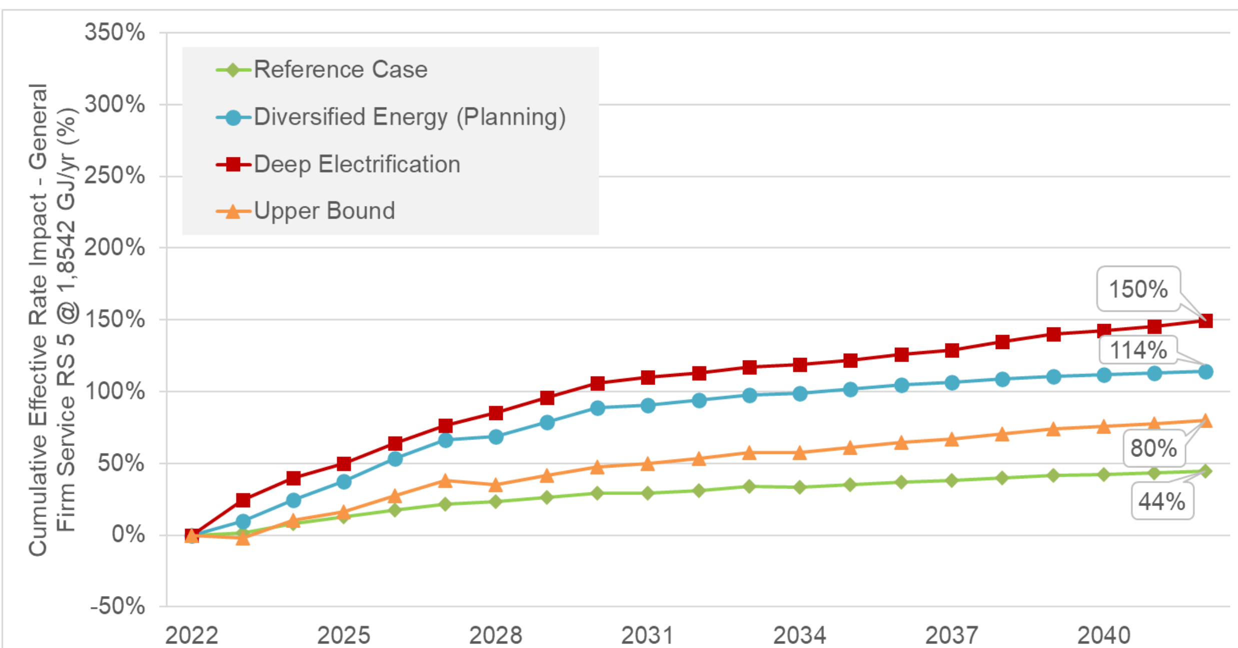

Table 9-2 below summarizes the cumulative effective rate impact projections as well as the equivalent annual rate impact over the 20-year period for each scenario.

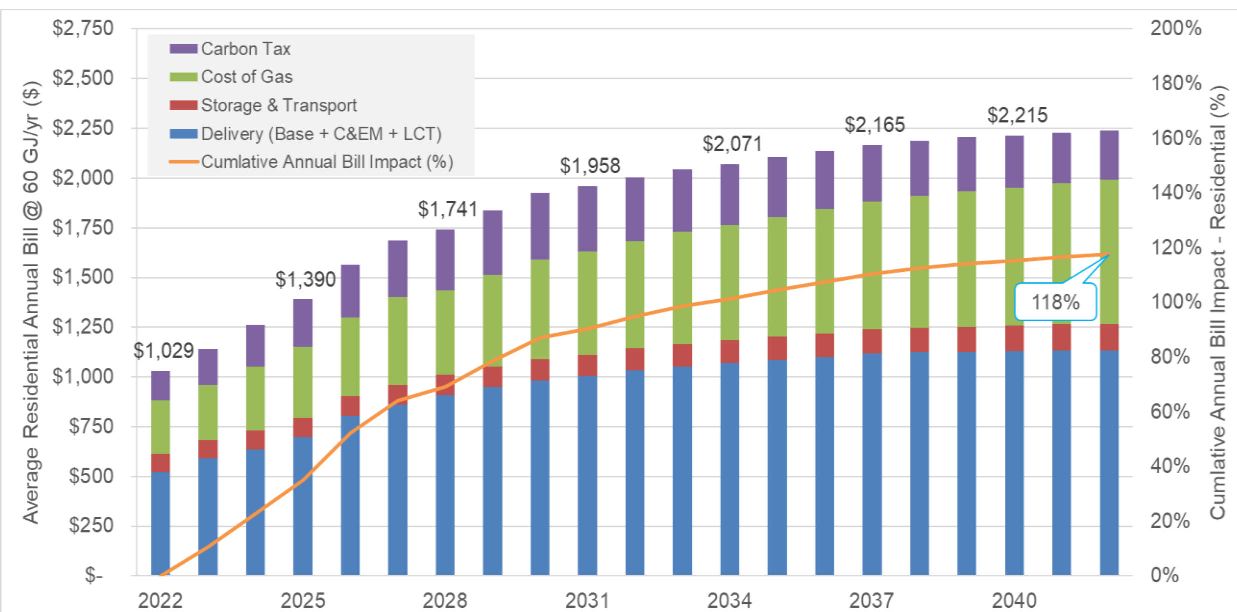
Table 9-2: Summary and Comparison of Average Projected Delivery Rate Changes

	Average UPC (2022 - 2042)	Effective Rate Change (2022 - 2042, %)							
		Reference		Upper Bound		Diversified Energy (Planning)		Deep Electrification	
		Cumulative	Annual	Cumulative	Annual	Cumulative	Annual	Cumulative	Annual
Residential (RS 1)	60	73%	2.8%	77%	2.9%	118%	4.0%	235%	6.2%
Small Commercial (RS 2)	293	41%	1.7%	64%	2.5%	102%	3.6%	207%	5.8%
Large Commercial (RS 3)	3,253	40%	1.7%	69%	2.6%	107%	3.7%	206%	5.7%
General Firm Service (RS 5)	18,542	44%	1.9%	80%	3.0%	114%	3.9%	150%	4.7%

The cumulative effective rate impacts shown in the figures above are made up of individual impacts in all components of FEI's rates, including delivery, cost of gas, storage & transport, and carbon tax. Using Residential (RS 1) as an example, Figure 9-11 below provides a breakdown of the annual bill projections for the average residential customer under the Diversified Energy (Planning) Scenario from 2022 to 2024. It can be seen that the total residential bill is estimated to increase from approximately $1,029 in 2022 to $1,958 in 2031, and to approximately $2,215 in 2040 under the Diversified Energy (Planning) Scenario. The cumulative effective rate increase by 2042 under the Diversified Energy (Planning) Scenario is driven by increases in all three components – 50 percent due to the delivery rate impact, 41 percent due to commodity related impacts (cost of gas and storage & transport), and 9 percent due to carbon tax increases.

Figure 9-11: Breakdown of the Cumulative Effective Rate Impact for Residential RS 1 under the Diversified Energy (Planning) Scenario



9.5 KEY DRIVERS IMPACTING THE NEED FOR INFRASTRUCTURE AND GAS SUPPLY RESOURCES ON FEI'S CLEAN GROWTH PATHWAY

The 2022 LTGRP has identified a number of key drivers that are impacting the need for resources, including both very traditional drivers for gas utilities as well as new and emerging drivers. No single one of these drivers is mutually exclusive of the others. There are many interrelationships among them. In many cases, proposed actions are aimed at addressing a number of these drivers and needs. For example, advancing the RGSD project as discussed in Section 6, addresses a number of the drivers including regional gas transmission constraints, improving diversity of supply, improving system resiliency and enabling the transition to renewable and low-carbon gas.

Table 9-3 summarizes key drivers impacting resource needs discussed in the 2022 LTGRP, indicates where in the LTGRP these drivers are discussed in more detail and identifies which Action Items presented in Section 10 are intended to address them over the next four years.

Table 9-3: Summary of Key Drivers impacting Resource Needs in the 2022 LTGRP

Key Drivers of Resource Needs[225]	Discussed in LTGRP Section(s)	Supporting Action Item(s) in Section 10									
		1	2	3	4	5	6	7	8	9	10
i. Increasing **DSM programs** to reduce demand and GHG emissions, continued exploration of innovative technologies leads to energy savings and deeper decarbonization.	3.4 5.1 – 5.7		√						√		
ii. Meeting **customer and demand growth** on FEI's system. Demand growth is primarily expected in the Low-Carbon Transportation and global LNG customer groups as well as the addition of a single large industrial customer – the Woodfibre LNG project.	4.1 – 4.9 7.3 7.4	√	√	√		√	√	√		√	√
iii. Addressing **regional supply constraints** resulting from demand growth in the Pacific Northwest. Gas supply resources in the region are becoming increasingly constrained and FEI needs to bring forward a solution(s) that protects the interests of its customers.	2.2.4 6.1 – 6.4					√	√		√	√	
iv. Improving access to **gas supply and system resiliency**. Weather extremes and aging	3.2.2.3 6.2.4 6.3	√				√	√	√	√	√	√

225 Numbering of key driver does not imply order of priority.

Key Drivers of Resource Needs[225]	Discussed in LTGRP Section(s)	Supporting Action Item(s) in Section 10									
		1	2	3	4	5	6	7	8	9	10
regional infrastructure are driving the need to improve system resiliency for serving FEI's customers.	7.5 App. E										
v. Meeting a **2030 GHG Reduction Standard** for gas utilities and a **legislated 2040 emission reduction target** on behalf of customers through the four pillars of the Clean Growth Pathway.	3.1 – 3.8 5.1 – 5.7 6.2.3 7.4 9.1 - 9.6	√	√	√	√	√			√	√	
vi. Incorporating an increasing proportion of **renewable and low-carbon gas into** FEI's gas supply portfolio. RNG and hydrogen will make up the largest proportion with smaller amounts of syngas and lignin anticipated along with CCUS. Regional and on-system gas supply resources need to address this shift.	3.3 6.2.2.2 6.2.3 7.4.1 9.1 – 9.6	√			√	√		√	√	√	√
vii. **Improving supply diversity** for sources of natural gas, renewable natural gas and hydrogen. Improving access to more production and trading areas will reduce price risk for customers, open up more optionality for supply and improve the resiliency of FEI's gas supply.	6.1-6.4 App. D	√				√	√		√	√	
viii. **Preparing for and participating in BC's emerging hydrogen economy.** FEI will be a catalyst for the development of a hydrogen economy in BC. Work is underway to better understand the implications of this transition for FEI's infrastructure and services as well as for FEI's residential, commercial, and industrial customers and communities.	3.3.3 6.2.2.2 6.2.3 7.4.1	√		√	√	√			√	√	√

9.6 *SUMMARY*

Key outcomes of FEI's Diversified Energy (Planning) Scenario are transformational reductions in carbon emissions, influences on energy related marketplaces, implications for customer rates and the need for new resources. As reflected in the discussion of these key outcomes above, the 2022

LTGRP highlights FEI's four pillars of the Clean Growth Pathway, the extent to which FEI initiatives contribute to BC's overall GHG reductions, and how variations in demand over the planning period can influence customer delivery rates. Since decreases in demand (whether through market trends or DSM programs) place upward pressure on delivery rates while increases in demand lead to the reverse effect, FEI will continue to explore opportunities for demand growth on the distribution system. This includes monitoring and, where applicable, participating in efforts to test and implement innovative natural gas energy technologies that help meet FEI's customers' needs while also supporting BC energy objectives.

FortisBC Energy Inc.
2022 LTGRP

Section 10:

ACTION PLAN

Table of Contents

10. ACTION PLAN

This Action Plan describes the activities that FEI intends to pursue over the next four years based on the information and recommendations provided in this 2022 LTGRP. FEI has built its Action Plan based on the Diversified Energy (Planning) Scenario modelled on the Clean Growth Pathway to achieve the GHG emission reduction targets outlined in the Roadmap. The Action Plan sets FEI on a path to decarbonization that provides the most viable opportunity to meet British Columbia's energy needs and carbon reduction targets, in a cost effective, reliable, and resilient manner.

At the time of writing this 2022 LTGRP, FEI is still in discussions with the provincial government to fully understand the policy requirements of the CleanBC Roadmap and their impact on FEI. The legislation and regulations required to implement the Roadmap will be understood for the next LTGRP. Based on its current understanding of BC government policies, the following are FEI's Action Items for the 2022 LTGRP.

1. Accelerate the development and acquisition of renewable and low-carbon gas supplies to meet customer energy needs and contribute to provincial emission reduction targets (Clean Growth Pathway – Pillar One).

The continued use, sustainment and growth of FEI's infrastructure along with a transition to increased production, delivery and use of renewable and low-carbon gas supplies is key to maintaining reliability, resiliency and affordability of BC's overall energy network in a low-carbon future. FEI will:

- Continue to accelerate the adoption of RNG, hydrogen, syngas, lignin and CCUS by familiarizing customers with these products and by implementing service offerings and rates to support the growth of this renewable supply;
- Support development of the renewable and low-carbon gas supply industry and market in BC and other jurisdictions through supply purchase agreements and project partnerships;
- Support the development of BC's hydrogen economy through implementing hydrogen blending and hydrogen hubs, and plan for transitioning to hydrogen compatible infrastructure;
- Grow expertise and capacity within FEI and BC generally for advancing renewable and low-carbon innovation through research, evaluation, pilot projects and full-scale production and be a leader in supporting BC's decarbonization initiatives;
- Continue to seize emerging market opportunities to provide gas delivery service that will reduce GHG emissions such as in the marine and other transportation sectors; and
- Continue to seek out partnerships with Indigenous groups and others to develop and implement innovative, clean energy solutions as part of FEI's Clean Growth Pathway.

2. Pursue approval of DSM funding for the period beyond 2022 by submitting for BCUC approval a DSM expenditure plan in 2022 (Clean Growth Pathway – Pillar Two).

FEI's future DSM expenditure plans will be informed by the results of the 2021 CPR and the 2022 LTGRP DSM analysis. FEI will continue to examine the potential for all forms of DSM programs to optimize the use of BC's energy infrastructure by implementing programs that help meet customer energy needs while reducing energy bills and meeting BC energy objectives. FEI will continue to explore the opportunity for DSM programs to transition and evolve to address deep energy retrofits, greater than 100 percent efficiency equipment, innovative technologies and behaviour change programs. FEI will:

- Develop DSM expenditure plans for the next funding period(s) reflecting an adequate and cost effective portfolio of DSM activities guided by the High DSM Setting, and apply to the BCUC for acceptance of those expenditures;
- Assess the implications of increasing amounts of renewable and low-carbon gas over the planning horizon on FEI's DSM activities, program modelling and reporting tools. For example, FEI will assess the impact of these supplies on cost-effectiveness models to understand how these fuels impact program offerings in alignment with the Roadmap;
- Continue to examine the potential for DSM activities to reduce peak demand on FEI's transmission and distribution systems, and thus defer or avoid infrastructure investments. FEI will continue to monitor studies and advancements across the gas utility industry on DSM related non-pipe solutions as well as evaluations of the effectiveness of such initiatives. FEI will consider opportunities for studies or pilot programs for such activity on its own system; and
- Continue to work with federal, provincial and municipal governments and other potential partners to explore and identify ways in which FEI's DSM activities can continue to help meet government objectives while ensuring benefits for FEI and its customers. This activity will include examining and understanding the impact of any changes to the BC Demand-side Measures Regulation on FEI's DSM programming, if and when such changes are enacted.

3. Continue pursuing FEI's LCT and global LNG initiatives to address market opportunities for load growth in support of customer rates and reducing local and global GHG emissions. (Clean Growth Pathway – Pillars Three and Four).

FEI will continue expanding its LCT service to a growing customer base wherein the displacement of higher carbon fuels by natural gas, renewable natural gas, or potentially hydrogen will result in a substantial reduction in both GHG emissions and other pollutants into the atmosphere. FEI will also continue to explore opportunities for its infrastructure to deliver lower carbon natural gas to customers in the form of LNG to displace higher carbon fuels currently in use both locally and abroad, thereby reducing GHG emissions around the world. In addition to the reduction of GHG emissions, expanding load growth in these markets will help to optimize the use of FEI's existing infrastructure, thus reducing overall gas customer rates and supporting all aspects of FEI's Clean

Growth Pathway. LCT initiatives include the continuation of established programs that provide incentives and fueling infrastructure investment as have been enabled through the BC-LCFS. FEI will:

- Continue to seek out new customers and load growth in the marine transportation, heavy duty transportation and remote industry markets for providing LNG fueling services in accordance with the BC-LCFS;
- Continue to seek out new customers and load growth in the medium and heavy-duty vehicle market in accordance with the BC-LCFS;
- Work with partners on innovative solutions for delivering fueling services in these important market segments;
- Continue to seize opportunities available to FEI to provide LNG to other jurisdictions in the global market where it can be used to displace higher emitting fuels; and
- Continue to work with governments to ensure that the benefits of FEI's energy infrastructure for reducing emissions in the transportation and global LNG sectors are considered in future regulatory changes and government initiatives.

4. Continually improve engagement processes and activities with Indigenous groups and BC communities on FEI's long-term gas resource planning.

Continual improvement in the way FEI engages with Indigenous groups and stakeholder consultation activities is an important part of the evolving resource planning process. The level of interest in energy planning, the urgency to address climate change, and the future implications of energy related policy and decision-making are more complex than in past LTGRPs. Engaging these groups regarding the LTGRP is one avenue through which to identify potential collaborative relationships on clean energy projects. FEI will:

- Continue to assess and incorporate the use of new communication technologies to provide greater reach and improved input into the LTGRP;
- Assess and implement the resources needed to improve engagement with Indigenous groups in FEI's resource planning activities, including securing additional sources of capacity funding to increase participation;
- Continue to improve the integration of LTGRP engagement activities with those of other groups within FEI; and
- Develop its engagement plans for the next LTGRP with implementation to start following upon the conclusion of the regulatory process for the 2022 LTGRP.

5. Seek BCUC approval for a deferral account to capture the costs of advancing the development of the Regional Gas Supply Diversity (RGSD) project.

The RGSD project is a critical infrastructure investment necessary for implementing FEI's Clean Growth Pathway, resiliency improvements, and gas supply risk management. The RGSD project is the preferred and recommended solution to meet the need for new regional pipeline infrastructure driven by three market conditions which are outside of FEI's control:

- Constrained capacity on the T-South system;
- Forthcoming increases in regional demand; and
- Expansion of renewable energy supply due to government policy:[226]

These market conditions and related regional system capacity constraints are discussed in more detail in Section 6.3.3. While many of these conditions exist independently of demand on FEI's own system, they will nonetheless result in significant costs and risks for FEI customers. The implemented solution must adequately consider project costs and benefits from the point of view of FEI's customers. Specific benefits of the RGSD project include:

- Facilitating FEI's decarbonization goals by enabling access to more RNG and hydrogen;
- Providing opportunities to build long-lasting, clean energy partnerships with Indigenous groups;
- Strengthening system resiliency for FEI and across PNW;
- Increasing gas transmission capacity for the PNW;
- Improving diversity of supply for FEI customers and the PNW; and
- Improving price stability for FEI customers.

FEI first needs to bring the development of the RGSD project to a point of readiness for FEI to bring a CPCN application to the BCUC for consideration. As such, FEI will:

- Seek approval from the BCUC to create a deferral account to capture costs related to further development of the RGSD project.
- Subject to BCUC approval of the deferral account:
    - Expand engagement and partnership discussions with Indigenous groups based on the principles of the UN Declaration on the Rights of Indigenous Peoples and adhering to the BC *Declaration on the Rights of Indigenous Peoples Act*;

[226] FEI and the BC Government are both advancing the use of hydrogen as a low-carbon fuel to help meet government policy and regulation regarding carbon emission reductions in the BC (see Section 2). Flowing hydrogen though pipelines in different potential blends requires greater pipeline capacity to move the same energy compared to natural gas since hydrogen has a much lower energy, although the lower energy content is partially offset by higher velocity capability due to differences in the flow characteristics of the gases.

- Initiate and conduct the necessary work to develop the RGSD project in preparation for a CPCN application; and
- Based on the outcome of this work, submit a CPCN application to the BCUC for approval of the RGSD project.

6. Continue to develop and implement FEI's Gas System Resiliency Plan.

The T-South incident and recent extreme weather events that have impacted infrastructure throughout BC have reinforced the need to improve the resiliency of FEI's gas delivery to customers and, in doing so, help to build more resiliency into BC's overall energy system. By pursuing the Clean Growth Pathway, FEI will contribute to building energy resilience for BC by maintaining and improving the diversity of energy sources, supplies and services available to customers in the province.

On FEI's own system, the TLSE and RGSD projects together with the AMI initiative are cornerstones of FEI's resiliency plan. The TLSE and AMI project CPCNs are currently before the BCUC and the RGSD project is the subject of Action Item 5, above. In addition to these projects and pursuing its Clean Growth Pathway, FEI will:

- Continue its ongoing system resiliency review and monitoring across all regions of its service network;
- Further define resiliency criteria for application when identifying and selecting preferred project alternatives to meet system growth and/or sustainment on the gas grid; and
- Continue to monitor regional issues in the PNW for developments that could impact the resiliency of gas supplies for FEI's customers.

7. Plan for and prepare CPCN applications for near-term system requirements identified in Section 7 to support safe, reliable and cost-effective gas delivery to FEI's customers.

In addition to the projects discussed elsewhere in these Action Items, the following system infrastructure projects FEI intends to submit CPCN applications over the near term include the following:

- FEI submitted a CPCN application for the Okanagan Capacity Upgrade in January 2021 but the proceeding is currently adjourned. In the interim, FEI continues to prepare and implement contingency plans for temporarily addressing the capacity deficit until a permanent capacity upgrade solution is approved and installed;
- Further capacity constraints on the Vancouver Island Transmission System are not expected within the forecast period other than the upgrades that will directly support the addition of the Woodfibre LNG project demand. It is expected that the system will meet the Traditional Peak Method for all other firm demand;

- The Southern Crossing Pipeline Class Location project discussed in Section 7.5.3, addresses pipeline safety factors;
- In 2022, FEI will be filing an application for the implementation of EMAT ILI through the Transmission Integrity Management Capabilities project for the Interior Transmission System as discussed in Section 7.6.4; and
- The ongoing evaluation of major bridge crossings will determine if upgrades need to be considered to improve the resiliency of piping during a seismic event. Major DP, IP and TP Lateral Pipeline Crossings are discussed in Section 7.5.2.1 including the Ironworkers Memorial Bridge in the Lower Mainland and Okanagan Lake between Kelowna and West Kelowna.

As FEI's planning efforts were and continue to be undertaken to ensure that planned improvements optimize operation of the system as a whole, these system upgrade requirements were integrated with reinforcement options that were considered to meet FEI's capacity needs.

8. Continue monitoring, analysing and contributing to the energy planning environment while working with government on policy framework for deep decarbonization.

FEI's transition to renewable and low-carbon gas supply and other integrated energy solutions requires innovation and collaboration with all levels of government, Indigenous groups and stakeholders as the province works together in understanding the complementary roles of the gas and electric energy systems into the future. FEI will:

- Continue working to understand the many and evolving factors that influence FEI's long-term analysis in order to provide context, results and recommendations that will be made throughout the next LTGRP process;
- Continue to monitor market and policy developments which may impact the procurement and development of clean energy supply, regional gas supply, customer demand and pricing;
- Continue to advise the BC government, as appropriate, on the options available to maintain secure, reliable and resilient energy services to customers cost effectively, while lowering GHG emissions and reducing risks associated policy decisions, including how FEI can support a net-zero future in BC; and
- Continue efforts to collaborate with other utilities and energy solution providers on growing a diverse, reliable, resilient and affordable energy system throughout BC.

FEI's low-carbon transition will influence the renewable and low-carbon gas marketplace in BC and beyond. FEI's investments in the decarbonization of buildings and the commercial and industrial sectors will provide both environmental and economic benefits to British Columbians. FEI's research and development, collaborative partnerships and support for innovation will reveal potential challenges as well as identify opportunities to improve on the secure, reliable, cost-effective and lower-carbon energy that FEI continues to provide to its customers.

9. Protect and promote the interests of FEI's customers by securing reliable, cost-effective, long-term gas supplies that include increasing proportions of renewable and low-carbon gas.

Constrained pipeline and storage resources in the region during the winter season continue to be a major concern and market developments are increasing supply and pricing risks for FEI's customers. FEI will continue to monitor these changes, proactively assess challenges, and identify opportunities to enhance supply security, diversity and resilience in order to meet the LTGRP objectives. With the advancement of renewable and low-carbon gas supply resources in the region, FEI's future infrastructure is also being planned to support the transition to a lower carbon future by providing increased resiliency and supporting a broader range of supply resources. FEI will:

- Manage supply risk and price volatility in the region by maintaining access to supply hubs (Station and AECO/NIT), hedging any supply exposure to the Huntingdon/Sumas market with financial hedges, utilizing a variety of storage and transportation resources, and using different pricing structures and contract terms;
- Continue using financial hedging strategies as approved by the BCUC in FEI's PRMPs and, where applicable, request BCUC approval for an expansion of financial hedging strategies via future PRMPs;
- Continue to support the regulatory approval processes for the TLSE project which will significantly increase the resiliency of FEI's natural gas system in the event of a critical disruption of regional pipeline supply;
- Evaluate opportunities within FEI's service territory to improve infrastructure resiliency and supply diversity, which will support diversity, reliability, and decarbonization over the long term;
- Evaluate opportunities to contract for long-term, non-recallable storage capacity at Mist, which will help manage security of supply concerns in the gas supply portfolio;
- Continue to accelerate the acquisition of renewable and low-carbon gas supplies for inclusion in FEI's gas supply portfolio as part of FEI's Clean Growth Pathway; and
- Assess the firmness of renewable and low-carbon gas supplies for year-round delivery to customers and assess the evolving marketplace for opportunities to apply traditional portfolio risk mitigation mechanisms to these renewable and low-carbon supplies.

10. Continue monitoring for and evaluating system expansion needs across FEI's service regions.

Key to providing a safe, reliable, and secure supply of gas to customers is identifying when and where any capacity constraints may appear and planning for the infrastructure and system resources that FEI requires to construct over the planning horizon. Growth in peak demand is among the most significant challenges for FEI's long-term planning. Contingency plans for higher or lower than forecast peak demand are inherent in the regional system capacity plans outlined in Section 7.3. Planning for and integrating hydrogen into FEI's gas network is a new challenge. Although still in early stages of consideration, the potential for non-pipe solutions to help defer or avoid infrastructure continues to gain attention in the gas utility industry. Given all of these factors, the location of each load addition or renewable and low-carbon gas initiative will have unique implications for FEI's infrastructure, adding to the challenge of assessing the system implications before such locations are known. FEI will:

- Continue monitoring customer and peak demand growth on FEI's system and assessing the implications for capacity related infrastructure requirements;
- Continue to assess the implications for FEI's infrastructure of introducing hydrogen into the pipeline system or otherwise leveraging FEIs pipeline network to enable hydrogen or other renewable and low-carbon gas service;
- Refine reinforcements that would be required to maintain system reliability and resilience for Core customers as LNG expansion occurs on the Coastal Transmission System and the Vancouver Island Transmission System;
- Refine criteria to identify and prioritize projects to address system resiliency in all FEI systems;
- Refine and implement mitigation plans to address the capacity shortfall in the Okanagan region of the Interior Transmission System until an Okanagan Capacity Upgrade project solution is approved and implemented;
- Continue evaluating other major system projects outlined in Section 7.5 and submit CPCN applications for these projects if required; and
- Continue to explore innovative opportunities for implementing DSM and non-pipe solutions to delay or avoid new infrastructure through further studies and potential innovative DSM pilots.

11. Prepare and submit FEI's next LTGRP.

As discussed throughout this LTGRP, the energy planning environment is rapidly changing and FEI is undergoing an important shift to decarbonize the energy it delivers to customers. These changes have implications for FEI's services and infrastructure that continue to need further study and discussion as part of the long-term resource planning process. As such, FEI believes the period between filing this LTGRP and filing its next LTGRP should be shorter than the previous interval. FEI anticipates filing its next LTGRP approximately 2 to 3 years following the conclusion of the regulatory process for its 2022 LTGRP.

CLEAN GROWTH PATHWAY TO 2050

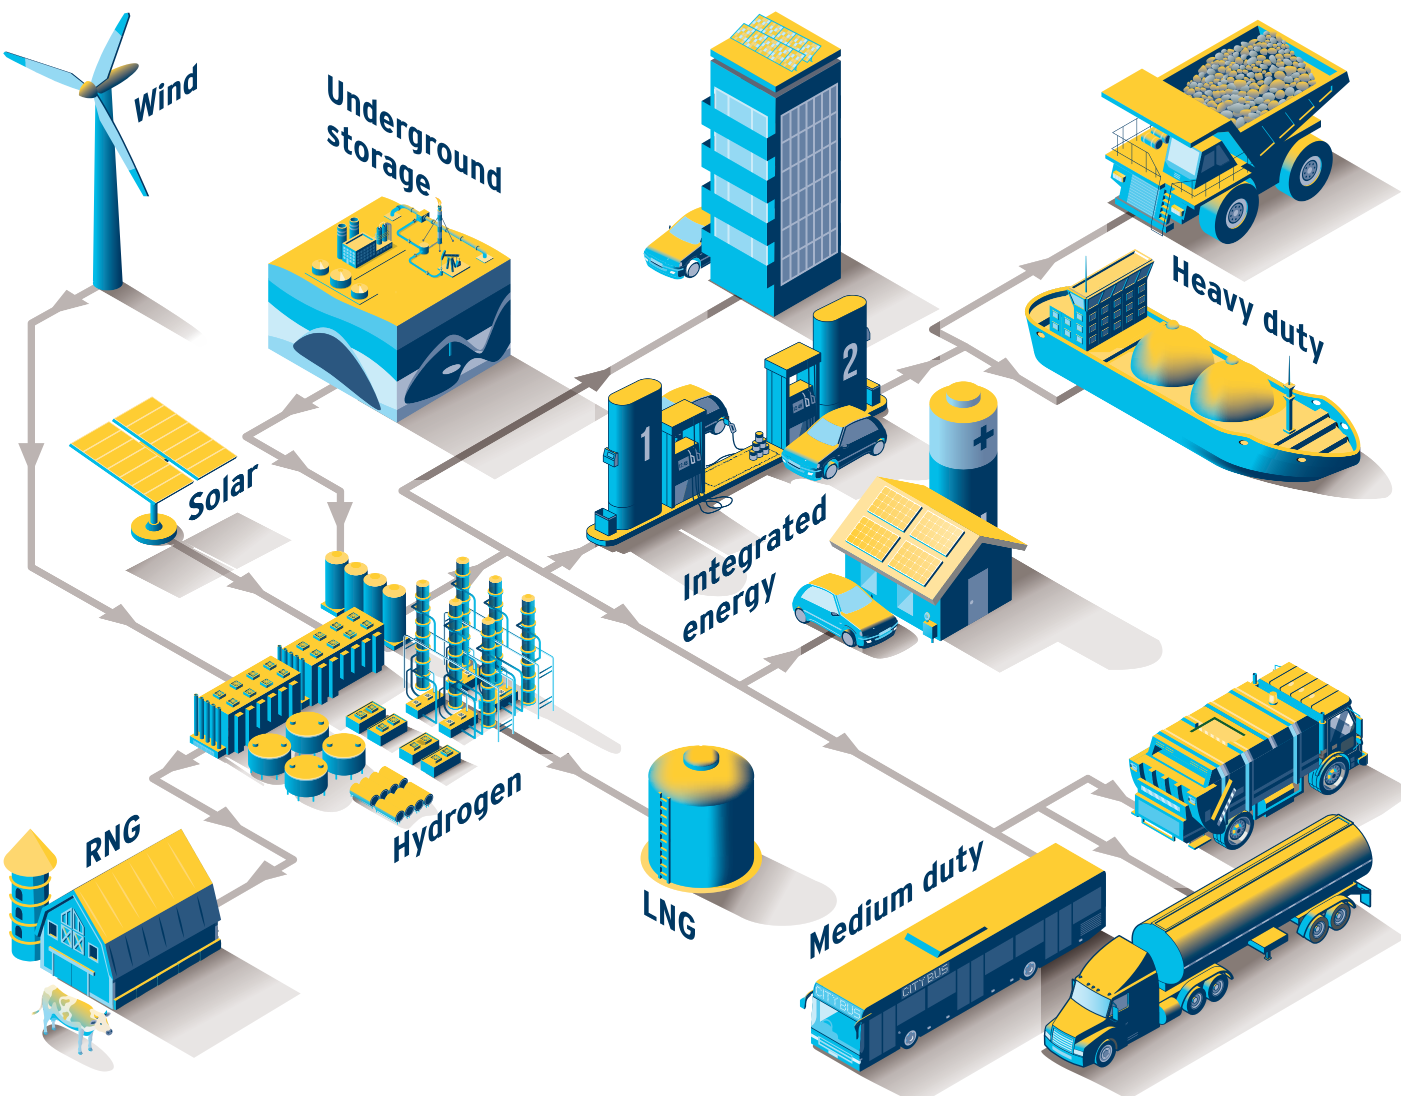
Clean growth pathway to 2050

Contents

Affordability, clean energy and efficiency: FortisBC's clean growth pathway

We believe FortisBC has an important role to play in helping British Columbia move to a low-carbon, renewable energy future. We see ourselves as an energy delivery company that has climate and economic solutions in the buildings and transportation sectors. Millions of British Columbians we serve in communities across the province look to us to deliver energy safely, reliably and affordably every day. As a subsidiary of our Canadian-based parent company, Fortis Inc., one of the largest energy companies in North America, we're committed to helping British Columbia achieve its climate goals and addressing climate change solutions in a global context. We're focused on providing practical solutions that can be implemented today by leveraging our existing infrastructure.

Figure 1: FortisBC's role in driving BC's sustainable prosperity



This paper presents FortisBC's pathway to align with the provincial government's goal to significantly reduce greenhouse gas emissions (GHG) while supporting economic growth and maintaining affordability and customer choice. Our approach combines several strategies that together outline a clear pathway to significant emissions reductions and signal a paradigm shift in the way we relate to energy.

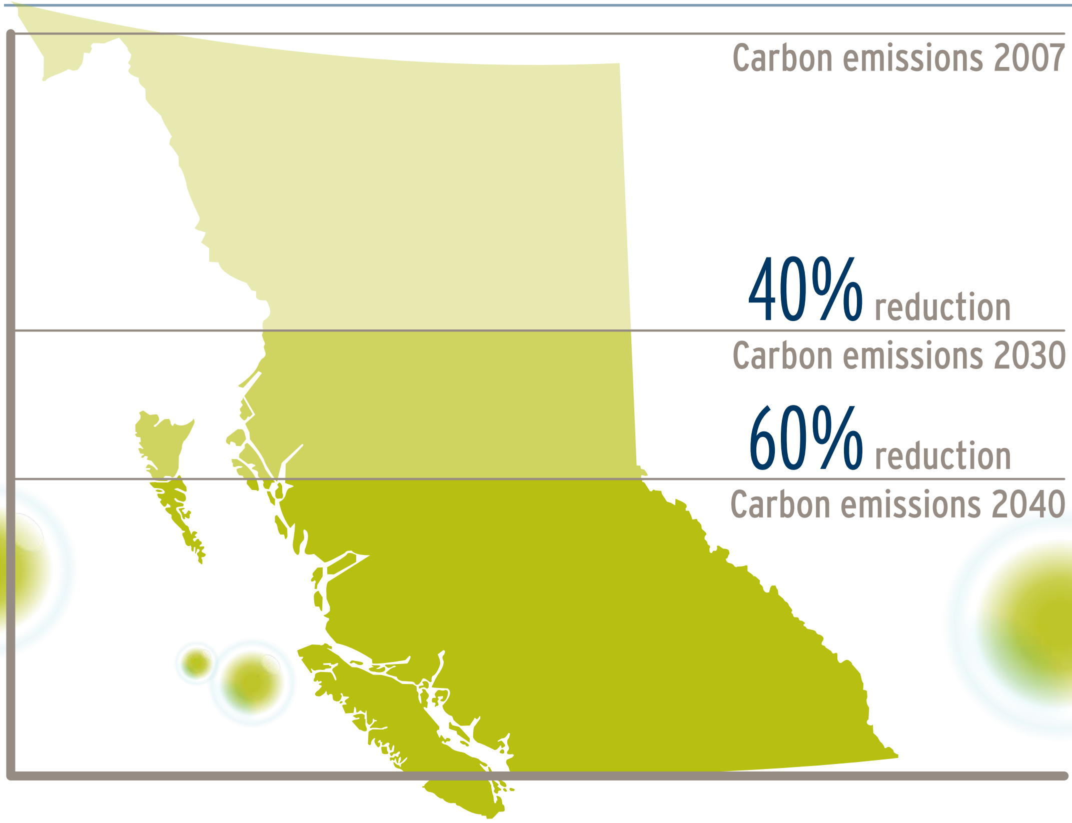
Our pathway calls for four significant shifts in our energy systems to foster market transformation:

- making significant investments in both low and zero carbon vehicles and infrastructure in the transportation sector
- transitioning from higher carbon energy sources to lower carbon sources by ramping up Renewable Natural Gas (RNG) and hydrogen deployment to achieve a ten per cent zero-carbon fuel supply by 2030 and a thirty per cent supply by 2050
- positioning BC as a vital domestic and international Liquefied Natural Gas (LNG) provider to lower global GHG emissions
- tripling our investment in energy efficiency in the built environment and developing innovative energy projects in BC's communities

Introduction

British Columbia (BC) has committed to achieving deep carbon reductions in greenhouse gas emissions by 2050. The province recently updated its climate targets to a 40 per cent reduction in carbon emissions from 2007 levels by 2030, and a 60 per cent reduction from 2007 levels by 2040. Achieving these long-term targets will require immediate and coordinated action by policy makers, regulators and industry. The province will need more than aspirations to achieve real, timely results.

Provincial Carbon Emission Goals



We believe we have a significant role to play in helping the BC Government deliver on its climate and energy goals. Our pathway is based upon our commitment to investing in projects that will make life more affordable for British Columbians, improve efficiency, reduce GHG emissions and drive innovation. By strategically managing BC's existing energy infrastructure and investing in new low-carbon energy supply, we see a long-term opportunity to continue creating sustainable, good-paying jobs across BC.

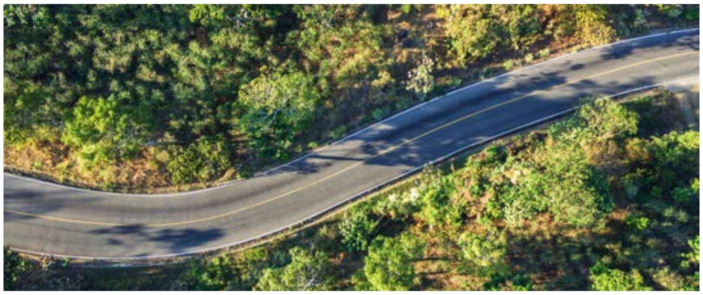
In 2015, BC's emissions were 63 million tonnes (Mt) of CO_2e. Most emissions fall into three categories: transportation, buildings and industry. We recommend any sectoral targets being considered should be proportionate to the sector's share of GHG emissions and the ability to deliver cost-effective emissions reductions using our current infrastructure.

25%

of BC's CO_2 emissions are from commercial transportation

For example, the commercial transportation sector is the largest contributor to BC's emissions at 25 per cent. The provincial government can achieve large emission reductions in transport using today's commercially-available technology. Practical and affordable solutions that can be implemented immediately should be differentiated from aspirational goals that require technology breakthroughs.

A made-in-BC pathway



As a utility serving gas, electric and alternative energy customers, FortisBC recommends developing an integrated, system-wide evaluation of achieving the province's carbon reduction objectives. Because FortisBC delivers the most energy to consumers of any entity in the province, we have a keen interest in British Columbians understanding the system-wide impacts of various pathways that meet the province's GHG emissions targets. BC's electric and gas energy systems work in tandem to provide reliable energy to British Columbians. Both systems complement one another, providing redundancy and a low-cost solution to delivering energy to British Columbians. FortisBC believes that the provincial pathway should be guided by strong analysis and pursue a strategy that utilizes 'every tool in the toolbox': all of our provincial energy resources and existing infrastructure will be needed to achieve long-term GHG emissions reductions.

Many low-carbon pathways have emphasized the importance of the electrification of end-uses. We agree that electricity will play a key role in reducing emissions but we also caution that there are significant challenges to this strategy. Notably, the direct substitution of electricity for gas to meet heating load, coupled with growth in other areas like electric vehicles, would far exceed the available electric infrastructure and add significant costs to the existing system which would be borne by all BC residents.

FortisBC supports the provincial government's commitment to undertake a review of BC Hydro and incorporate the findings into the Clean Growth Strategy. As we consider how best to transition to a sustainable and innovative economy, we believe there is a need to reflect the real cost of all energy in our long-term goals and strategies.

FortisBC believes that gas—as an energy carrier—will continue to be a critical component of a decarbonized energy system in BC. Gas infrastructure in the province is a multi-billion dollar asset that provides reliable, safe, affordable and high-quality energy services to British Columbians. This infrastructure is designed to serve difficult-to-decarbonize end-uses such as building and industrial heating and heavy-duty freight. Additionally, BC's gas infrastructure is equipped to handle decarbonization pathways that use drop-in fuels such as RNG and hydrogen, along with other key mitigation options like carbon capture and storage. The provincial government and stakeholders like FortisBC need to work to define the key role of the gas system to achieve our GHG reduction objectives and develop policies and other support mechanisms to leverage this system in a low-carbon transition.

Transportation

The transportation sector accounts for 39 per cent of BC's total emissions, making it the most important sector where we can achieve significant and immediate carbon reductions with technology that is available to us today. FortisBC is a leader in North America, providing innovative and clean technology that lowers emissions throughout the transportation sector.

BC's transportation sector accounts for

39%

of our CO_2 emissions

The decarbonization of BC's transportation sector will require the use of all tools available to us including:

- cleaner transportation systems, including increased investment in fuelling infrastructure, clean trade corridors
- displacing high-carbon fuels with cleaner fuels like natural gas, RNG, biofuels or hydrogen
- cleaner vehicles that use alternative fuels, electric power or hybrid technologies

Cleaner transportation systems

BC Ferries new Salish Orca is fuelled by natural gas—an innovative and clean solution that will provide benefits to BC Ferries' customers and the provincial economy.

Marine

The marine sector represents a massive GHG reduction and economic opportunity that should be the top priority in the province's Clean Growth Strategy. BC has had excellent early success in advancing liquefied natural gas (LNG) in the domestic marine sector that serves as a foundation to build upon for other markets.

BC Ferries launched their fourth LNG vessel this summer with a fifth expected next year and Seaspan Ferries now operates two LNG vessels in BC waters. With five LNG vessels in operation, BC Ferries, for example, expects to reduce their fuel costs by millions of dollars and CO_2 emissions by 21,500 tonnes annually, the equivalent of taking approximately 4,400 vehicles off the road per year. To put that in perspective, that's more than double the 2,200 battery electric vehicles that were purchased in all of BC in 2017.

The *Spirit of British Columbia* is the first vessel in the world to refuel LNG through delivery on a fully enclosed vehicle deck. In collaboration with BC Ferries, FortisBC developed a proprietary tanker truck technology to deliver fuel while on board the vessel. Innovative solutions like this help make it easier for transportation customers to make the switch to LNG.

The conversion of BC Ferries' two largest ships in the fleet, along with the introduction of three new natural gas-fuelled Salish Class vessels last year, improves sustainability and affordability for ferry users. FortisBC is proud to have partnered with BC Ferries to develop these innovative and clean solutions that will provide benefits to BC Ferries' customers and the provincial economy.

Clean Trade Corridors

FortisBC applauds the provincial government for initiating the Clean Transportation in BC Trade Corridors initiative. We see this multi-stakeholder collaboration as an essential forum to ensure that BC and Canada are in position to capitalize on international conventions that will reduce the use of dirtier fuels and drive the adoption of LNG in the marine sector. The group's mandate to improve competitiveness and reduce GHGs is well focused and timely—conventions set by the International Maritime Organization (IMO) will take effect by 2020 which is an incredibly short period to transition the practices of international vessels in BC's ports.

Marine vessels that regularly call at BC ports originate from ports of other countries are not included in the provincial emissions inventory, yet these vessels emit a significant amount of emissions when in transit and when berthed in our ports. GHG emissions from this segment of international marine transport are approximately 70 million Mt of CO_2e per year—greater than BC's total annual GHG emissions. These emissions should be considered as part of the province's global GHG reduction strategy by displacing high-carbon marine fuels with low-carbon LNG.

GHG emissions from international marine shipping currently represent around 2.6 per cent of total global emissions, but this share could more than triple by 2050 if measures are not taken to help speed a transition to a low-carbon environment in this sector. Following the Paris Climate Agreement, discussions began at the IMO to agree to an Initial Greenhouse Gas Strategy to stipulate significant measures to mitigate emissions. In April 2018, the IMO agreed on its first strategy to reduce GHG emissions in the international shipping sector to meet the Paris Agreement goals. The IMO strategy includes a target to reduce carbon emissions by at least 50 per cent compared with 2008 levels by 2050. This strategy presents a challenge for a sector that has traditionally faced significant barriers to innovation and an opportunity for BC to position itself as a low-carbon fuel provider in the form of LNG.

Low-carbon fuels such as LNG will be critical to achieving the IMO emission reduction targets. BC is well-positioned to assist in these efforts and become a world leader in LNG bunkering. The provincial government should consider developing policies to start addressing these emissions such as including the ability to generate compliance credits with the Renewable and Low Carbon Fuel Requirement Regulation if international marine vessels use lower carbon fuels such as LNG.

FortisBC was the first company in the world to offer onboard truck-to-ship LNG bunkering. This proprietary design was developed by collaborating with Seaspan Ferries, BC Ferries and their shipbuilders to create a customized solution to fit our customers' needs.

FortisBC has the infrastructure in place to be ready for 2020. FortisBC has completed construction of a $400-million LNG expansion project at our Tilbury facility which includes a new storage tank and additional liquefaction capacity. Plans are being developed to increase the Tilbury LNG facility's liquefaction capacity up to to three million tonnes per annum, expand LNG storage by another 92,000 cubic metres and provide ship loading facilities to serve these markets. Our Tilbury LNG facility is powered by electricity, creating safe, clean, low-GHG emitting LNG.

Expanding our natural gas liquefaction capacity by

92,000

cubic metres

Locally, other agencies such as the Port of Tacoma are also working to position themselves for success. Puget Sound Energy (PSE) is developing an LNG production facility that will enable LNG supply for marine and transportation markets in the region. This LNG facility will incorporate LNG liquefaction, storage and bunkering to the marine market. The project is scheduled to be completed in late 2019 and would compete with BC. FortisBC believes there is a limited window of time for BC to establish itself as an LNG bunkering hub before 2020. BC has an advantage as we have an ample supply of clean LNG available at globally competitive rates.

FortisBC recommends the following actions:

- Continue supporting the Clean Transportation in BC Trade Corridors initiative. Specifically, the opportunity to introduce a pilot program to convert drayage vehicles from diesel to compressed natural gas (CNG) and the advancement of the LNG bunkering in advance of 2020. The provincial and federal governments need to advance the regulation, financial tools for bunkering infrastructure and policies to establish BC as a global leader in LNG bunkering.
- Amend British Columbia's Renewable Low Carbon Fuel Reduction Regulation to generate credits for LNG bunkering that lower international shipping emissions.
- Work with the federal government to develop policies that account for the role of BC LNG in meeting global GHG reduction targets via Article Six of the Paris Agreement.

Cleaner fuels

FortisBC supports the provincial government's proposal to support the transition to cleaner fuels. We see RNG as being an essential component of this transition.

FortisBC was the first utility in North America to offer RNG to residential customers in 2011. RNG is a critical source of renewable energy that is helping the province achieve its GHG emission reduction target. Farms, landfills and other suppliers like the City of Surrey have teamed up with FortisBC to capture methane (CH4) from organic waste, which would otherwise escape into the atmosphere. This methane, also known as biogas, is purified to make RNG.

FortisBC's RNG program is enabled by a British Columbia Ministerial Regulation, the Greenhouse Gas Reduction Regulation (GGRR). The GGRR has facilitated the development of five operational projects which are forecasted to supply over 203,000 GJ of RNG this year. These facilities capture biogas, clean and upgrade the biogas into RNG, and inject the RNG into our distribution system. Since the RNG offering launched to residential customers in June 2011 and commercial customers in March 2012, over 9,000 customers have subscribed to this offering and have helped reduce GHG emissions an equivalent amount to removing 7,200 cars from the road.

Turning waste into fuel

Earlier this year, we joined the City of Surrey and the Government of Canada to open North America's first closed-loop waste management system. The facility will convert curbside organic waste into renewable biofuel to fuel the City's fleet of natural gas powered waste collection and service vehicles. Under this closed-loop system, waste collection trucks will literally be collecting their fuel source at curbside. Excess fuel will go to the new district energy system that heats and cools Surrey's City Centre.

Though FortisBC has achieved important early successes in the residential and commercial sectors, further work is required to grow BC's supply of RNG for use in the transportation sector. Innovations in biogas could boost our supply of RNG to between 25 and 46 per cent of FortisBC's annual natural gas demand by 2036. Power-to-gas, the process of converting electric power into carbon-neutral hydrogen, presents a further opportunity and could account for between five and 15 per cent of annual demand by 2036.

We believe that hydrogen will be a key driver towards reducing BC's carbon emissions, not only as an alternative fuel to enable the decarbonisation of heating, but as a means of storing renewable power (hydroelectric, solar and wind) and, through this, linking together the decarbonisation of the building, industry and transport sectors. We believe in taking a system-wide perspective of hydrogen as a technology that further integrates the electric and gas systems by acting as a high capacity storage medium for carbon-free power generation and a carbon-free fuel for heat and transport.

The potential of a low-carbon gas system

In our 2017 Long-Term Gas Resource Plan, FortisBC outlined a preliminary analysis of initiatives that could achieve significant GHG emissions reductions by 2030. Emissions reductions opportunities for FortisBC fall into three categories: i) decarbonizing pipeline gas with RNG, hydrogen and carbon capture and storage; ii) energy efficiency and demand-side management (DSM); and iii) fuel switching from more carbon-intensive energy to pipeline gas and LNG.

Should low-carbon gases like RNG and hydrogen achieve a notable share of the total supply in the gas distribution system, FortisBC estimates that the technical potential to reduce GHG emissions would be up to 2.7 and 5.0 Mt. This would reduce emissions from natural gas consumption by between 25 per cent and 42 per cent from 2007 levels in the industrial, commercial and residential sectors.

In the transport sector, FortisBC could achieve 0.3 Mt of domestic reductions and 10.7 Mt from international shipping by 2030. This highlights the significant potential for the gas system to be a key contributor to the province's climate objectives. Ambitious provincial incentives and other policy support would be required to expand the supply of low-carbon gas to this scale. But, maintaining a role for gas within a low-carbon transition ensures that customers maintain their choice of energy supply and lowers the technology risk and costs of a narrowly defined abatement pathway. Such a pathway would also ensure that provincial energy resources and infrastructure are leveraged for a made-in-BC solution.

Growing BC's low-carbon fuel sector will require a number of actions from the province:

- identify RNG as an essential component of the province's clean growth pathway
- address regulatory barriers to expanding utility investment in RNG projects
- streamline regulations to enable RNG production from agricultural waste
- provide support to advance the commercial production of hydrogen as a form of RNG

Domestic carbon reductions from international shipping of

10.7

metric tonnes

What is Renewable Natural Gas?

Renewable Natural Gas (RNG) is a carbon-neutral energy source, because it does not contribute any net carbon dioxide into the atmosphere. RNG is produced in a different manner than conventional natural gas. It is derived from biogas, which is produced from decomposing organic waste from landfills, agricultural waste and wastewater from treatment facilities. The biogas is captured and cleaned to create carbon-neutral RNG.

Peter Schouten, Owner Operator, Fraser Valley Biogas. One of FortisBC's first RNG suppliers.

Cleaner vehicles

Displace higher carbon fuels by expanding BC's natural gas vehicle sector

Commercial transportation accounts for 25 per cent of total GHG emissions in BC and more than half of these emissions originate from road freight transport. By increasing our efforts to displace higher carbon fuels in the heavy-duty vehicle and marine transport sectors, BC can achieve substantial emissions reductions.

By converting heavy-duty truck fleets and transit vehicles to LNG or CNG, we're helping the province meet its carbon emission reduction goals while helping operators save on fuel costs.

FortisBC natural gas for transportation customers are realizing anywhere from 25 to 60 per cent reduction in fuel costs. This helps improve the competitiveness of our private and public sector partners. Since initiating our efforts to introduce cleaner vehicles in 2010, we have eliminated more than 110,000 tonnes of CO_2e and displaced more than 145 million litres of diesel.

Natural gas can reduce GHG emissions by up to 30 per cent compared to diesel and gasoline. Additionally, switching to natural gas fuel can improve air quality: natural gas vehicles emit virtually no particulate matter, and they emit up to 95 per cent less nitrogen oxides (NOx).

FortisBC recommends the following actions:

- continue supporting investment in CNG transit vehicles and fuelling infrastructure to displace higher carbon fuels and reduce particulate emissions
- expand the GGRR and develop a BC Ports incentive program to convert the 1,700 trucks in BC's drayage sector to CNG or CNG/Hybrid trucks, covering the full cost of the vehicle and reducing both the particulate and GHG emissions associated with BC's ports
- expand eligibility for BC's CEV Specialty-Use Vehicle Program to include hybrid vehicles that include an alternative fuel, such as CNG or hydrogen
- undertake a review of Ministry of Transportation policy to permit low emission natural gas and hydrogen vehicles to use designated HOV lanes on key trade corridors such as Highway 99 and Highway 1

UPS' commitment to CNG

Earlier this year, we partnered with the world's largest package delivery company to launch a compressed natural gas fuelling station and vehicles in Vancouver, BC. Seven CNG highway tractors and 40 delivery trucks were added to the current Canadian UPS fleet of over 2,900 package cars, tractors and shifters. Presently, more than 40 per cent of the UPS fleet in Canada runs on alternative fuels. UPS Canada now joins over 800 transit buses, commercial vehicles and freight vehicles powered by natural gas here in BC.

Transform the light-duty transportation sector through electrification

The light-duty transportation sector accounts for 14 per cent of BC's total GHG emissions. This includes light-duty passenger vehicles and trucks that use gasoline or diesel. Electrification of this segment provides a promising pathway to reduce emissions, as cost and performance of the underlying battery technology has seen dramatic improvements in recent years. The automotive industry is responding with many new electric vehicle models arriving in the showrooms of almost every manufacturer.

Light-duty transportation accounts for

14%

of BC's total GHG emissions

Growth in the electric vehicle segment is happening in BC but further incentives will be required to achieve government's goal of 5 per cent of all new light-duty vehicle sales. EV sales in 2017 increased by 53 per cent compared to 2016 and were accelerated by an expanding lineup of fully electric vehicles. However, while there has been an increase in the sale of EVs since 2013, at approximately 1.7 per cent of total vehicle sales in 2017 for BC, EV sales are still a small portion of the overall market. FortisBC supports the province's proposal to continue providing vehicle incentives.

Additional EV charging infrastructure will be critical to advancing the adoption of EVs in the province. Without adequate charging infrastructure deployed throughout the province to allow zero emission vehicles to travel throughout BC safely and conveniently, it is unlikely that the EV market share will progress quickly. Further collaboration between the province, local governments and FortisBC and BC Hydro can address this gap.

We recommend that the province take the following actions:

- continue providing incentives for EV vehicles and infrastructure
- support increased utility investment in EV charging infrastructure in BC
- leverage existing FortisBC CNG fuelling infrastructure to include fast-charging EV stations
- develop measures to encourage charging station installations at businesses and other buildings as part of a smart grid

accelerate Kootenays

FortisBC is a core funder of the *accelerate* Kootenays initiative, a collaborative project that will address the charging infrastructure gap across the Kootenay region in Southeast British Columbia. Earlier this year, we opened five electric vehicle Direct Current Fast Charging (DCFCs) stations in the region, connecting the West Kootenays to surrounding regions for electric vehicle travel.

All West Kootenay stations were installed by Kootenay-based electricians, creating local employment opportunities for residents.

All are part of the broader *accelerate* Kootenays initiative which will ultimately facilitate the installation of 13 fast chargers and 40 Level two chargers in communities across the Kootenays, resulting in over 1,800 kms of connected electric vehicle travel. The fast-charging stations are critical infrastructure to allow electric vehicle drivers to travel to and through the region, and to facilitate increased adoption of electric vehicles locally.

Buildings & communities

FortisBC is uniquely positioned to be a key agent of the government's strategy to reduce GHG emissions in buildings and communities in a cost-effective, market-driven manner. We provide energy in the built environment through gas, electricity and as an alternative energy provider.

In 2017, we opened the door to our new LEED-equivalent Kootenay Operations Centre outside of Castlegar, BC.

The marketplace recognizes the affordable, high-quality, reliable and safe energy services delivered by FortisBC. Over three million British Columbians use natural gas every day with over 58 per cent of households using natural gas as their primary heating source. The preference for gas is reflected by our continued customer growth. In fact, 2017 was FortisBC's best-performing year for customer growth, with many new customers converting their home heating system from high carbon fuels such as heating oil. This emphasizes the foundational role of gas infrastructure in BC's energy system. To achieve the provincial government's GHG reduction objectives, consumer preference for gas as a low-carbon and affordable energy source should be recognized and harnessed.

Even though customer additions to FortisBC's gas system were at record-levels in 2017, the amount of gas used on a per customer basis declined by 1.8 per cent in 2017 on a weather normalized basis. This speaks to the success of energy-efficiency measures in the province including FortisBC's energy conservation programs, federal and provincial policies and the gradual but concerted shift in the built environment to more energy-efficient dwellings.

The unique aspect of the gas system is that it is specifically designed to address heating demand. Seasonal changes in heat demand (referred to as "peak load" or "peak demand") can be up to 400 to 500 per cent greater than FortisBC's average demand. For comparison, peak load in the FortisBC electric system is approximately 40 per cent higher than average load. If BC used electricity as the primary source for heat, the seasonal variability of heating load would create a huge need for energy storage. Hydropower could meet the storage requirement were it not for the magnitude of heat load in BC. The approximate peak-hour heating load in 2017 in FortisBC's gas system was over 12 GW of electrical capacity equivalent (at a one-to-one unit energy conversion basis). In other words, electrifying heating could require almost a doubling of the existing hydroelectric capacity in BC even before considering the electrification of some part of the transportation fleet or other energy end uses and the additional transmission and distribution requirements. Recognizing this, decarbonizing the gas flowing through the system while maintaining the use of that system is a prudent and low-cost strategy to ensure that BC achieves its climate targets.

Stronger codes and standards over time

We support stronger codes and standards that result in increased energy efficiency. We support an approach that is aligned with the current BC Building Code and BC Energy Step Code (BC ESC) targets. The BC ESC provides an incremental and consistent approach to achieving more energy-efficient buildings in a cost-effective manner while also reducing GHG emissions.

Codes and standards should stay consistent to achieve energy-efficiency gains

The BC ESC was developed after an extensive, multi-year engagement process. As a member of the Energy Step Code Council, FortisBC provided insights into the development of the BC ESC, particularly with respect to ensuring affordability needs for British Columbians are addressed, while supporting continuing innovation in the use of energy in buildings.

In addition to supporting long-term improvements in energy efficiency in the BC Building Code, the BC ESC ensures the consistency of building regulations in the province; a key to ensuring clear regulation for builders and developers looking to build in multiple municipalities. The BC ESC provides a provincial framework that replaces the patchwork of different green building standards that have been required or encouraged by local governments in the past. This allows local governments to play a leadership role in improving energy efficiency, while providing a single standard for industry, and build capacity over time.

The BC ESC focuses first on building envelope design with a goal of taking incremental steps to make buildings net-zero energy ready by 2032. It provides for a fuel neutral approach and focuses on the efficiency of buildings and equipment. By focusing on building and equipment efficiency, both overall energy usage and GHG emissions are reduced while building comfort is increased. While costs increase at higher levels of the code, energy usage decreases help offset the increase in overall costs to consumers. The BC ESC also provides flexibility to meet the changing needs and abilities of local governments, industry and technologies. It does this by providing local governments with the tools to pursue a long-term vision for the future of energy efficiency of buildings and related climate action initiatives. As a new code structure, the BC ESC, similar to other changes in the BC Building Code, requires time to learn, implement and see results. It is common practice to make changes to the code only every five to seven years to allow the industry and consumers to become familiar with the change.

Adding additional regulations into the BC ESC, such as the proposed GHG intensity (GHGi) requirement, before results of the adoption of the existing BC ESC are understood and realized would be premature and could lead to unintended consequences: higher energy costs, impaired housing affordability and a loss of choice for consumers. The provincial approach should support consumer choice, by allowing designers and builders to continue to choose gas, electricity, or other energy sources for their project. A fuel-neutral approach provides builders with the flexibility to make energy-efficient buildings using all the available technologies along with managing their costs. It also empowers builders and developers to pursue innovative, creative, cost-effective solutions, and allows them to incorporate leading-edge technologies as they come available. We believe that committing to the current

BC ESC is a prudent measure accounting for the scale of change that the new code presents to the market and the importance of aligning the code across the province.

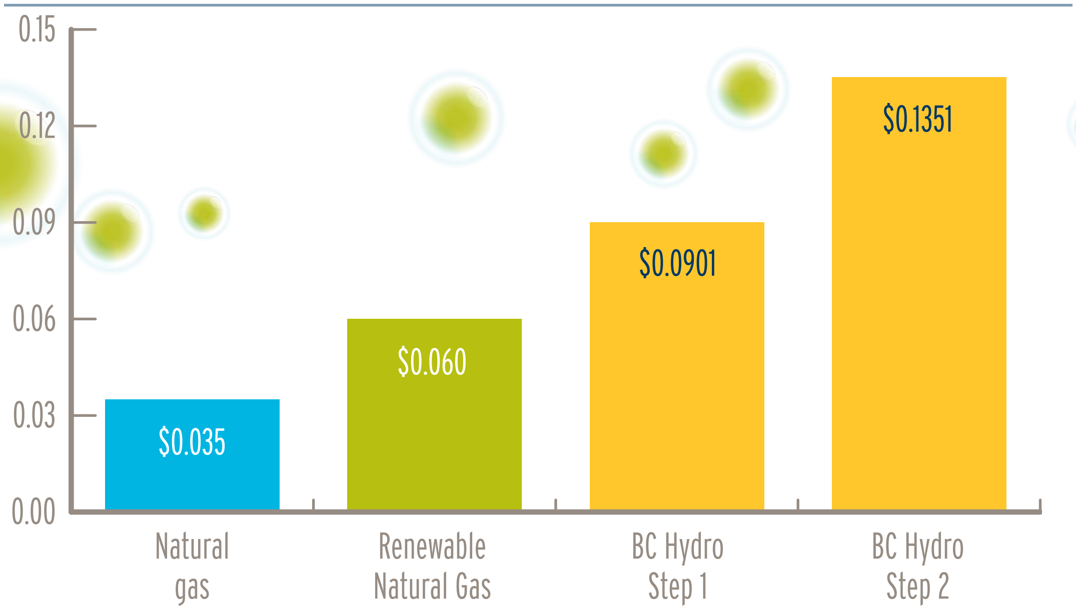
FortisBC has been, and continues to be, a strong advocate for the use of the BC ESC. For example, FortisBC and the City of Vancouver signed a Memorandum of Understanding (MoU) which ensured that the City would introduce pathways that used the BC ESC for builders to comply with the City's Zero Emissions Building Plan. Under these compliance pathways, builders can choose to follow the BC ESC without additional requirements such as a GHGi target. FortisBC also committed to developing a DSM program based on the BC ESC in the MoU. By having new pathways aligned with the BC ESC, FortisBC could provide DSM incentives to lower the costs of achieving the BC ESC to builders in Vancouver while still achieving meaningful improvements in the energy efficiency and GHG reductions of new buildings. Were the province to allow a patchwork of BC ESC along with municipally-specific GHGi requirements, FortisBC would not be able to provide DSM incentives to moderate the affordability pressures of new ambitious codes that restrict access to the gas system.

BC should seek alignment with national codes and standards to ensure consistency with other jurisdictions as it considers a new code for retrofits. The federal code for alterations to existing buildings should serve as a template for BC, as suggested. Because of the scale of the retrofit challenge, clear goals and objectives need to be identified to ensure that all players in this sector have a role. FortisBC is exploring innovative partnerships to demonstrate building energy retrofits and we believe that large GHG reductions consistent with the province's long-term GHG objectives are possible while still maintaining connection to the gas system.

Finally, we recommend that any further changes to the BC Energy Efficiency Standards Regulation should be aligned with federal standards to ensure consistency for equipment manufacturers. We agree with the Canadian Homebuilders Association that it is likely that manufacturers will focus efforts on areas with the greatest market share, national and international, and BC's initiatives may not be as lucrative to encourage the necessary research and development in comparison to federal approaches.

Maintaining affordability for BC energy consumers

Residential gas $/kWh price comparison



Affordability is the key concern among BC residents and FortisBC customers while producing energy locally is the top policy priority for government to consider. As we transition to a low-carbon economy, care must also be taken to ensure that we pursue cost-effective strategies that will not result in higher costs for energy consumers.

Consumer priorities on energy issues

In August 2018, FortisBC commissioned Innovative Research Group to conduct a survey on consumer priorities on energy issues. The survey found that:

- **For 42 per cent of respondents affordability is the top priority in their personal energy choices**, followed by the environment (24 per cent) and reliability (22 per cent).
- When it comes to government policy, the top priority is **helping the economy by producing energy locally (28 per cent)**, followed by affordability (27 per cent), with environment third (21 per cent).

The survey was conducted between August 3 and 14, 2018 among a sample of 1,328 randomly-selected British Columbians. The survey used a mixed-method online and phone methodology. Interviews in English (n=1,024) were conducted using a representative online panel and in-language interviews in Cantonese, Mandarin, and Punjabi (n=304) were conducted over the phone. Results were weighted to a sample size of n=1,200 based on age, gender, region of the province and mother tongue.

We also believe that regional differences in BC should be taken into account. For example, policies that restrict choice will disproportionately impact energy consumers outside of the Lower Mainland and Southern Vancouver Island that reside in BC's colder regions. Similarly, regions that rely on BC's natural gas industry to drive the provincial economy, should also be taken into account.

FortisBC's RNG, while more expensive than natural gas, is still approximately half the price of electricity in BC and with a lower carbon intensity. This demonstrates the potential for the gas system to achieve significant, affordable GHG reductions with low-carbon drop-in fuels such as RNG and hydrogen. To achieve this potential, supportive policies that provide incentives and opportunities to invest in low-carbon gas supply will be needed over the long-term. These investments will only happen as long as the gas system remains a viable productive asset and consumers have the choice to continue to connect to and use gas.

It is for all these reasons that we believe an approach that targets increased energy efficiency and allows for consumer choice and innovation is consistent with the broader government objectives: making life more affordable and growing the BC economy while taking action on climate change.

Incentives tied to energy efficiency and building improvements

We support increasing energy-efficiency incentives. FortisBC is seeking to significantly expand energy-efficiency investments in our DSM portfolio. Our proposal currently before the British Columbia Utilities Commission (BCUC) includes more than doubling energy efficiency spending from 2016 levels by 2019 and with further increases over the next four years. By 2022, we are committed to investing more than $96 million annually, approximately tripling our 2016 spending.

Committed to investing more than
$96 million
annually by 2022

FortisBC estimates that this increased funding would effectively double annual natural gas energy savings and GHG emissions reductions, with the majority of savings occurring in the built environment. Annual energy savings would be in the order of one million GJ of gas which will in turn lead to reductions in GHG emissions of approximately 50 thousand tonnes of CO_2e per year.

We are also seeking approval to expand our electricity DSM portfolio. In our 2019 to 2022 DSM Plan, which is currently before the BCUC for review, we are seeking a 21 per cent spending increase over what we put forward in our long-term DSM Plan. We expect to achieve 17 per cent more energy savings than set out in the long-term plan, or 130 GWh over the plan period.

Through assisting customers in moving to higher-efficiency equipment, supporting the BC ESC and advancing energy conservation in BC overall, our expanded energy efficiency programs will positively impact the province and support the achievement of BC's GHG emissions reduction goals. These measures will also support the BC government's commitment to improving affordability: individual customers will reduce their energy consumption and their energy bills.

FortisBC is supportive of the proposal to develop an incentive program to complement existing utility-led energy-efficiency programs focused on retrofits. We believe that if utility and provincial actions are well-designed, they could leverage each other and strengthen participation. We advocate for the provincial government to continue to work closely with utilities in designing this program.

Advanced Metering Infrastructure (AMI) is a valuable tool in helping our customers across BC improve energy efficiency and reduce GHG emissions in residential and commercial buildings. This technology is providing FortisBC's electric customers with more control over how they use energy. To date, we have installed over 134,000 AMI meters in our electric service territory and we seek to extend these benefits to our natural gas system. This technology is the foundation of a more modern natural gas system that improves the customer experience by empowering them to access data to make informed decisions about their energy use. With advanced meters, our natural gas customers will have the information they need to inspire mindful choices like using digital control to better manage use of heating appliances or making energy-efficiency upgrades to their homes. This technology could also help facilitate more investment in behind the meter solutions by identifying buildings well suited to energy-efficiency upgrades and integrating those solutions to the broader system to maximize energy-efficiency gains. We recommend that the provincial government provide support for wider deployment of AMI across BC's natural gas network.

Support for low-carbon innovation

FortisBC is well-positioned to identify innovation investments to reduce the carbon footprint of BC's energy system. FortisBC is interested in investing in core research focused on opportunities relevant to BC. This could include ultra high-efficiency gas-fired heat pumps, hydrogen production technologies, measures to reduce the carbon intensity of natural gas such as carbon capture and storage, and near zero GHG engines in vehicles. Without innovation funding from FortisBC or other agencies focused specifically on addressing GHG emissions within BC's unique energy system and fully integrated gas supply, transitioning the gas system to align with the provincial climate targets will be even more challenging.

We recommend that the province consider mechanisms for utility-led innovation investment aimed at reducing GHGs or directing a portion of Innovative Clean Energy (ICE) funding to utility-led projects.

FortisBC also seeks to expand BC's supply of clean energy. Wood and forest residues could significantly expand the amount of RNG supply in BC but, to unlock this potential, focused support for innovation from the public and private sectors will be needed. Of the total supply potential for RNG, wood has the largest share representing approximately 50 per cent of natural gas consumption in Canada. There are a number of other co-benefits of harnessing the potential of wood feedstocks for RNG. These include reducing GHG emissions in BC's forestry-based industries while providing them with new, meaningful financial benefits. This could increase the competitiveness and international market share of Canadian forest industries and boost employment in the sector. However, there are still important technological gaps and high costs associated with wood-based RNG production meaning that, to-date, there has been limited RNG production from wood. The provincial government should identify RNG from wood feedstocks as a key priority for its innovation and climate objectives and work with the forestry sector, FortisBC and the research community to realize this opportunity.

We are supportive of new policies that will support utility investment to broaden our supply of clean energy to include new forms of alternative energy. For example, FortisBC Alternative Energy Services (FAES) is a leader in providing cost-effective, high-performance thermal energy solutions (TES) in BC's building sector. For example, our Marine Gateway and Telus Gardens energy systems in Vancouver, both use renewable and recycled energy to improve efficiency and emissions by 50-80 per cent compared to conventional systems. To date, FAES has invested more than $62 million in high-efficiency energy systems which we own and operate on behalf of our customers.

To date, FAES has invested more than

$62 million

in high-efficiency energy systems

In order to accelerate FAES' contribution to providing highly efficient and low-carbon energy systems, we propose that government support a move to facilitate adoption of a regulated pooled cost model for TES providers. This recommendation would ultimately lead to faster market adoption of TES solutions.

Another example of low-carbon, FortisBC-led innovation is the proposed Ellison Community Solar Pilot project that could be the largest utility-owned solar project in BC. Interest in solar is on the rise and we seek to provide an easy, affordable option for our customers who want to use solar energy to meet a portion of their electricity needs. Our aim is to develop a solar program for customers who are interested in solar, but the upfront cost, placement, operation or maintenance of a rooftop system is not desirable. The province should create opportunity for future utility investment in clean energy projects where there is consumer demand for these offerings.

Energy-efficiency labelling information

FortisBC supports the province's goal to improve information for building owners and residents on the energy performance of buildings. As the province develops this program, total energy consumed, carbon footprint and overall cost should all be included in the energy labeling information. FortisBC looks forward to working with the province to further develop this proposal.

A clean growth program for industry

Industry is an important part of the Provincial economy and our customer base. Of FortisBC's million customers, less than a thousand are industrial clients, yet these firms consume approximately one-third of FortisBC's total gas demand. To these customers, gas is a low-cost, efficient, reliable and high-quality fuel source. FortisBC is proud to be the energy supplier of choice to the industries that propel BC's economy.

FortisBC agrees with the provincial government that reducing GHG emissions must happen alongside a strengthening economy. Reducing GHG emissions through investment, technology and sustainable growth must be fostered in a framework to ensure BC's businesses and industries are not put at a competitive disadvantage. The intention to develop an effective Clean Growth Program for Industry is an important objective of the provincial government. To this end, we believe that an incentive-based approach for industry is an important development.

We also believe that BC needs to be in alignment with the rest of Canada. The federal government's output-based system in the Carbon Pricing Backstop provides more relief to industry while still maintaining the same marginal incentive to reduce GHG emissions. BC should commit to reviewing and evaluating outcomes from the two systems. If the federal approach demonstrates better outcomes for emissions and the economy, then BC should adopt this system to create a level playing field for industries across Canada.

Industrial incentive

We believe that setting the performance benchmark at the level of the cleanest facilities in the world is an ambitious but achievable starting point as many industries in BC are already world-leading environmental performers. Because the Clean Growth Program for Industry aims to improve the international competitiveness of BC's industries, we support the benchmark level as the best performing international firm or facility.

Industries within BC or Canada should not be used to set the benchmark. This would force domestic firms to compete against each other and incur costs with no impact on their international competitiveness. As provincial carbon policy costs begin to align under the Pan-Canadian Framework, the incentive for domestic firms to reduce their carbon emissions is evened. In fact, BC's approach to tax all of a firm's carbon emissions up to $30 per tonne applies significantly more carbon costs than the approach used in the federal output-based allocation system which applies the carbon price only on emissions above the benchmark. This means that even with an aligned price on carbon, BC firms would be disadvantaged compared to other provinces.

A Canadian first

Climate change is a global issue, and FortisBC is committed to being part of the solution. One of the ways we're doing this is by exporting liquefied natural gas (LNG) to countries like China that are looking to significantly reduce their greenhouse gas emissions.

Late last year, FortisBC notched a milestone by delivering the first shipment of LNG from Canada to China. Since then, our shipments have continued, with the most recent one arriving in Shanghai in May.

As China's LNG imports continue to increase, analysts predict it could one day eclipse Japan as the world's biggest importer of natural gas. This presents a unique opportunity for FortisBC, which has the only two LNG storage facilities on Canada's West Coast.

FortisBC's LNG facility in Delta, BC has been operating since 1971 and in order to meet the growing demand for LNG it recently underwent a $400-million expansion.

This market shift is about more than just an economic opportunity for Canada. Underlying this trend is the fact that natural gas is a strong energy option for countries like China that are looking to transition from high-carbon fuels to cleaner and more affordable alternatives.

FortisBC offers an abundant supply of LNG that meets high environmental standards. In fact, when FortisBC's Tilbury LNG plant expansion is operational later this year it will be one of the cleanest LNG facilities in the world.

The additional GHG reduction that would be achieved by using domestic firms for the performance benchmark is marginal while simultaneously not improving the competitive position of BC firms in the international market. Because BC's firms compete for market share against international firms, ensuring that carbon costs are moderated compared to the next best international performer should be the key objective. We believe this makes both economic and environmental sense. Incentivizing firms to achieve the lowest carbon intensity than the next best global performer ensures that carbon leakage is minimized while firms in BC are allowed to grow.

The provincial government should use a consistent approach when setting the benchmark across all industries. This means that determining the benchmark for incumbent industries such as mining and pulp and paper should be the same as for nascent industries such as LNG exports. A consistent approach ensures industries of the future can compete for global markets just as today's industries can. FortisBC also supports the principle of consistency regarding the threshold to enter the program at 10,000 tonnes of annual GHG emissions. This will ensure that all large industries can access carbon tax incentives. The government should monitor this threshold and consider opportunities for smaller firms to opt-in to the program.

A threshold of
10,000 tonnes
will ensure all large industries can access carbon tax incentives

The threshold and the benchmark should also account for all emissions whether from combustion, process or fugitive. Firms that demonstrate real investments in technologies and practices that reduce process and fugitive emissions should be able to report those savings toward their emission intensity.

Clean Industry Fund

FortisBC supports the creation of the Clean Industry Fund as a way to invest carbon revenues into direct emissions reductions and innovation in low-carbon technologies. The fund should only be available to firms that are participants in the Clean Growth Program. The fund should be additional to existing government funds for innovation and technology and focused on industrial improvements. The scope for funding should be broad and include direct facility-level improvements, research and development, pilots and demonstrations and projects across the energy supply chain that will lower the carbon intensity of fuels. FortisBC anticipates that it would be a recipient of funds to develop leading technologies in, for example, efficiency, RNG and hydrogen that would improve the carbon intensity of industrial clients.

Investments from the fund should allow projects that achieve both short and long-term GHG reductions and be fuel neutral. A common and agreed framework to evaluate proposals that emphasized cost-effective short term reductions or long-term projects with high reduction potential should be negotiated with Clean Growth Program participants.

FortisBC believes that the government should target industry specific reductions along with system-wide initiatives that could reduce the carbon intensity of all industries. A priority list of actions could be developed in consultation with industry to earmark fund dollars for high-payoff strategies. We believe that one such strategy is to support clean gaseous fuels such as RNG and hydrogen. A specified and focused tranche of support from the fund could have an outsized role to improve the carbon intensity of all industries in BC.

FOREWORD

In 2018, FortisBC Energy Inc. (FortisBC) developed its Clean Growth Pathway to 2050, which outlined actions the company would take to help British Columbia (BC) achieve its greenhouse gas (GHG) emissions targets. The Clean Growth Pathway takes a diversified approach to GHG reduction by using BC's electricity and gas infrastructure. As owners and operators of reliable gas, electric, and thermal energy infrastructure, FortisBC will have a key role in leading the transition to lower carbon energy. As a regulated utility, FortisBC is accountable to the BC Utilities Commission and obligated to serve the interests of over 1 million homes and businesses across BC.

The provincial government's CleanBC plan aims to significantly reduce provincial GHG emissions and strengthen BC's economy. FortisBC delivers more energy to consumers than any other entity in the province and will be critical to ensuring BC can efficiently, reliably, and affordably achieve its plan. To help do so, FortisBC commissioned Guidehouse to chart a viable path for BC to achieve its 2050 targets while identifying solutions that are in the best interest of its customers.

FortisBC and Guidehouse worked with the BC Ministry of Energy, Mines and Petroleum Resources and the Climate Action Secretariat to ensure that CleanBC, provincial data, and projects are included in the analysis as much possible.

The goal of this report is to generate dialogue and solutions-focused thinking on how BC can achieve the transition to a lower carbon energy system while building understanding on factors such as maintaining a flexible, reliable, and resilient provincewide energy system. The report's analysis presents two pathways to achieving GHG emission reductions; neither reflect what is an expected future outcome by either Guidehouse or FortisBC. FortisBC welcomes an ongoing discussion on the merits and key challenges of the various pathways available. FortisBC has a long-standing role in serving British Columbians and, by engaging with the communities it serves, the company aims to continue providing low carbon, affordable, and reliable energy in the decades to come.

Guidehouse is a leading global provider of consulting services to the public and commercial markets with broad capabilities in management, technology, and risk consulting. We help clients address their toughest challenges with a focus on markets and clients facing transformational change, technology-driven innovation, and significant regulatory pressure. Across a range of advisory, consulting, outsourcing, and technology/analytics services, our teams help clients create scalable, innovative solutions that prepare them for future growth and success. Headquartered in Washington, DC, the company has more than 7,000 professionals in more than 50 locations. Guidehouse recently completed the Gas Decarbonisation Pathway 2020-2050 study for the Gas for Climate consortium; the study analyzes the transition toward the lowest cost climate-neutral system in Europe by 2050.

1. EXECUTIVE SUMMARY

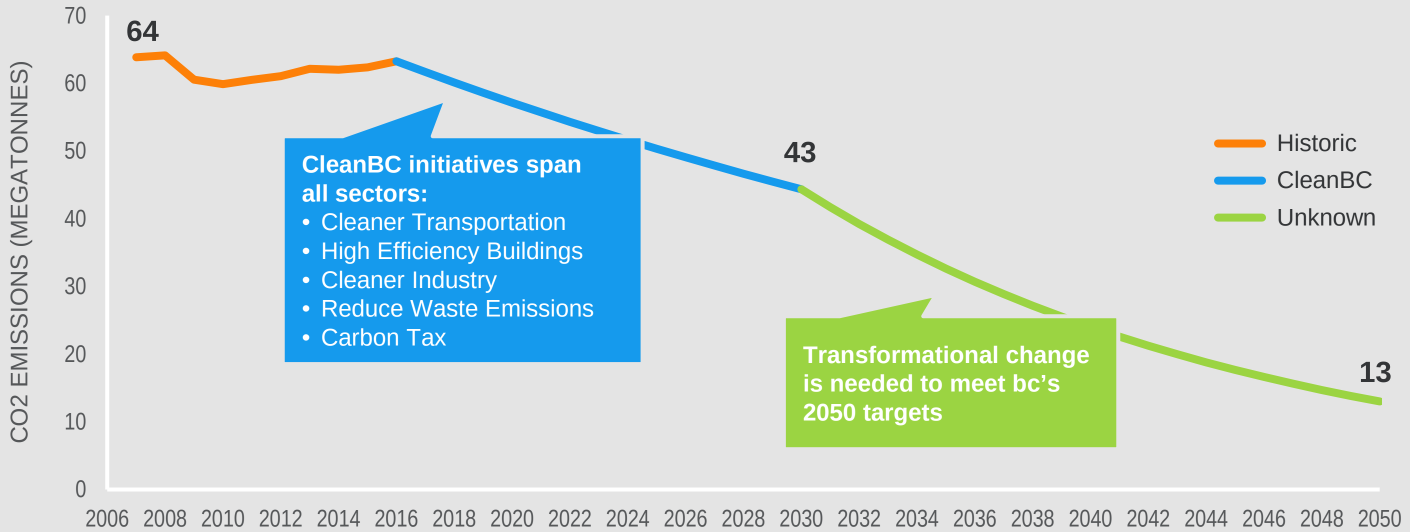
As part of its Climate Change Accountability Act, British Columbia (BC) has committed to reducing greenhouse gas (GHG) emissions to 80% below 2007 levels by 2050. The CleanBC plan puts the province on a path toward this goal, but only sets in action initiatives designed to meet a 2030 target (30% reduction below 2007 levels).[1] The pathway to meeting the 2050 goal is definable but a challenge. (Figure 1).

FortisBC commissioned Guidehouse to explore the role of the company's energy delivery system and the advantages that system could provide under ambitious decarbonization in the province. Over the past several years, Guidehouse has conducted detailed analyses of the role of utilities in decarbonization in Europe and North America.

Guidehouse experts have consistently found that a moderate, targeted approach to electrification tied with deployment of renewable gases while fuel switching away from petroleum is the most cost-effective and resilient method to achieve a lower carbon energy future.

To estimate the gas system's societal value, Guidehouse developed two energy pathways: an Electrification Pathway that focuses on deep electrification of all sectors, and a Diversified Pathway that includes a mix of expanded electrification and advances in low carbon gases and gas delivery infrastructure. The Diversified Pathway reflects the climate initiatives included in FortisBC's Clean Growth Pathway to 2050.

FIGURE 1. BC GHG EMISSIONS AND TARGETS



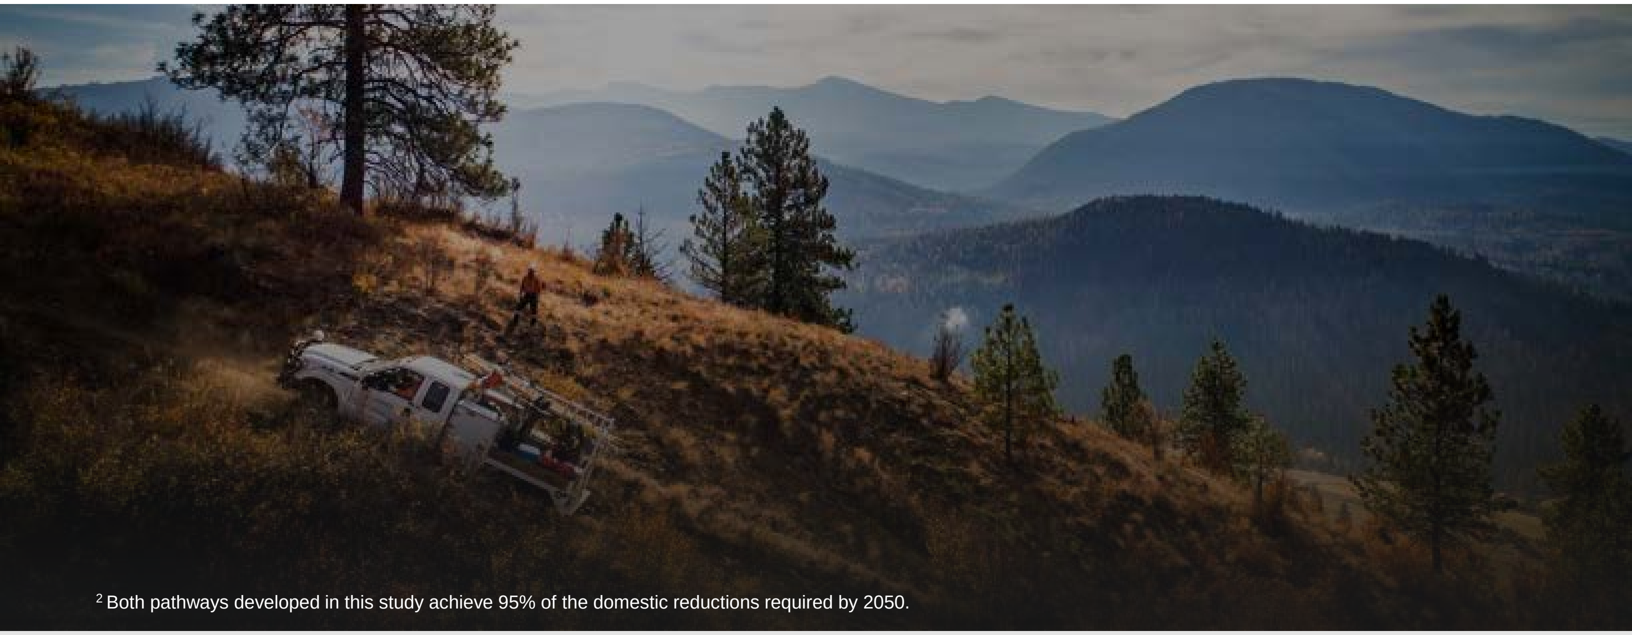
Source: Government of Canada – Canada's Greenhouse Gas Inventory; Government of British Columbia – CleanBC; Guidehouse Analysis

[1] The 30% reduction represents an adjustment of the interim 40% reduction by 2030 target, originally set in the Climate Change Accountability Act. The adjustment aligns with the provincial government's CleanBC plan, while the 80% reduction by 2050 target set in the Climate Change Accountability Act still stands.

The study's core conclusions are as follows:

- The Electrification and Diversified Pathways both achieve significant domestic GHG reductions in-line with the provincial government's 2050 targets.[2]
- The Diversified Pathway uses gas infrastructure and saves in excess of $100 billion by 2050.
- Both scenarios face challenges, including massive energy infrastructure deployment, and require significant technological improvement.
- Peak demand is an important factor that needs to be considered.
  - The Diversified Pathway will more efficiently meet customers' peak energy use.
- Peak demand in the Electrification Pathway would require thousands of megawatts of firm renewable electricity generation and energy storage to be built, which is made more difficult by the challenges of developing new large-scale hydroelectric power stations.

- Policy decisions made today will have long-term implications beyond the 2030 time horizon of CleanBC. Consequently, BC's approach to climate policy should consider how factors like peak demand will be met well beyond 2030 and what the long-term implications will be for costs.
- Hydrogen can be a key low or no carbon fuel that can be injected into the existing gas system. Hydrogen produced from renewable electricity can be stored in the gas system for use in peak times, which helps increase the value of renewable electricity in decarbonization pathways.
- The gas system provides valuable reliability and resiliency to the province's energy system. As decarbonization progresses, this resiliency increases in importance. As the gas system grows into serving new markets where decarbonization is more difficult, the system will be relied on as a fundamental tool. For example, liquefied natural gas (LNG) for international marine vessels is one of the primary near-term options to make meaningful GHG reductions.

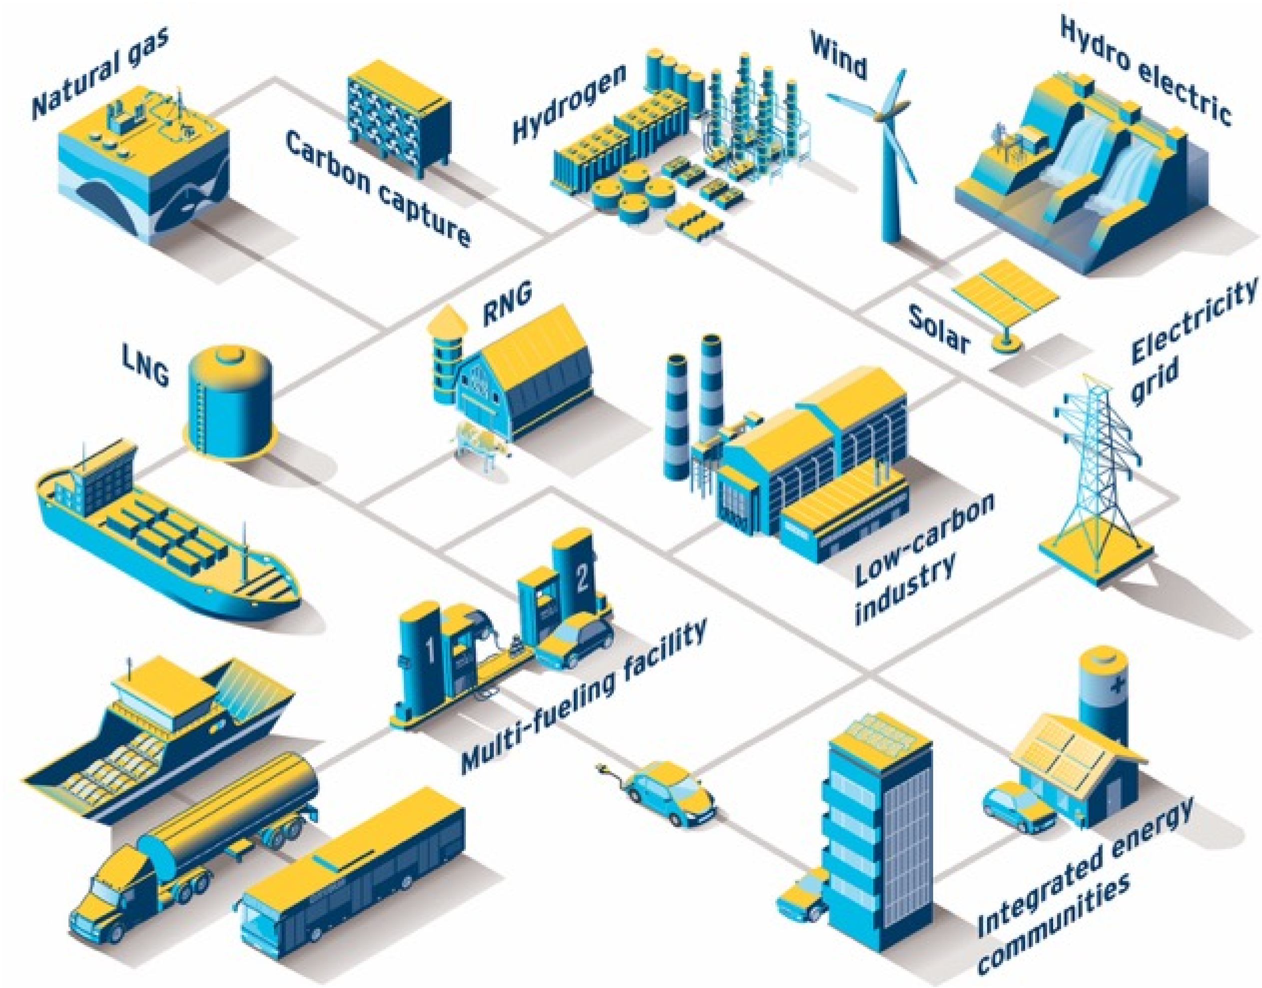


[2] Both pathways developed in this study achieve 95% of the domestic reductions required by 2050.

FortisBC's Clean Growth Pathway to 2050 is a diversified and flexible approach that supports BC's energy needs and GHG reduction targets. In 2050, gas infrastructure transports renewable natural gas (RNG), low carbon hydrogen (largely made from renewable electricity), and synthetic methane developed from captured carbon and hydrogen as well as natural gas. The system delivers this low carbon energy for specific end uses with high energy needs: space and water heating, medium and heavy duty (MHD) road vehicles, marine transportation, and industrial processes (Figure 2).

The Clean Growth Pathway also supports targeted electrification. Excess renewable power that would otherwise be curtailed or stored using expensive applications such as batteries or mechanical storage could instead produce hydrogen for use in the gas system.[3] In addition to providing flexible peak capacity, gas systems are key in stabilizing and securing the power grid, underpinning firm dispatchable electricity capacity and providing longer duration and affordable energy storage. Furthermore, Guidehouse's Gas for Climate study[4] demonstrates that deploying gas-fired dispatchable power (hydrogen and biomethane) as compared to more expensive solid biomass-fired dispatchable power can lead to annual cost savings of €54 billion across Europe.

FIGURE 2. FORTISBC'S CLEAN GROWTH NETWORK TO 2050



[3] It is unlikely that battery storage alone will be sufficient to meet the energy storage needs of the Electrification Pathway.

POLICY IMPLICATIONS

To moderate costs, reduce risks, enhance GHG reduction options, and maintain a reliable provincial energy system while achieving the 2050 goal, a number of outcomes need to be pursued:

- **Policy should be focused on fostering an integrated low carbon energy system.** It is critical to acknowledge that electricity and gas complement each other—both are needed and can reinforce each other. Taking a systemwide view of energy infrastructure that recognizes the value and coordinates the gas and electric systems to manage decarbonization affordability and resiliency provides the greatest overall benefits for BC.
- **Focus electrification efforts where they are most effective** to maximize limited ability to expand clean and firm generation resources. For example, in the passenger transport sector.
- **Prioritize the expansion and supply of renewable gas through a coordinated strategy** that invests in research and development (R&D), addresses policy barriers, and offers incentives for renewable gas development.
- **Support new technologies** that leverage the GHG reduction potential of the gas system including gas heat pumps, compressed natural gas (CNG)- and LNG-powered commercial vehicles, and carbon capture and storage.
- **Maintain the operational and financial health of the gas system** to allow for continued investment in infrastructure and programs that align with the 2050 target.
- **Leverage the potential of the gas sector to reduce GHG emissions internationally** through LNG marine refuelling (referred to as bunkering) and LNG exports.
- **Consider the cost and source of energy post-2030** in current and ongoing policy decisions.

2. INTRODUCTION

This report discusses potential pathways for BC to achieve its 2050 GHG reduction target, focusing on the roles of the gas and electric systems in the province. The report takes a BC-specific view of decarbonization considering the province's unique energy systems and resources. The objective is to discuss the tradeoffs of different approaches and to emphasize important points to consider when embarking on a long-term decarbonization pathway. The report is organized into the following sections:

- **BC's Energy Systems:** Focuses on the roles of energy delivery infrastructure and key operational and practical considerations.
- **Study Approach:** Describes the methodology used to analyze decarbonization pathways for BC. This section also outlines the main differences between the pathways and the key inputs and assumptions that went into the analysis.
- **Study Results – Side-by-Side Comparison of Pathways:** Compares the outcomes of the analysis, pathways, and key considerations.
- **Other Benefits of Using the Gas System for Decarbonization:** Discusses other benefits, in addition to results from the analysis of decarbonization pathways, that emphasize the importance of the gas delivery system.
- **Conclusions:** Provides general conclusions of the study.

3. BC'S ENERGY SYSTEMS

BC has an expansive energy system that includes the following:

- A large electrical grid primarily administered by BC Hydro and FortisBC electric
- A gas system operated primarily by FortisBC gas and Pacific Northern Gas
- Vast amounts of renewable electric and natural gas resources

BC has a large supply of biomass that could be used to sustainably produce renewable energy such as RNG. BC is connected to the US and other Canadian provinces and territories through electric interties and natural gas pipelines.

BC'S NATURAL GAS AND ELECTRIC SYSTEMS TODAY

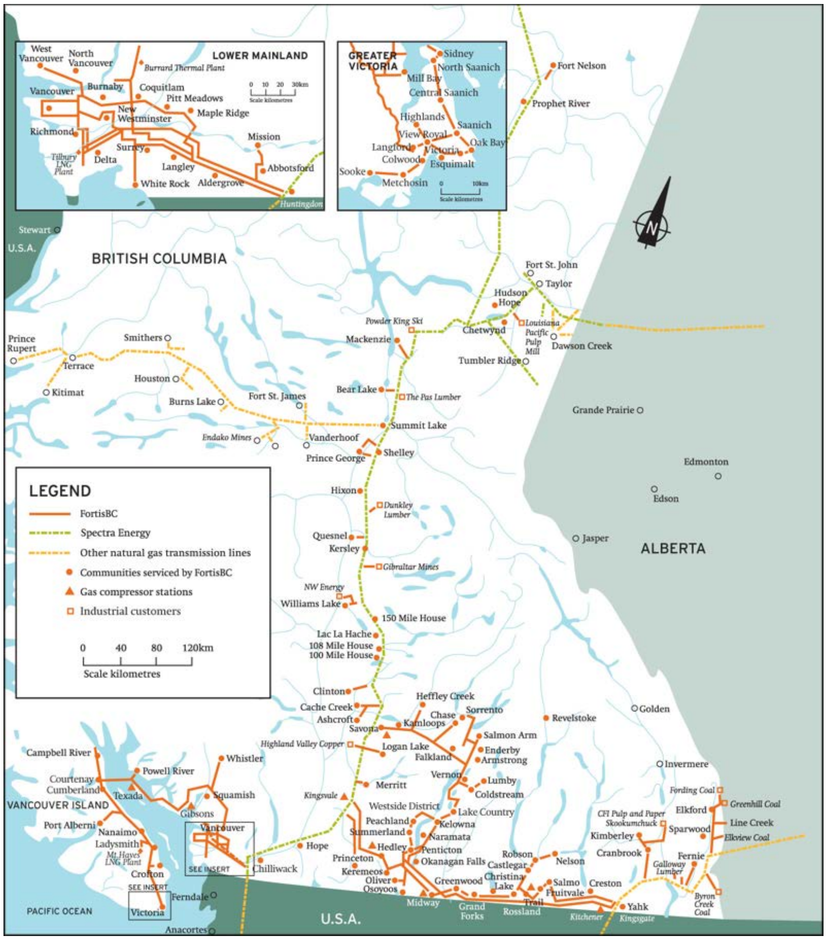
FortisBC operates approximately 49,000 km of natural gas transmission and distribution pipelines in BC. This infrastructure, along with the natural gas pipelines owned by Pacific Northern Gas, TC Energy, Enbridge, and other organizations, spans across the province. The system has multiple import/export points on the borders between Alberta, Yukon, and the US, as well as LNG on the west coast. All of this infrastructure is part of an integrated provincial system that represents billions of dollars of investment to supply natural gas to domestic markets and for export.

BC depends on energy delivered by the natural gas system (Figure 4). Over 30% of BC's total energy consumption[5] is transported through gas infrastructure.[6] Natural gas represents approximately 50% of residential and commercial end-use demand and almost 40% of industrial end-use demand in BC. The extensive coverage and interconnectivity of the gas network makes the system a critical vehicle to deliver low carbon energy to British Columbians.

BC also has an expansive electric system primarily administered by BC Hydro and FortisBC.

[5] Includes upstream energy consumption
[6] Canada Energy Regulator, "Canada's Energy Future 2019: Energy Supply and Demand Projections to 2040, Macro Indicators," accessed March 2, 2020.

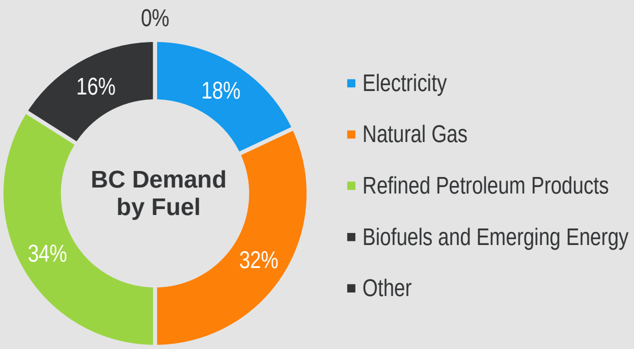
FIGURE 3. NATURAL GAS INFRASTRUCTURE SERVING BC

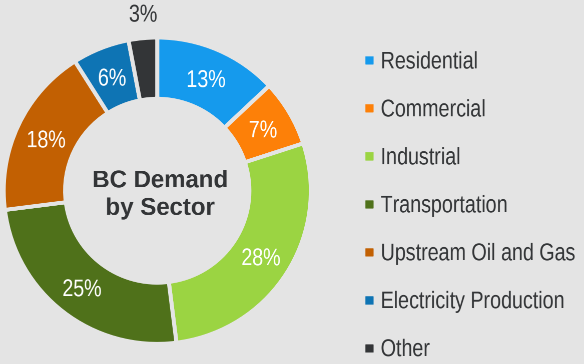


Combined, the two utilities serve over 2.16 million electricity customers through over 86,000 km of electric transmission and distribution lines. BC's electricity system is part of the Northwest Power Pool and is connected to Alberta and the US. Approximately 90% of BC's electric capacity is made up of hydro, with the remainder from wind, other renewables, and natural gas for peak electricity supply.

BC has large domestic resources of natural gas and electricity. In 2018, net electricity imports made up 2% of domestic generation. Over 90% of the natural gas consumed in BC is produced in BC (remaining supply is imported from Alberta). However, BC's total natural gas production is greater than its domestic demand and is exported to Alberta or the US. BC relies on deliveries from other provinces and from imports from the US for refined petroleum products like gasoline and diesel. BC imports almost double the volume of gasoline and diesel from Alberta and the US then it refines in domestic refineries.

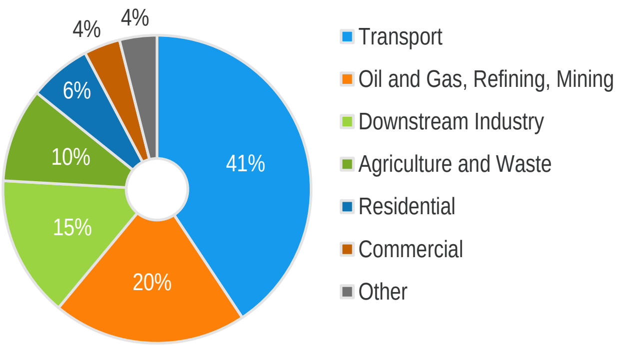
FIGURE 4. BC 2019 ENERGY DEMAND





Source: Canada Energy Regulator – Canada's Energy Future 2019 and CanESS (CANSIM)

FIGURE 5. BC EMISSIONS BY SECTOR



Source: BC GHG Inventory

The transport sector has the largest emissions footprint in BC, consisting of 41% of all GHG emissions (Figure 5). Industry, including oil & gas extraction and downstream manufacturing, makes up 35% of provincial GHG emissions. Residential and commercial buildings make up a comparatively smaller 10% of provincial GHG emissions.

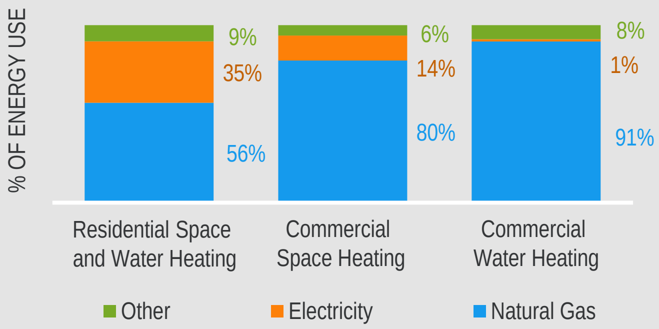
A focus on reduction of emissions across all sectors will be required to achieve the reductions targeted by 2050. Given the significant emissions associated with the transportation and industrial sectors, substantial efforts will be required in these sectors.

GAS SYSTEM IN BC ALLOWS FOR FLEXIBLE SUPPLY, SECURITY, AND STORAGE

Natural gas is one of the most flexible forms of energy because it can be stored relatively inexpensively for long periods of time. This flexibility allows the gas system to deal with large fluctuations in demand and volume, which is common in BC due to the seasonal nature of space and process heating loads in the province.

Most residential and commercial energy customers in BC depend on natural gas for space and water heating as well as cooking (Figure 6). Natural gas is also well-suited for combustion for heat. Many industries rely on natural gas because they can handle the high temperatures used in industrial applications. As well, natural gas use as a transport fuel for commercial vehicles and marine vessels is growing.

FIGURE 6. BC SPACE AND WATER HEATING BY SOURCE, 2016



Natural gas demand peaks in the winter and declines in the summer. Demand can be handled by the existing gas system seasonally. Figure 7 highlights the gas system's role in meeting peaks—i.e., the coldest days of the year.[7] On a summer day, throughput is approximately 3,000 MW, representing mostly water heating and industrial energy consumption. On an average winter day when most homes are using their gas heating systems, throughput on the system can increase by over three times and approaches the equivalent of 10,000 MW in electrical terms.

The gas system is designed to deliver significant volumes of energy to meet demand on very cold days. For example, on the coldest day in 2019, the volume of gas delivered was 40% higher than an average winter day and over three times the energy delivered on a summer day.

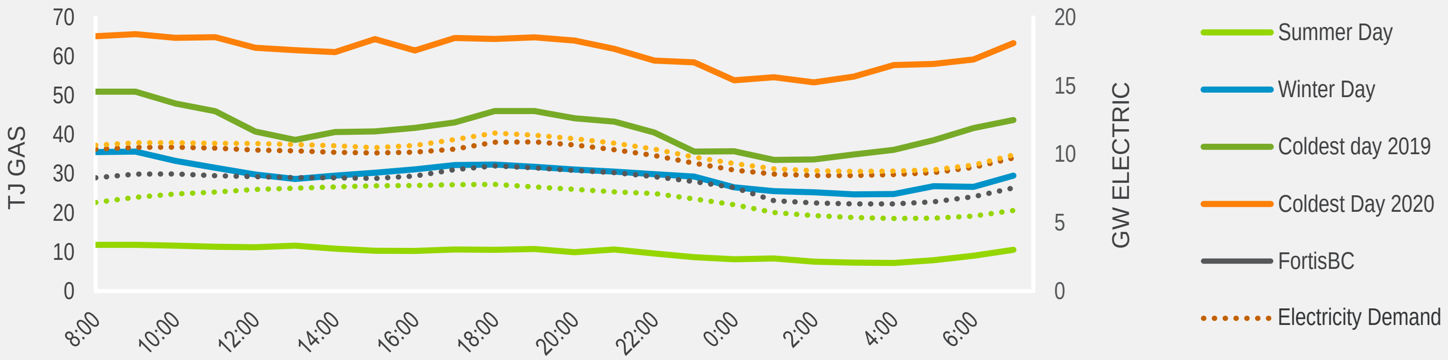
On a very cold day, such as January 14, 2020 when temperatures in the Lower Mainland approached -10°C, the energy delivered by the gas system can be double an average winter day and 50% higher than the coldest day in 2019.

The gas system provides critical versatility to meet peak energy demand. The electricity system needs to generate enough electrical energy at any one time to match the amount of consumption, whereas the gas system can store the energy and regulate flow on the system to meet demand. This means that electric systems need to have enough generating capacity to meet peaks while the gas system needs enough storage and pipeline throughput.

On January 14, 2020, the peak volume of gas delivered between 7:00 a.m. and 8:00 a.m. was equivalent to over 18,000 MW of electrical generating capacity, approximately 60% greater than the peak on the electric system during the same day and 50% larger than the entire hydroelectric generating capacity owned by BC Hydro (11,900 MW). While January 14, 2020 was one of the highest demand days on the gas system, some capacity remained to be distributed if demand continued to increase.

One of the gas system's main strengths is its ability to meet extreme peaks. It can store, ramp up, and deliver high volumes of energy on short notice and can handle large changes in volumes over time without operational, reliability, or financial strain. The electricity system would require significant investment to meet the province's space and water heating needs seasonally and daily in the electrification scenario.

FIGURE 7. HOURLY GAS AND ELECTRICITY DEMAND IN BC



Source: FortisBC

[7] Figure 7 represents actual natural gas flows in FortisBC's service territory. Electricity demand is gross telemetered load on BC's electricity transmission system.

The ability of natural gas to be stored adds to its value as a reliable energy source. FortisBC's affiliate, Aitken Creek Gas Storage, owns a large underground natural gas storage facility, which has over 90 PJ of gas storage to provide seasonal storage.[8] Gas storage is low cost—on average, the cost of storage at Aitken Creek is approximately $1 per GJ or 0.3 cents ($0.003) per kilowatt-hour in electricity storage equivalent.

Although electric storage costs are falling significantly, they are still much more costly between $50 and $90 per GJ equivalent comparatively.[9] In addition to Aitken Creek, several smaller natural gas storage facilities exist throughout BC. Natural gas is injected into seasonal storage in summer months when demand is low and is withdrawn in the winter when demand for natural gas is higher. Low cost gas storage allows for year-round gas production and for production to deviate from gas consumption. Storage more effectively manages the costs of gas production and disruptions in production when they occur.

Gas can also be stored in the transmission pipelines themselves—typically referred to as line pack. Transmission pipelines operate within a minimum and maximum pressure as determined by the volume of gas in the line. Line pack can allow segments of the gas line, for short periods in a day, to deliver more gas per hour to consumers than is being delivered per hour by suppliers.

Line pack poses small incremental costs and can be cycled, meaning it can be maintained or used with relative ease. The estimated seasonal variation in line pack of FortisBC's transmission pipelines between a period of high demand and low demand can be as high as 0.15 PJ. In electrical terms, this would be equivalent to 40 GWh—over 30 times larger than the entire electrical energy storage capacity of utility-scale batteries in the US in 2018.[10]

Natural gas and the gas delivery system can serve a critical role in extreme conditions. Global climate change has resulted in the increased prevalence of wildfires, which can severely impact electricity systems. California has experienced severe wildfires in recent years, including a 2019 wildfire that resulted in mass evacuations and blackouts, leaving millions of people without electricity.[11] A study by the California gas and electric utilities indicated that Southern California Gas' natural gas storage assets has played a vital role in addressing emergency situations like extreme weather and wildfires.[12]

Over the past 20 years, the average number of hours a customer is without electric power in a year has increased. With the large expected growth in electricity demand, this trend is expected to continue, highlighting the importance of natural gas use as a heating source; its use is especially important during the cold winters experienced in many parts of BC.

4. STUDY APPROACH

The Electrification and Diversified Pathways developed in this study achieve 95% of the domestic reductions required by 2050.[13] The remaining emissions are assumed to be addressed with continued advances in technology and changing consumer behaviors, as well as emissions reductions related to non BC-specific initiatives (e.g., commercial airline emissions reductions). The pathways differ in the extent to which renewable electricity and low carbon gas play a role in the scenarios. The Electrification Pathway aims to increase the use of electricity for all applicable end uses, so renewable and low carbon natural gas use is limited to those sectors where no alternatives are available. In the Diversified Pathway, renewable and low carbon natural gas is used to its full potential.

Guidehouse worked closely with FortisBC to characterize initiatives under each pathway that could contribute to reducing GHG emissions. The goal of the characterization was to identify, understand, and define GHG mitigation options relevant for BC and to develop a common understanding of initiatives to implement in the model and analyze deeply. Guidehouse leveraged other studies it conducted on the role of the gas system in decarbonization, as well as FortisBC's internal research group and BC-specific research, to build a set of technologies and initiatives that were characterized and input into the Canadian Energy Systems Simulator (CanESS), an economy-wide model. Guidehouse also used data from the BC Climate Action Secretariat to align modelling assumptions with those used in the CleanBC climate plan. Figure 8 highlights how initiatives were developed across four major sectors and modelled into the two pathways, which were compared to a business-as-usual (BAU) scenario.

[13] This study develops two future scenarios to achieve BC's GHG reduction targets and analyzes the required changes to the energy system and incremental societal cost to the province. The intent of the study was to determine the extent of change required in BC to meet climate reduction targets. The economy-wide energy models used in this exercise are key tools to outline the magnitude of changes required over the coming decades. These models are built from historical data and are extrapolated into the future based on announced policy initiatives, observed historical trends, and other assumptions. As such, the results of this energy modelling engagement are intended to be indicative of possible future scenarios, but they are not intended to be taken as definitive results. Various opportunities for emissions reductions were not included in this analysis, including emissions trading, initiatives targeted at international sectors (e.g., airlines and shipping), etc.

Technologies and initiatives were selected with consideration for how practical and defensible they are. The total societal cost for each pathway was assessed by considering the consumer commodity costs, utility system costs, incremental infrastructure costs, consumer equipment costs, retrofit costs, and government subsidies (Figure 9). The costs of an underutilized gas system were also estimated to reflect additional costs to customers should gas system utilization be meaningfully reduced.

PATHWAYS

Table 1 shows how Guidehouse modelled the five major initiative categories differently across the two pathways. In general, the Electrification Pathway focused on energy efficiency, fuel switching to electricity for space/water heating, industrial processes, and transportation. The Diversified Pathway focused on energy efficiency, implementation of efficient gas end uses, and the deployment of renewable gas. **The analysis described in this section presents two pathways to achieving GHG emissions reductions. While both are theoretically potential pathways, they are not forecasts of the future.** Guidehouse welcomes an ongoing discussion on the merits and key challenges of various pathways available.

TABLE 1. INITIATIVES BY PATHWAY

Initiative	Electrification Pathway	Diversified Pathway
Electric Peak Demand	Peak demand increases to 21,600 MW in 2050, requiring 8,800 MW of new peak capacity versus the BAU case.	Peak demand increases to 17,700 MW in 2050, requiring 4,900 MW of new peak capacity versus the BAU case.
Renewable Gas	Of end-use natural gas demand, 35% (26 PJ) is served by renewable gas in 2050 (mix of hydrogen and renewable natural gas). Incremental 1.8 MT of carbon sequestered per year through carbon capture by 2050.	Of end-use natural gas demand, 73% (136 PJ) is served by renewable gas in 2050 (mix of hydrogen, renewable natural gas, and synthetic methane). Incremental 1.8 MT of carbon sequestered per year through carbon capture by 2050.
Transportation	Transition to 100% zero-emissions light duty vehicles. Significant role for MHD electric vehicles (EVs) (60% EV, 40% CNG/LNG and internal combustion).	Transition to 100% zero-emissions light duty vehicles. Significant role for gases in MHD vehicles (75% CNG, 20% EV, 5% fuel cell vehicles).
Fuel Switching	Transition 100% of residential and commercial space and water heating to electricity with electric heat pumps and other appliances, 20% of industrial fuel switching.	Transition up to 25% of residential and commercial space and water heating to electricity, 10% of industrial fuel switching.
Energy Efficiency	Improve envelope of 1.6 million homes and 436 million m^2 of commercial floor space.	Improve envelope of 1.7 million homes and 328 million m^2 of commercial floor space. Deploy gas heat pumps in ~70% of buildings.

Table 2 includes select modelling inputs that have a major impact on the results. These inputs have been informed by:

- Past engagements carried out by Guidehouse
- Pilot programs and research assessments carried out by FortisBC
- Discussions with key BC stakeholders
- Various public sources

The assumptions in the table represent theoretically possible future scenarios—they are not forecasts of the expected future by either Guidehouse or FortisBC.

TABLE 2. SELECT MODELLING INPUTS

Input	Assumption/Description
Cost of New Electricity Generation	$126/MWh was assumed in both pathways. This value represents an estimate of the expected cost of Site C[14] and is considered a conservative estimate of new renewable power costs. It is conservative because solar, wind, and energy storage costs are significantly higher and do not provide the same level of inter-seasonal storage. These higher priced renewable assets may need to be deployed due to the difficulty of developing large hydro in Canada. It is assumed that hydro resources will be available at the levels modelled in the pathways, which further assumes the deployment of multiple large hydro facilities (similar in size to Site C) in both pathways.
Renewable Gas Costs	RNG production costs were derived from Hallbar Consulting's report on RNG potential in BC and range from $14 to $28 per GJ.[15] It is assumed that progress will be made in wood-to-RNG technology to achieve the levels of RNG modelled in the two pathways. Green hydrogen (i.e., hydrogen produced with renewable electricity) and synthetic methane costs were developed from current production cost estimates (roughly $40/GJ for hydrogen, ~$10/GJ extra to create synthetic methane based off FortisBC pilot projects). These costs were extrapolated for the forecast, taking into consideration cost declines due to technology improvements. Guidehouse also aligned hydrogen production costs with the cost of renewable electricity because that is the primary input for producing green hydrogen. The weighted average cost across all renewable gases for each pathway in 2050 are: • Electrification Pathway: $19/GJ ($0.068/kWh equivalent) • Diversified Pathway: $23/GJ ($0.083/kWh equivalent) The Diversified Pathway renewable gas cost is higher because it requires more RNG at higher prices and includes a small amount of synthetic methane, which is the most expensive renewable gas.
Peak Demand Impacts	Annual hourly load shapes were selected or developed using public sources for each of the initiatives described in Table 1. These load shapes were applied to the energy consumption of each initiative to determine peak demand impact.
Electric Heat Pump Characteristics	Electric heat pump costs were modelled to align with the BC Conservation Potential Review, which included a specific assessment of the achievable potential of electric heat pumps in BC. The incremental cost for electric heat pumps was modelled as approximately $376 per residential household and $16,500 per 1,000 m^2 of commercial floor space. Electric heat pumps were modelled with 190% efficiency for both residential and commercial applications.[16] This efficiency depends on climate and likely will vary by region within BC.

[14] Guidehouse calculated a levelized cost of energy (LCOE) for Site C based off capital cost estimates from the BCUC Site C inquiry, historical financials from BC Hydro, and internal estimates. The results were benchmarked against Lazard's published LCOEs.

[15] Hallbar Consulting, *Resource Supply Potential for Renewable Natural Gas in B.C.*, March 2017, https://www2.gov.bc.ca/assets/gov/farming-natural-resources-and-industry/electricity-alternative-energy/transportation/renewable-low-carbon-fuels/resource_supply_potential_for_renewable_natural_gas_in_bc_public_version.pdf.

[16] The 190% value is a conservative estimate for heat pump efficiency, which aligns with a baseline assumed efficiency for air-source heat pumps in Guidehouse's 2019 BC Conservation Potential Review. This conservative assumption was used to attempt to represent provincial efficiency as a whole because heat pump efficiency is assumed to vary significantly by climate zone.

Input	Assumption/Description
Gas heat Pump Characteristics	Gas heat pump costs were derived from a heat pump feasibility study provided by FortisBC and interviews with developers.[17] Initial costs were set at roughly $6,800 and $45,000 for a residential home and commercial building, respectively. Both residential and commercial gas heat pumps were modelled with a 140% gas utilization efficiency. This efficiency depends on climate and likely will vary by region within BC.
Natural Gas System Utilization	The utilization of the gas system differs significantly between the two pathways. In the Electrification Pathway, the 2050 throughput drops to roughly 40% of the 2019 throughput. Conversely, the 2050 throughput of the Diversified Pathway is not significantly less than the 2019 throughput.[18] Electrification Pathway: • 2019 throughput = 200 PJ • 2050 throughput = 75 PJ Diversified Pathway: • 2019 throughput = 200 PJ • 2050 throughput = 186 PJ

CanESS, which Guidehouse used to complete the pathway modelling, is an integrated, multifuel, multisector, provincially disaggregated energy systems model for Canada. CanESS enables bottom-up accounting for energy supply and demand, including energy feedstocks (e.g., coal, oil, natural gas), energy-consuming stocks (e.g., vehicles, appliances, dwellings), and all intermediate energy flows (e.g., electricity), including interprovincial imports and exports that may offer incremental opportunities to contribute to achieving regional GHG reduction targets.

Note: CanESS projections were based on extended trends observed in historical data (key data sources include CANSIM, Natural Resources Canada, and Environment Canada) and projections obtained from the Canada Energy Regulator (CER, Energy Future 2017). In addition, CanESS projections account for the expected effects of all approved legislation and regulation (including the CleanBC plan) and was driven by the best publicly available data from government sources. (Canada Energy Regulator (CER), Canada's Energy Future 2017, https://www.cer-rec.gc.ca/nrg/ntgrtd/ftr/2017/index-eng.html)

[17] Posterity Group, Prefeasibility Study on Natural Gas Heat Pumps, May 2017.

[18] Gas system utilization includes only gas consumed by the buildings, industry, and transport domestic end-use sectors. Natural gas throughput for LNG for marine vessels and for international export are excluded.

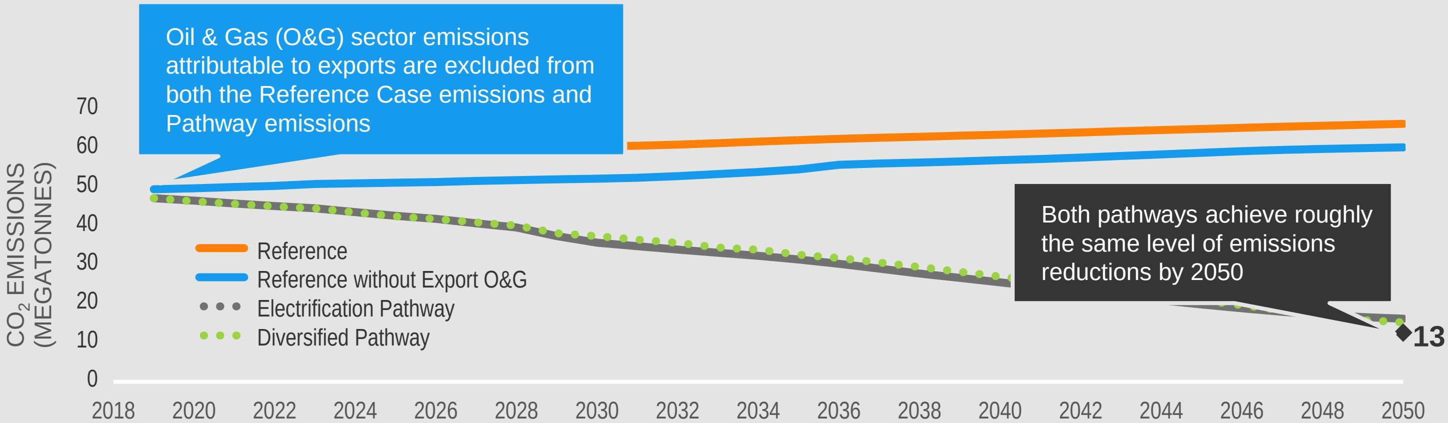
5. STUDY RESULTS – SIDE BY SIDE COMPARISON OF PATHWAYS

5.1 EMISSIONS REDUCTIONS

Each pathway meets 95% of the reductions required by 2050, representing greater than 32 million tonnes of CO_2e emissions avoided from BC annually in 2050 from a BAU scenario. The pathways use initiatives to different extents, but both pathways require transformative changes in every sector. The remaining 5% of emissions reductions must be achieved through initiatives that target sectors that cannot be modelled for BC in isolation—e.g., aviation fuel. These sectors are beyond the scope of this study.

The scope of this report is focused on BC's domestic GHG emissions. The pathways reduce domestic emissions by 80%. Emissions associated with energy exports, notably for LNG and other oil & gas for export, are separated out and are assumed to be addressed through a combination of nature-based carbon offsets, internationally transferred mitigation outcomes,[19] and technology improvements.

FIGURE 10. BRITISH COLUMBIA EMISSIONS REDUCTIONS UNDER ENERGY VISION PATHWAYS



Source: Guidehouse Analysis

As Figure 11 shows, light duty EVs have a large role to reduce GHG emissions in both pathways, as both pathways were modelled to include the Zero-Emission Vehicles [20] Act; the Zero-Emission Vehicles Act requires 100% of light duty vehicles sold in 2040 to be zero-emissions vehicles.[21] MHD vehicles is the second-most impactful initiative in the Electrification Pathway, which has been modelled such that 60% of MHD vehicles on the road in BC are electric by 2050. The most impactful initiative to reduce BC's domestic GHG emissions in the Diversified Pathway is renewable gas, which results in over 5 million tonnes of emissions reductions in 2050 by transforming the natural gas fuel mix to be mostly made up of RNG and hydrogen. Energy efficiency in buildings is also a critical initiative in both pathways. This initiative results in over 3 million tonnes of reductions by 2050 through the implementation of improved building envelopes, high efficiency heat pumps, and commercial automated building controls.

[19] Internationally transferred mitigation outcomes are identified in the Paris Agreement to facilitate compliance with national GHG reduction goals through the trade of emissions reductions between nations.

[20] ZEVs are modelled in this study as EVs and fuel cell vehicles.

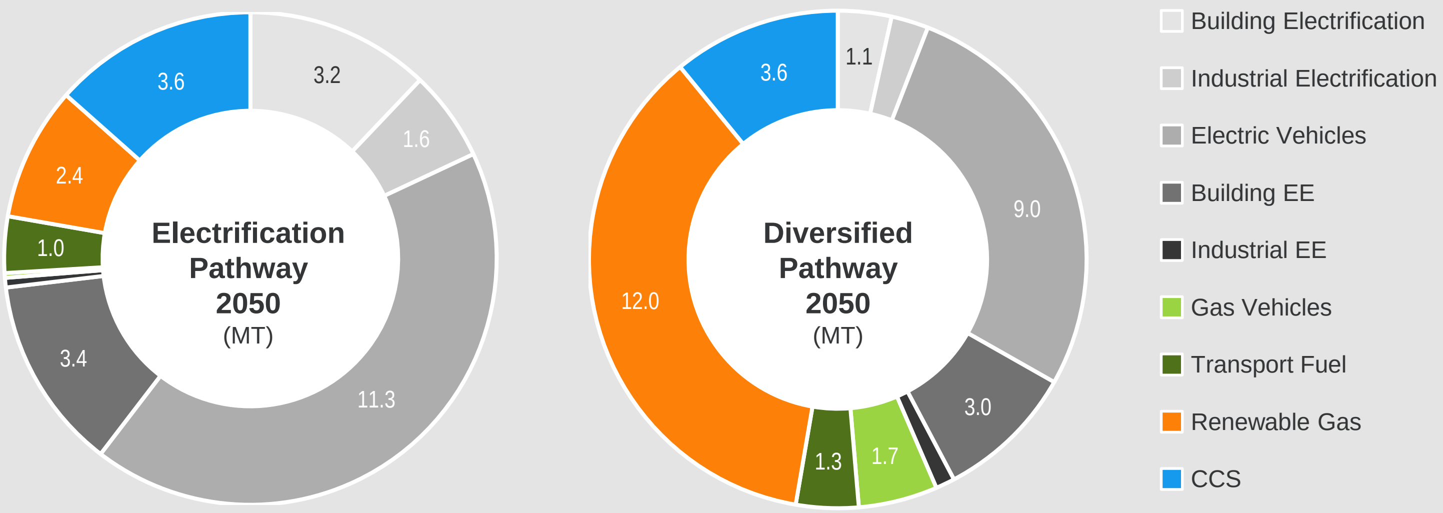
FIGURE 11. GHG REDUCTIONS BY INITIATIVE: 2050



* Note that summing up all the initiatives will not exactly match total emission reductions values in earlier slides. Source: Guidehouse Analysis

5.2 GAS SYSTEM ENABLES GHG EMISSIONS REDUCTIONS OUTSIDE BC

The gas system can also lead to GHG emissions reductions outside of BC. Although these reductions were not evaluated in this analysis, FortisBC has conducted separate evaluations on the role of the gas system to supply LNG to marine vessels and to displace carbon-intensive energy consumption in China with LNG exports. Both of these activities could have significant near-term emissions reductions.

For marine vessels, LNG from FortisBC's Tilbury facility has a 27% lower carbon intensity than the global average for LNG.

This means that LNG from FortisBC used in marine vessels would reduce life cycle emissions by between 20% and 27%. As the measures in CleanBC take hold, reducing methane emissions and extending electrification in natural gas production, LNG from BC could reduce GHG emissions by up to 30% and would make the carbon intensity of LNG from Tilbury half that of the global average. Because the GHG emissions associated with international marine vessels in their journeys to and from ports in BC are higher than BC's total annual GHG emissions, this would make an important contribution to global GHG reduction efforts.[22]

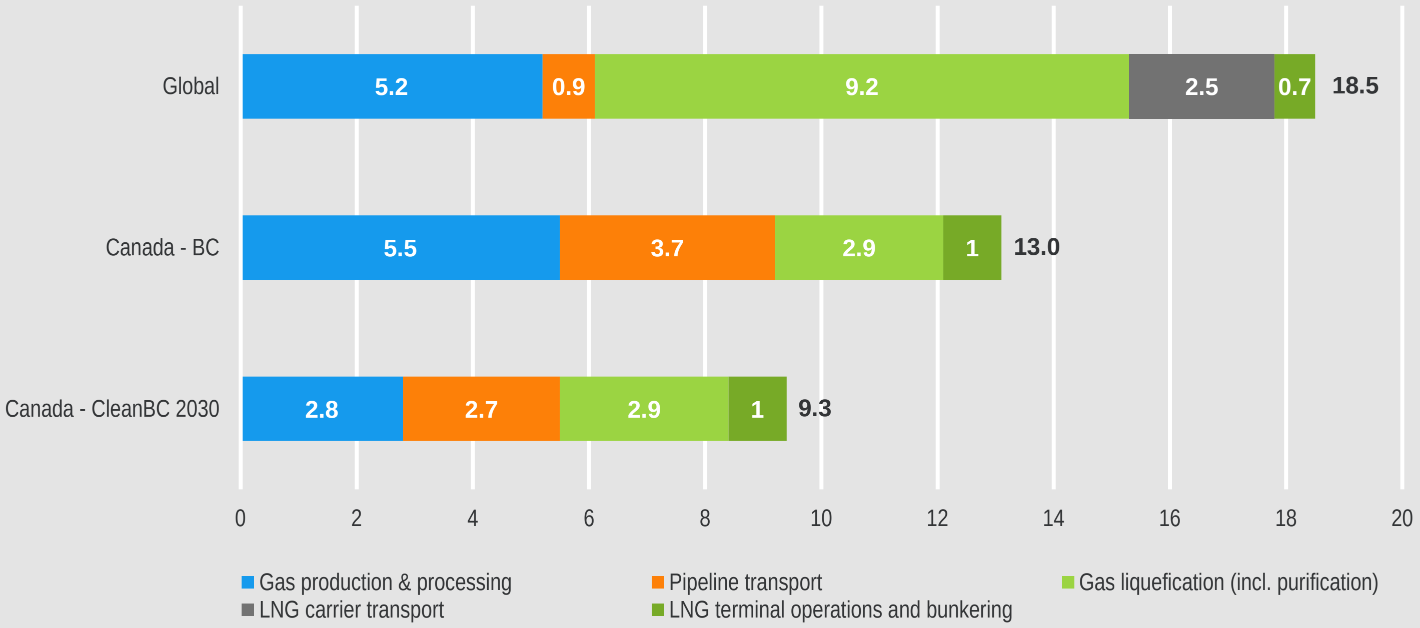
FIGURE 12. WELL TO TANK LNG CARBON INTENSITIES (g CO_2e/MJ)



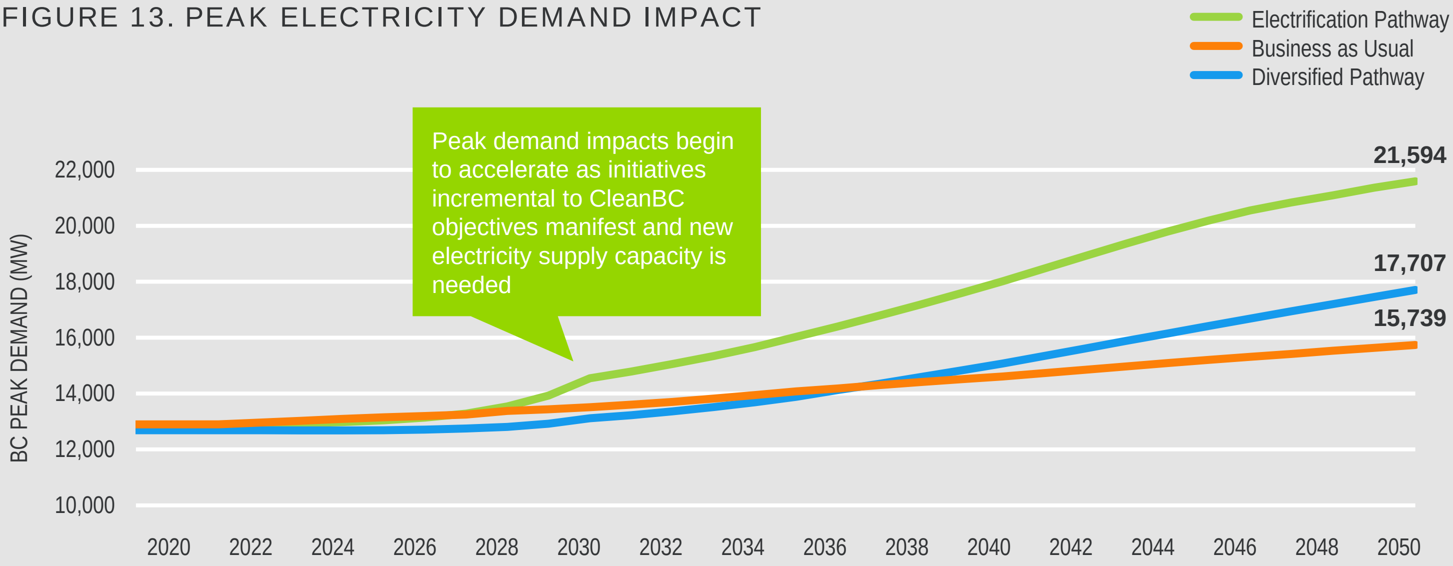
Source: Thinkstep, Life Cycle GHG Emissions of the LNG Supply at the Port of Vancouver: 2nd Project Phase, 2020

5.3 GROWTH IN LOW CARBON ENERGY SUPPLY

The 2050 peak demand of the Electrification Pathway is estimated to be 68% higher than the peak electricity demand of 2018. This will require the deployment of over 8,700 MW of peak capacity in the Electrification Pathway, which is double the requirement for the Diversified Pathway and triple the BAU requirement. The peak demand in both pathways increases from 2018 levels because of the significant deployment of EVs, electric heating, and fuel switching. However, the net increase in peak demand is significantly higher in the Electrification Pathway.[23] To achieve the 2050 GHG reduction targets, peak demand must be met with low or no carbon firm generating capacity. In this study, Guidehouse used the lowest cost supply option for peak capacity—hydroelectric generation. There are practical limitations to developing new hydroelectric generation in BC, however. This report does not assess those limitations but acknowledges other sources of peak capacity may be preferred.

[23] Peak demand impacts are based on conservative assumptions in both pathways (e.g., majority of MHD vehicle charging occurs in non-peak times).

FIGURE 13. PEAK ELECTRICITY DEMAND IMPACT

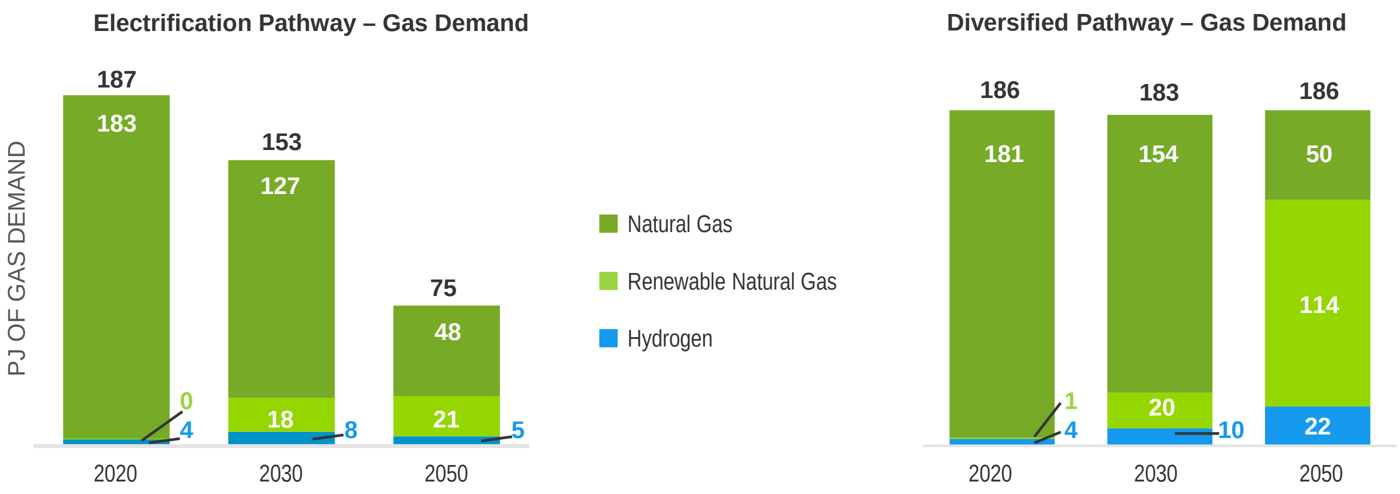


*Peak demand impacts are based on conservative assumptions in both pathways (e.g., majority of MHD vehicle charging occurs in non-peak times)
Source: Guidehouse Analysis

Natural and renewable gases are critical in the Diversified Pathway and support a more robust energy system in the province. Figure 14 shows that renewable gases will make up 35% of natural gas demand in the Electrification Pathway by 2050, aligning with current BC targets. Renewable gases make up 73% of natural gas demand in the Diversified Pathway.

In the Electrification Pathway, total gas demand declines by almost 60% between 2020 and 2050, while total gas demand (natural gas and RNG) remains flat during the same period in the Diversified Pathway.

FIGURE 14. END-USE GAS DEMAND IN EACH PATHWAY



Note: End-use natural gas demand includes consumption in residential and commercial buildings, industry, and transport but excludes gas consumption in upstream gas extraction, processing, and transmission.

Source: Guidehouse Analysis

TABLE 3. RENEWABLE GAS DESCRIPTIONS

Renewable Gas	Assumption/Description
Renewable Natural Gas (RNG)	RNG is natural gas created from renewable energy sources such as organic waste (i.e., from landfills) and agricultural waste. Guidehouse used a report by Hallbar Consulting commissioned by the Province of British Columbia, FortisBC, and Pacific Northern Gas to determine the level of RNG potential in BC and its associated production costs. The RNG amounts modelled in 2050 align with the long-term technical potential in the Hallbar Consulting report, which assumes improvements will be made in wood-to-RNG technology. It is assumed RNG can be injected directly into existing natural gas infrastructure without any associated complications, and all associated costs are covered in the production costs.
Hydrogen	Two types of hydrogen were considered in this report: green hydrogen, which is produced from an electrolysis reaction of renewable electric power with water, and blue hydrogen, which is produced from fossil fuel natural gas and cleaned up using carbon capture and storage. Blue hydrogen is cheaper than green, and its cost is not forecast to decline significantly in the forecast period. Guidehouse modelled the hydrogen mix to increasingly be composed of green hydrogen under the assumption that costs are likely to decline. Green hydrogen costs were based off production cost assessments from the *British Columbia Hydrogen Study*[24] and are forecast to decrease due to technology improvements. Guidehouse benchmarked these costs with production costs observed in other regions (e.g., Europe).[25] Green hydrogen costs are highly dependent on the price of electricity, so Guidehouse aligned the forecast to the cost of new renewable power in the future. Hydrogen was modelled to make up a maximum of 15% (by volume) of BC's natural gas mix to represent the estimated operational limitations of the gas system to incorporate higher volumes.[26]
Synthetic Methane	Synthetic methane is hydrogen that has been upgraded with CO_2 to create methane (CH_4) and that can be safely injected into the natural gas mix at any level. Synthetic methane is modelled as the most expensive renewable gas because its price includes the cost of hydrogen plus an incremental cost related to carbon capture and storage to provide the required CO_2. Guidehouse only modelled the production of synthetic methane when the requirement for renewable gas exceeded both the technical potential of RNG and the physical limit of hydrogen (i.e., 5% of the fuel mix).

Electricity's share of the energy supply increases significantly in both pathways. Refined petroleum, which makes up over 33% of total end-use energy demand in BC, will decline to less than 15% of end-use demand by 2050 in both pathways. This decline is due to the widespread adoption of vehicles that use alternative fuels to diesel and gasoline in both pathways—i.e., electric, fuel cell, CNG, and LNG. This analysis highlights the importance, costs and scarcity of low-carbon energy whether in the form of renewable gas molecules for the gas system or electrons through the electric grid.

Maximizing the potential of clean electrons or clean gas molecules should be pursued to harness the differences between these energy carriers. Because of the high cost of building new clean reliable electricity generation and transmission, electrification initiatives should be matched to their most effective and valued uses to reduce GHG emissions, while natural gas and renewable gas molecules should be delivered to end-uses where there are high-costs of electrifying and/or the GHG reduction potential is lower. This integrated approach to system-wide decarbonization should be pursued rather than a compartmentalized sector by sector approach.

[24] Zen and the Art of Clean Energy Solutions, British Columbia Hydrogen Study, June 2019, https://www2.gov.bc.ca/assets/gov/government/ministries-organizations/zen-bcbn-hydrogen-study-final-v6.pdf.

[25] Guidehouse, Gas Decarbonisation Pathways 2020–2050, April 2020, https://gasforclimate2050.eu/?smd_process_download=1&download_id=339.

[26] A maximum hydrogen blend concentration by volume in FortisBC's gas system is being analyzed and depends on several factors. FortisBC is conducting feasibility studies to outline the minimum safe blending volume with the current system. The gas system can also adapt over the coming decades as scheduled maintenance, asset integrity, and operational management advancements and infrastructure upgrades offer opportunities to increase the system's compatibility with hydrogen.

Renewable gases have been an area of growing interest around the world. Large utilities in North America are moving to expand the supply of RNG into their portfolios. In Quebec, the provincial government has set a 5% RNG blend target by 2025 and has devoted $70 million to increase the production of RNG. Southern California Gas has set a corporate target to expand RNG supply to 20% of its throughput in 2030. In some European countries, promotion of biogas and RNG has been an ongoing policy objective. Denmark is producing over 15 PJ of biogas, with approximately 10% of the throughput through its gas grid being RNG. In France, the government has set an objective to inject 10% RNG into the country's pipelines by 2030.

Hydrogen is also taking on a larger role in meeting global energy needs. Natural gas utilities in France recently recommended the government set a hydrogen target of 10% of the natural gas mix in 2030, increasing up to 20% thereafter.[27] The Guidehouse Gas for Climate work in the EU demonstrates support in the EU for setting a binding mandate for 10% gas from renewable sources (i.e., RNG and green hydrogen) by 2030. [28] Hydrogen is being considered as a replacement fuel for coal in electricity production. The largest municipal utility in the US, Los Angeles Department of Water and Power (LADWP), announced it would transform a coal-fired plant to run on green hydrogen. LADWP plans to run the coal plant on a blend of 30% hydrogen, 70% natural gas by 2025. By 2045, the plant is expected to be run completely on hydrogen.[29]

5.4 COST COMPARISONS

By 2050, the societal value of the Diversified Pathway is expected to be at least $100 billion higher than the Electrification Pathway. The cost of each pathway is roughly the same until the mid-2030s, when the costs of the Electrification Pathway rises much higher than the Diversified Pathway. This finding emphasizes the need to prioritize pathways over a longer time horizon because pathway costs represent incremental costs borne by society relative to the BAU case. These costs include commodity (the electricity and natural gas itself), infrastructure (the poles, wires, and pipelines needed to deliver energy), and initiative costs (the cost of efficient alternatives to existing equipment and fuel).

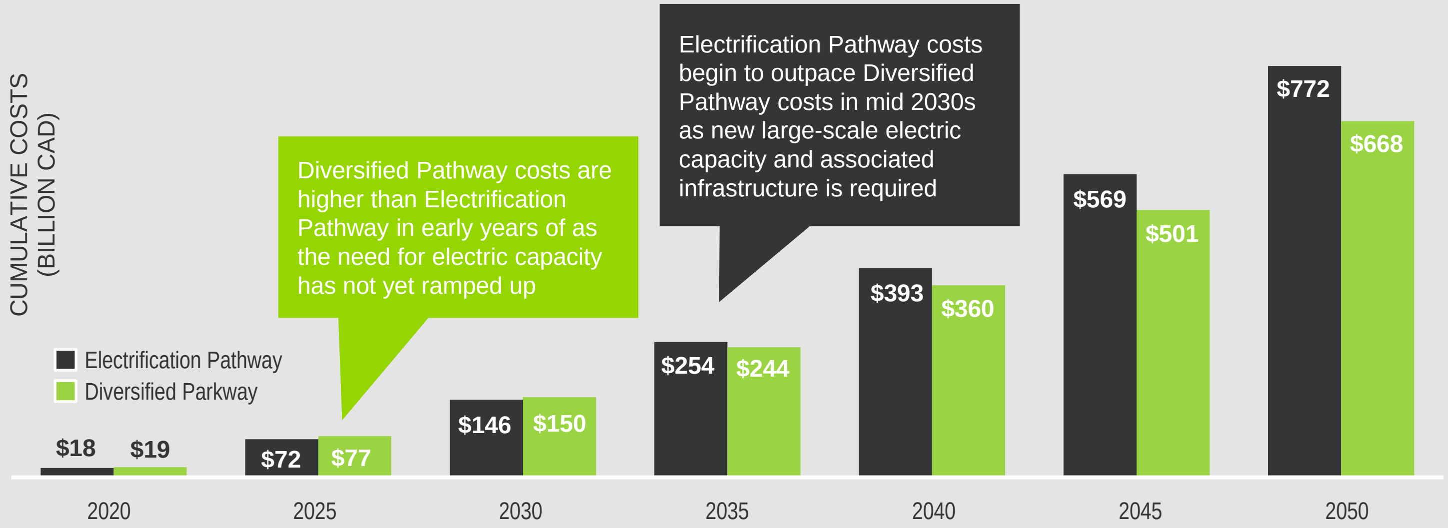
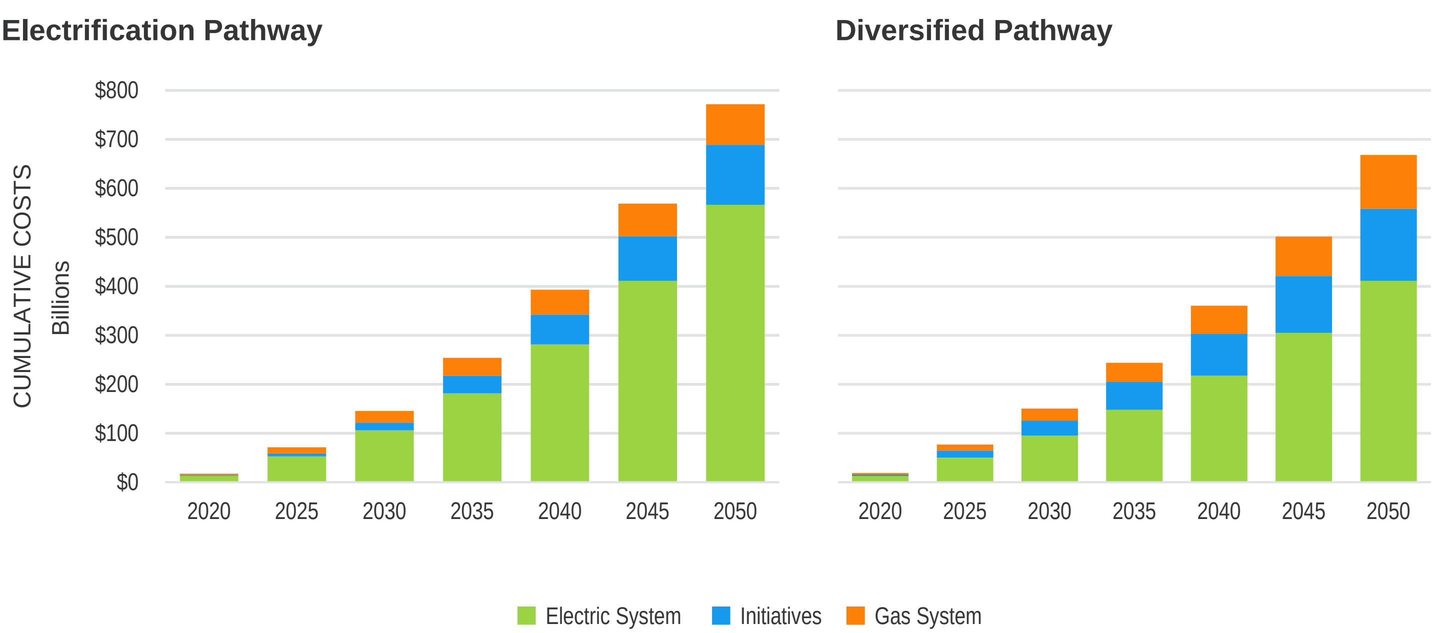
FIGURE 15. PATHWAY COSTS



Source: Guidehouse Analysis

The Diversified Pathway has higher initiative and gas system costs but significantly lower electricity system costs than the Electrification Pathway. Figure 16 compares the Diversified Pathway costs relative to the Electrification Pathway costs; the text following the figure describes the costs by component.

FIGURE 16. PATHWAY COSTS BY COMPONENT



Source: Guidehouse Analysis

- **$155 billion less spent on the electricity system:** Electricity system costs represent the incremental infrastructure needed to meet peak demand in both pathways. These costs include generation asset buildout, currently modelled to be the implementation of several large hydro generating stations in each pathway. These costs also include transmission and distribution infrastructure—this is money spent on the delivery system itself as opposed to the energy that passes through it. The Electrification Pathway has significantly higher electricity system costs due to the comparatively higher peak demand requirements.

- **$25 billion more spent on initiatives:** These initiatives are summarized in Table 1 and include vehicles, building envelope improvements, space and water heating, industrial process improvements, and renewable gases. The Diversified Pathway has higher initiative costs than the Electrification Pathway due to the large amount of renewable gas needed to decrease emissions. Further, the Diversified Pathway implements higher priced energy efficiency initiatives (e.g., gas heat pumps are more expensive than electric heat pumps).

- **$26 billion more spent on the gas system:** Gas system costs represent the expenses associated with the maintenance and operation of gas infrastructure. The Diversified Pathway has higher gas system costs because there is higher throughput during the forecast period.

The costs for both electric and natural gas ratepayers is higher in the Electrification Pathway as compared to the Diversified Pathway. Costs for electricity customers are higher because of the higher system costs in the Electrification Pathway, which are passed on to customers through electricity rates. Costs for natural gas customers are higher because significant reductions in gas consumption will not be enough to offset the cost of operating the system for a smaller number of remaining customers.

A cost sensitivity analysis was completed to determine the impact of a number of variables and found that cost drivers could increase the cost differential between the two pathways by $5 billion to $7 billion, or could narrow the gap by $5 billion to $12 billion. If conservative assumptions about key factors including the capital cost, the capital structure, or the cost of RNG or hydrogen are lower than expected, the cost differential between the two pathways will be greater. If these costs are higher, the Diversified Pathway will still be less expensive than the Electrification Pathway.

6. OTHER BENEFITS OF USING THE GAS SYSTEM FOR DECARBONIZATION

FortisBC asked Guidehouse to look at the total benefits of the gas system in BC. From a modelling perspective, the Diversified Pathway can achieve the same level of emissions reductions as the Electrification Pathway at a significantly lower cost in BC. In addition, the gas system can deliver other benefits related to security, stability, and flexibility that can advance BC's work toward a low carbon future.

GAS SYSTEM ALLOWS FOR A BROADER SET OF SOLUTIONS TO REDUCE EMISSIONS

Using the gas system to achieve GHG reductions diversifies the approach across multiple energy systems. A pathway that focuses on electrification could have higher risks should key barriers like developing new peak demand emerge. A broader approach to GHG reductions further into the scenario period could lower the risk of missing BC's 2050 target.

A significant amount of R&D has gone into various electrification and renewable technologies, resulting in widespread acceptance and economies of scale. For example, the cost on a dollars-per-watt basis of distributed solar PV has dropped over 55% between 2011 and 2018 (-11% compound annual growth rate). However, the opportunities for advancement in electrification may be reaching saturation and the development and improvement of some of these technologies is declining (e.g., the rate of solar PV cost declines is expected to slow down in the coming decade).[30]

There is more opportunity for R&D and efficiency improvements in the gas supply and corresponding end-use equipment that can be investigated alongside electrification initiatives. This opportunity could result in more economic development and societal benefit than if only electrification measures were prioritized.

Renewable gases are a major target for innovation and can play a vital role in the future of the natural gas industry. RNG, hydrogen, and synthetic methane all have great potential for the province. BC has the potential to be a major producer of RNG given its large forestry industry, which produces a large amount of woody biomass. Technical advancements are needed to more efficiently convert wood biomass waste to RNG, and researchers and organizations are identifying recommendations for technological improvement.[31] Assuming this technology meets its potential in the coming years, BC's RNG production potential could be 90 PJ per year, representing almost half of the natural gas currently delivered by FortisBC.[32] This estimate assumes only wood waste within a 50 km-75 km of natural gas compressor stations is used. If this radius can be expanded, BC's RNG potential would increase further.

[31] Gas Technology Institute, *Low-Carbon Renewable Natural Gas (RNG) from Wood Wastes*, February 2019, https://www.gti.energy/wp-content/uploads/2019/02/Low-Carbon-Renewable-Natural-Gas-RNG-from-Wood-Wastes-Final-Report-Feb2019.pdf.

[32] Hallbar Consulting, *Resource Supply Potential for Renewable Natural Gas in B.C.*, March 2017, https://www2.gov.bc.ca/assets/gov/farming-natural-resources-and-industry/electricity-alternative-energy/transportation/renewable-low-carbon-fuels/resource_supply_potential_for_renewable_natural_gas_in_bc_public_version.pdf.

Hydrogen and synthetic methane also represent key initiatives to lower emissions in BC. Hydrogen and synthetic methane production technologies have not reached the limit of technical ability and offer a great opportunity for improvement through R&D and pilot projects.

Natural gas heat pumps are a gas-consuming technology that represent an opportunity for R&D and innovation. Gas heat pumps are more efficient than conventional gas space heating systems, but they have not yet reached their full market potential in Canada due to cost, availability, and other factors. However, there is strong federal support for gas heat pumps because they are expected to be instrumental in helping Canada meet its 2030 and 2050 emissions reductions targets.[33]

DROP-IN FUELS CAN BE MORE FEASIBLE AND COST-EFFECTIVE THAN FUEL SWITCHING

For many residences and businesses, switching to different heating systems may be difficult or undesirable. For policymakers focused on reducing GHG emissions, relying on broad-based fuel switching to different heating systems will involve mobilizing millions of building owners to switch. The policies and strategies to make this happen are not well understood or are infeasible.

Deploying low carbon drop-in fuels like renewable gas would leverage existing policy and regulatory frameworks and involve fewer players.[34] While it would be a challenge to develop the volume of low carbon fuels needed by 2050, governments and industry have experience in promoting low carbon energy in other sectors—notably in the electricity sector, where policy and financial incentives have led to a massive increase in renewable power investment. This model could be emulated for renewable gases.

The findings in this analysis suggest drop-in fuels would be more cost-effective than fuel switching to electricity. The cost per tonne of reducing emissions in difficult-to-address sectors like buildings with renewable gases is approximately half that of fuel switching when accounting for the full system cost impacts. Figure 17 shows that the cost per tonne to reduce residential building emissions by fuel switching is higher than reducing residential building emissions using low carbon fuels in both pathways. The components of each option are summarized below:

- Fuel switching includes residential electric heat pump costs, electric system impact costs (i.e., system buildout to meet peak demand), and energy costs to switch from electricity to gas. Both electric system impact costs and energy costs are net of energy efficiency improvements.
- Low carbon gas includes the deployment of RNG/hydrogen and the implementation of gas heat pumps, building envelope improvements, and other efficiency measures.

[33] Energy and Mines Ministers' Conference, *Paving the Road to 2030 and Beyond: Market transformation road map for energy efficient equipment in the building sector*, August 2018, https://www.nrcan.gc.ca/sites/www.nrcan.gc.ca/files/emmc/pdf/2018/en/18-00072-nrcan-road-map-eng.pdf.

[34] Drop-in fuel refers to a fuel that can be added to an existing energy system without significant reconfiguration.

FIGURE 17. COST PER TONNE OF FUEL SWITCHING VS. LOW CARBON GAS AND ENERGY EFFICIENCY

SOCIO-ECONOMIC IMPACT OF AN OPTIMIZED GAS SYSTEM

The Electrification Pathway would eliminate portions of BC's natural gas industry. This elimination may result in the loss of thousands of jobs and billions of dollars of unused gas pipelines that the province has committed to financially. As a result, the province will have an under-utilized gas system, which does not provide a significant benefit. The cost to maintain and oversee this infrastructure will adversely impact British Columbians. In contrast, the Diversified Pathway optimizes the gas system to continue to deliver low carbon solutions, resulting in higher societal value.

GAS SYSTEM CAN BE USED TO REDUCE GLOBAL CARBON EMISSIONS

BC has significant natural gas resources, with remaining raw reserves of approximately 1,165 billion cubic metres. Over 60 billion cubic metres of natural gas was produced in 2018.[35] However, domestic use will likely decrease over time to reach BC's 2050 target. BC's natural gas can be exported as LNG to Asia to displace higher carbon fuels like coal, which could result in a net reduction of global GHG emissions. BC's LNG can also power large ocean vessels, which would displace higher emissions fuels like diesel and heavy oil. An analysis conducted by thinkstep concluded that LNG from BC used in marine shipping could reduce GHG emissions by up to 27%.[36]

As the policies in CleanBC are implemented (e.g., electrifying upstream gas production and implementing regulations to reduce methane emissions), the carbon intensity of the LNG supply chain in BC in 2030 would be half that of the current global average.

MAINTAINING THE GAS SYSTEM WILL SPEED INNOVATION AND ALLOW FOR FLEXIBILITY IN FUTURE TECHNOLOGY SOLUTIONS

We have modeled two pathways that both nearly achieve the required GHG emission reductions in 2050. Each pathway has been modelled by relying primarily on existing proven technologies and solutions. Continued innovation is expected to accelerate decarbonization, particularly in years after 2030. Maintaining both the gas and electric infrastructure as part of the future energy system will provide more flexibility in which innovative solutions can be easily developed and deployed. This will allow BC to achieve accelerated deployment of innovations in clean technologies and even faster decarbonization.

ROLE OF THE GAS SYSTEM IN OTHER JURISDICTIONS

Guidehouse carried out an analysis similar to this one for Gas for Climate, a group of European natural gas companies. The group commissioned a study to assess the possible role and value for gas used in existing gas infrastructure in a net-zero emissions EU energy system compared to a situation in which a minimal quantity of gas would be used.

[35] BC Oil and Gas Commission, *British Columbia's Oil and Gas Reserves and Production Report*, 2018, https://www.bcogc.ca/node/15819/download.

[36] thinkstep, *Life Cycle GHG Emissions of the LNG Supply at the Port of Vancouver: 2nd Project Phase*, 2020.

The Gas for Climate analysis[37] involved developing two scenarios to meet the EU's decarbonization requirements by 2050:

- **Minimal gas scenario:** Almost full electrification of buildings, industry, and transportation sectors.
- **Optimized gas scenario:** Moderate electrification of the abovementioned sectors, as well as large deployment of renewable and low carbon gases in select applications (heavy road transport, building heating in peak demand times, and some electricity production).

Guidehouse found the following conclusions from the Gas for Climate analysis:

- Both scenarios meet EU decarbonization requirements by 2050.
- Both scenarios need substantial quantities of renewable electricity.
- Green/blue hydrogen and RNG can help meet heating and industrial needs at low/no carbon.
- Significant benefits exist in the optimized gas scenario related to energy flexibility (i.e., gas and electric systems are used).
- Higher societal value of optimized gas pathway (over €200 billion annually across the energy system by 2050).
- The cost to decommission the gas infrastructure (in minimal gas pathway) is high.

The results of this analysis mirror that of the FortisBC study and support to the concept that gas networks have a clear role in a decarbonized future.

[37] Guidehouse, *Gas Decarbonisation Pathways 2020–2050*, April 2020, https://gasforclimate2050.eu/?smd_process_download=1&download_id=339.

7. CONCLUSIONS

This analysis indicates that the Diversified Pathway can achieve the same level of provincial GHG emissions reductions as the Electrified Pathway at a significantly lower cost to British Columbians. Although initiatives are used to different extents, both pathways defined in this study would require transformative changes in every sector of BC's economy. By 2050, the societal value of achieving the Diversified Pathway is expected to be in excess of $100 billion higher than the Electrification Pathway.

Other benefits of maintaining a robust natural gas system are preserved by adopting a strategically diversified approach. The existing gas infrastructure represents a vital component to servicing current energy demand and can continue to benefit BC by providing security, flexibility, and storage to the overall energy system. The gas system delivers cost-effective energy services, energy reliability, and significant economic benefits to the province. The gas system also provides an opportunity for a broader set of technologies and initiatives to help achieve BC's 2050 GHG reduction goal.

Appendix A-3

HYDROGEN STRATEGY FOR CANADA

HYDROGEN STRATEGY FOR CANADA

Seizing the Opportunities for Hydrogen

A Call to Action

December, 2020

DISCLAIMER

The Hydrogen Strategy for Canada (the “Strategy”) provides the perspective of numerous stakeholders from across governments, and industry, as well as Indigenous organizations, non-governmental organizations, and academia. While the Government of Canada led the development of the Strategy and consulted broadly with industry, the contents, findings, and recommendations expressed in the Strategy reflects a combined view and may not be unanimously endorsed by all of the participating organizations and their employees.

Aussi disponible en français sous le titre : Stratégie canadienne pour l’hydrogène
Cat. No. M134-65/2020E-PDF (Online) ISBN 978-0-660-36760-6

Foreword to the Hydrogen Strategy for Canada

For more than a century, our nation's brightest minds have been working on the technology to turn the invisible promise of hydrogen into tangible solutions. Canadian ingenuity and innovation has once again brought us to a pivotal moment.

As we rebuild our economy from the impacts of COVID-19 and fight the existential threat of climate change, the development of low-carbon hydrogen is a strategic priority for Canada. The time to act is now.

The Hydrogen Strategy for Canada lays out an ambitious framework for actions that will cement hydrogen as a tool to achieve our goal of net-zero emissions by 2050 and position Canada as a global, industrial leader of clean renewable fuels.

This strategy shows us that by 2050, clean hydrogen can help us achieve our net-zero goal—all while creating jobs, growing our economy, and protecting our environment. This will involve switching from conventional gasoline, diesel, and natural gas to zero-emissions fuel sources, taking advantage of new regulatory environments, and embracing new technologies to give Canadians more choice of zero emission alternatives.

As one of the top 10 hydrogen producers in the world today, we are rich in the feedstocks that produce hydrogen. We are blessed with a strong energy sector, and the geographic assets that will propel Canada to be a major exporter of hydrogen and hydrogen technologies.

Hydrogen might be nature's smallest molecule but its potential is enormous. It provides new markets for our conventional energy resources, and holds the potential to decarbonize many sectors of our economy, including resource extraction, freight, transportation, power generation, manufacturing, and the production of steel and cement.

This Strategy is a call to action. It will spur investments and strategic partnerships across the country and beyond our borders. It will position Canada to seize economic and environmental opportunities that exist coast to coast. Expanding our exports. Creating as many as 350,000 good, green jobs over the next three decades. All while dramatically reducing our greenhouse gas emissions. And putting a net-zero future within our reach.

The importance of Canada's resource industries and our clean technology sectors has been magnified during the pandemic. We must harness our combined will, expertise and financial resources to fully seize the opportunities that hydrogen presents.

This strategy is the product of three years of study and analysis, including extensive engagement sessions, where we heard from more than 1,500 of our country's leading experts and stakeholders. But its release is not the end of a process. This is only the beginning.

Together, we will use this Strategy to guide our actions and investments. By working with provinces and territories, Indigenous partners, and the private-sector and by leveraging our many advantages, we will create the prosperity we all want, protect the planet we all cherish and we will ensure we leave no one behind.

The Honourable Seamus O'Regan
Canada's Minister of Natural Resources

Contributors

For the past three years, the Government of Canada, under the leadership of Natural Resources Canada, has been working with private sector stakeholders, Indigenous organizations, non-Government organizations, and governments at all levels to inform the development of a *Hydrogen Strategy for Canada*. This Strategy contains input from hundreds of companies, organizations and individuals sourced through a variety of different forums, workshops, teleconferences, bilateral discussions, and dialogue through existing working groups. While the Government of Canada led the development of the Strategy and consulted broadly with industry, the contents, findings, and recommendations expressed in the Strategy reflects a combined view and may not be unanimously endorsed by all of the participating organizations and their employees.

The Government has also commissioned a number of key studies on topics such as hydrogen codes and standards, awareness, demand modelling, and GHG emissions reduction potential. These studies along with key international reports, for example from the International Energy Agency and Hydrogen Council, have helped inform the development of the Strategy.

Zen and the Art of Clean Energy Solutions (Zen) is the lead author of this strategy on behalf of the Government of Canada. Zen together with the Institute for Breakthrough Energy + Emission Technologies (IBET) led the aggregated 2050 hydrogen demand modelling work to determine the potential role hydrogen can play in Canada's future energy system. The Strategy summarizes and integrates stakeholder inputs and previous studies, as well as recent modelling and analysis, into a single cohesive document.

The *Hydrogen Strategy for Canada* is a strategic directional document based on best available information at this time. Adjustments will be made as technology, research, codes and standards, the international hydrogen landscape, and policy evolves. Additional research and analysis outlined as recommended actions in this document are planned through the Implementation Strategic Steering Committee, dedicated Working Groups, and Regional Blueprints.

Consultations

Consultations were held with over 1,500 stakeholders from across the value chain to ensure engagement opportunities were as comprehensive as possible. Stakeholder groups include, but are not limited to the private sector, associations and NGOs, academia and research groups, Federal and Provincial Governments, and Indigenous Organizations, communities, and businesses.

Linkages with Industry Working Groups

The Government has also collaborated closely with the Transition Accelerator, the Canadian Hydrogen and Fuel Cell Association (CHFCA), the Canadian Gas Association, and other industry associations which are pursuing actions closely aligned with those identified in the Strategy. Once the strategy is released, Canada will establish a Strategic Steering Committee, with several targeted task teams, to ensure progress toward the recommendations in the strategy is made and measured.

LIST OF FIGURES

Executive Summary

TIME TO ACT

The world's energy systems are undergoing radical transformation driven by the need to mitigate climate change. Development of an at-scale, clean hydrogen economy is a strategic priority for Canada, needed to diversify our future energy mix, generate economic benefits and achieve net-zero emissions by 2050.

The time to act is now. Governments around the world are releasing and executing hydrogen strategies that are building global momentum. In 2019, Canada seized this momentum by developing and launching a new Hydrogen Initiative under the Clean Energy Ministerial, designed to be the cornerstone for global hydrogen deployment.

Now, one year later, Canada is poised to leverage this momentum, to grow the domestic opportunity for hydrogen, while also benefiting from growth in global demand through export opportunities, guided by this Strategy.

This Strategy seeks to modernize Canada's energy systems by leveraging Canadian expertise – including increased participation from marginalized and underrepresented groups – through building new hydrogen supply and distribution infrastructure and fostering uptake in various end-uses, that will underpin a low-carbon energy ecosystem in the near- and long-term. It will set the foundation to do this over the next five years by:

- Encouraging early deployment HUBs in mature applications, and Canadian demonstrations in emerging applications;
- employing regulations, including the forth-coming Clean Fuel Standard to drive near-term investments; and
- framing new policy and regulatory measures needed to reach net-zero by 2050.

These activities in the short-term will be followed by the growth and diversification of the sector from 2025 to 2030. Thereafter, through rapid expansion until 2050, Canada will start to realize the full benefits of the hydrogen strategy.

Those benefits include:

- positioning Canada to become a world-leading supplier of hydrogen technologies;
- sparking economic recovery while growing domestic low-carbon fuel production to reduce emissions for the longer term, including unique opportunities for Indigenous communities and businesses;
- generating more than 350,000 high-paying jobs nationally; and
- employing hydrogen as a key enabler to reach net-zero emissions by 2050.

The International Energy Agency (IEA) has recommended that governments put clean energy solutions such as hydrogen at the heart of stimulus plans. Green infrastructure investments are key to achieving Canada's post-pandemic economic recovery, clean growth and climate change objectives.

By applying its world-class expertise at home, Canada can showcase hydrogen's real-world applications and benefits and the role hydrogen can play in transforming energy systems. Early deployment HUBs will set Canada on a path for widespread deployment in the mid- and long-term where hydrogen's decarbonization potential can be fully realized.

CONTEXT

Canada has played an important role in the development of the growing global hydrogen economy, starting more than a century ago with innovation in hydrogen production technology and four decades ago as pioneers in fuel cell technology. Canada continues to be an R&D and technology leader in the sector.

Under the Paris Agreement, Canada has committed to reducing GHG emissions by 30% below 2005 levels by 2030. It has also announced a target to achieve net-zero emissions by 2050, joining 72 other nations in this ambitious pledge. In a net-zero future, Canada's economy will be powered by electricity and low carbon fuels – with low carbon fuels expected to provide up to 60% or more of our energy needs. As the lowest carbon fuel, hydrogen is essential to decarbonizing the top third of Canada's most energy intensive and hard-to-abate end-use applications, and there is much work to do to roll out hydrogen at scale domestically.

Canada is not alone in seeing hydrogen as a critical part of the solution to combat climate change and improve air quality, while driving economic growth in a carbon-constrained world. Countries around the world have developed strategies to inform the optimal supply pathways and end-use applications for hydrogen, as well as to define export strategies.

The demand for hydrogen in global energy systems is dramatically increasing, with projections indicating at least a tenfold increase in demand over the next three decades. Studies indicate that hydrogen could provide up to 24%[1] of global energy demand by 2050. The number of countries with polices that support investment in hydrogen technologies is increasing, along with the number of sectors they target. Canada is uniquely positioned to become a large-scale exporter of hydrogen to serve this growing market, but domestic deployments must lead.

For three years, the Government of Canada, under the leadership of NRCan has been working with private sector stakeholders and governments at all levels to inform the development of the *Hydrogen Strategy for Canada.* The release of this strategy comes during unprecedented times. The world has been shaken by COVID-19, and there is daily evidence mounting that climate change poses an ever-increasing risk to the world's economies, habitats, biodiversity, human health, and our future way of life.

Canada has all the ingredients necessary to develop a competitive and sustainable hydrogen economy. The modernization of Canada's energy systems towards a low-carbon economy presents a unique opportunity to leverage Canadians' expertise to build new infrastructure assets to serve as a backbone for a low-carbon energy ecosystem across Canada with hydrogen playing an integral role, delivering up to 30% of Canada's end-use energy by 2050.

This strategy is a call to action. Achieving decarbonization targets requires bold action and radical transformation of Canada's energy system that must begin with the end in mind rather than working incrementally based on old paradigms.

---

[1] Bloomberg NEF. (2020). *Hydrogen Economy Outlook*. Retrieved from https://data.bloomberglp.com/professional/sites/24/BNEF-Hydrogen-Economy-Outlook-Key-Messages-30-Mar-2020.pdf

CANADA'S ADVANTAGES

Canada has unique competitive and comparative advantages that position the country to become a world-leading producer, user, and exporter of clean hydrogen, as well as hydrogen technologies and services. A strong hydrogen economy will lead to financial, environmental, and health benefits for Canadians.

- **Rich in feedstocks to produce hydrogen**

  Canada has among the lowest Carbon Intensity (CI) electricity supplies in the world given our hydroelectric generation capacity and status as a Tier-1 nuclear region. Canada also has abundant fossil fuel reserves, world class CO_2 storage geology, potential for growth in variable renewables, large scale biomass supply, and freshwater resources. All of these can be leveraged to produce hydrogen.

- **Leading innovation and industry position**

  Canada is known for its leading hydrogen and fuel cell technology companies and expertise. As of 2017, there were >100 established companies, employing >2,100 people, generating revenues >$200 million. Canada also has significant expertise in carbon capture technology, one of the keys to the production of low CI hydrogen from fossil fuels.

- **Strong energy sector**

  Canada's energy sector accounted for 832,500 direct and indirect jobs as of 2019, with assets valued at $685 billion[1]. This skilled labour force coupled with strategic infrastructure assets position Canada to rapidly pivot to include at- scale hydrogen as an energy currency.

- **Established international collaborations**

  Canadian government, industry and academia are involved in international collaborations related to hydrogen that position Canada as a leader both from an innovation and commercial perspective.

- **Energy export channels to market**

  Canada's proximity to hydrogen import markets including Japan, South Korea, California, the UK, Germany, and all of Europe, along with export assets such as deep water ports, established pipeline networks, and an emerging LNG industry, position Canada to be an exporter of hydrogen as the global economy evolves.

- **Canada's Unique Starting Point**

  Canada is recognized as a global leader in the hydrogen and fuel cell sector, seen as a hub for technical expertise, intellectual property, and leading products and services. Canada is one of the top 10 hydrogen producers in the world today. An estimated three million tonnes are produced per year from natural gas. Canada is home to the largest clean hydrogen production facility in the world to produce hydrogen from natural gas with carbon capture and permanent storage for the resulting CO_2 emissions.

By leveraging these advantages to develop a vibrant and robust clean hydrogen economy, Canadians will benefit from:

- **Economic growth and jobs**

  Canada's hydrogen economy will create new green jobs in R&D, manufacturing, and services supporting increased participation from traditionally marginalized and under-represented groups as part of an inclusive transition. Hydrogen will become a new export currency for both regional energy economies in Western, Central, and Eastern Canada, as well as in the international market. This will allow

[1] NRCan. (2018). *10 Key Facts on Canada's Energy Sector*. Retrieved from https://www.nrcan.gc.ca/sites/www.nrcan.gc.ca/files/energy/pdf/10-Key-Facts-on-Canada_s-Energy-Sector-2018-en%20.pdf

Canadian energy companies to move up the value chain as a fuel provider in a zero-emissions future. If Canada fully seizes the opportunity presented by hydrogen, it could lead to more than 350,000 sector jobs and direct revenues of over $50B/year by 2050.

- Transformative opportunity for Canada's petroleum sector

  Hydrogen is critical to transforming oil and natural gas industries to net-zero emissions. It provides an opportunity to leverage Canada's diverse talent pool, valuable energy reserves, and infrastructure assets in a way that is carbon-free at the point of use, providing a future pathway to utilize these assets.

- Energy resilience

  Hydrogen can act as an energy carrier to enable increased penetration of renewables by providing time shifting and energy storage capabilities. Hydrogen adds optionality in a future net-zero mix, complementing other energy vectors such as direct electrification and biofuels, and serving as a bridge between energy grids in an integrated energy system.

- Cleaner air

  Hydrogen does not produce greenhouse gases, black carbon, particulates, SO_x, or ground-level ozone at the point of use. When used in an electrochemical fuel cell, it emits only water and heat. Increased hydrogen adoption leads to cleaner air, with improved health outcomes for Canadians.

- Meeting decarbonization goals

  Hydrogen uniquely closes the gap in hard-to-abate, energy intensive applications such as long-range transportation, high-grade heat production, and as a feedstock in industrial processes. Hydrogen has the potential to make significant contributions to Canada's required GHG emission reductions by 2050.

CANADA'S OPPORTUNITY

Clean hydrogen has the potential to deliver up to 30% of Canada's end-use energy by 2050, abating up to 190 Mt-CO_2e of GHG emissions through deployment in transportation, heating, and industrial applications.

With Canada's strong starting position, emissions reductions from an optimistic transformative scenario could contribute up to 45 Mt-CO_2e reduction by 2030. This scenario is more likely to be achieved with strong pricing and regulatory incentives in place at the federal and provincial level to drive hydrogen adoption, supported by immediate and aligned action across government and industry. Canada's recently announced Strengthened Climate Plan, including carbon pricing, the Clean Fuel Standard and the $1.5 billion dollar Low-carbon and Zero-emissions Fuels Fund, is already putting in place foundational federal initiatives that will enable the broad suite of measures contemplated in this Strategy. Benefits realized by hydrogen will accelerate beyond the 2030-timeframe, with potential under the transformative scenario to contribute up to 190 Mt-CO_2e reductions per year, by 2050.

H_2 Opportunity

	2030	2050
% of Delivered Energy	6%	30%
Hydrogen Demand	4 Mt-H_2	20 Mt-H_2
GHG Emissions Abated	up to 45 Mt-CO_2e	up to 190 Mt-CO_2e

Production

Canada's rich feedstock reserves, skilled energy labour force, strategic energy infrastructure assets, and leading position in innovation in hydrogen and fuel cell technologies position Canada to become one of the top three global producers of clean hydrogen.

Canada is one of the top ten global producers of hydrogen today, producing an estimated 3 million tonnes (Mt) annually via steam methane reformation (SMR) of natural gas. While SMR is not considered a clean hydrogen pathway without carbon capture, Canada is well placed to transition to clean pathways going forward. Canada has established production supply chains, primarily in Alberta for fuel upgrading/refining and nitrogen fertilizer production that can be leveraged in the near term. By 2050, Canada could grow production by a factor of seven to meet domestic demand, producing >20 Mt of low CI hydrogen per year, with potential for significant expansion to meet global demand.

Hydrogen can be made from a variety of feedstocks, including water and electricity, fossil fuels, biomass and as a by-product from industrial processes. The CI of the hydrogen pathways can vary significantly, and Canada must be focused on developing cost-effective, low CI pathways in the near and mid term while ultimately transitioning to an increasing percentage of renewable or zero-emission feedstocks over the long term. Canada is working with countries around the world to develop a common methodology to determine and independently certify the CI of hydrogen, which will be necessary to facilitate trade.

Hydrogen production in Canada is expected to be based on a mix of pathways. The aggregate hydrogen demand projected in 2050 highlights the need for Canada to explore all low CI hydrogen production opportunities.

- Electrolytic Hydrogen

  Hydrogen can be produced from water via electrolysis using clean electricity. Canada is the sixth-largest global producer of electricity in the world and has one of the lowest carbon intensity grids due to our vast hydroelectricity generating assets. There are also synergies between hydrogen production, nuclear and renewable electricity. Hydrogen can be produced via electrolysis using off-peak nuclear electricity in the near term, while high-temperature thermal processes or coupling with small modular reactors are viable in the longer term. Hydrogen can also play a role in daily to seasonal storage of variable renewable resources, enabling a higher penetration of intermittent renewables on the grid.

- Hydrogen from fossil fuels

  Clean hydrogen can be produced from fossil fuels when combined with Carbon Capture Utilization, and Storage (CCUS) or the carbon can alternatively be sequestered in the form of solid carbon. Canada is the world's fourth largest producer of natural gas. Provinces with the highest natural gas and petroleum reserves are Alberta, British Columbia, and Saskatchewan, and the Atlantic Provinces, and these provinces are best suited for hydrogen production from fossil fuels.

- Hydrogen from biomass

  Hydrogen can be derived from the gasification of dry biomass. This is considered to be both renewable and carbon neutral. Most provinces in Canada have access to biomass residues through forest and agriculture sectors.

- Industrial by-product hydrogen

  Hydrogen in Canada currently produced as a by-product of industrial processes including chlor-alkali and sodium chlorate production can be captured, purified, and used directly. Vented hydrogen from large-scale plants can be sufficient to support some near-term needs, but is limited in supply.

The hydrogen supply network in Canada could include both large-scale centralized plants in Canada's natural-gas rich provinces or in regions with high penetration of low-cost renewables, and smaller-scale distributed electrolytic production near demand centers. Delivered hydrogen costs of $1.50-3.50/kg are projected to be achieved as production scale is realized and investment is made in distribution infrastructure.

Industry and Provincial Governments will play an important role in determining which hydrogen production pathways will come to fruition in Canada, and over what timeframes.

End-Use

Domestic deployment of hydrogen is critical to supporting Canada's world-leading hydrogen and fuel cell sector, as well as to meeting climate change objectives. The earlier deployment starts, the sooner scale and user acceptance will be achieved, allowing the realization of longer-term projections on uptake and associated benefits.

Adoption of hydrogen will be focused on energy-intensive applications where it offers advantages over alternative low-carbon options. This includes using hydrogen as a fuel for long-range transportation and power generation, to provide heat for industry and buildings, and as a feedstock for industrial processes.

- **Fuel for Transportation**

Hydrogen can be used directly as a fuel in fuel cell electric vehicles, which have twice the efficiency of combustion engines and zero harmful emissions at the tailpipe. Hydrogen combustion and co-combustion engine technology is also under development as a transitional opportunity.

Fuel cell light-duty passenger vehicles are commercially available today globally, and in limited numbers in Canada. The Government of Canada has set federal targets for zero-emission vehicles (ZEV) to reach 10% of light-duty vehicles sales per year by 2025, 30% by 2030 and 100% by 2040. Canada considers battery electric vehicles (BEVs), fuel cell electric vehicles (FCEVs), and plug-in hybrid electric vehicles (PHEVs) to qualify as ZEVs. BC and Quebec have led provincially with the adoption of consumer purchase incentives for ZEVs and sales regulations. Both of these provinces have started to deploy hydrogen fueling infrastructure and light-duty FCEVs.

Battery electric vehicles are expected to take a significant portion of the market share for light-duty applications in Canada. FCEVs offer choice for consumers desiring longer range and faster fueling times and are well suited to larger passenger vehicle platforms.

Public transit agencies around the world are shifting towards low- and zero-emission vehicles. Fuel cell electric buses (FCEBs) are commercially available today, with more than 2000 FCEBs[1] in service worldwide, and approximately half of those are powered by Canadian technology. Canada has unique potential for a 'made-in-Canada' solution with New Flyer Industries and Ballard Power Systems leading the market with commercial fuel cell electric bus deployments in North America.

The zero-emission bus (ZEB) initiative[2] underway in Canada encourages government to support school boards and municipalities in purchasing 5000 ZEBs over the next five years. Canada can leverage the local supply chain to provide economic value if FCEBs are a portion of the mix. These buses are well suited to longer routes and cold weather climate that Canadian transit agencies service.

Fuel cells are expected to play a significant role in medium- and heavy-duty trucks, rail, and ships that have operations with high power demand, coupled with energy-intensive and long duty cycles. For example, heavy-duty trucks travelling long distances would require many heavy batteries, reducing the load capacity beyond that which would be acceptable to operators. Long charging times could also impact operations negatively. The improved energy density and fast fill characteristics of fuel cell electric trucks will likely make them an optimal choice for certain applications.

There is a similar value proposition for hydrogen use in mining equipment, including material handling vehicles. Hydrogen presents an opportunity to reduce widespread reliance on diesel for mining vehicles and stationary power equipment. Hydrogen offers the added benefit of reducing harmful exhaust emissions, especially in underground mines. The Canadian Minerals and Metals Plan (CMMP) aims to capitalize on opportunities to strengthen Canada's competitive position within the global mining sector and emphasizes the importance of developing and adopting alternative energy sources, such as hydrogen.

In the near term, as costs and availability of fuel cells challenge uptake, hydrogen-diesel co-combustion in truck applications offers an alternative pathway to create the demand for hydrogen and support infrastructure development.

♦ Fuel for Power Generation

Hydrogen can be used as a fuel for power production through either hydrogen combustion in turbines or electrochemical conversion in stationary fuel cell power plants. Hydrogen provides load management, long-term energy storage, and a path to market that enables the growing use of intermittent renewables.

In the longer term, hydrogen can play a role in greening Canada's electricity grids where there is still a reliance on fossil fuels for power production. Hydrogen can also provide stability for off-grid renewables-based power solutions in remote communities and remote industrial sites such as mines that are today largely dependent on expensive, highly emitting diesel power.

♦ Heat for Industry

As a heating fuel, hydrogen is a cleaner-burning molecule that can be a substitute for the combustion of fossil fuels in applications where high-grade heat is needed and where electric heating is not technically or economically the best solution.

In Canada's oil and gas sector, low CI hydrogen can offer emissions reduction benefits in both upstream extraction (combusted as a heat source) and downstream refining (used as a chemical feedstock). For example, in upstream operations, low CI hydrogen can replace natural gas combusted to produce steam for steam-assisted gravity drainage (SAGD) in-situ bitumen production. Hydrogen can lower the CI of conventional refined petroleum products in this way and could offer a compliance pathway for the federal Clean Fuel Standard.

Other heavy industry in Canada that relies on a large amount of high-grade heat production includes cement and steel manufacturing, the pulp and paper sector, and industrial processes relying on steam production. These sectors can also reduce emissions by converting to blends of hydrogen and natural gas or pure hydrogen for heat production.

♦ Heat for Buildings

Hydrogen can play a role in reducing emissions in heating applications in the built environment. Natural gas (NG) utilities are looking to decarbonize the NG grid by introducing both Renewable Natural Gas (RNG) and hydrogen as alternative low-carbon chemical fuels. Canada's cold climate results in heating accounting for almost 80% of energy use in the home.[1] Since NG is used for both space heating and water heating, hydrogen is gaining increased attention from utilities as a low-carbon option, either as a blend with natural gas or as a replacement fuel. Several jurisdictions in Canada and worldwide are conducting pilot projects to determine the technical feasibility of blending hydrogen into existing natural gas systems. Codes and standards work will be required to support opportunities for the potential blending of hydrogen.

Due to possible technical constraints, beyond blending limits of ~20% by volume, dedicated

[1] NRCan. (2017). *Residential Sector*. Retrieved from https://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/menus/trends/handbook/handbook_res_00.cfm

hydrogen pipelines start to become an attractive alternative. In a net-zero future where distributed combustion emissions need to be largely eliminated, hydrogen may become the new chemical fuel of choice for heating in Canada, and utilities will play an important leadership role in that transition.

- **Feedstock for Industry**

Hydrogen is used as a feedstock in several industrial processes in Canada today. Most feedstock hydrogen is currently produced via steam methane reforming.

Hydrogen is used as a feedstock for:

- Petroleum refining
- Bitumen upgrading
- Ammonia production
- Methanol production
- Steel production

The greatest use of hydrogen globally today is for refining and upgrading crude oil, where hydrogen-based processes remove impurities like sulphur and process heavy hydrocarbon chains into lighter components. The majority of hydrogen required for refining is produced on-site from either dedicated production facilities or as a by-product. Because of this integration of hydrogen production within refining facilities, production is primarily supplied by natural gas reforming methods. The most significant opportunity to reduce emissions associated with hydrogen in the oil and gas industry is retrofitting existing conversion technology with carbon capture and storage or deploying new clean hydrogen technology that does not produce CO_2.

Availability of low cost, low CI hydrogen can create new industry in Canada. This includes methanol production and liquid synthetic fuel production, an innovative process combining clean hydrogen and carbon captured from the air to produce carbon-neutral, energy-dense liquid fuels that are well suited to applications such as aviation and large marine vessels. Renewable nitrogen fertilizer production also presents an opportunity for a new Canadian industry.

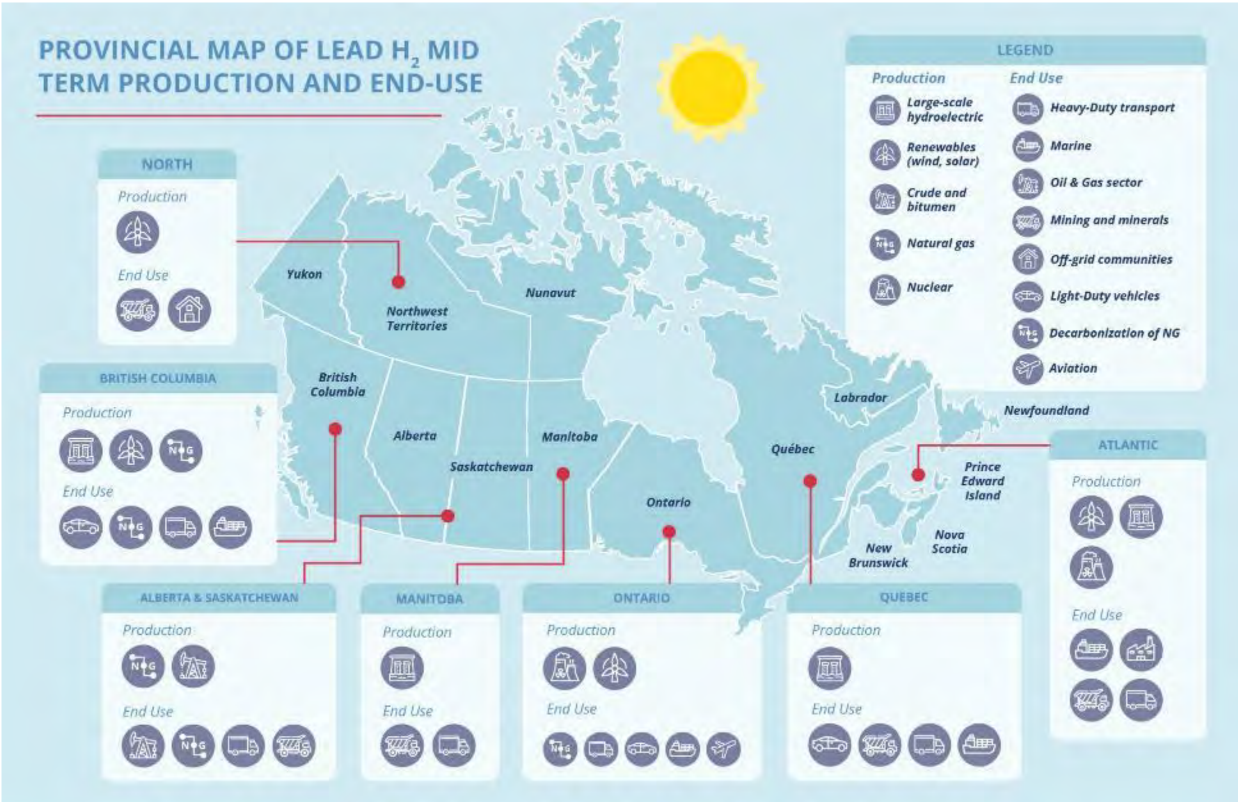
Export

With worldwide demand for hydrogen increasing, the global market is expected to reach more than $2.5T by 2050. There is a significant export opportunity for Canada as energy importers are actively looking to Canada as a potential supplier.

As an energy rich nation with significant clean hydrogen production capacity, established international trade partnerships, and strategic infrastructure assets such as deep water ports and established pipeline networks, Canada is positioned to become top global supplier of clean hydrogen. A 2019 BC study shows an export potential of $15 billion by 2050 from that province alone. Another recent study indicated that hydrogen exports could reach ~$50 billion by 2050[1], doubling the economic potential of the domestic market projected for Canada in that same timeframe. With import countries looking to decarbonize their energy systems, hydrogen could contribute to a significant portion of the energy export market share in the coming decades.

Just as Canada is working to capture the global LNG export market, we can build on this experience to advance a hydrogen strategy with strong early actions and a national plan that builds on Canada's regional strengths. Taken together, we can lead in the emerging hydrogen export market.

[1] The Transition Accelerator. (2020). *Towards Net-Zero Energy Systems in Canada: A Key Role for Hydrogen*. Retrieved from https://transitionaccelerator.ca/wp-content/uploads/2020/09/Net-zero-energy-systems_role-for-hydrogen_200909-Final-print-1.pdf



REMAINING CHALLENGES

Economic and Investment

The factors limiting hydrogen use in some applications today are economic rather than technological, where hydrogen is not yet cost-competitive compared to other conventional fuel options.

While hydrogen can be among the lowest cost alternatives for reducing carbon emissions on a dollar-per-tonne-abated basis, a challenge today is that even with some form of carbon pricing, GHG emissions are not always adequately reflected in the market cost of baseline fuels. Implementation of the federal Clean Fuel Standard will be an important step forward.

The cost of end-use applications that rely on fuel cells is also a barrier to adoption, and R&D and scaled-up manufacturing processes are needed to drive down costs. Development of supporting infrastructure requires significant coordinated investments, which is challenged by uncertain demand creating high risk for investors.

Achieving scale is also critical to economic competitiveness of the industry. While the sector must ultimately be self-sustaining, strong policy and fiscal support are needed in the next 5-10 years to attract and de-risk industry investment.

Technology & Innovation

Canada was an early leader in the hydrogen and fuel cell sector and is recognized worldwide as a region rich with technical expertise, intellectual property, and leading products and services. While some hydrogen and fuel cell technologies are at a level of commercial readiness, support for R&D is needed to reduce costs further, develop solutions in the less mature applications and discover new breakthrough technologies to benefit the sector. Continuing to stay at the forefront of innovation is critical to sustaining Canada's competitive advantages.

Other countries have been rapidly increasing investment to support innovation in the sector, whereas between 2008 and 2016, Canada slowed investment in fundamental research in this sector. While more recently, Canada has again committed to being a global leader in clean tech innovation, this gap in support has resulted in the fact that some Canadian companies developing research centres and/or moving parts of their operations to other countries where there is more support for technology advancement. It is important for Canada to act now to prevent loss of critical intellectual property.

Policy & Regulation

Clean hydrogen projects around the world have primarily been in regions with a combination of supporting policies and regulations. Policies and regulations that encourage the use of hydrogen technologies include low carbon fuel regulations, carbon pricing, vehicle emissions regulations, zero-emission vehicle mandates, creation of emission-free zones, and renewable gas mandates in natural gas networks. Mechanisms to help de-risk investments for end-users to adapt to regulations are also beneficial.

Canada currently lacks a comprehensive and long-term policy and regulatory framework that includes hydrogen. Where policies are in place, they are not consistent across regions resulting in a 'patch-work' approach that slows adoption.

Availability of Hydrogen Infrastructure

Domestic supply of low CI hydrogen is limited in many parts of Canada today, and this is preventing both pilot and commercial rollout. For some applications, there is a need to transport and store hydrogen from the site of production to the end-user. This includes refueling infrastructure for transportation applications.

Over time, as domestic production and demand grow, there will be a need for dedicated infrastructure such as hydrogen pipelines and liquefaction plants. Ensuring that these crucial assets can be built in a coordinated and timely manner will be essential to ensuring low cost, low CI hydrogen can be delivered to both domestic and international markets.

Codes & Standards

The deployment of hydrogen is in the early stages across many jurisdictions and sectors in Canada, and there are gaps in existing codes & standards that need to be addressed to enable adoption. Harmonizing codes and standards across jurisdictions will ensure that best practices are applied across the global hydrogen economy to facilitate the growth of trade and export markets.

Awareness

There is a lack of awareness about the opportunities and safety around hydrogen within the general public, as well as within industry and government. Increased awareness about hydrogen as a viable decarbonization pathway that is safe and provides economic benefits is critical to establishing a vibrant hydrogen sector.

PATH FORWARD

Vision for 2050

If Canada seizes the opportunities for hydrogen, by 2050 the country could realize the following:

- Up to 30% of Canada's energy delivered in the form of hydrogen
- Canada is one of top 3 global clean hydrogen producers, with domestic supply >20 Mt/year
- Established supply base of low carbon intensity hydrogen with delivered prices of $1.50 - $3.50/kg
- >Five million FCEVs on the road
- Nationwide hydrogen fueling network
- >50% of energy supplied today by natural gas is supplied by hydrogen through blending in existing pipelines and new dedicated hydrogen pipelines
- New industries enabled by low-cost hydrogen supply network
- ~350,000 hydrogen sector jobs
- >$50 billion in direct hydrogen sector revenue for the domestic market
- Established and competitive hydrogen export market
- Up to 190 Mt-CO_2e annual GHG reduction

Near Term: Laying the Foundation

The focus of the next five years will be on laying the foundation for the hydrogen economy in Canada. This includes planning for and developing new hydrogen supply and distribution infrastructure to support early deployment HUBs in mature applications while supporting Canadian demonstrations in emerging applications. Regulations such as the Clean Fuel Standard will be fundamental to driving near-term investment in the sector. Introduction of new policy and regulatory measures will also be needed.

Mid Term: Growth and Diversification

Activities to stimulate the sector in the next five years will be followed by growth and diversification of the sector in the 2025 – 2030 timeframe. As the technology matures and the full suite of end-use applications is at or near commercial technology readiness levels, hydrogen use will be focused on applications that provide the best value proposition relative to other zero-emission technologies.

Long Term: Rapid Market Expansion

In the 2030-2050 timeframe, Canada will start to realize the full benefits of a hydrogen economy as the scale of deployments increase and number of new commercial applications grows, supported by Canada's foundational supply and distribution infrastructure.

RECOMMENDATIONS AND IMPLEMENTATION

Recommendations

The release of this strategy is the first step in the next phase of Canada's hydrogen journey. The recommendations will inform the development of concrete actions by all players across the hydrogen ecosystem.

In the implementation phase following the release of the strategy, there will be ongoing engagement with public, private and Indigenous stakeholders to continue the momentum, initiate and track activities related to the recommendations, follow progress, and identify new priority areas as the market evolves. Actions will be coordinated through a Strategic Steering Committee and Working Groups.

The Strategy's recommendations have been developed in consultation with stakeholders and represent actions needed to lay the foundation and maintain momentum for maximizing the benefits of hydrogen in Canada's future energy system mix.

There are 32 recommendations across the eight pillars of the *Hydrogen Strategy for Canada*. Not all of these actions will happen at once - the figure on page XXII outlines how Canada must sequence actions to seize the hydrogen opportunities over time, cementing its essential role in our low-carbon future.

The Strategy's recommendations represent sector-wide themes, highlighted throughout the Strategy. Recommendations have been proposed in eight pillars:

Pillar 1: Strategic Partnerships *- Strategically use existing and new partnerships to collaborate and map out the future of hydrogen in Canada.*

Pillar 2: De-Risking of Investments *- Establish funding programs, long-term policies, and business models to encourage industry and governments to invest in growing the hydrogen economy.*

Pillar 3: Innovation *- Take action to support further R&D, develop research priorities, and foster collaboration between stakeholders to ensure Canada maintains its competitive edge and global leadership in hydrogen and fuel cell technologies.*

Pillar 4: Codes and Standards *- Modernize existing and develop new codes and standards to keep pace with this rapidly changing industry and remove barriers to deployment, domestically and internationally.*

Pillar 5: Enabling Policies and Regulation *- Ensure hydrogen is integrated into clean energy roadmaps and strategies at all levels of government and incentivize its application.*

Pillar 6: Awareness *- Lead at the national level to ensure individuals and communities are aware of hydrogen's safety, uses, and benefits during a time of rapidly developing technologies.*

Pillar 7: Regional Blueprints *- Implement a multi-level, collaborative government effort to facilitate the development of regional hydrogen blueprints to identify specific opportunities and plans for hydrogen production and end use.*

Pillar 8: International Markets *- Work with our international partners to ensure the global push for clean fuels includes hydrogen so Canadian industries thrive at home and abroad.*

Strategic Partnerships

1. *Collaborate across multiple levels of government and with Indigenous groups through Intergovernmental Working Groups to establish priority areas for deployment and to share knowledge, best practices, and lessons learned through early deployments.*
2. *Expand public/private partnerships leveraging Canada's innovative clean technology companies and world-leading hydrogen and fuel cell expertise to accelerate deployment projects across the value-chain.*
3. *Foster cross-sector collaborations within domestic deployment hubs to show the economic and operational benefits of multiple applications operating as part of an integrated ecosystem.*
4. *Leverage international collaborations and pursue synergistic international initiatives to attract direct foreign investment and to accelerate opportunities for Canada in global markets.*

De-Risking Investments

5. *Implement long-term policies that create hydrogen demand certainty and de-risk the private sector investments needed to establish supply and distribution infrastructure.*
6. *Establish multi-year programming as well as a clear and long-term regulatory environment to support early production and end-use projects, including support to assess the feasibility of projects.*
7. *Develop regional deployment HUBs to demonstrate, validate, and implement business cases across the full value chain, from production and distribution to end-use.*
8. *Facilitate co-funding opportunities, leveraging multiple levels of government and the private sector.*

Innovation

9. *Develop strategic fundamental research priorities where Canada can sustainably excel and provide economic value; set technology performance and cost goals.*
10. *Establish dedicated funding for sustained RD&D to ensure Canada retains its leadership position in hydrogen and fuel cell technologies.*
11. *Leverage expertise in academia, government labs, and private sector labs to create regional research hubs and to encourage mission-oriented approaches to research, development, and pilot deployments.*
12. *Foster collaboration between Federal labs, industry, and academia as well as international partners, by supporting consortium-based projects for fundamental research and by coordinating reviews and information sharing.*

Codes and Standards

13. *Update, harmonize and recognize codes and standards (including the Canadian Hydrogen Installation Code) to enable deployments and to facilitate new technology and infrastructure adoption in early markets.*
14. *Establish a codes and standards working group, which includes inter-provincial Authorities Having Jurisdiction representatives, to share lessons learned and identify gaps in codes and standards.*
15. *Develop standards that are performance based versus prescriptive, and ensure hydrogen is not excluded from broader codes, standards, and regulations due to restrictive language.*
16. *Facilitate Canadian leadership and participation on international standard and certification efforts (e.g. development of global carbon intensity metrics, blending levels for hydrogen in natural gas systems), simplifying international trade.*

Enabling Policies and Regulations

17 *Ensure that governments at all levels consider hydrogen's essential role in Canada's energy future as they develop new policies, programs, and regulations.*

18 *Encourage governments to modernize and update existing policies, programs, and regulations to facilitate growth of domestic hydrogen production and end-use.*

19 *Ensure hydrogen is part of integrated clean energy roadmaps at national and provincial/ territorial levels.*

20 *Establish technology-neutral, performance-based standards to define a hydrogen carbon-intensity threshold. Establish tiered, time-based requirement for renewable hydrogen content in government supported projects.*

Awareness

21 *Support community engagement and outreach where deployment HUBs are established.*

22 *Establish awareness and outreach campaigns to educate government, industry, the public, and other important influencers about hydrogen safety, uses, and benefits.*

23 *Develop a suite of tools and resources for early hydrogen markets to help end-users quantitatively evaluate hydrogen as an option for their operations. Host the tools and resources through a central, government-run website.*

24 *Support collaborations between industry and academia to develop hydrogen-specific curriculums to build awareness, interest, skills development, and training to develop the next generation talent pool and prepare the labour force for new opportunities.*

Regional Blueprints

25 *Facilitate the development of regional hydrogen blueprints, as a multi-level government collaborative effort, to identify specific opportunities and plans for hydrogen production and end-use. Ensure federal participation to capture synergies with the Hydrogen Strategy for Canada.*

26 *Identify opportunities for the establishment of regional HUBs, comprised of projects along the entire value-chain.*

27 *Include utilities, major industry from adjacent sectors, and cleantech companies in development and implementation of blueprints.*

28 *Identify areas for alignment and replication with other provinces/regions to facilitate and accelerate overall adoption.*

International Markets

29 *Develop a strong Canadian brand, positioning Canada to be a global supplier of choice for low carbon hydrogen, and the technologies to use it.*

30 *Invest in infrastructure to connect Canadian supply to international markets, such as liquefaction assets for energy dense hydrogen transport and hydrogen pipelines from western Canada to the US.*

31 *Establish domestic flagship projects that highlight Canada's expertise, attract investments into the domestic market, and that can be replicated internationally.*

32 *Leverage existing international fora (e.g. Clean Energy Ministerial Hydrogen Initiative, G20, IEA) to showcase Canada's leadership, and advance new market opportunities.*

	NEAR-TERM (2020-2025) *Laying the Foundation*	MID-TERM (2025-2030) *Growth & Diversification*	LONG-TERM (2030-2050) *Rapid Market Expansion*

WHY HYDROGEN IN CANADA?
Rich in Feedstocks
Low carbon intensity grid, abundant fossil fuel reserves, fresh water
Established International Collaborations
Strong Energy Sector
Head Start: One of top 10 H_2 producers in world
Leading Innovation & Industry Position
>100 H_2 and Fuel Cell companies
Skilled labour force, strategic infrastructure assets
Energy export channels to market
Unique Competitive and Comparative Advantages

Economic Growth
• New green jobs
• Moving up the fuel value chain
• Export potential
Decarbonization
Closes the gap in hard-to-abate, energy intensive applications
Clean Air
Improving the health of Canadians through reduced emissions in transportation, heating and industry
Energy Resilience
Carbon free energy carrier enabling increased renewables
Transformative opportunity for Canada's petroleum sector
...Creating Benefits for Canadians

1. Why Hydrogen in Canada?

Canada has all the ingredients necessary to develop a competitive and sustainable hydrogen economy, from rich feedstocks to produce hydrogen and world-leading innovation, to a strong energy industry and vast international relationships. This places Canada in a unique and advantageous starting position on the road to establishing a clean hydrogen economy. If Canada fully capitalizes on its advantages, by 2050 Canadians can benefit from more than $50B in domestic revenues, the conventional oil and gas sector can be transformed, a vibrant export market can be established, and the use of hydrogen can reduce emission by up to 190Mt-CO_2e while improving air quality across the country.

CANADA'S ADVANTAGES

Rich in Feedstocks

Canada has one of the lowest carbon intensity (CI) electricity supply systems in the world, abundant fossil fuel reserves, world-class CO_2 storage geology, large scale biomass supply, and freshwater resources, all of which can be leveraged to produce hydrogen.

Canada is the sixth-largest global producer of electricity, generating 652 TWh of electricity in 2017.[1] Sixty-seven percent of Canada's electricity comes from renewable resources and 82% from non-GHG emitting sources. Canada is the world's third-largest producer of hydroelectricity, making up 60% of today's total generation capacity.[2] Canada also has significant potential to expand the deployment of variable renewables such as wind and solar. Electricity from wind energy is one of the fastest-growing sources of electricity in the world and Canada. Wind accounts for 4% of electricity generation in Canada today, and both wind and solar photovoltaic deployments are growing. Canada is a Tier-1 nuclear supplier, and 14.6% of nationwide electricity generation comes from Canada's nineteen operating power reactors at four nuclear-generating stations in Canada. Canada is exploring the potential to expand nuclear capacity through small modular reactors that can provide non-GHG emitting power in remote communities, building on Canadian innovation in this sector.

Canada has the third-largest oil reserves in the world as well as one of the largest proven natural gas reserves, and at current rates of consumption can meet the country's needs for 300 years, with enough

[1] NRCan. (2020). *Electricity facts*. Retrieved from https://www.nrcan.gc.ca/science-data/data-analysis/energy-data-analysis/energy-facts/electricity-facts/20068

[2] IEA (2020). Key World Energy Statistics 2020. Retrieved from https://www.iea.org/reports/key-world-energy-statistics-2020

remaining for export[1]. Canada is home to one-fifth of the world's large-scale carbon capture utilization and storage (CCUS) projects in operation, and a number of leading CCUS innovators that can be leveraged to support emissions reductions in multiple sectors - including low carbon intensity hydrogen production. Canada has a large supply of renewable forest biomass, as well as access to forest industry by-products and residues. B.C., Ontario, Alberta, Quebec, and New Brunswick are the provinces with the largest biomass capacity and generation. Finally, Canada has 7% of the world's fresh water. Water is an important feedstock in the production of hydrogen using electrolysis powered by clean electricity.

Leading Innovation, Intellectual Property, and Industry Position

As a result of early leadership in RD&D and clean tech development Canada is known for its leading hydrogen and fuel cell technology companies and expertise. As of 2017, there were more than 100 established hydrogen and fuel cell companies spanning the full value chain, employing more than 2100 people in direct jobs within Canada, and generating revenues in excess of $200 million. The sector spends upwards of $90 million in revenue per year to keep Canadian companies at the forefront of innovation.[2] There are new and established hydrogen and fuel cell companies as well as large energy companies and utilities developing and deploying hydrogen solutions in most provinces within Canada. British Columbia, Ontario, and Quebec host the largest clusters of companies in the sector.

Increasing global demand for hydrogen has led to export market opportunities for Canadian companies. For example, more than half of fuel cell buses deployed around the world contain Canadian fuel cell powertrain technology.[3] Canadian companies are well positioned to supply technology, products and services in support of hydrogen production, distribution, storage, and fueling infrastructure, and end-use applications such as trains, heavy-duty vehicles, material handling equipment, marine and aviation propulsion systems, and back-up and stationary power solutions. Canadian technologies in areas related to electrolyzer products and advanced storage materials and engineered solutions also play a significant role in renewable energy systems across the world, integrating with wind and solar technologies. A Canadian supply chain has emerged that provides parts, components, testing equipment, and engineering and financial services to global hydrogen and fuel cell technology developers. Strategic partnerships between industry, academia, and federal labs have been instrumental in developing new intellectual property (IP) and training the next generation of talent for the sector.

Since 2012, Canadian funding to hydrogen clean tech and innovation has dropped, allowing other countries to catch up. Reinvesting in RD&D will enable Canada to capitalize on our head start and maximize Canadian technology penetration in emerging global markets. However, technology development alone will not secure Canada's place in global markets. Following the release of the Hydrogen Strategy, it will be critical to continue to engage on an industrial strategy to further quantify the opportunity and set Canada on a clear path to secure our place in the Global hydrogen economy.

To grow clean hydrogen production in Canada, renewed support for CCUS is also required. Canada's early leadership in this technology space is slipping, as competing countries are strengthening policy incentives and funding to drive RD&D and commercial deployment. Canada needs to take similar action to level the playing field with the US and other countries, and entice our world-renowned technology developers to deploy their expertise at home in support of domestic reductions as well as abroad to capitalize on the growing multi-billion-dollar global market for CCUS climate solutions.

---

Strong Energy Sector

Canada's energy sector is critical to supporting the restart and recovery of the Canadian economy as it emerges from the COVID-19 pandemic. It accounted for 832,500 direct and indirect jobs as of 2019 , with assets of valued at $685 billion as of 2019.[1] It was also , and the energy sector was responsible for directly and indirectly contributing 10.2 percent % to Canada's nominal GDP in that same timeframe.

A key component of this is the hard hit oil and gas industry, which is facing exceptional challenges due to fall in oil prices and a collapse in global oil demand because of the pandemic. Despite this, the petroleum sector remains an engine of recovery, employing 576,000 Canadians, including 11,000 Indigenous people, working in 4,500 companies across Canada.

Further reinforcing the energy sector's strength and resilience is that existing and developing energy infrastructure assets can be repurposed for clean hydrogen. For example, Canada's extensive network of natural gas transmission and distribution pipelines could act as large-scale energy storage and distribution networks for hydrogen, carrying either a blend of hydrogen and natural gas or pure hydrogen over the long term.

Storage assets such as depleted wells, saline aquifers and salt caverns can be an important enabler for wide-spread deployment by serving as permanent CO_2 storage, and potentially for storing hydrogen at scale. In addition, Canada already produces abundant hydrogen from natural gas in the oil and gas sector used for upgrading and refining petroleum products, and these hydrogen generation assets can be leveraged and combined with new assets to produce abundant low CI hydrogen.

Canadian talent in the energy sector is extensive and spans all levels of the value chain in a wide range of areas relevant to hydrogen for at-scale production. From strategic R&D in the chemicals industry, to manufacturing of components and products ranging from materials to complete turnkey solutions, to construction and service and maintenance expertise, Canada's energy labour force is well positioned to pivot to bring hydrogen into the energy fold.

Established International Collaborations

Canada has several bilateral and multi-lateral agreements in place, which formalize and strengthen collaboration with countries and regions around the world, including Germany, the EU, Portugal, and Japan. Over the last three decades, Canada has been a founding member of several international initiatives across the value chain and continues to leverage these strategic partnerships to advance global collaboration on hydrogen.

- Canada was a founding member of the IEA Hydrogen and Advanced Fuel Cell initiatives, which evolved into the current Technology Collaboration Programs (TCPs) - designed to coordinate private and public researchers to accelerate R&D, demonstrations and advance innovation on a global basis.
- Canada is a founding member and key partner in the International Partnership for Hydrogen and Fuel Cells in the Economy (IPHE). Member countries have committed to commercializing fuel cell and hydrogen technologies to address awareness and essential codes and standards.

- Most recently, Canada led the development and launch of a Hydrogen Initiative under the auspices of the Clean Energy Ministerial (CEM). Canada co-leads this Initiative, comprised of more than 20 member countries, with the objective to be the cornerstone of global hydrogen collaboration and to incorporate hydrogen's essential role in the global energy transformation in discussions of energy Ministers from around the world.

Canadian industry has also initiated international collaborations to accelerate and leverage R&D efforts and share learnings related to business case and practical deployment considerations. For example, the Canadian Hydrogen and Fuel Cell Association (CHFCA) and Australian Hydrogen Council (AHC) recently signed an MOU to strengthen collaboration between Canada and Australia in the commercial deployment of hydrogen and fuel cell technologies, including in mining and transportation applications.

Several of Canada's most important energy partners, including Japan, South Korea, China, and the US have released national strategies or announced significant investments into their hydrogen economies (see Figure 10). This recent interest is driven by multiple factors and forces but some of the most important include:

- The movement toward decarbonization across all sectors;
- The increasing penetration of variable renewable energy sources;
- The uncertainty of future investments in the oil and gas sector; and
- The rapidly falling costs of hydrogen production technologies.

Unlike previous rounds of excitement around hydrogen, today's interest is driven by the realization that hydrogen will be an essential tool to address climate change. While there are still many challenges to overcome, the message is clear: hydrogen will have a critical role in a carbon neutral future and most of the world's largest economies are already developing the strategies and investments required to make this a reality.

Energy Export Channels to Market

With over $100 billion in exports[1] as of 2017, Canada has established trade relationships for existing energy commodities such as natural gas, crude, refined petroleum products, and electricity that can be leveraged to offer a new low-carbon fuel to the market.

In addition, Canada's proximity to hydrogen import markets including Japan, South Korea, California, and Europe, along with export assets such as deep-water ports, a developing Liquefied Natural Gas (LNG) industry, and established pipeline networks as well as natural gas and oil transportation companies, position Canada to be an exporter of hydrogen as the global economy evolves.

[1] CER. (2017). *Market Snapshot: Energy's Share of Canadian Exports Growing Again*. Retrieved from https://www.cer-rec.gc.ca/nrg/ntgrtd/mrkt/snpsht/2017/09-03nrgshrcndnxprts-eng.html

OUR UNIQUE STARTING POINT

Canada has played an important role in the advancement of hydrogen production technology and storage and distribution equipment and has been a pioneer in fuel cell technology for more than 40 years. Canadian ‘hydrogen firsts’ include the first patent for electrolysis technology in 1915, and the first major breakthrough in proton exchange membrane (PEM) fuel cell power density in the early 1990s to prove the technology as viable for transportation applications.

Canada has a head start in deploying both production and end-use applications. For example, Canada deployed the first industrial-scale production of hydrogen in the 1920s, the first fuel cell bus demonstration in the 1990s, and the first fuel cell forklift and light-duty fuel cell electric vehicle in the early 2000s.

Today, Canada is one of the top 10 hydrogen producers in the world today, with an estimated 3 million tonnes of hydrogen produced per year. Most hydrogen in Canada is produced by the chemical industry and the oil and gas sector from fossil fuels. Geographically, most hydrogen is produced in Western Canada, followed by Central Canada and Atlantic Canada. With the anticipation of Canada’s federal low carbon fuel standard, existing users of hydrogen, including refinery operations, are exploring alternative pathways for hydrogen production. Alternative production pathways include electrolysis or steam methane reforming (SMR) of natural gas coupled with CCUS, to use cleaner hydrogen as a feedstock and compliance pathway to reduce carbon intensity of conventional fuels.

Industrial gas companies operate in both Ontario and Quebec, with hydrogen production and liquefaction assets. Air Liquide’s addition of a 20 MW proton exchange membrane (PEM) electrolyzer at its plant in Bécancour, Quebec which it describes as the largest in North America, increases the facility’s production capacity by 50%. Over and above this, there are a number of other new hydrogen production projects in development across Canada.

Canada continues to be an R&D and technology leader in the sector. For example, Canadian heavy-duty fuel cell engine technology powers more than half of worldwide fuel cell electric buses in revenue service in a range of international markets and climates. In 2018, Canadian technology was used in the first hydrogen powered commuter train. Novel hydrogen production techniques are being pioneered across the country, positioning Canada as a global leader in next-generation clean hydrogen generation. Canada’s expertise and technologies are exported and used in countries around the world, demonstrating the opportunity for growth and deployment on an international scale.

Despite this success, there are currently few large-scale domestic hydrogen projects. This impacts Canada’s global competitiveness in several ways. First, Canadian companies are not able to point to relevant examples of local deployments when promoting their technologies abroad. Second, Canadian talent is being drawn to other jurisdictions where there are more opportunities to develop hands-on experience. Finally, industrial clusters supporting hydrogen technology development, deployments and supply chains are unable to build or retain a critical mass of activity.

While domestic deployments are limited, the sector is not starting from zero. There are activities related to low CI hydrogen production and use happening across Canada, as shown in Figure 2. There are strategic hydrogen production and liquefaction assets in Eastern Canada, and end-use applications range from deployments of light-duty FCEVs and hydrogen retail fueling infrastructure, to pilot projects to explore blending of hydrogen into natural gas networks to decarbonize natural gas. There are also many projects in development and regional studies being conducted to explore hydrogen opportunities. This infographic does not include production and use of grey hydrogen in the oil and gas and nitrogen fertilizer production sectors. These industries represent an opportunity for conversion to low CI supply, providing important anchor tenants as production capacity of low CI hydrogen in Canada is expanded.

Current global momentum on hydrogen presents a significant opportunity for Canada if it is able to continue to be a leader in technology development supported by new local deployments. Without local projects and active investment, other countries will erode this first mover advantage and Canada's technology is at risk of becoming outdated. Now is the time to act and invest in Canada's hydrogen future.

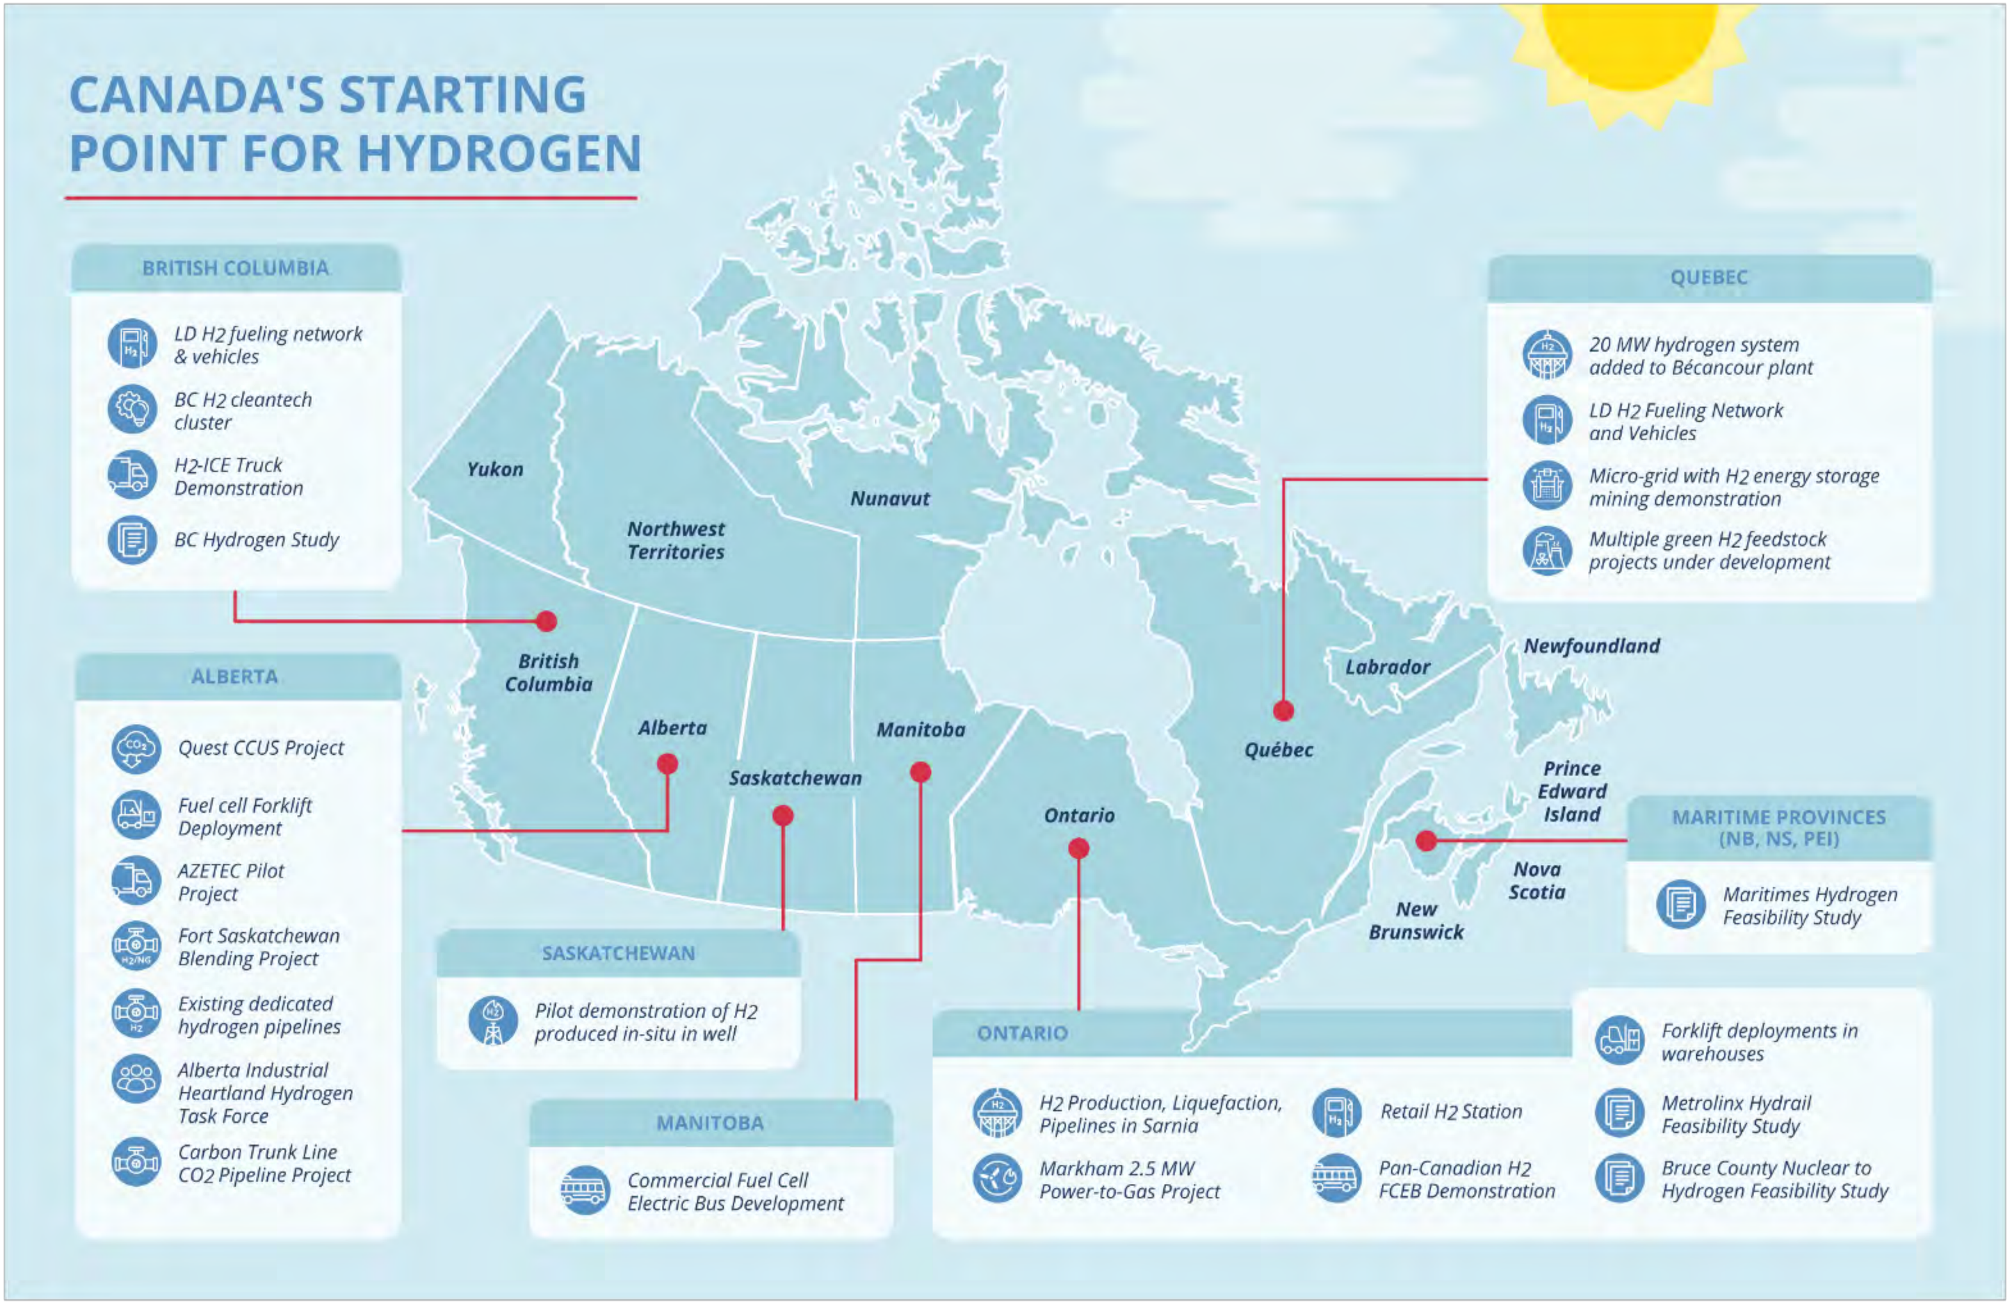

Figure 2 – Canada's Starting Point for Low-CI Hydrogen Production and Use

HYDROGEN AT SCALE DELIVERS REAL BENEFITS FOR CANADIANS

Economic Growth

Canada's hydrogen economy will create new jobs in R&D, manufacturing, and services. Hydrogen will also become a new export currency for both regional energy economies in Western, Central, and Eastern Canada, and in the international market. This will allow Canadian energy companies to move up the value chain as an end-use fuel provider in a zero-emission future. Canadian companies already export goods and services related to hydrogen and fuel cell technologies, as well as in adjacent complementary sectors like CCUS, throughout the world. Growth of domestic deployments will serve as important reference projects to help these Canadian businesses continue to thrive and grow.

If Canada seizes the hydrogen opportunity, the domestic market for direct hydrogen and related product sales could be worth more than $50 billion per year by 2050, with additional opportunity related to indirect revenues and export offering the potential to approximately double the value of the sector. It is estimated that more than 350,000 Canadians could be working in the hydrogen sector by 2050, providing an opportunity to pivot some of the >800,000 workers in traditional energy sector jobs as well as create new jobs. This also provides the potential to create more equitable and inclusive workforces, by mobilizing participation from underrepresented groups including but not limited to women, youth, and people with disabilities. Hydrogen production and use also provides opportunities for Indigenous communities and organizations to lever their existing resources to open new market opportunities.

Transformative Opportunity for Canada's Petroleum Sector

Hydrogen is critical to achieving a net-zero transformation for oil and natural gas industries. It provides an opportunity to leverage valuable energy and infrastructure assets, including fossil fuel reserves and natural gas pipelines, in a way that is carbon-free at the point of use, providing a pathway to maximize these valuable assets in a 2050 carbon neutral future. The petroleum sector is an important part of Canada's energy sector and contributor to the Canadian economy, especially in Alberta. The recent decline in oil prices has had a large impact on Canada's oil and gas industry, which in turn creates ripple effects in other industries. Advancing a hydrogen economy will reduce the carbon intensity of conventional fuels and provide opportunities to diversify the sector.

In a net-zero energy system of the future, distributed combustion of fossil fuels like natural gas will be limited, meaning that gas utilities must transform their current suite of products and services, if they are to remain competitive. Renewable natural gas and landfill gas can displace natural gas, but supply is limited. Hydrogen produced at scale can be the long-term answer for Canada's natural gas utilities to stay competitive in a carbon constrained future.

The role of hydrogen in Canada's petroleum sector will shift over time. Initially low CI hydrogen offers a compliance pathway to reduce carbon intensity of conventional fuels. In parallel as the demand for hydrogen as a transportation fuel grows through increasing deployments of fuel cell vehicles, the sector will determine how best to participate in the value chain. Liquid synthetic fuels combining non-emitting hydrogen with CO_2 recovered through direct air capture may also play a role as a feedstock for GHG neutral, energy-dense liquid fuels for end-use applications like industrial processes as well as large marine vessels and aircraft still utilizing internal combustion engines.

Energy Resilience

Hydrogen is a versatile energy carrier that can be created from a number of different pathways, and this diversity of feedstock creates resilience in Canada's energy system. Hydrogen can help regions reliant on energy imports to become more energy independent. Hydrogen can also be the energy vector to tie disparate energy systems together into a more optimized and resilient, integrated energy system.

Hydrogen does not compete with direct electrification, but rather can help enable increased penetration of renewables by providing time shifting and energy storage capabilities. While the primary source of renewable energy in Canada is hydroelectricity which comes with inherent energy storage capability, wind power capacity has been growing steadily in the last 10 years. Electricity from wind energy is one of the fastest growing sources of electricity in the world and in Canada, now making up 4% of the national electricity generation with Ontario and Quebec leading in capacity.

As seen in countries like Germany, hydrogen can be the best option for utility scale energy storage as electricity grids reach greater penetrations of variable renewables as a ratio of the overall mix. Prince Edward Island by way of example, with 98% of local electricity generation coming from wind, currently relies on importing dispatchable grid power from New Brunswick. Hydrogen could be a solution to provide dispatchable power to increase energy independence and could also be used directly for heating in the winter as a hybrid system to offset seasonal spikes in electric heating demand. The flexibility of hydrogen as an energy carrier provides customizable options for each region in Canada.

Cleaner Air

When hydrogen is used in an electrochemical fuel cell, it emits nothing but water, completely eliminating particulate emissions, SO_x, NO_x, and ground-level ozone. When combusted, it is cleaner burning than other chemical fuels. Increased hydrogen adoption leads to cleaner air, and cleaner air means improved health outcomes for Canadians.

Although substantial efforts have been made to improve air quality in Canada over the last few decades, indicators suggest that outdoor air pollution continues to be an important public health issue in Canada[1]. Approximately 2% of deaths, excluding deaths from injuries, can be attributed to ozone exposure and 0.8% to fine particulate exposure, and the proportion of deaths that can be attributed to ozone shows an increasing trend. Global deployment of hydrogen in zero-emission fuel cell vehicles is focused both on meeting health-based air quality standards and greenhouse gas emission reduction goals. It is anticipated that more cities will impose further restrictions and bans on PM2.5-emitting diesel trucks to improve air quality for their citizens through initiatives such as the C40 Cities program.[2]

Meeting Decarbonization Goals

Hydrogen's ability to contribute to decarbonization of energy systems is the biggest driver for adoption.

Under the Paris Agreement, Canada committed to reducing GHG emissions by 30% below 2005 levels by 2030, setting a 2030 target of 511 Mt. The Government of Canada has also announced a target to achieve net-zero emissions by 2050. The magnitude of the challenge is 729 Mt-CO_2e reduction over the next 30 years based on 2018 emissions levels. In reality that challenge is far greater, as increasing population and economic growth will be competing forces in the efforts to decarbonize.

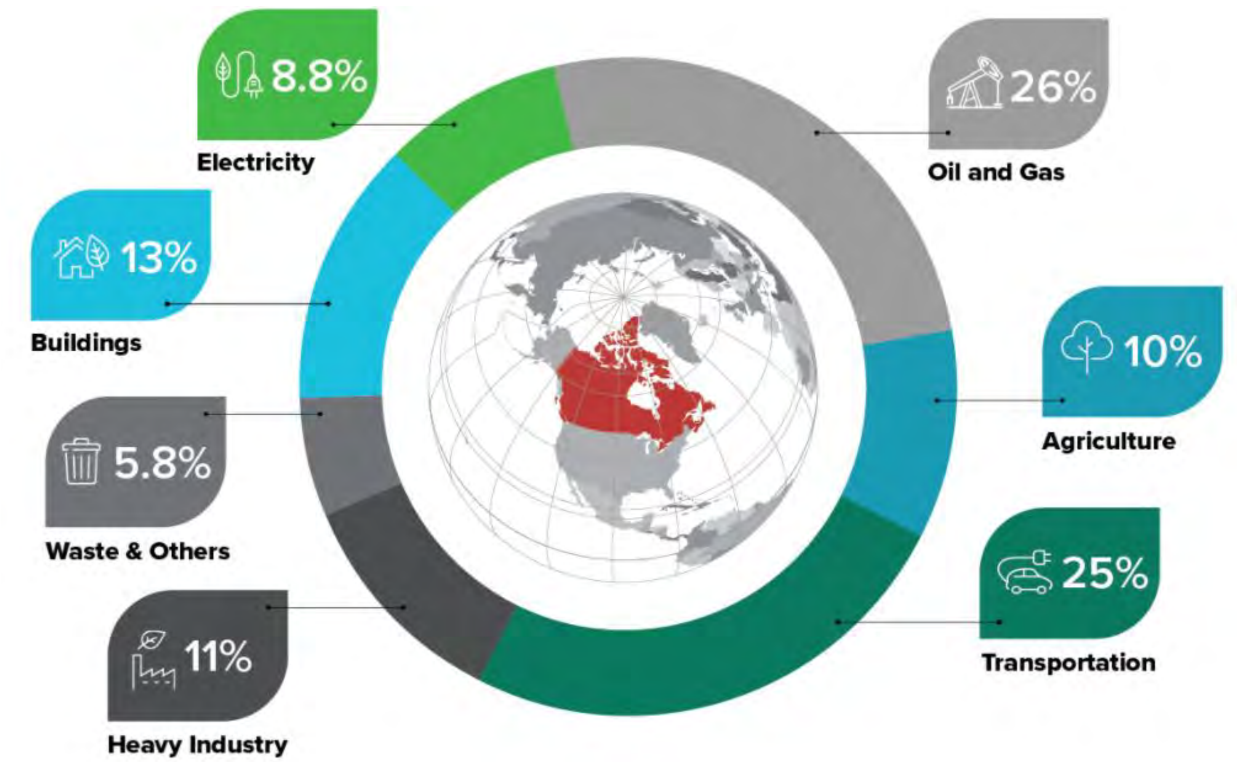

Figure 3 – Canada's 2017 GHG Emission Inventory[1]

Distributed combustion of carbon-based fuels is a significant contributor to Canada's GHG emissions in oil and gas, transportation, buildings, electricity, and heavy industry sectors.

Many levers will be needed to achieve Canada's net-zero emissions target by 2050. Low CI hydrogen shows the potential to contribute to the 2050 GHG reduction challenge, addressing the toughest third of applications where other options like direct electrification may not be technically or economically favourable. Applications such as long-range transportation, high-grade heat for industry and buildings, and for use as a feedstock in industrial process are best served by low carbon intensity hydrogen.

[1] Government of Canada. (2017). *Canada's actions to reduce emissions*. Retrieved from https://www.canada.ca/en/services/environment/weather/climatechange/climate-plan/reduce-emissions.html

2. What is Hydrogen?

Hydrogen's decarbonization potential is garnering significant global interest as a critical element in net-zero energy systems. However to fully understand the economic and environmental opportunities that hydrogen presents, it is important to understand some hydrogen fundamentals. Hydrogen is a versatile, carbon-free energy carrier that can be produced from a variety of feedstocks that are abundant across Canada. Hydrogen can be converted to electricity through a fuel-cell in electric vehicles and power generation equipment, combusted to produce heat, or used as a feedstock in a range of chemical and industrial processes.

HYDROGEN FUNDAMENTALS

Hydrogen is the first element on the periodic table as it is the simplest and lightest element on earth – approximately fourteen times lighter than air. Hydrogen is the most abundant element in the universe, accounting for about 75% of all mass. In its natural and gaseous state, hydrogen is invisible, odorless, tasteless, and non-toxic, making it difficult to detect. Like electricity, hydrogen is an energy carrier that transports useable energy created elsewhere to another location. Hydrogen has the highest energy per mass of any fuel; the energy in 1 kg of hydrogen is the same as approximately 2.8 kg of gasoline. However, hydrogen has a low volumetric energy density and as a result cost-effective distribution and storage is a challenge.

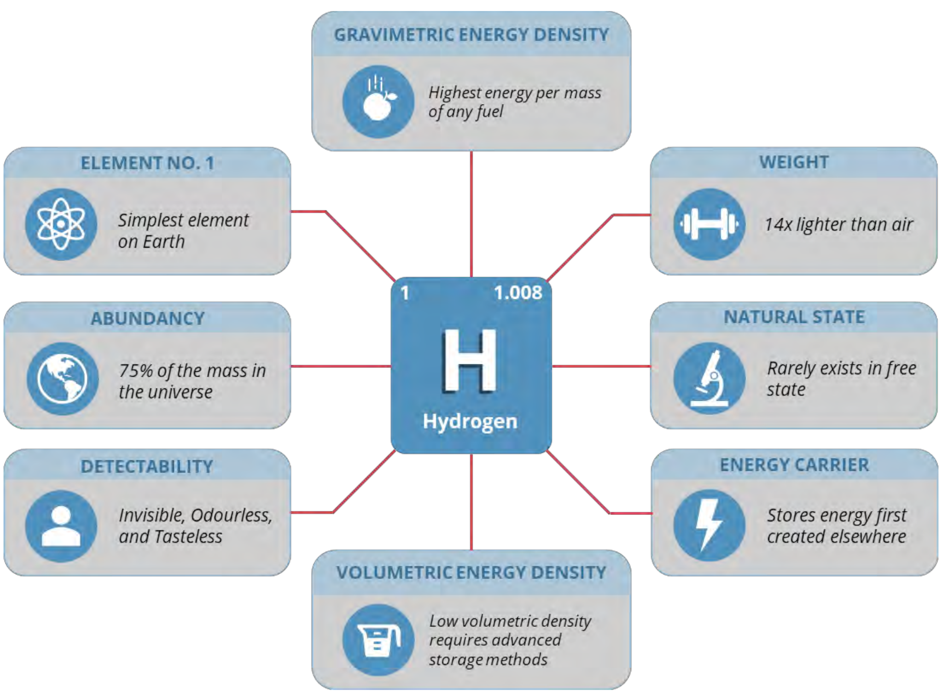

Figure 4 – What is Hydrogen?

Its ability to produce electricity with limited by-products makes hydrogen a desirable alternative fuel. The chemical reaction between hydrogen and oxygen produces electricity, heat, and water, with no pollutants or carbon emissions released at the point of use. Hydrogen is also a clean burning fuel when combusted. Despite the abundance of hydrogen in the universe, it is rarely found in its natural state on earth and is commonly found bonded in other sources such as water (H_2O) and methane (CH_4). Electrolysis and steam methane reforming are common practices used to extract hydrogen from water and methane, respectively.

Benefits

Hydrogen is a versatile and unique energy carrier that enables economic and environmental benefits and can play a significant role in decarbonization of energy systems. As a compressed gas or liquid, hydrogen is a multifaceted energy carrier. It has the highest energy per mass of any fuel allowing it to transfer large amounts of energy from its point of production to end-use application. Hydrogen can be produced from clean energy sources and is carbon and pollutant-free at its point of use when used in a fuel cell.

Hydrogen is suitable for energy-intense applications where electrification is challenging or limited, and where applications currently relying on low-cost natural gas are more suited to energy-dense chemical fuels. Similarities between natural gas and hydrogen include their safety considerations, ability to be transported over long distances via pipeline or road, and versatility as energy carriers, making hydrogen an excellent alternative to natural gas in a range of applications.

Figure 5 – Key Benefits of Using Hydrogen

Hydrogen use as a fuel for FCEVs is quickly becoming an attractive zero-emission alternative for transportation, especially heavy-duty vehicles and transit buses that require energy dense fuels. Hydrogen can also be used as a fuel for power generation which allows for load management, and energy storage. This enables the growth of the variable renewable power sector.

Hydrogen can be burned directly or as a blend with natural gas to reduce carbon emissions in providing building heat and high-grade heat for industry.

Hydrogen is commonly used as a feedstock for industrial processes such as petroleum refining, bitumen upgrading, ammonia production, methanol production, and steel production.

GLOBAL MOMENTUM FOR CLEAN HYDROGEN

Current Global Hydrogen Production by Energy Source

Figure 7 shows the global production of hydrogen by energy source in 2018. The total global production of hydrogen in 2018 was 144 Mt, in which 67% of production was deliberate, and 33% was produced as a by-product to industrial processes.[1]

Most of the hydrogen produced today is made from fossil fuels. In 2018, 48% of total hydrogen produced worldwide was derived from natural gas. Hydrogen production from coal, which is mostly due to its popularity as an energy source in China, accounted for 18% of production. Electricity and oil each contributed 0.48%, and the balance was produced as a by-product of another industrial process such as sodium chlorate and chlor-alkali production.

Current Global Hydrogen Demand

Global demand for hydrogen in 2018, displayed in Figure 8, was 115 Mt-H_2.

Applications utilizing pure hydrogen accounted for 60% (69 Mt-H_2) of all demand. Pure hydrogen for oil refining and ammonia production were the most common end-uses, accounting for 33% and 27% of total demand, respectively. The remainder of pure hydrogen use in 2018 included transport, chemicals, metals, electronics, and glass making industries.

Demand for mixed hydrogen covered the remaining 40% (46 Mt-H_2) of the market with other end-uses such as heat generation from steelworks arising gases and by-product gas from steam crackers accounting for 23% of total demand. Other uses of mixed hydrogen included production of methanol and direct reduced iron steel (DRI).

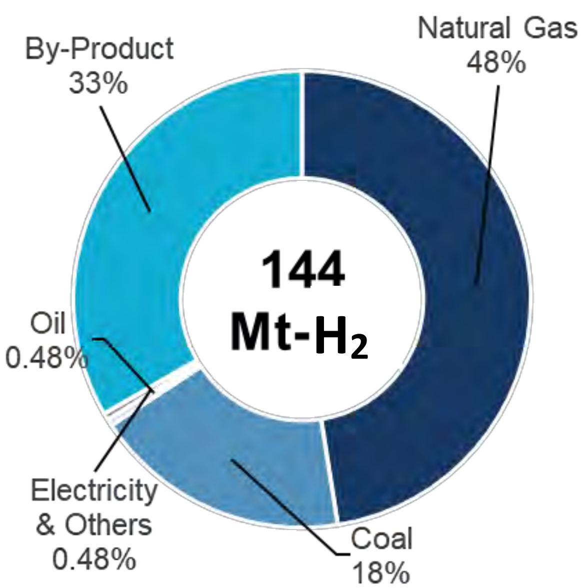

Figure 7 – Global Hydrogen Production by Energy Source (2018)[1]

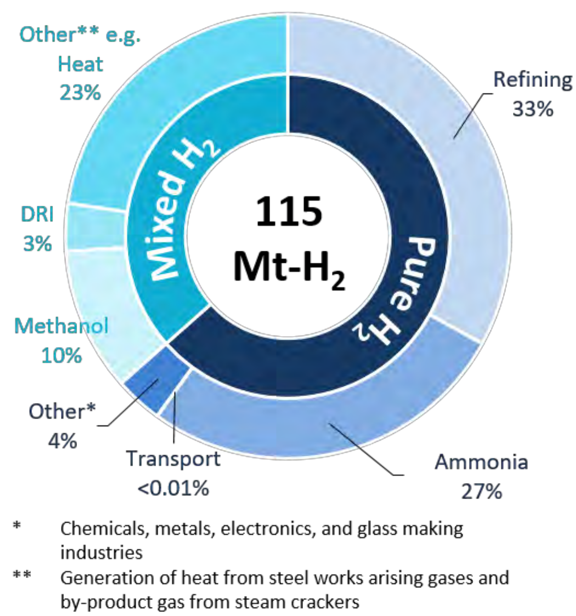

Figure 8 – Global Hydrogen Demand by End-Use (2018)[1]

[1] IEA. (2019). *The Future of Hydrogen*. Retrieved from https://www.capenergies.fr/wp-content/uploads/2019/07/the_future_of_hydrogen.pdf

Interest in hydrogen in the global energy transformation is growing rapidly with projections indicating at least a tenfold increase in demand in the coming decades. Since 2010, global demand for hydrogen has grown by a moderate 28%. However, studies indicate that hydrogen, backed by the right incentives, investments, and policies, could provide between 18% and 24% of global energy demand by 2050[1], with some countries being much higher. The five largest consumers of hydrogen are expected to be China, the EU, Japan, South Korea and California, based on their existing strategies and targets.

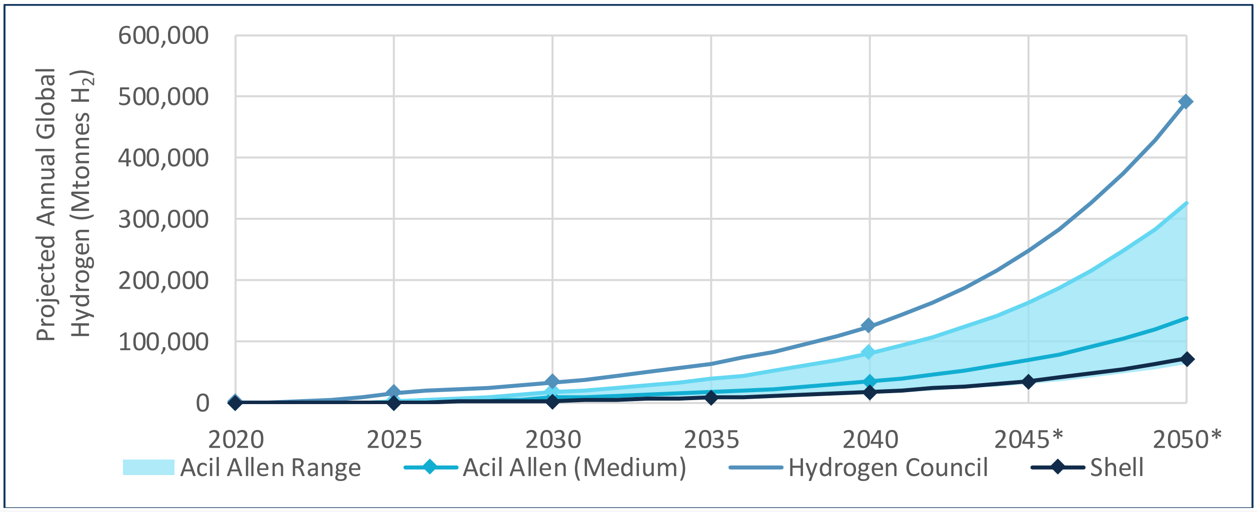

Figure 9 – Ranges of Estimates for Annual Global Hydrogen Demand

Countries around the world are developing strategies and roadmaps to inform their unique paths toward a hydrogen economy. These country- and region-specific strategies seek to make optimal use of supply pathways and end-use applications for hydrogen to power their clean economies and to position themselves in the international market. The number of countries with polices that directly support investment in hydrogen technologies is increasing, along with the number of sectors they target. Figure 10 shows announcements of national or regional strategies, major project plans, and other major plans or investments in the last two years. According to the Hydrogen Council, as of January 2020, 18 governments, whose economies account for more than 70 per cent of global GDP, have developed hydrogen national strategies.[2]

3. Canada's Production & Distribution Opportunities

Canada is well positioned to become a top global producer of clean hydrogen. Specifically, hydrogen can be made from a variety of Canadian feedstocks, including water and clean electricity, fossil fuels, biomass and as a by-product from industrial processes. The scale of projected domestic and global hydrogen demand will require Canada to maximize use of all low carbon intensity pathways across the country. This will give all regions the opportunity to benefit from their unique mix of production, based on local resources and economic factors and Canada's extensive natural gas pipeline network, combined with new storage and distribution assets, can be leveraged to move hydrogen from production to end-use locations.

PRODUCTION PATHWAYS

Hydrogen is a chemical energy carrier that can be made from a variety of feedstocks, including water and electricity, fossil fuels including natural gas and crude oil, biomass, and as a by-product from industrial processes. Canada has a distinct advantage as a hydrogen producer owing to its significant low-cost hydrocarbon resources and abundant clean electricity supply from sources including hydroelectricity, nuclear, wind and solar. The various ways hydrogen is produced, from input feedstocks to output bulk gas, are known as its production pathways. All energy carriers, including fossil fuel and electricity, experience conversion losses when they are produced, distributed, and used. These losses accumulate along the production pathway and affect the overall efficiency of the energy carrier. In the same way, the carbon intensity of the various processes in the production pathway add up to the overall carbon intensity, typically expressed in grams-CO_2e/MJ. In evaluating hydrogen production pathways, together and relative to other energy carriers, the conversion efficiency, carbon intensity, feedstock availability, cost, and storage and distribution impacts must all be considered.

Hydrogen molecules do not generally exist on their own in a free state in nature but are found in many abundant compounds. Hydrogen must be produced from feedstocks using energy inputs. When investigating viable local hydrogen pathways, the availability of both feedstocks and energy sources should be considered. Hydrogen also has the advantage of being carbon free at the point of use, making it ideal for both distributed and centralized consumption. When combusted, hydrogen does not produce greenhouse gases, particulates, SO_x, or ground-level ozone, although there can be NO_x emissions. When used in an electrochemical fuel cell, it emits nothing but water. However, production of hydrogen can lead to greenhouse gas emissions and the production pathway defines the carbon intensity. Given that a big driver for the use of hydrogen in Canada is the GHG reductions it can offer, it is important for Canada to focus future hydrogen production on economic low carbon intensity pathways.

Canada is a major hydrogen producer today with an estimated 3 million tonnes produced annually primarily via steam methane reforming of natural gas for industrial uses including fuel refining and nitrogen fertilizer production, ranking in the top ten of global hydrogen producers. While steam-methane reforming alone is not considered a low carbon intensity hydrogen pathway, Canada is well placed to transition to clean pathways going forward.

Colours are often used to represent the different hydrogen production pathways. For reference, common colour definitions are provided in Table 1. While this terminology is widely used, definitions and delineations are not standardized and can lead to ambiguity. In this section, the various production pathways will instead be described in terms of their input feedstocks and estimated carbon intensities.

Canada has among the lowest CI electricity supplies in the world given our hydroelectric generation capacity and status as a Tier-1 nuclear region, abundant fossil fuel reserves, world class CO_2 storage geology, potential for growth in variable renewables, large scale biomass supply, and freshwater resources, all of which can be leveraged to produce hydrogen.

Table 1 – Common Hydrogen Feedstock and Production Pathways Being Researched and Deployed

Production Process		Feedstock & energy source	Pros and Cons	Examples
GREY	Produced by steam methane reformation **without** carbon capture and sequestration (CCS)	**Feedstock:** natural gas, gasified coal	Pros: lowest cost, abundant Cons: highest carbon intensity	Canada produces approximately 3 million tonnes of grey hydrogen per year primarily for industrial use.
BLUE	Produced from fossil fuels by steam methane reformation, pyrolysis or other processes **with** carbon capture and sequestration (CCS).	**Feedstock:** natural gas, coal, crude bitumen	**Pros:** low-cost, abundant, low CI, pyrolysis offers scale and siting flexibility **Cons:** SMR pathway siting is constrained by CCUS, feedstock is not renewable	Alberta's Quest project
GREEN	Produced from water by electrolysis using renewable electricity such as hydroelectricity, wind or solar.	**Feedstock:** Water **Energy source:** Renewable electricity	**Pros:** lowest carbon intensity, scalable **Cons:** highest cost, opportunity cost - competes with electrification demand	Air Liquide's 20 MW electrolyzer plant in Becancour, Projects developing in BC to support hydrogen fueling network.
NUCLEAR	Produced from water by electrolysis or high temperatures from nuclear energy	**Feedstock:** Water **Energy source:** Uranium / nuclear electricity	**Pros:** low carbon intensity **Cons:** limited availability and siting constraints	Feasibility study planned in Bruce County.

An overview of mature Canadian production pathways is shown in Figure 11. Additional emerging technologies are under development and also show promise.

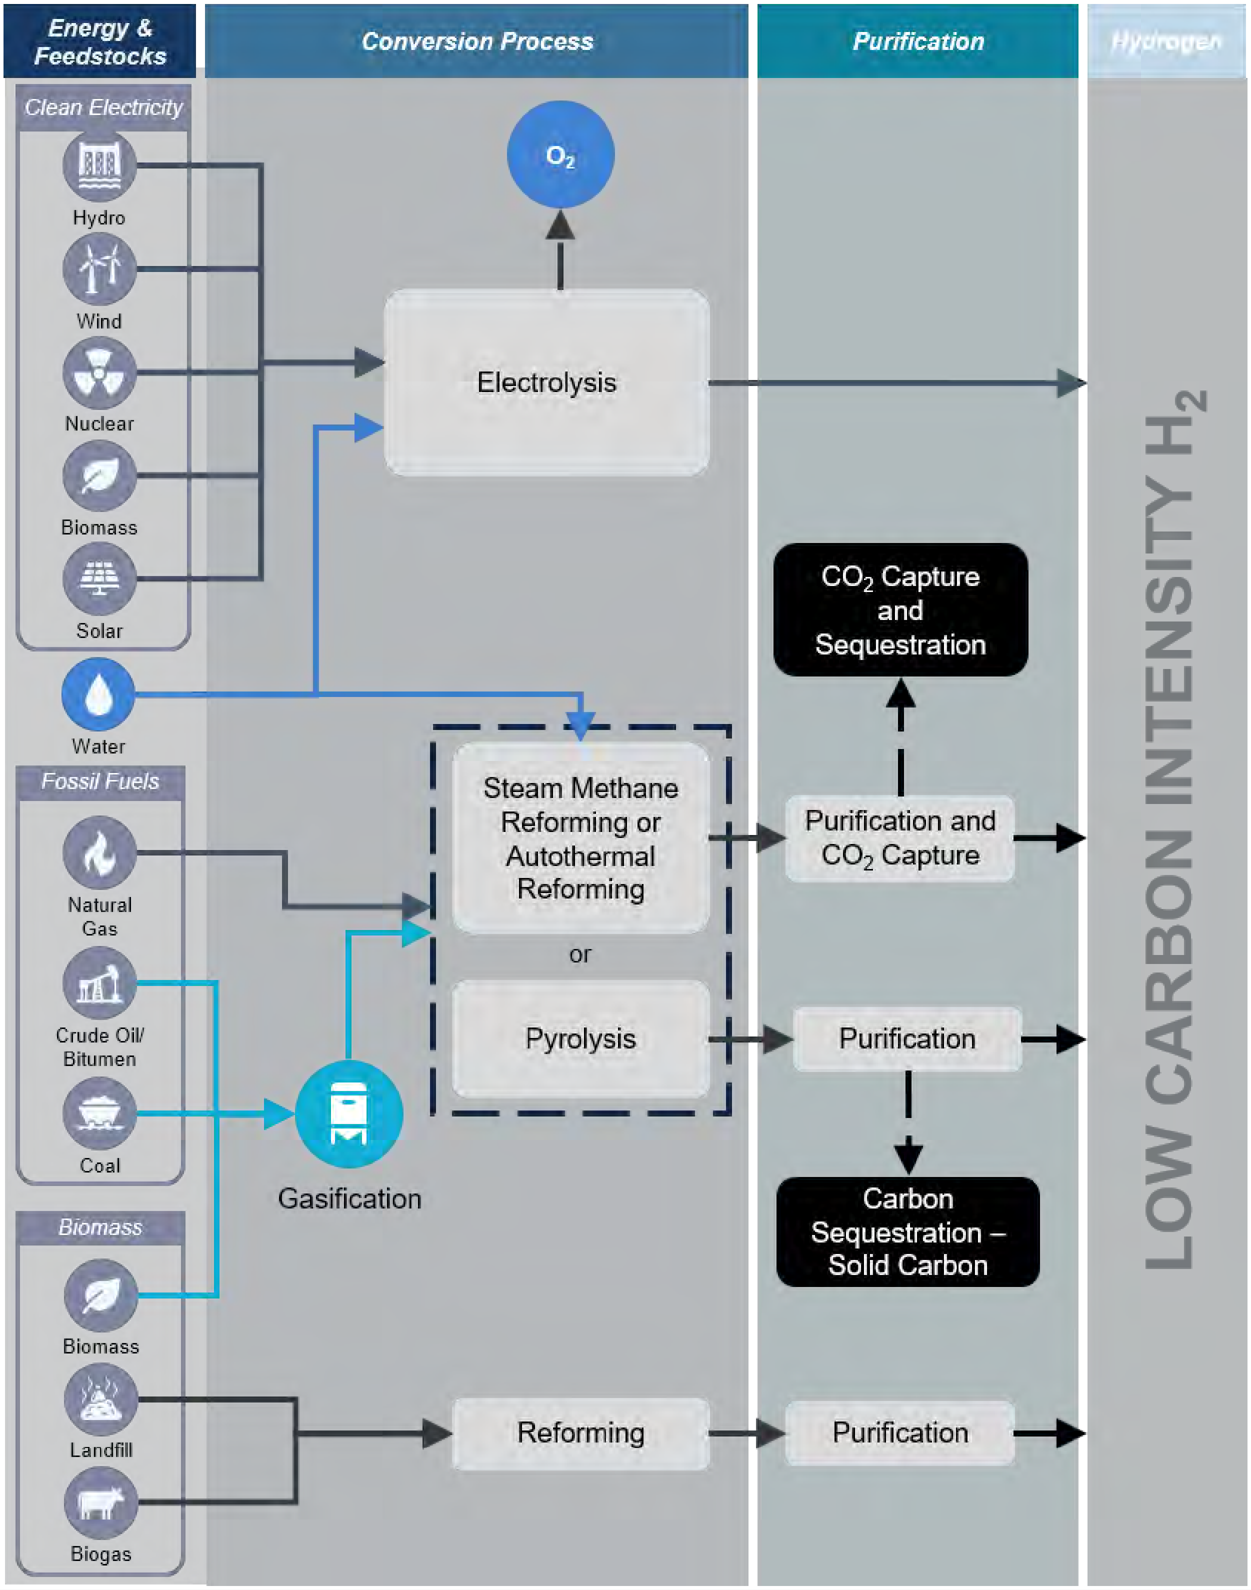

Figure 11 – Hydrogen Production Pathways in Canada

Hydrogen Production from Water & Electricity

Canada is well positioned as a producer of hydrogen from electricity given that 67% of Canada's electricity supply comes from renewable sources and 82% from non-GHG emitting sources[1]. Canada is also the world's third largest producer of hydroelectricity. These large, predictable, and low-carbon sources of electricity are favourable for the large-scale production of hydrogen using electrolysis.

Electrolysis is the process by which electricity is used to split water into hydrogen and oxygen. In this process, water is split into hydrogen and oxygen using an electric current and an electrolyte or membrane. About 9 L of freshwater is required for every 1 kg of H_2 and 8kg of O_2 produced. The resulting hydrogen is very pure and can be used directly in transportation and other end-uses without further processing. The oxygen, while often vented, can also be used in medical or industrial applications.

The main electrolyzer technologies are alkaline, Proton Exchange Membrane (PEM) and Solid Oxide Electrolysis Cells (SOEC). Alkaline is an older technology that has been in use for over a century. It operates best with a constant load, has low capital costs and can scale to larger than 150 MW. PEM electrolyzers rely on the same membrane technology as PEM fuel cells. They can be operated at a range of loads and can respond dynamically making them advantageous for electrical utilities looking for flexible demand to pair with variable renewables. The final technology, SOEC, is still being commercialized and operates at high temperature. There is potential to combine these electrolyzers with output heat from nuclear power plants, and geothermal and solar thermal systems.

Renewables & Hydro

Canada is the world's third largest producer of hydroelectricity. The provinces with the greatest portion of hydroelectric power production are:

- Manitoba: 96.8% hydroelectric generation
- Quebec: 95% hydroelectric generation
- Newfoundland and Labrador: 93.7 % hydroelectric generation
- Yukon: 92% hydroelectric generation
- British Columbia: 90% hydroelectric generation

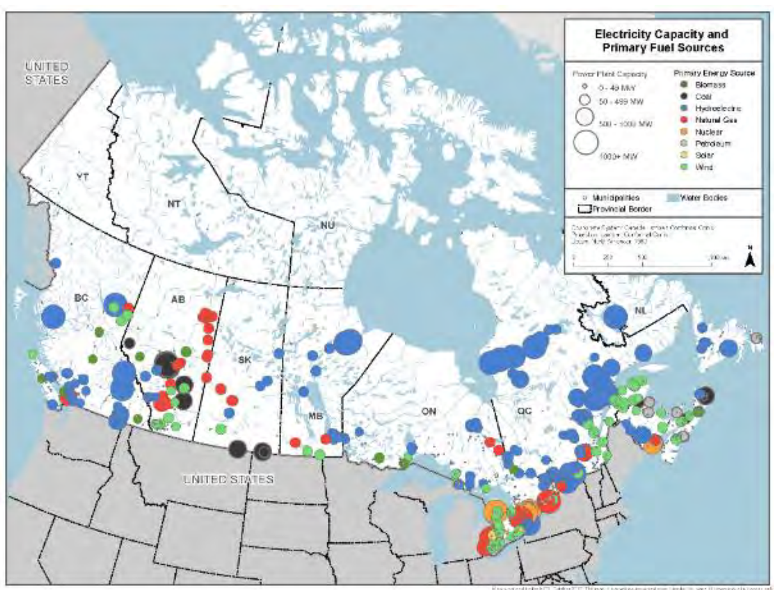

Figure 12 – Electricity Capacity and Primary Fuel Sources per Province in Canada

[1] NRCan. (2020). *Electricity facts*. Retrieved from https://www.nrcan.gc.ca/science-data/data-analysis/energy-data-analysis/energy-facts/electricity-facts/20068

In these provinces, the electric utility providers could play an important role in the hydrogen value chain. Electrolyzer farms co-located at generation facilities can provide grid regulation services, and the hydrogen produced can provide an alternative high-value revenue stream for the utilities. Decentralized production via electrolysis can also be co-located close to demand centers. Electrolyzers are inherently scalable, and many equipment manufacturers have developed containerized solutions that are easy to site.

Independent Power Producers, for example operating run of river, wind, or solar power generating assets, can also play an important role in the value chain, particularly in provinces where power purchase agreements are up for renegotiation.

As increasing wind and solar are brought into Canada's energy mix, they offer the potential to expand the production of low carbon hydrogen and reduce costs for variable supply. Hydrogen can in turn improve the economics of variable renewables by providing large-scale energy storage that optimizes the utilization of these power generation assets. For example, Ontario curtailed in the order of 6-8 TWh of renewable electricity in 2016 that resulted in significant lost revenue, that could instead have been used to produce hydrogen.[2] Canada ranks 9th in the world for both wind and solar installations. Generation from wind farms and solar photovoltaic panels grew from a negligible amount in 2005 to approximately 5% of total electricity generation in 2018, with Canada's wind power capacity at 13.0 GW and solar power capacity at 2.9 GW. The majority of the wind facilities in Canada are located in Ontario, Quebec, and Alberta, while Ontario is home to over 98% of Canada's solar installations.

Nuclear

Nuclear reactors produce electricity as well as process heat that can be used in the production of low CI hydrogen. Large reactors are suitable for large-scale centralized hydrogen production, while small modular reactors will be more suitable for distributed hydrogen production. Hydrogen can be made via electrolysis using inexpensive off-peak electricity from existing nuclear power plants. There are efforts underway to study the economics of nuclear hydrogen production in Ontario at the Bruce Nuclear Generating Station. Opportunity for nuclear hydrogen production today is in Ontario, where three of the four nuclear generation stations are located, and in New Brunswick.

Small modular reactors are under development in Canada and around the world. Some small modular reactor designs can produce high temperature process heat, which enhances the overall efficiency of hydrogen production (see below). Commercial deployment of advanced reactors and small modular reactors is not expected to be a near-term opportunity but offers a longer-term opportunity for production of hydrogen.

High Temperature Nuclear and Electrolysis

There are several hydrogen production pathways that utilize the high temperature heat produced by nuclear reactors. One method is to use the steam produced by nuclear reactors as the reactant in the steam methane reformation process described above. This would eliminate the need to use natural gas to create steam and would simplify and lower the cost of carbon capture.

Using steam in the place of liquid water in an electrolyzer can also reduce the electricity input requirements as steam is easier to separate than water. SOEC electrolyzers, which operate at elevated

[1] CER. (2017). Retrieved from https://www.cer-rec.gc.ca/nrg/ntgrtd/mrkt/nrgsstmprfls/mg/cnd-mp-lctrct-eng.pdf

[2] Environmental Energy Commission. (2018). *2018 Energy Conservation Progress Report, Volume One*. Retrieved from http://docs.assets.eco.on.ca/reports/energy/2018/Making-Connections-07.pdf

temperatures, could take advantage of the steam produced by nuclear reactors to improve the efficiency of hydrogen production and make use of heat that would otherwise go to waste.

As new nuclear reactor designs are commercialized, including small modular reactors, high temperature fission reactors, and eventually fusion reactors, the output water temperature will continue to increase. Thermochemical water splitting uses heat from 500-2000ºC and reusable chemical reactants such as cerium oxide and copper chloride to generate hydrogen. Because the process is a closed system, the chemicals are reusable. High temperature nuclear hydrogen production could be a valuable cogeneration process for Canada's next generation nuclear sites, improving the overall system efficiency.

Hydrogen Production from Fossil Fuels with CCUS

Canada has vast fossil fuel resources in the form of natural gas, crude oil, and bitumen. When combined with Carbon Capture, Utilization, Storage (CCUS), these resources can be converted into low CI hydrogen. This pathway has the advantage of being the lowest cost production method of large-scale, clean hydrogen based on today's technologies and commodity costs, and with Canada's fossil fuel reserves and CO_2 storage capacity can meet large-scale demand for many decades. This section summarizes the main commercial hydrogen production pathways from fossil fuels in Canada and their associated options for CCUS.

There is significant growth potential in CCUS and hydrogen production in Canada, which could have a major impact on emissions reductions. Based on recent analysis by the Transition Accelerator, there is an upper bound potential for eight times the current domestic production of hydrogen from natural gas in a 2050 net-zero energy system in Canada. The CCUS requirement for this magnitude of hydrogen production would be approximately 203 Mt CO2 per year. Given Canada's current CCUS operational projects capture and store about 4 Mt of CO2 per year, this would represent a significant increase in CCUS activity. These opportunities have also been identified in Alberta's Natural Gas Vision and Strategy goal of large-scale blue hydrogen production with CCUS deployment across the province by 2030.

TRANSITION PATHWAY FOR CANADA' OIL & GAS SECTOR

Canada has the potential to produce vast amounts of hydrogen from natural gas coupled with CCUS. Provinces with the highest natural gas production are Alberta and BC, followed by Saskatchewan, and these are the provinces most suited to this hydrogen production pathway.

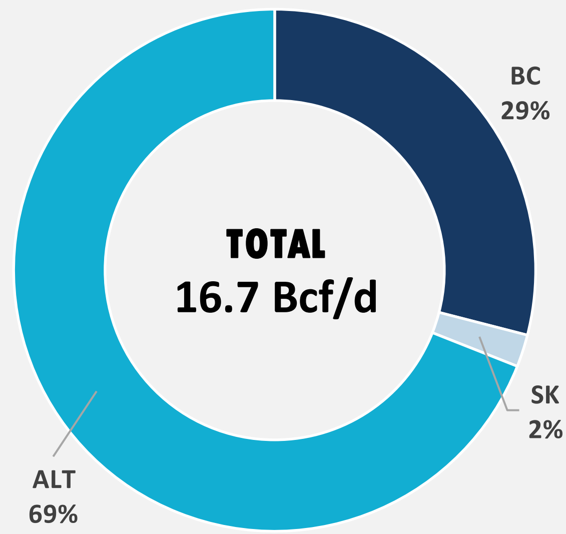

Figure 13 – Canada's 2018 Marketable Natural Gas Production by Province

In Alberta, a new Task Force has been announced to advance the hydrogen economy in Alberta's Industrial Heartland to seize this transformative opportunity. The Task Force will bringing together production, distribution and supply industries in the area to de-risk investments, with a particular focus on heavy-duty transport. This type of multi-facetted deployment, covering actions across the value-chain is an example of an early HUB for deployment.

Natural Gas

Canada is the world's fourth largest producer and sixth largest exporter of natural gas. Canadian marketable resources of natural gas can sustain current production levels for up to 300 years. However, when burned or utilized directly as methane, GHG emissions are released. If the methane is instead converted into hydrogen and combined with CCUS, the carbon intensity of the resulting fuel can be reduced by approximately 90%. Hydrogen production from natural gas offers a unique opportunity to leverage Canada's vast gas reserves to produce a low carbon intensity energy carrier while other production technologies are being scaled.

The carbon, when captured in the form of CO_2, can be used for enhanced oil recovery or as an industrial feedstock, provided the emissions do not go back into the atmosphere. It can also be stored underground provided the right sub-surface geology exists. The production of hydrogen from natural gas via steam methane reforming with CCUS will be constrained by the availability and accessibility of carbon storage geology. Alberta, BC and Saskatchewan have both large natural gas reserves and CO_2 storage potential making them favourable for this production pathway. In the production of hydrogen from natural gas via the pyrolysis pathway, the carbon is captured in the form of solid carbon and this enables distributed production close to demand without geological constraints.

There are three main commercially available methods to convert natural gas into hydrogen and carbon by-products: 1) Steam Methane Reforming (SMR) which uses high temperature water as an oxidant and a source of hydrogen, 2) Autothermal Reforming which use both water and air oxidants, and 3) Pyrolysis which relies on methane splitting into hydrogen and solid carbon using high heat.

In SMR, natural gas is used both as feedstock and as fuel to generate steam. In the first reaction, the methane is combined with steam (H_2O + Heat) to produce a synthetic gas consisting of CO_2, CO and H_2. The synthetic gas is then separated using a Water Gas Shift (WGS) reactor and Pressure Swing Adsorption (PSA). Adding carbon capture at various places in the process adds costs and reduces overall efficiency, but improves environmental performance. Capturing CO_2 from both the WGS and the PSA can reduce emissions by about 60%, while also capturing the flue gas CO_2 can achieve 90% total carbon capture at an additional cost of 45%[1]. SMR is the most widely used technology for hydrogen production in Canada and is expected to continue to be one of the primary pathways going forward, with the addition of CCUS to achieve lower carbon intensities.

[1] Layzell DB, Young C, Lof J, Leary J and Sit S. 2020. Towards Net-Zero Energy Systems in Canada: A Key Role for Hydrogen. Transition Accelerator Reports: Vol 2, Issue 3. https://transitionaccelerator.ca/towards-net-zero-energy-systems-in-canada-a-key-role-for-hydrogen

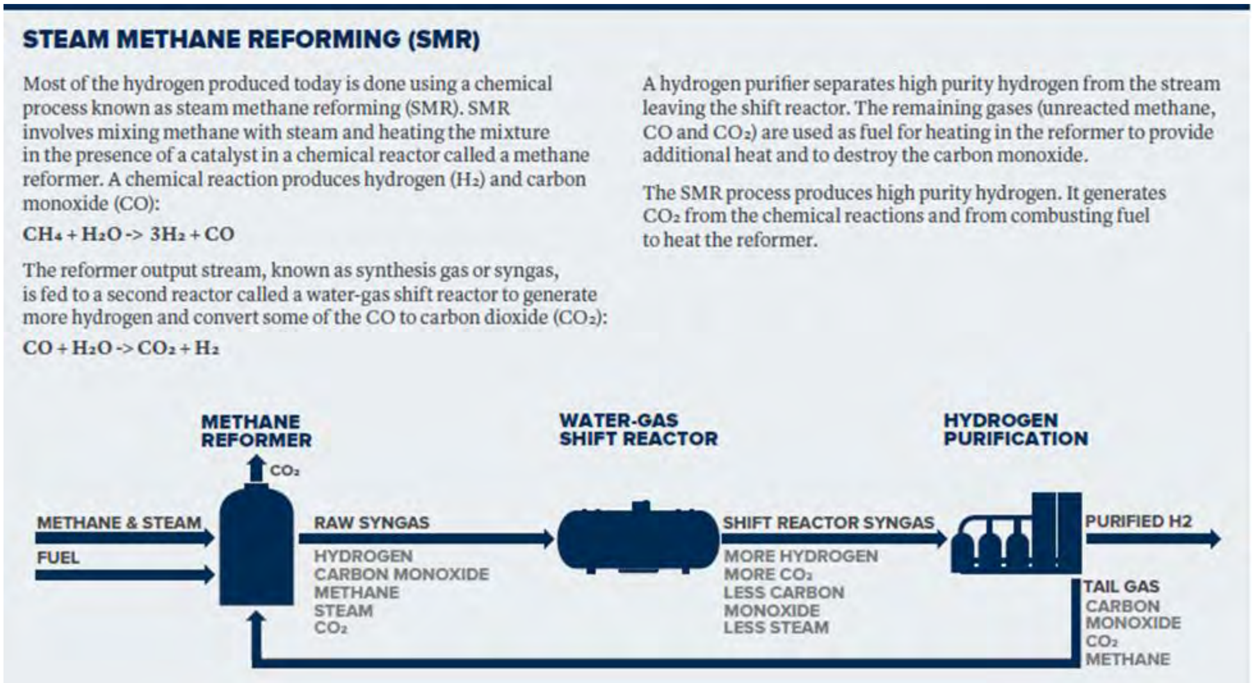

Figure 14 – Steam Methane Reforming (SMR) Process and Description[1]

Autothermal Reforming (ATR) is another technology that uses the heat produced in the reformer itself to achieve higher CO_2 recovery rates. All the CO_2 from the process is produced within the reformer so there is no additional flue gas from heat generation requiring decarbonization. This lowers the cost of CO_2 capture as the resulting gases are more concentrated. ATR is widely used in the ammonia and methanol industries and pilot ATR+CCUS plants are being planned in the UK and EU[2].

Pyrolysis is a developing hydrogen production technology which uses high temperature heat to split the methane molecule into its constituent elements. The result is a very pure form of hydrogen gas and solid carbon. The two main pyrolysis technologies are thermal and plasma pyrolysis. In thermal pyrolysis, heat from natural gas is used to break up the methane molecule. Some of the feedstock methane is not reacted and this is recaptured for use as the process fuel. This reduces the conversion efficiency and increases the CO_2 emissions. Plasma pyrolysis is a specific type of pyrolysis which uses an electric arc to generate a high temperature plasma. While there are significant heat losses, the overall system efficiency can be better than using the electricity to power an electrolyzer[3]. There are many other ways to provide heat to the pyrolysis system and systems based on microwave and photo catalysts are also being developed. The solid carbon is chemically stable and can be used in a variety of industrial materials such as rubber, plastics and in printers. Pyrolysis technology has been deployed commercially but remains limited primarily as a source of commercial solid carbon (thermal black). It is now being developed as an economic alternative to SMR for hydrogen production. Pyrolysis has the potential to produce distributed hydrogen at the point of use, using natural gas as a feedstock and leveraging existing distribution pipeline networks. Because the carbon is sequestered as a solid carbon, production does not need to be co-located where CO_2 can be sequestered.

[3] Ibid

Crude Oil, Bitumen, and Coal

In addition to Canada's natural gas reserves, there are also substantial resources in the form of crude oil and bitumen in the regions of Northern Alberta and Saskatchewan, and coal in Alberta and British Columbia. Gasification of crude oil, bitumen, or coal uses a process similar to gasification of biomass. The feedstocks are reacted with steam and/or oxygen at a high temperature producing a synthetic gas mixture that can be further separated into CO_2 and H_2. This process can take place in an industrial plant once the feedstock has been extracted, in which case CCUS would need to be employed to capture the resulting CO_2. In-situ gasification is an emerging technology currently being developed in Alberta and Saskatchewan for crude oil and bitumen feedstocks. In this process, the gasification takes place deep underground, such as in an existing oil field, and the hydrogen is filtered using a selective membrane. This has the advantage of leaving the CO_2 already underground and sequestered, saving cost and reducing complexity. The selection of reservoirs with appropriate geological properties to hold the CO_2 underground in a stable state is an important consideration for this technology.

Carbon Capture, Utilization, & Storage

To achieve Canada's net-zero by 2050 target, all hydrogen production will need to be carbon-neutral - which includes electrolytic hydrogen from non-GHG emitting electricity, or hydrogen produced from fossil fuels coupled with CCUS – or it will need to be offset, for example through direct air capture of CO_2. At present, fossil fuel derived hydrogen with CCUS is more cost-competitive than electrolytic hydrogen in Canada[1], particularly due to our abundance of low-cost natural gas.

[1] IEA, Energy Technology Perspectives, 2020

Canada has decades of experience in CCUS with leadership in technology innovation; an abundance of suitable geology for permanent CO_2 storage, notably in the Western Canadian Sedimentary Basin[1]; transferable expertise from the oil and gas sector; and growing markets and emerging pathways for CO_2 utilization. Canada is also home to one-fifth of the world's large-scale projects in operation, which has been enabled by the existing policy environment and a strong history of advancing the technology through public-private partnerships. However, challenges remain in terms of high technology costs for some applications, technical and commercial risks, required infrastructure investment, and competitiveness with other countries like the US, UK and Norway with stronger policy incentives in place. Canada's early CCUS leadership has included work to advance hydrogen production with CCUS. Projects include the Shell Quest Project, and the Sturgeon Refinery linked to the Alberta Carbon Trunk Line.

NRCan is considering opportunities for a CCUS sector that will leverage Canada's natural advantages and capabilities to support emissions reductions in industrial sectors (e.g. oil and gas, cement, iron & steel, chemicals, power), enable low carbon hydrogen, other CO_2 based fuels and products, and negative emissions solutions like direct air capture (DAC) and bioenergy with CCS (BECCS).

There is significant growth potential in CCUS alongside clean hydrogen production in Canada, which could have a major impact on emissions reductions. Based on recent analysis by the Transition Accelerator – a pan-Canadian, non-profit organization working on emissions reductions solutions for business and society – there is an upper bound potential for eight times the current domestic production of clean hydrogen from natural gas in a 2050 net-zero energy system in Canada. The carbon capture and storage requirement for this magnitude of clean hydrogen production would be approximately 203 Mt CO2 per year. Given Canada's current CCUS operational projects capture and store about 4 Mt of CO2 per year, this would represent a very significant increase in CCUS activity. These opportunities have been identified in includes Alberta's Natural Gas Vision and Strategy goal of large-scale blue hydrogen production with CCUS deployment across the province by 2030.

Capture & Compression

Capturing CO_2 at the point of conversion of fossil fuels into hydrogen is much easier than capturing it once released into the atmosphere. The concentration of CO_2 in the source gas process stream is a significant driver of cost and energy requirements of capturing CO_2, and these capture and compression costs dominate the overall costs of CCUS[2]. Large, high-concentration CO_2 emissions such as those from ethanol, natural gas processing, and hydrogen production typically have the lowest CO_2 capture costs[3]. Adding

CCUS to SMR plants leads, on average, to cost increases of about 50% for CapEx and requires 10% extra fuel. It also leads on average to a doubling of OpEx as a result of CO_2 transport and storage costs[1].

The Shell Quest Project located in the Scotford Upgrader is a high profile SMR+CCUS project currently operating in Alberta capturing ~1.2Mt-CO_2/year. The captured carbon is dehydrated, compressed, and transported via pipeline ~65 km to a saline aquifer north of Redwater, AB, and injected more than two kilometres underground. In the five years since its start up, Quest has captured and safely stored five million tonnes of CO_2 at a lower cost than anticipated. According to Shell, the cost to operate Quest is about 35% lower than what was forecast in 2015, due to an excellent storage reservoir with significant capacity for CO_2 injection, and strong capture reliability. In addition, if Quest were to be built today, it would cost about 30% less as a result of capital efficiency improvements.[2] Other CCUS projects globally, such as the Northern Lights CCS project in Norway, have incorporated lessons from Quest – which has been sharing knowledge and lessons learned over the last five years to encourage more widespread implementation of CCUS.

CO_2 Transportation & Low-carbon Industrial Hubs

Compressed CO_2 can be transported by ship, pipeline and road. Pipelines are the most economical way of transporting CO_2 in large quantities onshore. The Alberta Carbon Trunk Line (ACTL) pipeline is a major CCUS project in operation and has the capacity to carry ~14.6Mt-CO_2/year along a 240km pipeline. It is supplied by two CO_2 sources, one of which is a byproduct of hydrogen produced via the gasification of heavy oil bottoms at the Sturgeon Refinery. The ACTL has 85% available capacity to facilitate CCUS uptake at additional hydrogen production and other high-emitting facilities in Alberta's Industrial Heartland.

As hydrogen production from fossil fuels scales up, more CO_2 pipelines more will be required to scale up CCUS deployment. Development of low-carbon industrial hubs are trending as a way to advance CCUS opportunities to spur innovation, enable new business models, and encourage development of cost-effective CCUS technologies at scale. Industrial hubs link emitting facilities with CO_2 storage or utilization projects, providing the benefit of shared CO_2 infrastructure, economies of scale, and decreased commercial risk across multiple stakeholders. CCUS hubs are best suited for regions where CO2 storage or utilization opportunities are near clusters of high emitting facilities.

Utilization & Storage

The last stage of CCUS is its long-term storage and sequestration underground or its use in industrial and commercial processes. CO_2 can be stored in porous sedimentary formations including depleted gas, crude oil, and bitumen reservoirs, deep saline aquifers, salt caverns and in coal seams. The long-term suitability of these options depends on their accessibility, the overlying cap rock formations and other factors. Canada is rich in geology that is suitable for CO_2 storage, including sedimentary basins, saline formations and oil and gas formations in proximity to a significant portion of emitting industries.[1] The Western Sedimentary Basin is a geological formation that covers Northern BC, Alberta, and parts of Saskatchewan and contains many potential sites for storage. Deep saline aquifers are the most secure and most widely available storage locations in Canada.

Overall, CO_2 storage is safe, permanent, and well-demonstrated in Canada, with decades of monitoring that proves that injected CO_2 remains within reservoirs. It is important to note that CO_2 storage and use, particularly for enhanced oil recovery, has been in commercial operation since 1972 with hundreds of millions of tonnes of CO_2 successfully sequestered all over the world. As an example of advanced protocols, California Air Resources Board (CARB) under the low carbon fuel standard (LCFS) rules allows negative emission CO_2 anywhere in the world to be sequestered and receive LCFS credits for the CO_2. As part of that they have a monitoring and verification protocol for ensuring that the CO_2 stays sequestered and anyone claiming the credit must comply with that protocol.

A number of new technologies and products are emerging that utilize CO_2 either as feedstock or offer long term sequestration potential, for example in the form of useful products like concrete, liquid synthetic fuels, and consumable beverages. A number of Canadian companies are leading in this space, offering complementary technology expertise that can ultimately also benefit the hydrogen sector.

Hydrogen Production from Biomass

Biomass gasification is considered both renewable and carbon-neutral and is a viable hydrogen production pathway in Canada. Plants consume CO_2 as they grow, so the release of CO_2 through this type of process is net carbon-neutral over its life cycle. Any renewable organic resources comprised of mostly carbon, hydrogen and oxygen can be used a biomass feedstock. Biomass gasification technology extracts hydrogen by gasifying and then reforming forest or agricultural residues or other dry organic wastes. Hydrogen production using bio-energy with carbon capture and storage (BECCS) presents an opportunity not only to decrease emissions on hydrogen production, but in other sectors as well, thanks to the carbon negativity of the process.

Forestry and Agricultural Biomass Gasification

Biomass gasification is a stable technology that uses high temperature steam (generally >700°C) and oxygen from the air to break down biomass into hydrogen and other products without combustion. Biomass gasification is generally undertaken in two stages, 1) An initial gasification stage, and 2) a water-gas shift reaction in which carbon monoxide (CO) is converted to carbon dioxide (CO_2), generating additional H_2. PSA is then used to purify the hydrogen and remove the CO_2.

The economies of scale associated with biomass gasification are substantial, so producing hydrogen in this way requires a centralized production model. Forest and agricultural biomass are in demand in Canada for producing liquid biofuels, renewable natural gas and co-processing in petroleum refineries. While technically viable, biomass gasification requires a large, dependable supply of locally-/regionally-sourced feedstocks to be a major production pathway. Incorporating existing forest product facilities into the hydrogen infrastructure network could capitalize on their position as an aggregator of biomass and serve to improve overall efficiency of resource use. There is also the potential to develop 'biohubs' to help with regional supply challenges. Arguments can be made for investing in biomass collection, storage and processing to support hydrogen production and should be explored further in regional hydrogen plans.

Landfill/Sewage/Agricultural Gas Reformation

Methane gas (CH_4) resulting from the breakdown of organic matter in landfills, sewage treatment plants and agricultural waste sites is another potential source of hydrogen from biomass. Similar to the natural gas SMR or ATR processes, the methane from these sources is collected, reacted with steam, and the hydrogen is separated out. The CO_2 from this feedstock originates from the atmosphere; therefore, the only additional emissions created from the process come from the heat require to generate the steam. Like solid biomass feedstocks, these gaseous waste streams are regionally specific, and are in limited supply. Given the increasing demand for renewable natural gas (RNG) as an alternative fuel, it is likely that these feedstocks will be used directly in methane form rather than be converted to hydrogen.

Other Hydrogen Production Pathways

Industrial By-Product Capture

Many industrial plants produce hydrogen as a by-product. In some cases, by-product hydrogen is captured and used as a feedstock in chemical production, and in others it is simply vented to the atmosphere. A 2019 *British Columbia Hydrogen Study*[1] found that, approximately 18.5 tonnes of relatively pure hydrogen is currently vented to the atmosphere every day in BC. This represents an important near-term hydrogen source for this province and an opportunity to create a new market for industrial plants to sell by-product hydrogen. This production method requires minimal cleanup and represents a low-cost, low carbon intensity hydrogen supply estimated at $0.88/kg prior to distribution and storage, based on the heating value of the fuel. Supply of by-product hydrogen in the near-term is low-cost relative to dedicated new production, and these chemical plants that currently vent hydrogen could become focal points around which near-term deployment HUBs are based.

The supply of this source of hydrogen in Canada that is not already utilized or sold is estimated at about 70,000 tonnes per year[2], or 190 tonnes per day. Canada's chlor-alkali and sodium chlorate plants tend to be located where electricity costs are lowest, including BC, Manitoba, Saskatchewan, and Quebec.

CANADA'S REGIONAL HYDROGEN PRODUCTION RESOURCES

The production pathways adopted in each region of Canada will depend on the availability of feedstocks, energy inputs, and in some cases suitable sites for CCUS. Each region/province will need to carefully consider their entire energy system before investing in any particular production pathway. Overall, the production pathway that makes the most sense for each region will minimize costs and carbon intensity while maximizing the use of local feedstocks and energy sources.

Industry and Provincial Governments will play a key role in determining which hydrogen production pathways will come to fruition over what timeframes in Canada, with government playing the role of establishing policy, for example setting CI limits, and industry determining the most economical pathways that fit within the limits. Overall, a balanced, regional approach to developing Canada's hydrogen supply from a mix of fossil fuel-derived and clean electricity-derived sources is anticipated to evolve. This diversification of fuel sources would best enable production volumes to support the development of domestic and export markets. Figure 15 shows the most likely potential pathways for each province/region based on their existing electrical grid and access to feedstocks.

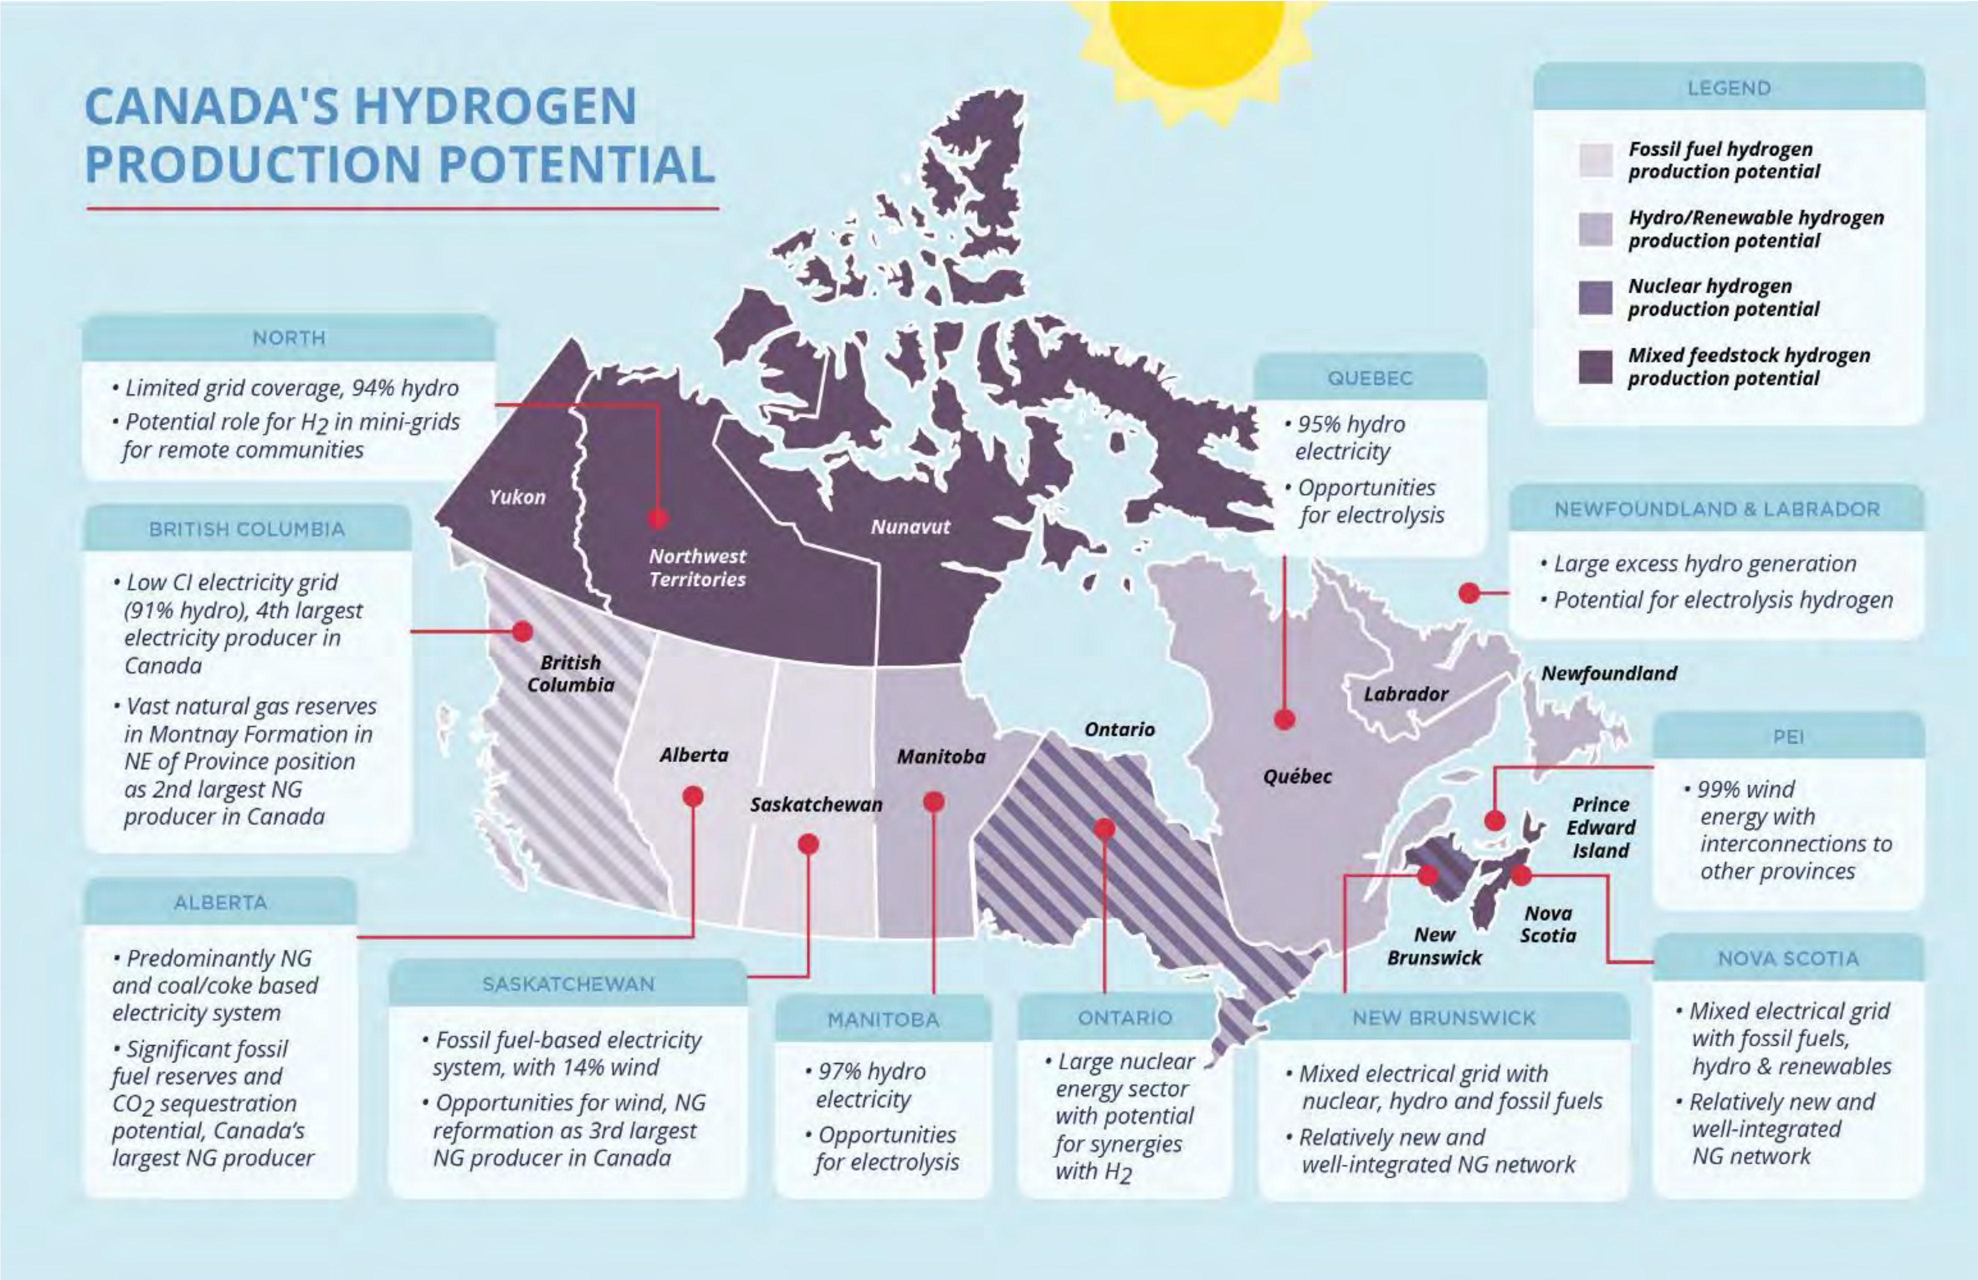

Figure 15 – Provincial Map of Potential Hydrogen Production Pathways

PRODUCTION PATHWAYS' COST & CARBON INTENSITY

The production cost of hydrogen for various pathways is influenced by technical and economic factors, including feedstock costs (e.g. natural gas, electricity), capital costs and ongoing operating costs. According to the IEA, fuel and feedstocks are the largest component of production costs and account for between 45% to 75% depending on where in the world the hydrogen is being produced[1]. Canada has one of the overall lowest cost of production in the world for both SMR+CCUS and hydroelectric electrolysis according to a 2018 report from the Asia Pacific Research Centre[2]. This cost advantage provides an opportunity for Canada to begin producing low-cost, low-CI hydrogen almost immediately. Currently, low CI hydrogen production at scale in Canada is lowest cost when using fossil fuel feedstocks compared to electrolysis pathways. While Canada has competitive electricity prices relative to international markets, costs need to be in the range of <$40/MWh to produce hydrogen at target price points. Industrial tariffs with high peak demand charges and tariff structures that do not recognize decarbonizing benefits can be a barrier to electrolysis pathways.

As demand grows, economies of scale and technical advances will further lower the cost of hydrogen production in Canada, and this will provide time for more renewables to be added to the grid for even lower carbon intensity production. Figure 16 compares projected bulk hydrogen production costs (not including distribution costs) by different pathways projected over time from a range of international and Canadian studies. By 2030, the cost of SMR+CCUS hydrogen is expected to be in the range of ~$1.00 - $2.00/kg-$H_2$ when produced at scale (>100 tons per day - TPD) in Canada based on studies out of Alberta and British Columbia, while the cost of electrolysis from dedicated renewables shows potential to be in the $3.20/kg-$H_2$ range in that timeframe.

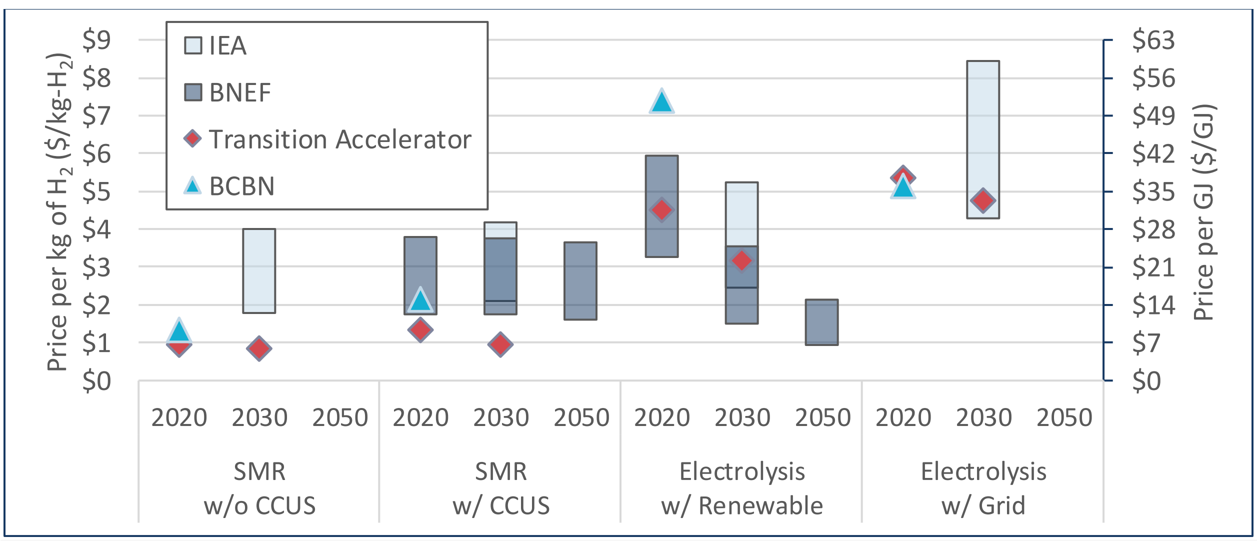

Figure 16 – Comparison of Hydrogen Production Pathway Costs 2020, 2030, and 2050[1,2,3,4]

BloombergNEF predicts the global levelized cost of hydrogen from large renewable energy powered projects will be cost competitive with low carbon hydrogen from natural gas via SMR w/CCUS by 2030. Their study shows that by 2050, renewable hydrogen could be produced for less than a dollar per kilogram[4]. This may not be directly applicable to Canada, but the general trend of renewable hydrogen

[4] BloombergNEF: Hydrogen Economy Outlook, March 20, 2020,

costs coming down over time is valid and warrants further study regionally in Canada. However, this renewable hydrogen would be variable and not at the scale required on its own for large continuous petajoule energy applications. The situation in Canada may favour fossil fuel-based hydrogen over electrolytic hydrogen due to our inexpensive and plentiful natural gas and access to CCUS. However, it should be noted that scale and transportation costs are important factors that have a big impact on delivered cost of hydrogen, particularly as the market is developing. Hydrogen produced vis SMR + CCUS requires significant scale to be economical, which requires high capital investments and relatively long buildout timing. Electrolyzers are modular and easily scaled and can be situated close to end-use applications. It is therefore expected that both will play an important role.

The Carbon Intensity (CI) of hydrogen production is a method for comparing the end-to-end lifecycle GHG emissions of hydrogen as it moves from primary energy source/feedstock to delivered energy commodity. End-use can also sometimes be considered in the lifecycle analysis, but for simplicity this is separated from production pathway emissions herein. In the case of hydrogen made from natural gas via SMR + CCUS, this includes the upstream emissions required to recover the gas, and the emissions released during the SMR or ATR process (minus any CCUS). Upstream emissions vary regionally in Canada, and there are national and provincial efforts underway to lower emissions through actions such as reducing fugitive methane emissions and electrifying upstream equipment.

For hydrogen produced through electrolysis, the CI can be almost zero if produced from emission-free sources of electricity such as hydroelectricity, wind, solar, and nuclear. Hydrogen produced with electricity from a grid with mixed sources will have a CI relative to the mix of sources. For example, a grid fed from nuclear and renewables will have a much lower CI than one fed mainly from coal power plants. It is important to note that hydrogen produced through electrolysis is not necessarily cleaner than hydrogen produced through SMR, and as regions throughout Canada develop hydrogen supply, the CI measure is critical for comparing different production pathways and sources. Hydrogen can in fact help to lower the CI of electricity grids in regions with mixed generation sources that include generation from fossil fuels; this is discussed further in the end-use opportunities section. Figure 17 compares hydrogen pathway CI based on Canadian and international sources.

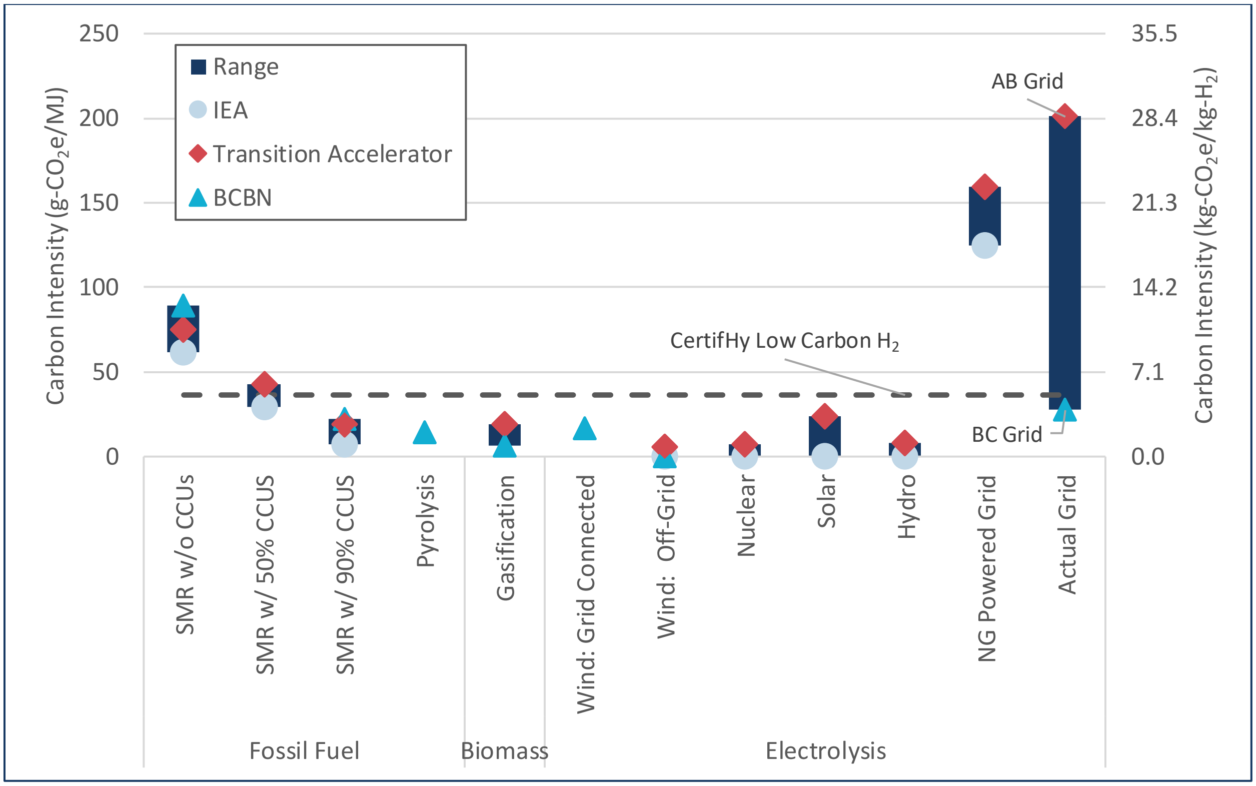

Figure 17 – Carbon Intensities of Hydrogen from Different Production Pathways[1,2,1,4]

It will be important for Canada to develop and adopt national definitions and standards for 'clean' hydrogen, whereby CI thresholds are established and can be independently certified. Hydrogen's decarbonization benefits will only be realized if Canada adopts low CI hydrogen, and any government investment in the development of new supply in Canada needs to reflect this. It is recommended that Canada coordinate efforts underway internationally, to facilitate trade in the longer term as well as benefit from extensive efforts that have already been initiated to quantitatively define and measure hydrogen CI from a range of pathways. For example, the European Commission has initiated a pilot program called CerifHy to develop an EU-wide Guarantee of Origin scheme for green and low carbon hydrogen that considers both the origin of the hydrogen and its greenhouse gas (GHG) intensity. The recommended threshold for GHG intensity is set at a 60% below the intensity of hydrogen produced from natural gas, currently set at 36.4 gCO_{2e}/MJ.[2]

Over time, the mix of production pathways will shift based on their overall CI reduction and their cost per tonne of CO_2 abated. This will likely eventually go from a blend of fossil fuel derived hydrogen with and without CCUS and hydrogen produced via grid connected electrolysis, to non-emitting and renewable sources with very low or zero CI. The timeframe for this transition is dependent on a number of factors including feedstock cost, demand and technical innovation, and market forces that will ultimately drive the production pathway development in Canada. However, the potential low cost of negative emissions means that Canada will likely use low cost hydrocarbons for a long time to come unless strong policy

[1] IEA. 2019. The Future of Hydrogen: Seizing Today's Opportunities.

[1]Asia Pacific Energy Research Centre, "Perspectives on Hydrogen in the APEC Region.pdf," Jun. 2018 [Online]. Available: https://aperc.ieej.or.jp/file/2018/9/12/Perspectives+on+Hydrogen+in+the+APEC+Region.pdf

[1] BloombergNEF: Hydrogen Economy Outlook, March 20, 2020,

[1] BCBN BC Hydrogen Study, Zen and the Art of Clean Energy Solutions Inc., 2019

[2]https://www.certifhy.eu/images/media/files/CertifHy_2_deliverables/CertifHy_H2-criteria-definition_V1-1_2019-03-13_clean_endorsed.pdf

measures are put in place. Production of hydrogen from fossil fuels without CCUS should be coupled with greater than 50% CCUS as soon as possible and move to predominantly greater than 90% CCUS by 2030.

The fossil fuels with CCUS pathway will dominate production until more renewable sources can be built and cost reduction makes the overall energy transition to renewables gain momentum. The drive for fuel switching to direct electrification will increase overall electricity demand over the same timeframe that hydrogen demand grows, and hence the market will make decisions for the best overall blend of pathways for hydrogen production with this as a consideration. It is recommended that in addition to establishing CI thresholds, provinces with input from the Federal Government set longer-term objectives to transition to renewable hydrogen supplies through establishing tiered thresholds of required renewable content over time should the economics make sense when compared against viable but non-renewable clean energy vectors. The CI thresholds and timing will likely vary by province based on local resource availability and economic factors. Canada needs policy to drive adoption of multiple pathways in order to ensure both decarbonization and ultimate sustainability goals are met. Establishing tiered CI thresholds will also ensure that electrolysis assets that are scalable and economic can be deployed to match demand in the early years as demand is growing, and do not get stranded as lower cost centralized hydrogen produced from fossil fuels with CCUS comes online.

One way to establish a balanced supply of clean hydrogen is to require that government funded projects utilize a portion of low carbon hydrogen. Provincial funding programs such as Emissions Reduction Alberta are already setting requirements, such as requiring domestic hydrogen supply, with the goal to stimulate hydrogen production supply chain development together with end-use rollout. Adding renewable content requirements is another important aspect to consider, and in regions with nuclear generation the definition can be focussed on non-emitting hydrogen rather than restricted to renewable. The federal Clean Fuel Standard (CFS) takes a technology neutral approach by using the CI of the fuel to determine eligibility for credits and then amount of credits awarded; it does not specifically provide extra credit for renewable pathways. The design of the CFS will incentivize the use of low CI fuels, thereby driving increasing uptake of lower CI hydrogen production pathways over time.

STAKEHOLDER INPUT: HYDROGEN PRODUCTION

Opportunities

- *Sixty-seven percent of Canada's electricity comes from renewable resources and 82% from non-GHG emitting sources which could be used for electrolysis*
- *Canada is one of the top ten global producers of hydrogen today, producing an estimated 3 million tonnes annually via steam methane reformation (SMR) of natural gas.*
- *Canada is the world's fourth largest producer and sixth largest exporter of natural gas.*

Challenges

- *Bias against certain pathways puts overall hydrogen industry at disadvantage and unlevel playing field in near term*
- *CI of grid for electrolysis may be very high in some regions for near-mid term*
- *Regionality of CCUS, lack of acceptance and concern over long term stability*
- *Predictable, long-term demand is critical before industry can invest in projects*
- *Cost of electricity for electrolysis pathway driven by peak demand and no special rate tariffs.*
- *Large capital investment to scale production requires demand to grow concurrently*

Findings

- *Focus on carbon intensity of hydrogen as primary near term performance-based metric.*
- *Government support for supply development to be limited to low CI pathways, with clear threshold set and independent certification capabilities established. Align with international standardization efforts (E.g. CertifHy @ 36.4 gCO_2e/MJ).*
- *Transition to increasing hydrogen with low to net-zero content is needed over time. Set increasing thresholds for renewable content in government supported projects over time. (e.g. 33% now to 50% by 2050)*
- *Strategic focus for Canada should be on CCUS innovation and engineering expertise given potential for low CI, low cost hydrogen derived from fossil fuels that rely on bulk CCUS potential.*

HYDROGEN STORAGE & DISTRIBUTION

Hydrogen can be stored and transported from the point of production to point of use in a number of ways. Storage and distribution must be considered from the outset as regional hydrogen deployment HUBs are built up across Canada. This part of the value chain has significant economic and emissions implications which affect the overall hydrogen delivered cost and GHG lifecycle emissions.

Hydrogen Storage

Hydrogen's low volumetric energy density makes storage a challenge, both as a bulk commodity at the point of production and in end-use applications such as fuel storage on-board vehicles. Physical storage, materials--based storage, and chemical carrier storage are the broad categories defining how hydrogen can be stored. The method of hydrogen storage is often based on the end-use requirement, including weight and volume available for energy storage.

Physical storage refers to hydrogen stored as either a compressed gas in high pressure cylinders, or as a cryogenic liquid in specialty insulated tanks. In end-use applications, such as on board vehicles, gaseous hydrogen is typically stored in high-pressure tanks with pressures ranging from 350 to 700 bar (5,000 to 10,000 psi). Hydrogen tanks for forklifts, buses and heavy-duty vehicles today generally use hydrogen compressed to a pressure of 350 bar. Light-duty vehicles store hydrogen at 700 bar as higher pressures allow for smaller tanks which can be fit more easily into conventional vehicle designs. In the future, liquid hydrogen may be used for onboard storage for certain applications such as trucks, similar to LNG trucks currently available. Bulk hydrogen for non-mobile applications can be stored as a compressed gas in tanks above and below ground, as liquid hydrogen in large insulated tanks, and in natural gas pipelines, salt caverns, and depleted wells. As volumes grow, for example if hydrogen is used to provide daily or seasonal energy storage, the ability to utilize existing pipeline networks or geological storage options becomes necessary due to both practical footprint considerations and cost.

Gaseous hydrogen can be stored effectively underground in salt caverns, as has been proven in projects in the UK, US, and throughout Europe. These regions are targeting the use of hydrogen for utility scale energy storage where bulk storage is required for technical and economic viability. Engineered salt caverns are utilized for NG storage in many provinces in Canada. These caverns are created by first boring a hole to storage depths and creating the storage space via solution mining, which dissolves the salt by pumping in fresh water and pulling out the brine stream. The compact structure and composition of salt rock formations make the structures inherently gas tight, and the cavern's only surface access is the borehole, which is plugged to prevent leakage. Dried and compressed hydrogen can be injected through the borehole and effectively stored in the cavern indefinitely. As demand for hydrogen grows around the world, depleted gas wells are also being considered for bulk storage of hydrogen and offer mid-term potential in Canada in a number of provinces.

Storage of hydrogen as a cryogenic liquid is another physical storage method. Canada has hydrogen liquefaction assets in both Quebec and Ontario, owned and operated by large industrial gas companies. Liquid hydrogen (LH_2) is a far denser energy carrier than gaseous hydrogen. However, hydrogen liquefies at -253°C , and requires approximately 10 kwh/kg-H_2 of energy to cool the gas to the liquid state, which is approximately 30% of the heating value of the hydrogen, resulting in increased economic costs. LH_2 must be stored at cryogenic temperature in insulated storage tanks to avoid boil off or evaporation of hydrogen similar to how LNG is stored. Moving hydrogen as a liquid becomes cost effective as higher quantities are needed. Liquid storage is also effective where the footprint is constrained at end-use locations, such as at retail fueling stations for light- and heavy-duty vehicles. Liquid hydrogen is typically vaporized and dispensed in gaseous form for most fuel cell vehicle applications today. However, applications such as rail or large marine vessels require high amounts of fuel and are considering storing liquid hydrogen onboard.

Emerging technologies allow hydrogen to be stored in the form of compounds called chemical carriers. There is more hydrogen in a litre of gasoline than in a litre of liquid hydrogen. Hence, liquid chemical carriers are easy to handle and can contain large quantities of hydrogen by volume. Methylcyclohexane (MCH) and ammonia (NH_3) are the most common chemical carriers used to store hydrogen.

Hydrogen can also be stored by adsorbing the gas on powders. One advantage of this method is that the amounts of energy required to adsorb (bind) the hydrogen to the powder should be less than required to form chemical bonds, as per the chemical storage methods above. As technologies advance, adsorbent storage may make it possible to store relatively high densities of hydrogen – comparable to compressed gases – at lower pressures. While promising technologies are available, more research is needed to show ultimate potential.

Hydrogen Distribution

Gaseous hydrogen is primarily transported in tube trailer trucks today, at pressures of up to 250 bar with 180-200 bar being more typical. Transport Canada regulates transport of gaseous hydrogen through the Transport of Dangerous Goods (TDG) Regulations. Steel tube trailers are most commonly employed for gaseous delivery today, but weight regulations limit how much can be delivered by each truck. A number of companies are developing 450 bar hydrogen storage delivery systems using composite materials to increase the amount of hydrogen that can be delivered by each truck, thereby reducing costs and transportation emissions.

Cryogenic liquid hydrogen is transported in liquid super-insulated, cryogenic tanker trucks. For hydrogen distribution at longer distances in moderate amounts where dedicated hydrogen pipelines are not an option, liquified hydrogen is currently the most economical distribution method due to its significantly higher energy density.

Distribution can add significantly to the final delivered cost of the fuel. The cost of delivering hydrogen as a compressed gas or a cryogenic liquid by truck is a function of distance; estimated costs from a recent BC study are shown in Figure 18.

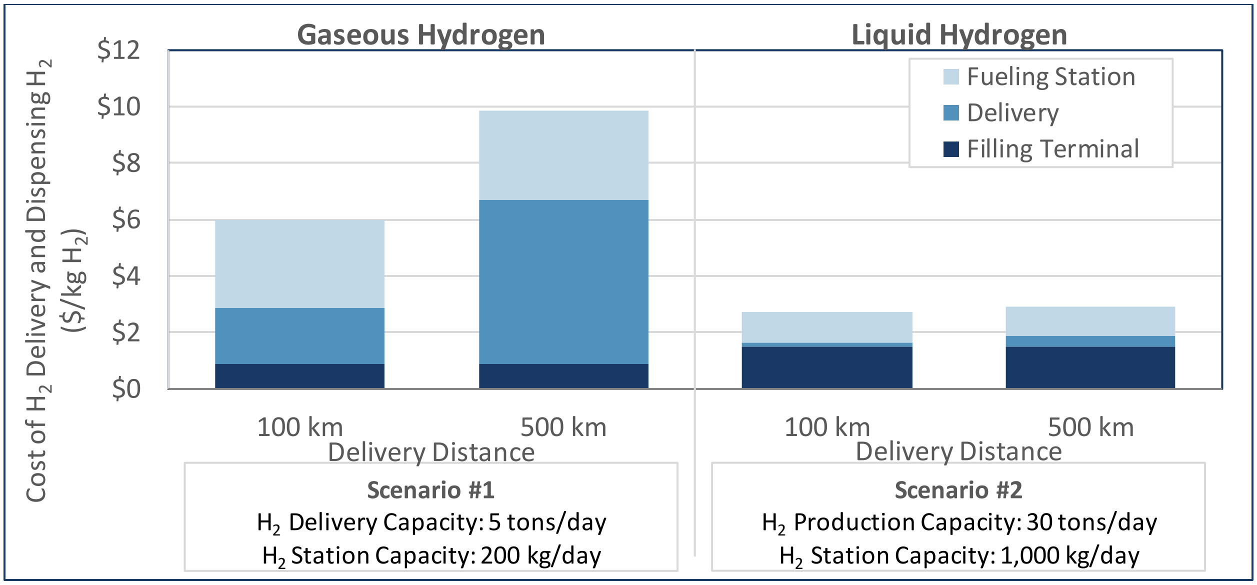

Figure 18 – Truck-Based Delivery Cost for Hydrogen as a Compressed Gas and Cryogenic Liquid[1]

Natural gas pipelines can be used to both store and transport hydrogen. Canada has one of the world's largest pipeline networks delivering natural gas from production areas to markets in both Canada and the US.

Hydrogen can be blended into NG pipelines, typically at pressures less than 100 bar, taking advantage of the inherent storage capacity in the network. Once blended into the NG pipeline, the hydrogen-NG mixture can be used in many applications in place of pure NG. Blend ratios of up to 20% hydrogen are being trialed around the world, with limited impact on infrastructure and end-use appliances. While there is a significant technology development focused on separation technologies, it is currently difficult to separate the hydrogen from the NG once blended. This may become viable in the mid term and would allow the separated hydrogen to be used in fuel cell applications.

Where pure hydrogen is required, dedicated hydrogen pipeline systems may become an attractive option for low cost transportation of hydrogen at scale, for example Figure 19 shows an existing dedicated hydrogen pipeline. The challenge with building hydrogen pipelines is the initial investment

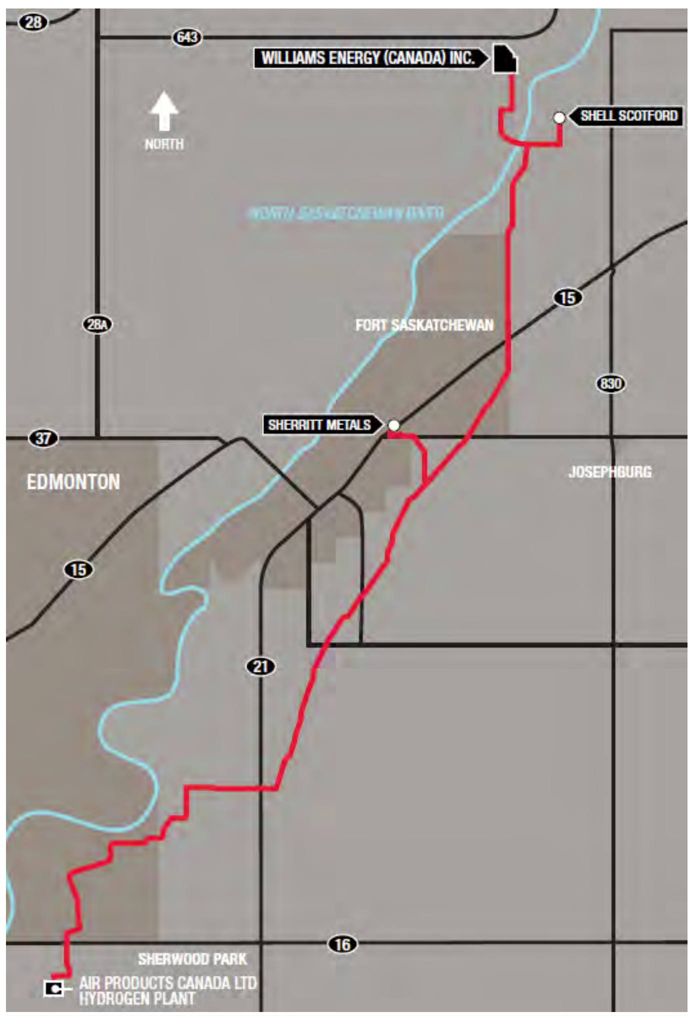

Figure 19 – Air Products Hydrogen Pipeline in Alberta

[1] BC Hydrogen Study, Zen and the Art of Clean Energy Solutions Inc., 2019

needed, and the risk of making these large capital investments while demand is growing and uncertain. Building new NG pipelines to allow for future conversion to hydrogen is an important consideration for NG utilities investing in new infrastructure. This is particularly true in regions like the Maritimes where the NG networks are still relatively new and in the growth stage. The US DOE has established dedicated technical targets for hydrogen pipelines including target capital costs of $520,000 $/mile[1] as a long-term target. Similar to the US, a backbone network of hydrogen pipelines could be a strategic infrastructure asset for Canada. This backbone would be fundamental to facilitating trade and cooperation across provinces. Once the infrastructure is in place, this is by far the lowest cost and lowest emissions means of bulk transportation. It is recommended that a dedicated infrastructure group study this potential further.

[1] https://www.energy.gov/eere/fuelcells/doe-technical-targets-hydrogen-delivery

STAKEHOLDER INPUT: DISTRIBUTION & STORAGE

Opportunities

- Canada already has dedicated hydrogen pipelines in Alberta, and an expanded buildout could give Canada a hydrogen advantage
- Canada has unique geological reserves including salt caverns and depleted NG wells that can be leveraged for bulk hydrogen storage
- Canada's extensive natural gas pipeline network can be leveraged to both store and transport hydrogen
- Hydrogen liquefaction assets will position Canada to distribute hydrogen locally and to global markets

Challenges

Canada is lagging other countries in developing standards for hydrogen in NG pipelines

Storage and transmission can be best optimized when regions collaborate across provincial boundaries

Hydrogen transportation costs can be significant if key infrastructure is lacking

Technical limitations exist for bulk storage and transport on rail and ship

Liquefaction is energy intensive and presents safety challenges, but is required for large scale distribution

Lack of technical data on feasibility of leveraging and modifying Canada's pipeline infrastructure to support large-scale hydrogen distribution

Findings

- *Fast-track regulatory approvals for high pressure gaseous distribution in Canada (450 bar)*
- *Accelerate updating Canadian codes & standards related to pipeline blending*
- *Begin scaling up natural gas injection and power-to-gas demonstrations in different regions including investment support, policy/regulatory incentives and support for R&D and innovation*
- *Scale H_2 transport and distribution networks starting with refuelling station networks in urban areas and in industrial clusters*
- *Invest in strategic liquefaction assets in Western Canada to complement Eastern Canadian assets*

4. Hydrogen End-Use Opportunities

The potential for hydrogen use in Canada is as diverse as the pathways to create it. Adoption of hydrogen will be focused on energy-intensive applications where it offers advantages over alternative low-carbon options. This includes using hydrogen as a fuel for long-range transportation and power generation, to provide heat for industry and buildings, and as a feedstock for heavy industrial processes, like steel and cement making. Domestic deployment of hydrogen will be critical to supporting Canada's world-leading hydrogen and fuel cell sector, as well as to meeting our climate change objectives.

Figure 20 – Hydrogen End-Uses

FUEL FOR TRANSPORTATION

Hydrogen can be used in transportation applications through several different pathways as shown in Figure 21.

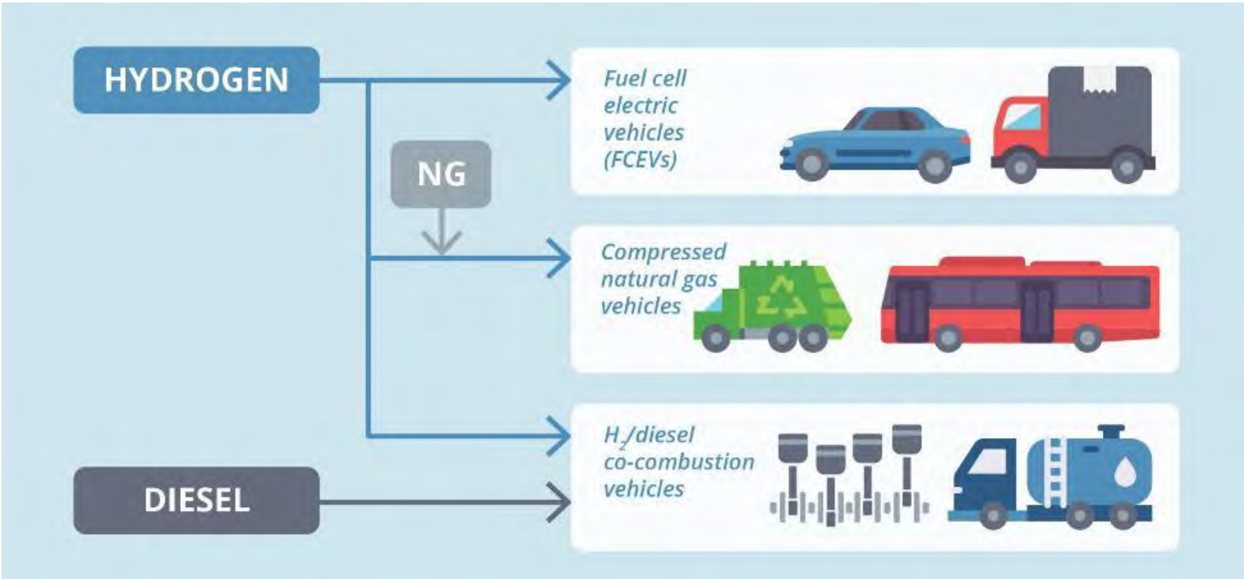

Figure 21 – Hydrogen Uses in Transportation

Hydrogen can be used directly as a fuel in fuel cell electric vehicles (FCEVs), which have two times the efficiency of combustion engines and zero emissions at the tailpipe. Fuel cell light-duty passenger vehicles and transit buses are commercially available today globally and deployed in limited numbers in Canada. Hydrogen FCEVs show strong promise in long-haul, heavy-duty trucking applications where batteries have limitations. The recently approved zero-emission truck regulation in California is driving significant activity by fuel cell system developers, tier 1 engine suppliers, and vehicle OEMs[1]. The focus is on quickly moving beyond the current pilot demonstration phase and developing commercially available medium- and heavy- duty trucks for the North American market in the next few years. Specialty industrial vehicles, trains, marine, and aviation applications are in the pilot demonstration phase and show long-term promise due to the high energy demands in these applications. In Canada, FCEVs can offer advantages in remote and Indigenous communities in colder climates where battery chemistries are negatively impacted. Fuel cells do not suffer the same inherent performance degradation in cold temperatures, and waste heat from the fuel cells can be used for cabin heating to further differentiate extended range of FCEVs in these cold climates.

In addition to being used directly as a fuel in FCEVs, hydrogen can enable higher amounts of renewable gas in natural gas supply networks that provide fuel for compressed natural gas (CNG) vehicles. For example, in British Columbia efforts are underway to recognize hydrogen as an eligible renewable gas under the CleanBC goal to achieve 15% RNG in the natural gas distribution system by 2030. Demand from CNG fleet operators to use lower emitting renewable gas is high, and hydrogen can help to meet that demand. There can be technical challenges related to using an H_2/CNG blend in some vehicles, including tank embrittlement in older type tanks, as well as NO_x emissions. However, with the right materials and engineering a hydrogen / CNG blend can reduce emissions of CNG vehicles and has been demonstrated

[1] Advanced Clean Truck regulation enacted by California Air Resources Board on June 25, 2020. https://ww2.arb.ca.gov/our-work/programs/advanced-clean-trucks

in several pilot projects. As hydrogen separation technology matures and more hydrogen is present over a wider portion of the NG network, there is the potential for fueling stations with dual fuel sources – CNG and hydrogen – where the fuels are separated at the point of use.

Hydrogen can also be used in conjunction with diesel in internal combustion engine trucks using co-combustion technology. Co-combustion offers the advantage of lower entry cost for end-users, as existing diesel engines can be retrofit. However, these engines do not provide the efficiency advantages of fuel cells and they only reduce tailpipe emissions approximately proportionally to the percentage of hydrogen injected, which is anticipated to reach levels of up to 30%. Moreover, combusting hydrogen can lead to increased NO_x emissions. This technology is generally seen as an intermediate steppingstone toward the transition to FCEVs, and can play an important role in supporting hydrogen demand in the near term. This could help build out hydrogen fuelling infrastructure that will be compatible with heavy-duty FCEV trucks as that technology moves from pilot to commercial introduction.

Light-Duty Vehicles

Hydrogen will play an important role alongside electrification in the transition to zero-emission light-duty vehicles. The Government of Canada has set federal targets for zero-emission vehicles to reach 10% of light-duty vehicles sales per year by 2025, 30% by 2030 and 100% by 2040. Canada considers battery electric vehicles (BEV), fuel cell electric vehicles (FCEV), and plug-in hybrid electric vehicles (PHEV) as ZEVs. BC and Quebec have led provincially with the adoption of ZEV purchase incentives and sales regulations, and both provinces have started to deploy hydrogen fueling infrastructure and FCEVs in limited quantities. To date, approximately 110 light-duty vehicles are in operation in Canada, supported by 3 retail fueling stations in BC, 1 in Quebec, and 1 in Ontario. Four new stations are under development in BC, which will represent an important milestone as vehicle OEMs have indicated that 7-8 stations are needed in a region for coverage and redundancy to enable wider rollout of vehicles. BC also just announced funding for an incremental 10 new stations to continue to expand the network. It is expected that an additional ~150 LD vehicles will be deployed in the coming months as the new stations come online.

BEVs are expected to take a significant portion of the market share for light-duty applications in Canada. FCEVs offer choice for vehicle owners preferring larger vehicles, extended range, fast refueling, and no-compromise performance in cold climates. Canadian consumers have shown increasing demand for larger vehicles, with 80% of nationwide spending on new vehicles in 2019 going to trucks, vans, or SUVs.[2] This is an indication that consumers will continue to want choice and will not always focus on picking the highest efficiency vehicle option, but rather will weigh performance and vehicle size preferences in decision making. Trends such as autonomous driving and ride

Figure 22 – Hyundai Nexo in Vancouver's Modo Carshare Network[1]

[1] Modo. (2019). Image from: *Press Release: Hyundai NEXO Fuel Cell sees success with Modo, Vancouver-based carsharing co-operative*. https://modo.coop/blog/press-release-hyundai-nexo-fuel-cell-sees-success-with-modo-vancouver-based-carsharing-co-operative/

[2] Source: Statistics Canada. Table 20-10-0002-01 New motor vehicle sales, by type of vehicle

sharing may also drive greater demand for FCEVs given the higher energy intensive duty cycles required for these applications which are well served by hydrogen. Battery and charging technology continue to advance at a rapid pace, and larger vehicles with extended range are expected to reach the market in the near term. Ultimately both BEVs and FCEVs will have a role in decarbonizing LDVs.

FCEVs are likely to be more attractive for drivers in Canadian urban centers where a higher proportion of households live in multi-unit residential buildings (condominiums, apartments, townhouses with shared garages) where cost and strata bylaws can make retrofits of home charging stations expensive and difficult, providing they feel well-served by hydrogen fueling infrastructure. In addition, households which rely on street parking may opt for FCEVs over BEVs due to convenience. As market penetration rates of BEVs increase in urban centers, electric grid energy and demand capacity for vehicle charging may present an additional constraint. The addition of new electrical substations and distribution networks can be prohibitively expensive, and land may not be available. Hydrogen fueling can offer an important option to optimize overall ZEV infrastructure costs.

Although light-duty FCEVs are currently available on the market, they are still produced at a relatively small scale and one of the greatest impediments to deployment in Canada in the near-term is supply. Availability of refueling infrastructure is another key challenge, and the two are related as vehicle supply is limited in part because OEMs will deploy their limited number of vehicles only in regions with installed retail fueling networks. Regions with a combination of ZEV regulations and incentive programs to stimulate the buildout of fueling infrastructure have been the most successful in attracting deployments of FCEVs. Strategic regional partnerships leveraging public/private procurement can be another effective mechanism to solve this dual challenge.

Since FCEVs are currently produced in small volumes, they remain more expensive than comparable ICE vehicles or BEVs. Until technology advancements and production scale drive down costs, consumer subsidies will be important to support adoption. Incentive programs in Canada have price caps in place that exclude FCEVs at this time, due to their high costs[1]. One option to address this impediment to consumer adoption of FCEVs would be to stage incentive programs based on the maturity of each technology.

The adoption rate of FCEVs in Canada will be highly dependent on cost reduction driven by manufacturing at scale, the commitment to achieving national ZEV targets, as well as provincial policies and regulations around ZEVs and buildout of hydrogen fueling infrastructure.

Medium- and Heavy-Duty Vehicles

Buses

Public transit agencies around the world are shifting towards low- and zero-emission vehicles. Battery electric buses (BEBs) and Fuel Cell Electric Buses (FCEBs) are the two powertrains that are considered zero emission in transit applications. FCEBs are commercially available today, with more than 2000

Figure 23 – New Flyer's 40' Fuel Cell Electric Bus (Retrieved from NewFlyer Website)

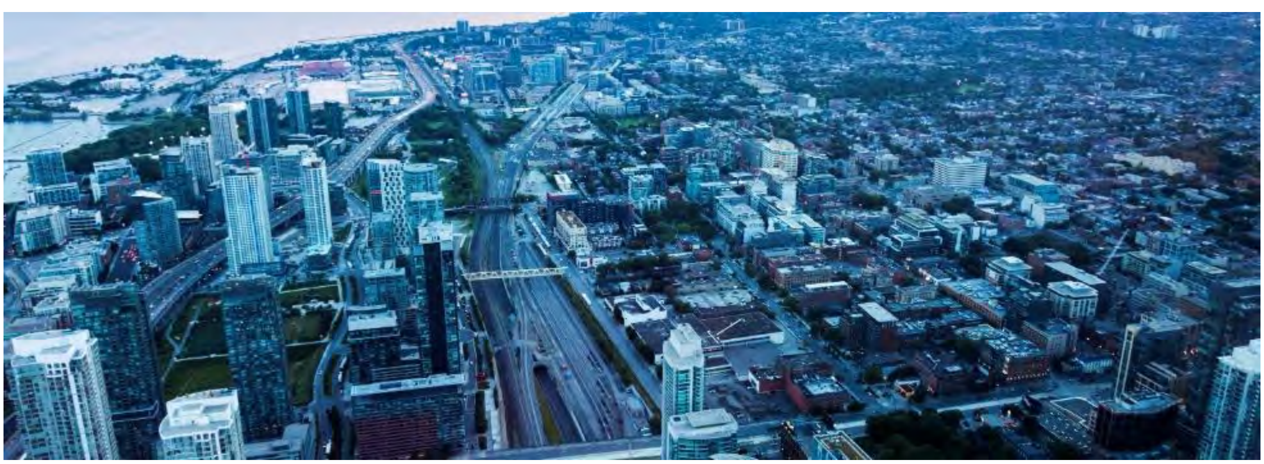
[1] https://tc.canada.ca/en/road-transportation/innovative-technologies/zero-emission-vehicles/list-eligible-vehicles-under-izev-program

FCEBs[1] in service worldwide, and approximately half of those are powered by Canadian heavy-duty fuel cell engine technology. With over 15 years on the road and millions of kilometers in passenger service in a range of hot and cold climates, FCEBs have proven their performance. Canadian companies such as New Flyer Industries, Ballard Power Systems, Hydrogenics, and Dana TM4 hold positions in the FCEB value chain, offering a true 'Made-in-Canada' solution.

FCEB is the only zero emission technology that can match the performance of conventional diesel buses and are advantageous compared to BEBs on long routes with higher power requirements. FCEBs can also provide a one-to-one replacement ratio, meaning that transit agencies do not need to buy more vehicles to provide the same level of service as conventional buses. This is important from both a up-front cost and footprint perspective, as often agencies struggle to fit ZEV fleets into their constrained depot space. FCEBs can be refueled at comparable speeds and in a similar way as CNG buses, whereas BEBs require much longer charging times today.

California has been leading the way in zero emission transit in North America, with the adoption of the Innovative Clean Transit regulation (ICT) in 2018. This regulation requires that 100% of all new bus purchases be ZEB by 2029, and by 2040 all buses on the road in California must be zero emission. Large transit agencies were required to file transition plans with the California Air Resources Board (CARB) in summer 2020. As agencies moved from thinking about small scale pilots to planning full transitions, there has been an increase in interest for hydrogen FCEBs. Energy resilience considerations have also come into play, as several days of liquid hydrogen fuel can be stored on site in a compact footprint, providing continuity in service even in the case of grid brownouts that are increasing in frequency in California. California's deployments provide an excellent learning opportunity for Canadian transit agencies exploring ZEB options.

There are challenges limiting deployment of FCEBs in Canada today. There is currently no regulatory driver for agencies to transition to zero emission. While some agencies are exploring alternative fuel strategies to reduce emissions, a national commitment to zero-emission public transit would increase the pace of transition to full zero emission versus driving incremental change. Another challenge is that the initial deployment requires a significant capital investment for fueling infrastructure, and upgrades to maintenance facilities if the depot is not equipped with safety systems for CNG buses. While a strong business case can be made for cost effectiveness, compactness, and operational efficiency of hydrogen fueling over depot charging at scale (e.g. >20 buses), this makes it difficult for agencies to run an initial pilot to get familiar with the technology and train staff, a gating step in broader rollout.



[1] https://www.ballard.com/docs/default-source/web-pdf's/white-paper_fuel-cell-buses-for-france_final-english-web.pdf?sfvrsn=939bc280_0

Canadian cities need public transportation, and it must be zero emission for Canada to become carbon neutral and to improve air quality in urban centers. The zero-emission bus initiative[1] underway in Canada encourages government to support school boards and municipalities in purchasing 5000 zero-emission buses over the next 5 years. Canada's 'made-in-Canada' FCEB solution will provide economic value and critical local reference projects to the sector if fuel cell electric buses are a portion of the mix. There is an initiative underway to encourage 1000 of the 5000 buses to be powered by hydrogen. These buses are well suited to longer routes and cold weather climates that Canadian transit agencies service.

The adoption of FCEBs in Canada will be dependent on a successful pilot depot conversion in the next 5-7 years in order to gain acceptance and understanding of the technology among local agencies, and to test operational benefits on extended routes in Canada's cold climates. A depot conversion will also provide an opportunity to test the updated Canadian Hydrogen Installation Code published for review and provide experience to AHJs in terms of siting at-scale infrastructure at a depot. Bus costs are coming down due to increasing demand in other countries, and Canada could help drive this by coordinating larger procurements across agencies.

Trucks

Fuel cells are expected to play a significant role in trucking in applications where hydrogen's high gravimetric energy density combined with fast fueling times offer strategic benefits. For example, in heavy-duty trucks travelling long distances with heavy payloads, the weight of the batteries to provide the energy needed would result in reduced cargo load carrying capacity that is unacceptable to operators. Long charging times could also impact operations negatively in an industry where the bottom line is driven by the ability to move goods as quickly as possible. While showing significant promise, fuel cell trucks are in the pilot demonstration phase and are not yet commercially available.

Figure 24 – Fuel Cell Electric Drayage Truck
(Photo curtesy of Ballard Power Systems)

The past few years have seen heightened interest in fuel cells for class 8 long-haul trucks, known colloquially as freight trucks, semi-trucks or tractor-trailers. Nikola Motor, Toyota, Daimler, and Hyundai are all developing fuel cell powertrains for this market segment. Cummins Inc. acquired Canadian Hydrogenics Corporation and has been investing heavily in development. A number of demonstration projects have been piloted, including the Alberta Zero-Emissions Truck Electrification Collaboration (AZETEC) project, which will trial two class 8 fuel cell trucks on the corridor between Edmonton and Calgary using a Canadian-made hydrogen fuel cell propulsion system.[2] The initial project will start with two fuel cell vehicles and one refuelling station, with plans to expand in Phase 2 as part of the Alberta Industrial Heartland Hydrogen initiative.

[1] https://cutaactu.ca/en/blog-posts/new-federal-government-unveils-its-priorities

[2] Lowey, M. JWN. (2019). *$15-million Project to test Hydrogen Fuel in Alberta's Freight Transportation Sector*. Retrieved from https://www.jwnenergy.com/article/2019/3/15-million-project-test-hydrogen-fuel-albertas-freight-transportation-sector/

In June 2020, California adopted a rule requiring that more than half the trucks sold in the state be zero emission by 2035. This regulation aims to improve local air quality, a major health issue in the state that is negatively impacted by diesel truck emissions particularly in freight corridors, many of which run through disadvantaged communities. The regulation will also reduce GHG emissions, contributing to decarbonization objectives. This regulation has led to acceleration of activity in fuel cell truck development, and Canada stands to benefit as more commercial fuel cell trucks become available.

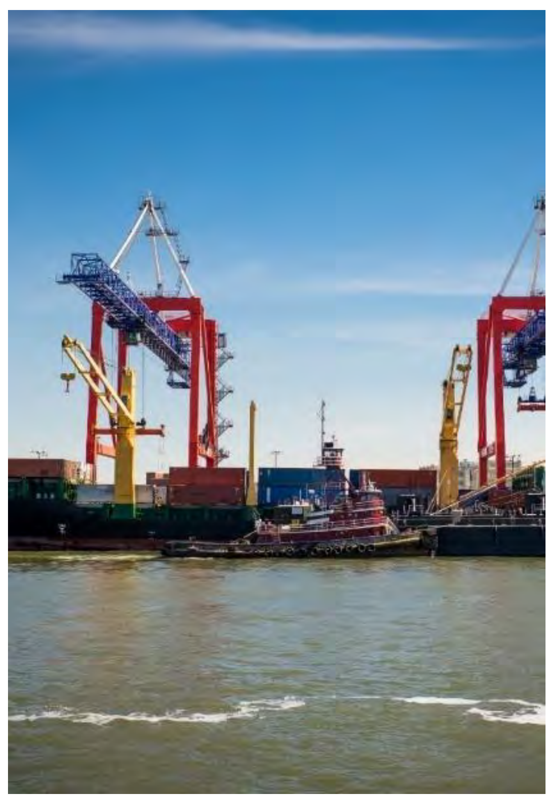
The current pilot under development in Alberta will be an important proof point for hydrogen deployment in the trucking sector, as will market evolution driven by the recently adopted mandate in California. Ultimately Canada will need a zero-emission option for long haul trucking to reach decarbonization goals. In September 2019, Canada was the first nation to endorse a pledge through the Global Commercial Vehicle Drive to Zero initiative to speed adoption of zero-emission and near-zero emission medium- and heavy-duty vehicles in urban communities by 2025 and achieve full market penetration by 2040. Commitments made to drive action in support of that pledge will impact the pace of adoption.

Other Transportation Applications

Goods Movement Equipment, Ports

There is a range of goods movement equipment powered by hydrogen fuel cells in operation today, with varying levels of commercial readiness. Fuel cell forklift trucks are commercial, with more than 35,000 units in operation across North America. Most deployments have been in the US in high-throughput distribution centers where the fuel cells offer a compelling business case over lead acid batteries through productivity improvements. The US Federal tax credit for fuel cell systems was instrumental in establishing this market and favored deployments in the US over Canada. However, there are fuel cell forklift trucks in both Alberta and Ontario with more deployments expected given the commercial competitiveness of these units.

Sea ports are users of heavy diesel equipment and are under pressure to reduce emissions that lead to poor air quality and contribute to global warming. Ports can be hosts for early deployment hubs of fuel cell equipment, with multi-modal transportation applications converging on a single location that can share hydrogen infrastructure at scale. Equipment used at ports tends to be high power with intesive duty cycles and can provide the fuel demand needed in a single location to drive scale and cost-effective deployment of fuel. Other goods movement equipment that can be deployed at ports includes drayage trucks, yard trucks, gantry cranes, straddle carriers, and rail yard switchers. Hydrogen fuel cell generators can also provide shore power for vessels in harbor, and power for transport refrigeration units staged at the port. Figure 25 shows the location of Canada's major ports. While the total number of vehicles may be small in terms of the overall opportunity for Canada, lighthouse projects hosted by ports can demonstrate the benefits of multiple end-use applications sharing common infrastructure and could be a significant catalyst for the sector in the next 5 years.



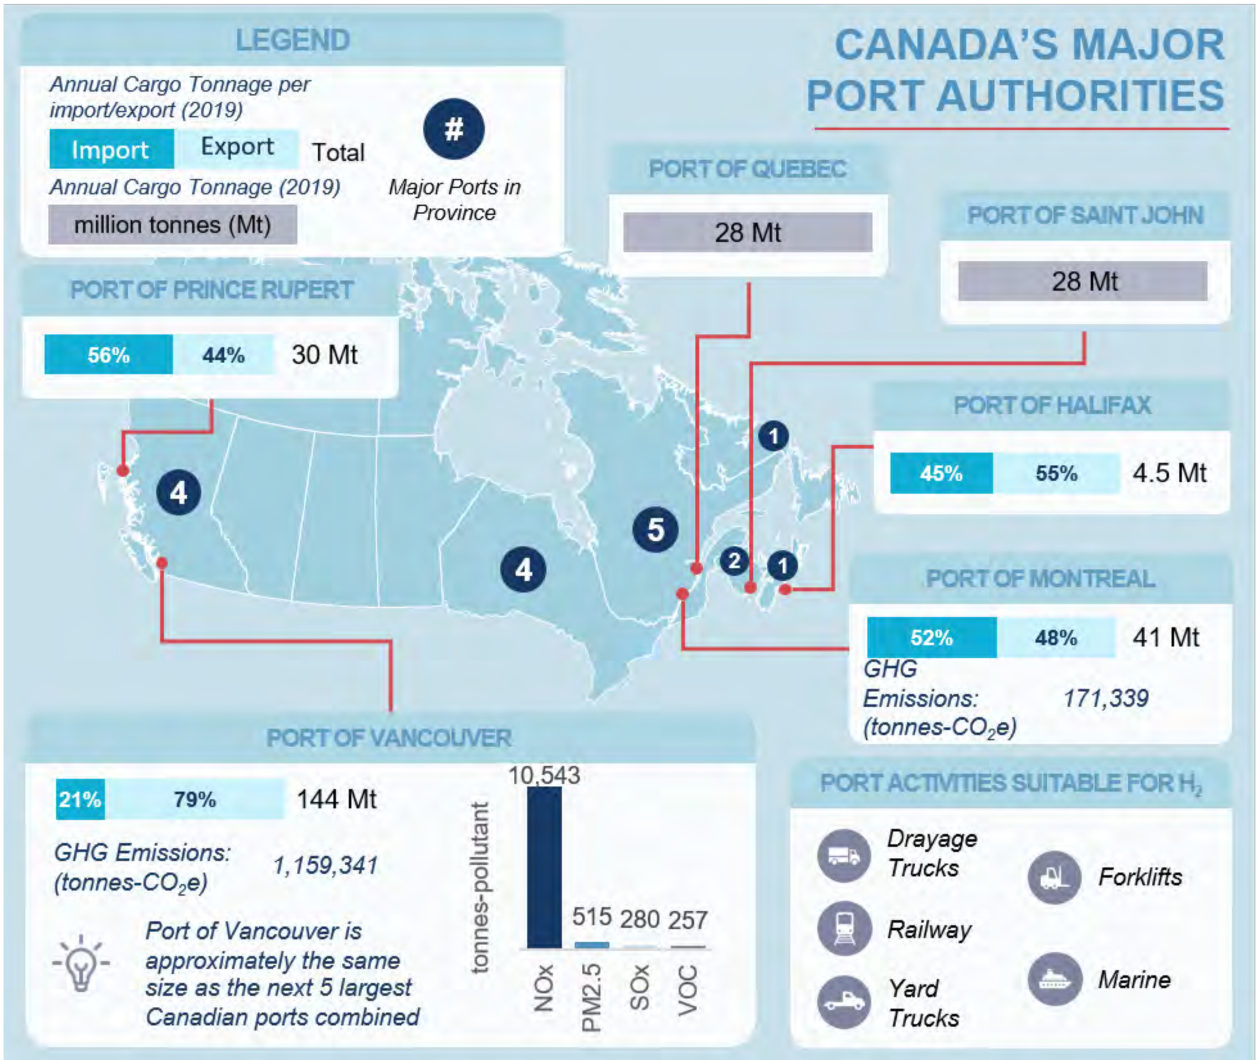


Figure 25 – Canada's Ports as Hosts for Early Hydrogen Deployment HUBs

Mining

There is a similar value proposition for hydrogen displacement of diesel in Canada's mining operations to reduce emissions. Canada's mining industry is one of the largest in the world. Producing more than 60 metals and minerals, Canada is among the top five worldwide producers of 14 different commodity metals and minerals[1]. Mines in northern and remote regions are largely dependent on expensive, high emission diesel power. Stakeholder consultation indicated that Canada's mining sector consumes approximately 2 billion litres of diesel on an annual basis. Hydrogen presents an opportunity to reduce widespread reliance on diesel power for both above ground and underground mining vehicles and can also be integrated into microgrid stationary power systems.

[1] https://www.statista.com/topics/3067/canada-s-mining-industry/#:~:text=Canada's%20mining%20industry%20is%20one,different%20commodity%20metals%20and%20minerals.

In heavy-duty mining vehicles, the high gravimetric energy density and fast fueling times offered by hydrogen in FCEVs provide technical and operational benefits and higher productivity. Zero emission fuel cells used in underground mining equipment eliminate diesel combustion exhaust emissions such as carbon monoxide, NO_X, and PM, and this can ultimately reduce the ventilation requirements in mines which can contribute 30-40%[1] of a mine's total operating costs. Heavy-duty vehicles powered by hydrogen can also reduce emissions from Canada's oil sands mines.

The Canadian Minerals and Metals Plan (CMMP) aims to capitalize on opportunities to strengthen Canada's competitive position within the global mining sector. The CMMP emphasizes the importance of developing and adopting clean technologies and alternative energy sources, such as hydrogen. As mining companies are faced with mounting social and economic pressure, it is evident they may need to go beyond what is demanded by law and the applicable industry environmental, social, and other standards if they wish to gain, or maintain, their "social license" to operate. NRCan's CanmetMINING have been studying and testing the potential for hydrogen in mines, including understanding safety considerations of bringing hydrogen into underground mines. This initiative has played an important role in informing Canada's hydrogen safety code development and will serve as a hub of information for the mining sector to understand opportunities for hydrogen in their operations.

Demonstrations of hydrogen in mining applications started in the early 2000s. In Canada NRCan supported a project at the Raglan Nickel Mine in Northern Quebec starting in 2015 where hydrogen is used as an energy storage solution to reduce diesel consumption in the site's stationary power generation system. Despite early demonstrations, the sector has been slow to adopt hydrogen in any meaningful way. However, there appears to be momentum in industry to start deploying hydrogen in mining operations and Canadian companies are playing a role. A number of mining companies are exploring fuel cells for ultra-heavy-duty haul trucks. Each of these vehicles is anticipated to use approximately 1 TPD of hydrogen, equivalent to running ~33 buses, showing the potential for a single mine site to deploy hydrogen at significant scale.

To move beyond single vehicle demonstrations, it will be important for OEMs such as Komatsu and Caterpillar to commit to developing commercially available hydrogen-powered equipment. Costs and a demonstrated business case continue to be a challenge in this sector, and ultimately hydrogen must be considered as part of the overall integrated ecosystem in the mining operations, together with other renewables, to optimize performance and economics.

Collaboration with other regions can help Canada advance deployment of hydrogen in mines. In July 2020, the Canadian Hydrogen and Fuel Cell Association (CHFCA) and Australian Hydrogen Council (AHC) signed a Memorandum of Understanding (MOU) to strengthen collaboration between Canada and Australia in the commercial deployment of zero-emission hydrogen and fuel cell technologies, including identifying opportunities for joint projects in mining. While international collaborations are important, Canada must also consider how deployment of made-in-Canada solutions could provide a competitive advantage to Canada's mining companies that are operating in an intensively competitive sector and protect potentially valuable IP. It will be important to see a Canadian hydrogen mining project as a proof point that the sector will consider adoption of hydrogen as a replacement to diesel, and the first step will be support for a feasibility study that looks at hydrogen as part of the overall mining operations.

Rail

Rail, marine and aviation applications are well suited to hydrogen because their energy intense duty cycles and long ranges make them particularly hard to electrify. There is increasing interest in hydrogen fuel cells for these applications, but to date activity has been primarily focused on European and Asian markets. These do show strong potential in Canada over the longer term, and early pilots in rail and marine can be integrated into port demonstration hubs leveraging solutions being developed for other markets to enable Canada to leapfrog from its current position.

Figure 26 – Alstom Hydrail with Hydrogenics Engine (Photo courtesy of Alstom)[2]

Hydrail offers a cost-effective way to electrify rail service compared with the traditional electrification approaches using overhead catenary wires or a third rail. Greenhouse gas emissions from diesel trains are a significant contributor to global warming and transit trains produce local air contaminant emissions that contribute to poor air quality in urban areas. Authorities are under growing pressure to reduce carbon emissions from rail service, but other electrification options are costly and require massive infrastructure upgrades. Hydrail trains require no electrification infrastructure, but rather run on existing unmodified tracks. Hydrail enables a gradual transition to electrification, one train at a time, versus alternative infrastructure rebuilds that disrupt service and require an upfront investment to electrify all trains concurrently.

Canadian companies are playing an instrumental role in the value chain in hydrail applications. Ontario-based Hydrogenics provided the fuel cell systems for the first commercial hydrogen powered trains that entered service in in Germany in 2018, built by French train manufacturer Alstom. The trains are capable of travelling 1,000 km without refuelling, which is comparable to a diesel alternative.[1] BC-based Ballard Power Systems is working on hydrail projects in Europe and in China. To date no hydrail trains have been deployed in Canada, but there has been interest supported by studies to investigate viability.

Canada is home to a large and well-developed coast-to-coast rail system that transports mainly freight, with 49,422 km of track.[3] The sector is dominated by CN, CP, and Via Rail which are regulated by the Railway Safety Act.

[3] Transport Canada, Overview of the Hydrogen Rail Status in Canada, March 2019

Figure 27 – Canada's Coast to Coast Rail System

Passenger rail transport in Canada serves 450 communities, with 12,500 km of rail. The most widely used passenger rail is along the Quebec City – Windsor Corridor, moving some 4 million passengers/year. Toronto, Montreal and Vancouver are host to commuter rail systems, and Calgary, Edmonton, and Ottawa currently have light rail systems in operation with new systems in construction in Edmonton, Waterloo and Toronto.

The most comprehensive look at Hydrail in Canada to date has been through the Metrolinx Hydrail study, published in 2018 to look at the feasibility of using hydrogen fuel cell (HFC) trains to electrify the GO networks as an alternative to electrification using conventional overhead wires in Ontario. The study concludes that it is technically and economically feasible to build and operate the GO network using HFC-powered rail vehicles, and the costs of building and operating a Hydrail System are equivalent to that of a conventional overhead electrification system. Implementation of a Hydrail system of this scale and complexity would be innovative and provides a unique set of risks and benefits that Canada could be at the forefront of studying. While no firm commitment to selecting Hydrail has been made, Metrolinx is intending to engage a contractor to upgrade the GO network using a Design-Build-Finance-Operate-Maintain (DBFOM) model. As part of the tender process, bidders will be able to propose both hydrail and overhead wire technology to electrify the GO network.

There are also hydrail passenger train projects proposed in BC both in the Fraser Valley corridor and the Okanagan, though neither has yet moved to the implementation phase.

While no concrete hydrail projects have been initiated in Canada, it is expected that advancements led by Europe and Asia using Canadian core IP will eventually lead to domestic deployments. Applications in Canada could include: rail yard switchers / shunt locomotives, passenger rail, and freight locomotives. Early studies assessing freight applicability of hydrail concluded that hydrail for freight switching is technically and economically feasible.[1] Retrofitting locomotives and replacing diesel engines with zero-emission fuel cell engines is a viable and cost-effective alternative to purpose built hydrail trains, which is an important opportunity given the long (50 year+) lifecycle of locomotives.

[1] Change2Energy Services, Assessment of the Design, Deployment Characteristics and Requirements of a Hydrogen Fuel Cell Powered Switcher Locomotive, June 2020

Marine

Marine applications also show strong potential for hydrogen adoption in Canada. Potential applications include hydrogen fuel cell propulsion systems as well as auxiliary power systems for ships. Fuel cell systems can also provide shore power for ships in harbor. The International Maritime Organization (IMO) is driving aggressive emissions reductions in the shipping industry through adopted emissions and energy-efficiency regulations. The IMO has identified ammonia (made with renewable hydrogen) and hydrogen used directly as a fuel as potential fuels of the future in a decarbonized shipping industry.

Early applications for hydrogen in marine include ferries, tugboats, and coastal and inland barges. Canada's extensive waterways make it home to over 180 different ferry routes with a route presently operating in each province and the majority of the territories. These ferries represent a mix of private and publicly operated routes as well as a mix of passenger, freight, and mixed-use ferries[1]. Canada does not currently have any marine hydrogen deployments, but a variety of studies have been initiated in the Maritimes, Ontario, and BC. Canada can benefit from activities led primarily out of Europe, such as hydrogen-powered car ferries under development in Norway.

Aviation

Hydrogen can play a role in the aviation sector as well, with hydrogen's high gravimetric energy density offering significant advantages as an aviation fuel. Hydrogen fuel cell power may also have a role in providing energy for on-board systems, reducing overall jet fuel consumption. While not yet commercial, there are a wide range of applications in the study and pilot demonstration phase. Applications range from Unmanned Aerial Vehicles (UAVs), or drones, to propulsion systems in manned aircraft. Big players like Audi, Aston Martin, Boeing, Daimler and most recently Hyundai, through their new urban Air Mobility Division, are exploring alternative approaches to aviation enabled by zero-emission technologies[2]. These news modes of transport could radically change mobility options in urban environments, reducing ground level congestion and reducing both GHG emissions and local criteria pollutants. In September 2020, Airbus unveiled three hydrogen-powered aircraft concepts that could enter service by 2035.[3] In some aviation concepts hydrogen is being considered as a fuel for auxiliary power units, rather than as the primary propulsion fuel.

The main alternative to hydrogen in zero emission aviation is lithium ion batteries. Hydrogen can offer advantages over lithium ion batteries given the higher energy density that can be achieved in heavier duty cycle applications, and the shorter refueling times. These advantages enable longer range and greater load-bearing capacity. UAVs for both commercial and military applications incorporating hydrogen fuel cells have been gaining traction. In 2019, Plug Power acquired Montreal-based EnergyOr to integrate the small, ultra-lightweight fuel cell technology into their product line.

Canada's aerospace industry contributes over 200,000 jobs and $25B annually to the Canadian Economy[4]. The sector is under intense pressure to maintain Canada's position in a climate with increasing competition, to tackle GHG emissions, and to address major industry disruptions caused by COVID-19. The industry has identified hydrogen fuel cells and hydrogen combustion as promising options to reduce CO_2 emissions.

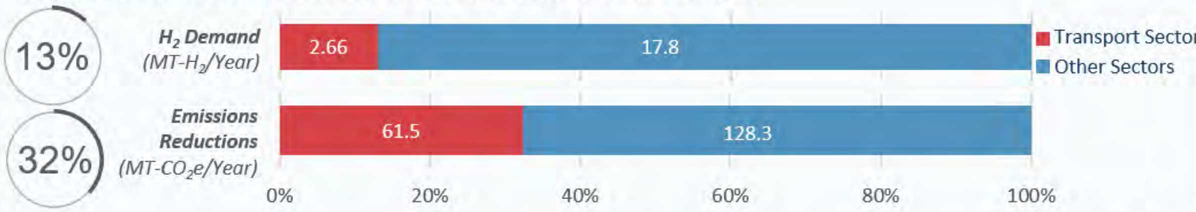
STAKEHOLDER INPUT: TRANSPORTATION

Opportunities

Transportation Sector Contribution in 2050 Transformative Scenario



- *1 in 4 LD vehicles could be an FCEV by 2050*
- *Fuel cells offer greatest advantages over batteries in HD applications with high payloads, long ranges, & intensive duty cycles*

5MM — *Light-duty vehicles*

160k — *Trucks*

6500 — *Buses*

Challenges

Lack of available hydrogen fueling infrastructure; requires clusters of 7-8 stations before vehicle OEMs will roll out FCEVs to a region

Higher vehicle costs due to lower maturity level and lower volumes

Perceived competition with BEVs vs complementary technology with each playing important role; for example, in heavy duty sector

Proven, commercially viable on-road applications, lack of vehicle supply impedes uptake. Other modes (e.g. rail, marine) in early deployment

Findings

- *Stronger policy / regulation supported by incentives and infrastructure investments to drive adoption of zero emission vehicles*
- *Existing programs / policies should reflect lower market maturity of fuel cell vehicles compared to other alternatives*
- *Coordinated H_2 fueling infrastructure investment plan, focused on hub regions and expanding to connector stations for both LD (700 bar) and HD (350 bar), co-located where possible*
- *High profile full depot FCEB pilot project to raise awareness and share data for transition planning*
- *Requirement for Canadian Transit Agencies to develop zero emission transition plans*
- *Federal ZEV procurement policy to add to demand certainty*
- *Pilot deployments of lower TRL transportation – trucks, rail, marine, aviation*

FUEL FOR POWER GENERATION

Hydrogen can be used as a fuel for power production through either hydrogen combustion in turbines or use in stationary fuel cell power plants. Combustion turbines designed to combust a blend of hydrogen and natural gas are currently commercially available. Existing natural gas turbines could likely operate with a blended hydrogen/natural gas fuel supply of up to 10% to 15% hydrogen by volume. However, major modifications to or replacement of infrastructure and equipment would be required to combust larger proportions of hydrogen in existing power plants. Turbines capable of combusting 100% hydrogen are in development and are expected by 2030. Hydrogen can also provide load management capabilities, daily and even seasonal utility scale energy storage capabilities, and is an enabler for the growing variable renewable power sector.

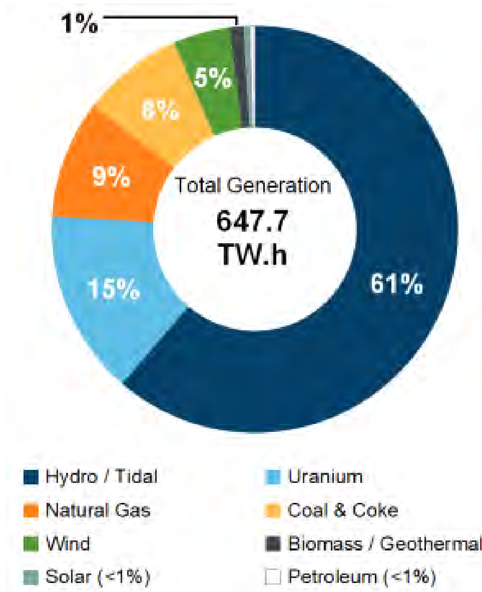


Figure 28 – Electricity Generation by Fuel Type in Canada, 2018, source: Canada Energy Regulator

While Canada's electricity grid is on average considered low carbon intensity, some regions are significantly higher than the average and rely on combustion of fossil fuels to produce power. Overall, approximately 17% of Canada's grid power is supplied via combustion of fossil fuels. Low carbon intensity hydrogen can help to reduce emissions related to power generation and can help green the electricity grid.[1] It is expected that the levelized cost of electricity from hydrogen-fueled combustion turbines will decrease and become cost-competitive on a lifecycle basis with natural gas-fueled combustion turbines by 2050.[2]

In Alberta for example, hydrogen made via conversion of NG or petroleum, with carbon abatement could be used in place of natural gas-powered turbines to provide dispatchable power. Nunavut is reliant on diesel for electricity generation, and hydrogen, either imported in liquid form similar to current diesel supply or generated locally through electrolysis from non-emitting electricity, can help to reduce the carbon intensity of electricity in the region as well as improve local air quality. Other provinces that are reliant on carbon emitting fossil fuels for power generation and that could benefit from low carbon intensity hydrogen for power generation include Saskatchewan, Nova Scotia, Northwest Territories, and New Brunswick.

[2] IEA technology perspecitves 2020

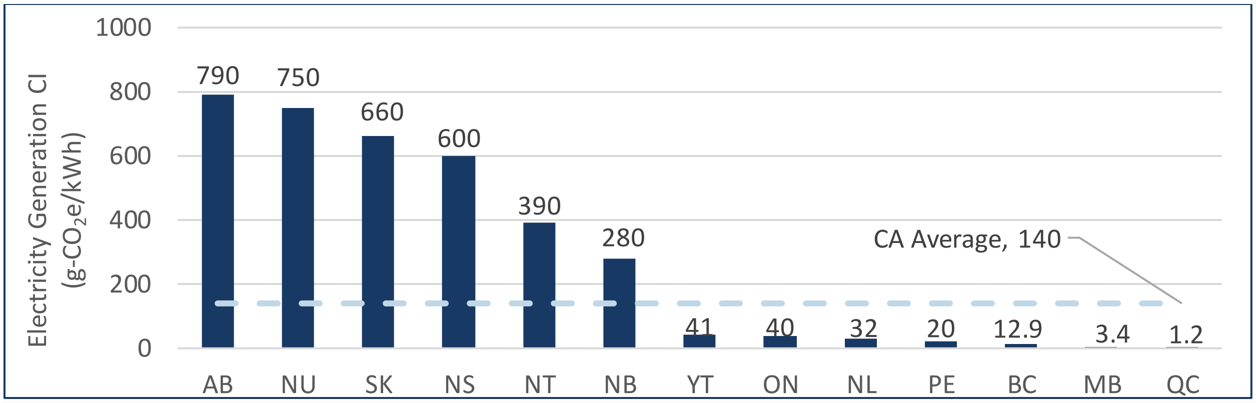

Figure 29 – Carbon Intensity of Provincial Electricity Generation Sources

Japan has been leading the way with vision for large scale power production, using imported hydrogen generating power through turbines. An 80 MW plant recently started operation, and their goal is to have a 1 GW plant in operation by 2030. Europe is also exploring the potential for power generation through both hydrogen turbines and turbines that run on a blend of hydrogen and natural gas. This technology will only be economically viable in Canada if large scale supply of low cost, low carbon intensity hydrogen is available.

Hydrogen as a utility scale energy storage vector can be an enabler for increased renewable penetration in the grid. Hydrogen can be produced via electrolysis from variable renewable power sources such as wind and solar, where power is not needed during off-peak times or the power producer can only secure low or even negative rates. Integrating hydrogen as energy storage can result in an improved business case. Hydrogen storage is a key factor in determining the feasibility of hydrogen use in the power sector, factors such as: geological location, volume stored and duration stored play a role in the cost of storing the hydrogen. The hydrogen can either be stored on site and used to produce electricity during peak demand times via a turbine or PEM fuel cell, or can be injected into the natural gas network as a means to decarbonize natural gas, or alternatively fed into dedicated hydrogen pipelines and used as a high-value transportation fuel or used as an industrial feedstock.

Hydrogen made from surplus renewable electricity via electrolysis and injected into the natural gas network is commonly referred to as power-to-gas (P2G). P2G provides a means of connecting the electric and natural gas energy systems; it can also be a key enabler of the transition from a fossil natural gas grid to a decarbonized one. Rising P2G interest in Europe has been driven by aggressive GHG reduction targets and an increasing supply of variable renewable electricity.

There are a few P2G projects in development in Canada. Canada's first P2G facility began operation in Ontario in July 2018 when a 2.5 MW PEM electrolyzer from Hydrogenics was installed under contract to the Ontario Independent Electricity System Operator (IESO). The electrolyzer provides grid energy demand response functions to the IESO and the hydrogen produced is injected into the Enbridge gas distribution network. There are several projects in development elsewhere in Canada, ranging in scale up to ~ 150 MW.

Hydrogen can also be integrated into renewable energy systems in remote and indigenous communities in Canada. Remote communities are defined as not being connected to North America's integrated electrical or natural gas grids, and they rely on costly and GHG emitting diesel generated electricity. Diesel generators are a source of criteria air contaminants, especially in small communities where air quality and health impacts may be an issue. Diesel can be displaced with either imported or locally produced hydrogen. The hydrogen can supply a microgrid system, either centralized, or distributed with co-generation of heat and power. Renewable energy sources can also be incorporated to produce hydrogen using electrolysis, reducing reliance on imported fuel.

HEAT FOR INDUSTRY & BUILDINGS

As a heating fuel, hydrogen is a cleaner-burning molecule that can be a substitute for combustion of fossil fuels in applications where high-grade heat is needed and where electric heating is not the best option. Hydrogen can be burned directly or blended with natural gas to reduce carbon emissions.

Heat for Industry

The industrial sector uses natural gas as a source of process heat, as a fuel for the generation of steam. When natural gas is combusted to generate heat, carbon emissions are released. It is very challenging to capture carbon emissions at the point of use outside of large industrial plants where there is the potential for capturing CO_2 from concentrated flue gas.

Canada's oil and gas sector is a significant contributor to GHG emissions, responsible for 26% of 2018 total emissions[1]. Low CI hydrogen can offer emissions reduction benefits in both upstream extraction (combusted as heat source) and downstream refining (used as a chemical feedstock, discussed in Hydrogen as a Feedstock section) processes. For example, in upstream operations, low CI hydrogen can replace natural gas combusted to produce steam for steam-assisted gravity drainage (SAGD) in-situ bitumen production. Hydrogen can lower the CI of conventional refined petroleum products in this way, offering a compliance pathway for the federal Clean Fuel Standard.

Other heavy industry in Canada that relies on large amounts of high-grade heat production includes cement manufacturing and the pulp and paper sector, and any industrial processes relying on steam production. These sectors can also reduce emissions by converting to blends of hydrogen and natural gas or pure hydrogen for heat production. A number of these sectors in Canada are investigating the opportunity to lower emissions through the use of hydrogen.

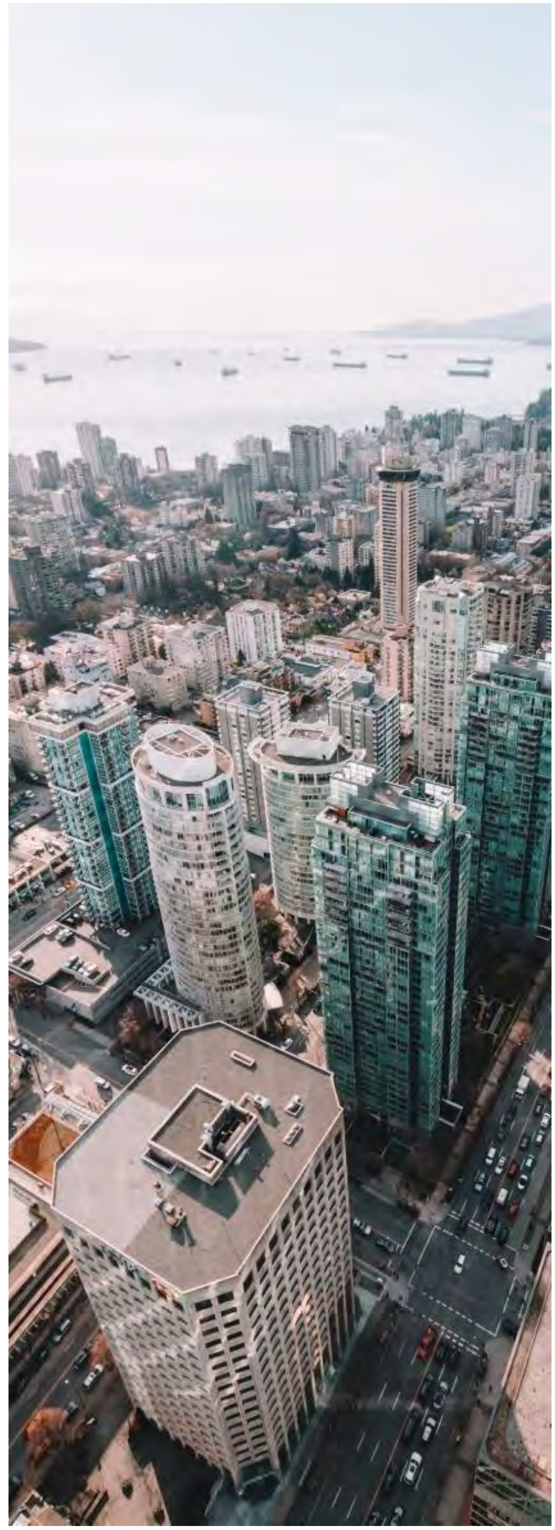
Integration of hydrogen generated via electrolysis directly at large industrial facilities can offer value-added benefits. For example, some of these sectors can leverage oxygen and / or waste heat produced in the electrolysis process. Oxygen can enhance combustion and enable a wider range of feedstocks to be used in cement kilns, and can be used in the pulp process in place of merchant oxygen. Industrial facilities typically have made investments in substations, which enables lower electricity rate tariffs and lower cost hydrogen. Hydrogen production for these industrial sectors can offer an opportunity to diversify business if excess hydrogen is produced and sold to generate a new revenue stream.

[1] Environment and Climate Change Canada. (2020). *National Inventory Report 1990 – 2018: Greenhouse Gas Sources and Sinks in Canada*. Retrieved from http://publications.gc.ca/collections/collection_2020/eccc/En81-4-1-2018-eng.pdf

Heat for Buildings

Hydrogen can also play a role in reducing emissions in heating applications in the built environment. Natural gas utilities are looking to decarbonize the natural gas grid by introducing both RNG and hydrogen as alternative low carbon chemical fuels. Canada's cold climate results in space heating accounting for >60% of energy use in the home, with water heating coming in second at >19%[1]. Natural gas is used for both in some provinces in Canada, and hydrogen is gaining increasing attention from utilities given it can be produced in high capacities compared to RNG which is in limited supply.

Several jurisdictions worldwide are piloting the blending of hydrogen into their natural gas systems as part of efforts to reduce emissions associated with home heating. Hydrogen blending has been started in Germany, Dunkerque in France (hydrogen blending of up to 20% in the GRHYD demonstration project), and Keele in the UK (hydrogen blending of up to 20% in the HyDeploy project at Keele University in 2019). The H21 Leeds City Gate project plans to convert Leeds into a city that is 100% fueled with hydrogen by 2028[2].



Technical Considerations

Implementing hydrogen blends into the natural gas network for use in both industrial applications and the built environment can impact pipelines, gas properties and safety systems, metering equipment, and end-use equipment and appliances. Many gas utilities around the world, including Canadian natural gas utilities in partnership with the Canadian Gas Association, are working to understand and overcome technical challenges around introducing hydrogen as a blend. Technical considerations include the following:

Material Compatibility - Embrittlement

Some metal pipes can degrade when exposed to hydrogen over long periods, particularly for the higher hydrogen concentrations and pressures that may occur when it is injected into high-pressure natural gas transmission systems. Embrittlement effects depend on the type of steel and on operating conditions and must be assessed on a case-by-case basis.

[1] NRCan. (2017). *Residential Sector*. Retrieved from https://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/menus/trends/handbook/handbook_res_00.cfm

[2] https://rienergia.staffettaonline.com/articolo/33278/Hydrogen+is+the+key+for+a+green+European+gas+network/Chatzimarkakis#:~:text=In%20the%20Hydrogen%20Roadmap%20Europe,7%25%20by%20volume%20until%202030.&text=By%202050%2C%20hydrogen%20could%20provide,by%20European%20households%20for%20heating.

Natural gas transmission pipelines in Canada are typically made of high-strength steels and operate at higher pressures compared to distribution networks, making them more susceptible to hydrogen embrittlement. The steels used for natural gas distribution systems are not generally susceptible to hydrogen-induced embrittlement under normal operation. Other metallic pipes including iron (ductile, cast and wrought) and copper are free from embrittlement concerns as are the polyethylene (PE), polyvinylchloride (PVC) and elastomeric materials more common in recently installed natural gas distribution networks.

Pipeline Standards and Policy

The amount of hydrogen presently allowed in natural gas infrastructure is limited by country-specific codes and standards. International standards currently range from allowing hydrogen injection values of 0.1% (vol.) in the United Kingdom (UK) and Belgium to 12% (vol.) in Holland, and many countries are actively working to update or introduce standards. Standards defining hydrogen quality and allocable contamination levels are also needed. Hydrogen injection and quality standards have yet to be established in Canada and elsewhere in North America, and development of these standards is a critical step in enabling hydrogen blending in Canadian Provinces and Territories. Inter-provincial coordination is required given that pipelines cross borders in some cases.

Gas Properties and Safety Systems

Hydrogen has a lower volumetric energy density than natural gas. At any pressure, the volumetric energy density of hydrogen is about one third that of natural gas. Therefore, hydrogen injected into natural gas networks will result in a mixture with less energy on a volume basis. Delivering the same amounts of energy to end users would therefore necessitate increased volumetric flows. To accommodate higher flows as blend ratios increase, pipelines and distribution networks will need to increase system pressure and increase the density of the gas mixture flowing through the pipeline. Pipelines' pressure ratings may therefore constrain the amount of hydrogen injection into existing natural gas infrastructure.

Gas properties such as explosivity, flammability, ignition, dispersion, and ability to add odorants for leak detection are all different with hydrogen blends versus pure natural gas systems. Modeling and testing have been initiative to understand impacts and identify where safety systems need to be updated to accommodate blends. General findings indicate that blends of up to 20% hydrogen do not require modifications to safety systems. Further analysis and testing in the Canadian context is needed, and results will likely vary based on local natural gas networks.

Gas Metering

Hydrogen blends can influence the accuracy of existing gas meters. Studies have shown that gas meters would not need to be tuned for low hydrogen blend levels.[1] However, further validation testing is needed and new meters may be required for higher blending levels.

Appliances and End-Use Equipment

Appliances must be able to operate safely and at equivalent performance levels in order to introduce hydrogen blends into the built environment without requiring retrofit. Testing in Canada and other regions such as the UK and Australia implementing hydrogen blending shows that ratios up to 30% do not impact appliances[2] such as natural gas stoves, furnaces and fireplaces. Beyond those levels, modifications such as new burners may be required. Industrial equipment such as turbines, compressors, and boilers can also be impacted by hydrogen blends, as can some older CNG tank materials. For example, hydrogen

[1] Zen Clean Energy Solutions (2019). British Columbia Hydrogen Study.

[2] ATCO (2020). Retrieved from: https://www.atco.com/en-ca/for-home/natural-gas/hydrogen.html

produces more water vapour than natural gas for the same amount of energy delivered when combusted, which can lead to more condensate in boilers. In compressors designed to be leak tight for natural gas, hydrogen leakage can occur. Hydrogen also produces lower radiant heat than natural gas, which can impact industrial heating applications. Introduction of hydrogen blends with industrial customers will require significant study and pilot testing and must be evaluated on a case by case basis.

Canadian Context

While the allowable concentrations of hydrogen in natural gas pipeline networks remains an area of active research and evaluation, recent studies have concluded that transmission pipelines can accept hydrogen concentrations of between 5% and 20% (by volume) with minimal risk.[1] Hydrogen blending limits can be overcome by localizing portions of the natural gas infrastructure or end customers who can tolerate higher hydrogen concentrations, with the potential to have 100% dedicated pipelines in some regions of Canada.

Enbridge Gas in Ontario is one of the first utilities to propose a demonstration to blend hydrogen into the natural gas network, and BC and Quebec have enacted provincial policies that have stimulated R&D and development of pilot projects for blending hydrogen into the NG grid. ATCO in Alberta has announced a blending project in Fort Saskatchewan, Alberta where up to 5% hydrogen by volume will be blended in a section of the residential gas distribution network starting in 2021. Stakeholder engagement identified up to nine hydrogen projects currently being developed by utilities in Canada. However, hydrogen injection standards have yet to be established Canada and this is a challenge for broader rollout. Technical specifications and interface requirements for hydrogen blending will need to be established and pilot projects will support development of these standards.

Ultimately, utilities recognize that in a net-zero energy system of the future, distributed combustion of fossil fuels must stop, and this is a threat to their business. Renewable natural gas and landfill gas can displace natural gas, but supply is limited. Hydrogen produced at scale can be the long-term answer for Canada's natural gas utilities to stay relevant in a carbon-constrained future. Hydrogen provides an opportunity to utilize Canada's valuable natural gas pipeline infrastructure investments to deliver energy intense low carbon fuel for high-grade heating applications where electric heating is not the best option. In regions with heat pumps, hydrogen can also be used to provide heat during winter season with hybrid heating systems.

Blending low carbon intensity hydrogen into Canada's natural gas networks, for use in both industry and the built environment, provides the largest potential demand opportunity for hydrogen. However, it is also the most economically challenging given today's low-cost natural gas commodity prices in Canada, and when combusted, there is no efficiency improvement as there is in fuel cell applications. One benefit of hydrogen use in the natural gas network is that the hydrogen can be produced in bulk quantities close to injection points into the natural gas network, and does not have to be compressed to high pressures.

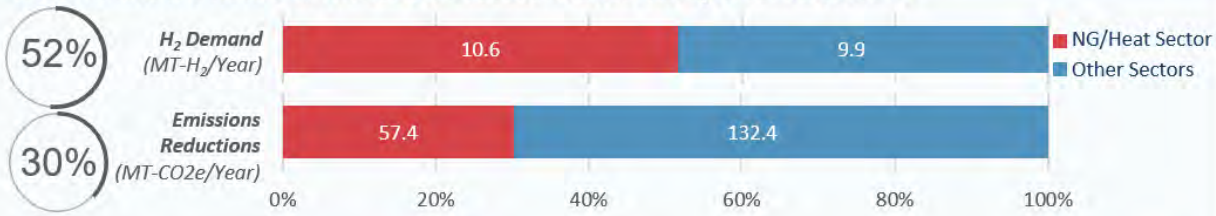
STAKEHOLDER INPUT: HEAT FOR INDUSTRY & BUILDINGS

Opportunities

Decarbonized NG Networks & Heat Contribution in 2050 Transformative Scenario



- *By 2050, H_2 could make 86% by volume on average of the fuel in the gas network*

- *Blending of H_2 in the gas network at a low level is technically feasible today*

Challenges

Safety and reliability must be successfully proven in pilot stage before technology can be fully adopted

Impact to gas properties and equipment limitations complicate the direct substitution of H_2 into industrial processes

Natural gas is currently low cost in many parts of Canada, and while H_2 can compete with RNG the higher cost is a challenge particularly for industry

Lack of standards and research into defining blending limits in Canada

Findings

- *Define plan & approach to safely increase H_2 blending percentages, include regulators, AHJs and international organizations and standards bodies*
- *Develop and implement a federal Clean Fuel Standard to mandate the steady ratcheting down of fuel carbon intensities through upstream, process & end-use improvements*
- *Develop suite of public tools (e.g. TCO model) & resources to help end-users evaluate H_2 options*
- *Expand pilots for H_2-integrated mini-grids at industrial sites and along strategic transportation corridors to pool sources of supply and demand*
- *Increase research and development into end-use equipment and applications including boilers, safety and monitoring equipment, and embrittlement issues*
- *Increase awareness around hydrogen as option for low carbon heating, e.g. with municipalities*

FEEDSTOCK FOR INDUSTRY

The largest current use for hydrogen, both in Canada and globally, is as a feedstock in emission-intensive industrial sectors. The top four single uses of hydrogen today (in both pure and mixed forms) are: oil refining (33%), ammonia production (27%), methanol production (11%) and steel production via the direct reduction of iron ore (3%).[1] Most of this feedstock hydrogen is currently produced via SMR of natural gas without CCUS. Low CI hydrogen presents a major opportunity for these industries to lower the carbon intensity of their products and overall emissions.

Carbon pricing and regulations like the Clean Fuel Standard are expected to drive demand for clean hydrogen in these industries. However, most industrial applications are capital intensive and slow to change so large-scale demonstration could take up 10 years to materialize. These demonstration projects will also depend on significant financial support, policy support, technology enhancements, and energy market reform. The future competitiveness of hydrogen use in industrial applications will depend on the development of low-cost, low CI hydrogen production pathways such as electrolysis and SMR+CCUS.

Oil and Gas Industry

Hydrotreatment and hydrocracking are the two main uses for hydrogen in the oil and gas sector. In hydrotreatment, impurities such as sulphur are removed from the raw fuel stocks (e.g. crude oil and bitumen) to lower the sulphur content which causes air pollution when burned. Hydrocracking is a way to break up the heavy residual oils into higher-value products such as kerosene, gasoline, and diesel. For bitumen processing, around 10kg of hydrogen is need for each tonne of bitumen produced. For biofuels made from animal fats or vegetable oils, 38kg of hydrogen is required.[2]

The IEA projects a 7% increase in demand for hydrogen in the oil and gas sector under existing policies[3]. Tighter pollution regulations will increase demand for hydrogen as a feedstock but will also result in an overall decrease in fossil fuel demand. In the longer term the demand for hydrogen in this sector will also be highly dependent on the use of oil and gas as end-use fuels in a decarbonizing world.

The majority of hydrogen required for refining is produced on-site either from dedicated production facilities or as a by-product. Because of this integration of hydrogen production within refining facilities, production is primarily supplied by natural gas reforming methods or naphtha reforming. On-site hydrogen production is unable to address the hydrogen demand of larger refineries and these facilities

[1] IEA. 2019. The Future of Hydrogen: Seizing Today's Opportunities.

[2] Ibid.

[3] Ibid.

will typically rely on merchant gas suppliers. This option is particularly important for densely industrialized areas where shared hydrogen pipelines can be built to serve multiple customers.

The most significant opportunity to reduce emissions associated with hydrogen in midstream oil and gas is retrofitting existing conversion technology with carbon capture and storage. Hydrogen use is responsible for about 20% of global emission from refining (~230MtCO_2e/yr), according to the IEA. The Alberta Carbon Trunk Line project is an example of an operating CCUS plant which has been successfully implemented and is currently capturing around 4.5 tonnes CO_2/day (See Figure 30).[1]

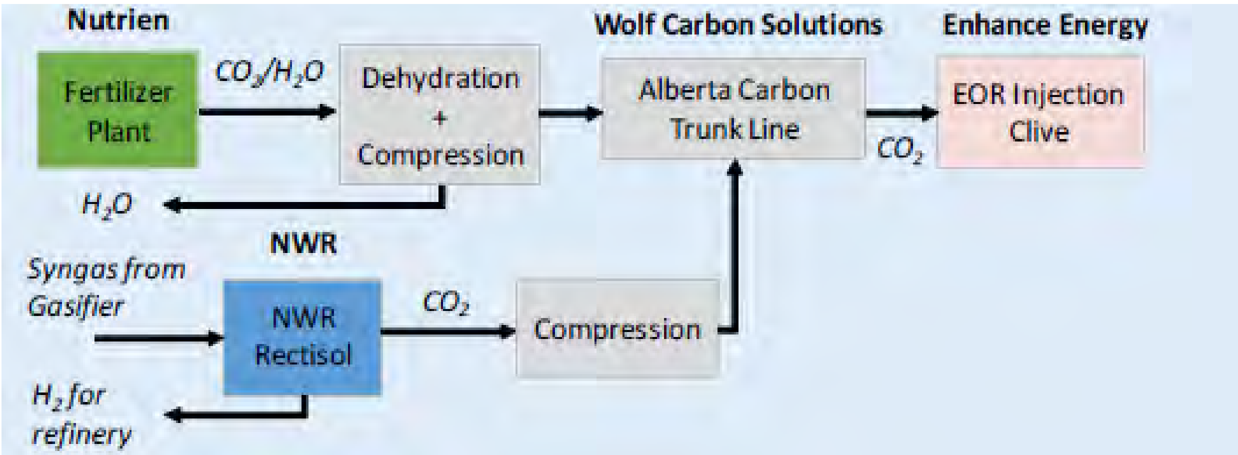


Figure 30 – The Alberta Carbon Trunk Line project[1]

There is also some potential to use electrolytic hydrogen in fuel upgrading, although the costs and carbon intensity of this pathway would depend heavily on the electricity source and the fuel end-use. Hydrogen can also replace natural gas in upstream operations, particularly in the oil sands where heat generation for extraction is a large source of emissions. In the Canadian context, this has the special potential to help decarbonize a portion of oil sands operations in Alberta.

Synthetic Fuels

Availability of low cost, low CI hydrogen has the potential to create new industry in Canada as well. This includes synthetic liquid fuel production, an innovative process combining non-emitting hydrogen and carbon captured from the air to produce carbon-neutral, energy dense liquid fuels that are well suited to applications such as aviation and large marine vessels.

Chemicals and Ammonia Production

Global demand for hydrogen in the chemical industry is mainly split between ammonia production at 31Mt H_2/yr and methanol production at 12MtH_2/yr. Other minor applications, such as plastics, solvents, and explosives account for approximately 3MtH_2/yr[2]. Ammonia (NH_3)is the main ingredient in nitrogen fertilizers such as urea and ammonium nitrate and is produced at large scale in Canada. Methanol (CH_3OH), also known as methyl alcohol is used for a variety of industrial processes and as a precursor to other chemicals such as formaldehyde, acetic acid, and many specialized chemicals.

[1] Layzell DB, Young C, Lof J, Leary J and Sit S. 2020. Towards Net-Zero Energy Systems in Canada: A Key Role for Hydrogen. Transition Accelerator Reports: Vol 2, Issue 3. https://transitionaccelerator.ca/towards-net-zero-energy-systems-in-canada-a-key-role-for-hydrogen

[2] IEA. 2019. The Future of Hydrogen: Seizing Today's Opportunities.

Demand for hydrogen in the chemicals industry is expected to grow from 46 Mt/yr today to 57 Mt/yr by 2030, driven by diverse industrial applications. The CO_2 emissions generated globally from ammonia and methanol production are around 630 Mt-CO_2/yr, with hydrogen production accounting for a large percentage. As with oil refining, the vast majority of this hydrogen (65% for ammonia and 30% for methanol) is produced from fossil fuel sources, with the rest coming from coal and by-product industrial processes. Adding CCUS to the hydrogen production pathways or using electrolytic hydrogen for these products would significantly decrease their overall carbon intensities.

Iron and Steel Production

The demand hydrogen in iron and steel production is the fourth largest after oil and gas and chemicals at 4MtH_2/yr.[1] As with the oil and chemical sectors, the hydrogen is used both as a feedstock and as a process fuel and is mostly derived from fossil fuel sources without CCUS.

Hydrogen is used in the direct reduction of iron-electric arc furnace (DRI-EAF) method of steel production which accounts for 7% of primary (i.e. non-recycled) steel production globally. By 2030 the hydrogen requirements for the DRI-EAF route could more than double, according to the IEA. By 2050 this method could be main process for primary steel production and lead to a 15X increase in hydrogen demand.

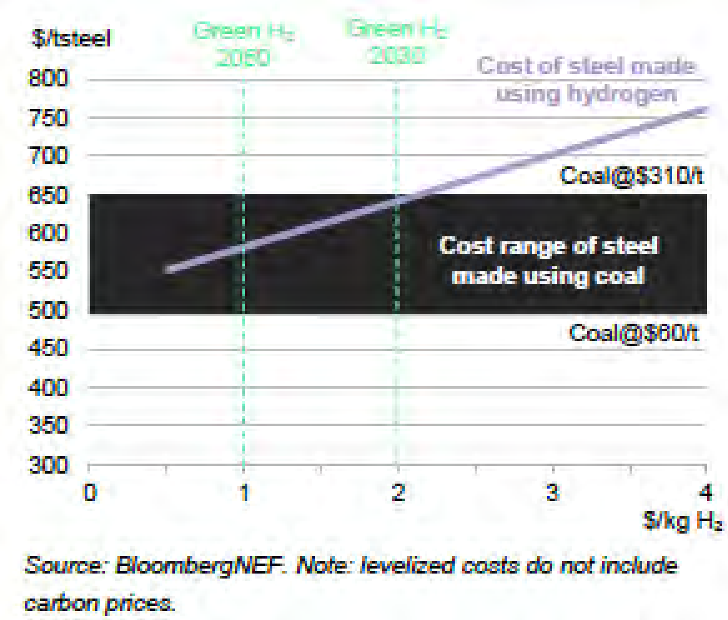

Figure 31 – Levelized Cost of Steel Production

Today, steel production is one of the world's largest emitters of CO_2, accounting for about 7 to 9 per cent of global CO_2 emissions from the global use of fossil fuels.[2] There are several ways the CO_2 emissions from steel production can be avoided or reduced. Most are still experimental or in the pilot phase but could substantially increase demand for hydrogen if implemented at scale. DRI-EAF using low-CI hydrogen as a reducing agent instead of coal, avoids the carbon emissions in the process. Currently pilot plants using this approach can run on up to 30 percent supplemental hydrogen, but higher percentages are technically feasible. Several ongoing global projects are currently testing the use of hydrogen for steelmaking. HYBRIT, a recently formed Swedish joint venture by SSAB, LKAB, and Vattenfall, is demonstrating low-carbon steelmaking using DRI with hydrogen from water electrolysis.[3]

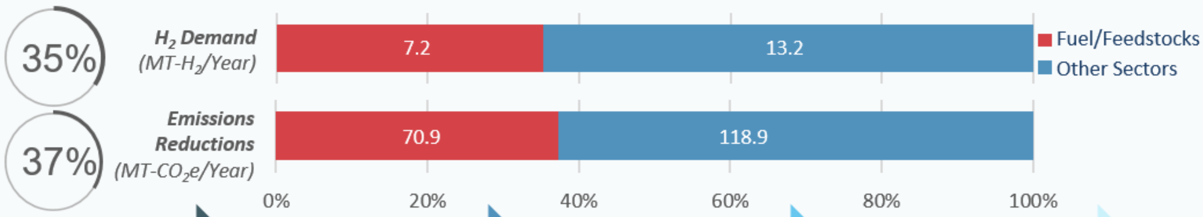
STAKEHOLDER INPUT: INDUSTRIAL FEEDSTOCK

Opportunities

Fuel Production & Feedstocks Contribution in 2050 Transformative Scenario



Canada has electricity, fossil fuel reserves, CCUS potential, and a specialized workforce that can pivot into a new Low Carbon Fuel industry

The petroleum/ petrochem industry is already the largest user of H_2 and up-/mid-stream demand could grow substantially

The proposed federal Clean Fuel Standard has potential to drive significant GHG reductions and spur technology development for export

H_2 can be used as an energy source and feedstock in steel and ammonia production, displacing significant amounts of coal and NG

Challenges

Fuel production and industrial processes are optimized for scale and continuous operations; pilot scale projects can be less effective

Process, equipment, and safety implications of hydrogen blending into essential feedstocks needs to be understood and derisked

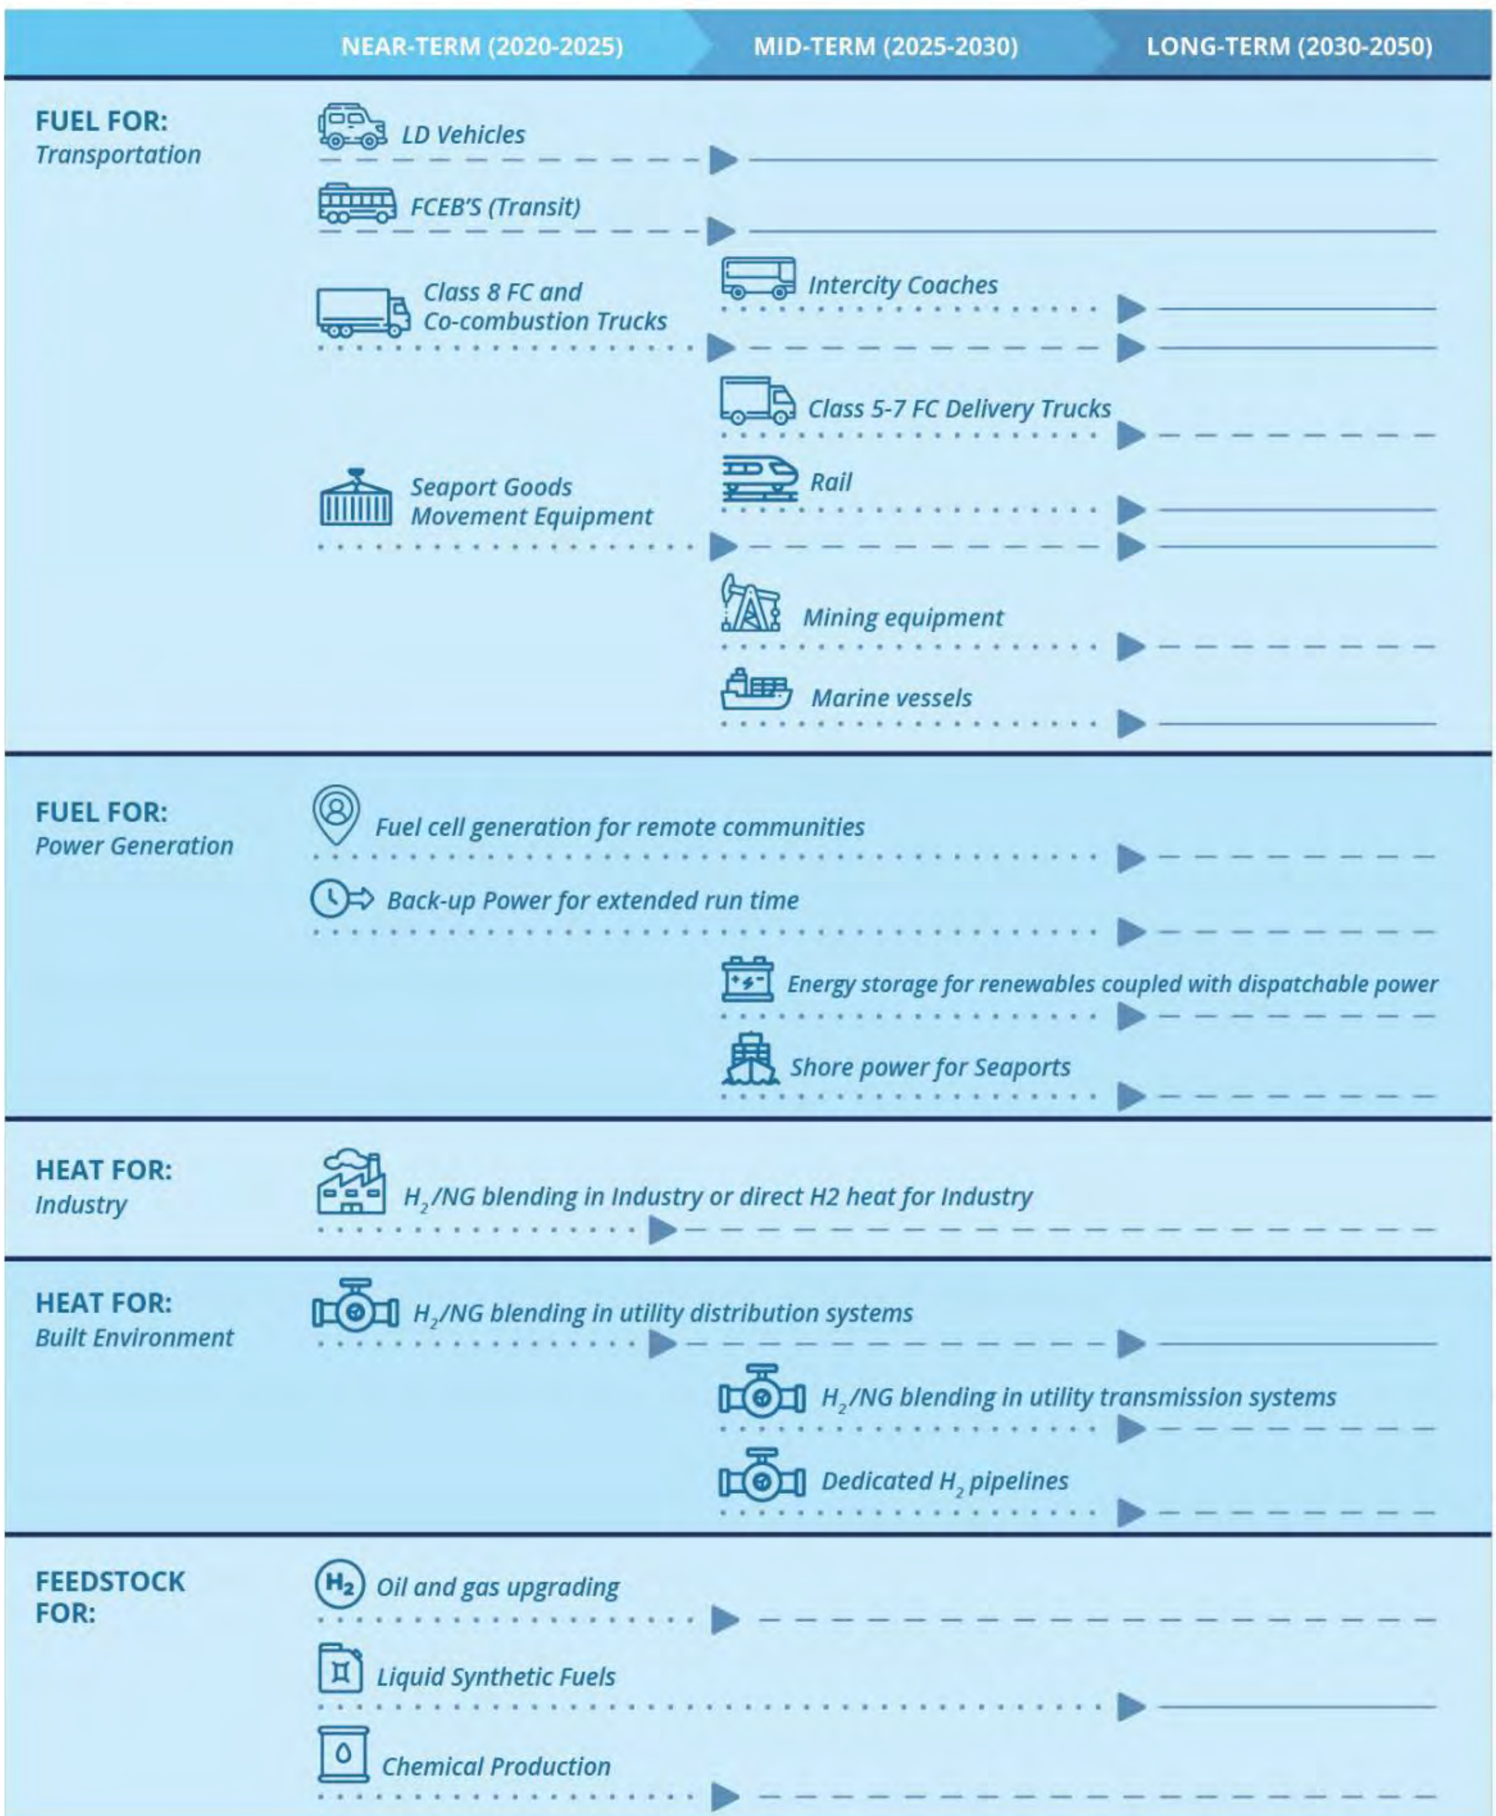
Predictable, long-term demand for LCF and industrial products is critical before industry can invest in these projects

CO_2 storage requirements will be significant in long term transition of sector

Findings

- *Ensure Canada's path to 2050 includes hydrogen and low carbon fuels as key components*
- *Implement CFS and recognize hydrogen role in pathways definitions*
- *Explore synergies between hydrogen and other bio-based renewable fuels, such as liquid biofuels, methanol, synthetic fuels, biogas and renewable natural gas (RNG)*
- *Ensure policy frameworks provide long term certainty that encourages private sector investment and innovation in actions across the hydrogen value chain, from production to end-use*
- *Begin developing international/overseas markets for exports of LCFs, steel and fertilizer—Canada should actively promote the low carbon intensity of its value-added products internationally*
- *Collaborate across upstream & down-stream industries to ensure supply & demand are matched*
- *Use of low-carbon products in domestic infrastructure could be encouraged to create a local market demand of low-carbon product and de-risk investment*

HYDROGEN USE IN CANADA



5. Putting it All Together: Canada's Hydrogen Opportunity

Hydrogen presents real pan-Canadian opportunities. Each region of the country can utilize their unique resources to produce and deploy hydrogen domestically as well as to supply a growing export market. According to modelling undertaken for this Strategy, hydrogen made through Canada's clean, abundant and diverse pathways has the potential to deliver up to 30% of end-use energy by 2050, while abating up to 190 MT-CO_2e of emissions if deployed in a transformative scenario, across all sectors of the economy from transportation, to power generation, to heating, to industrial applications. Implementing the hydrogen strategy can spark early economic recovery, and by 2050 build a $50B domestic hydrogen sector generating more than 350,000 high paying jobs from coast to coast.

HYDROGEN AS PART OF AN INTEGRATED ENERGY SYSTEM IN CANADA

Canada's hydrogen opportunity will be most optimally realized as regions develop the full hydrogen value chain tailored to local energy profiles and feedstocks for production, with end-uses prioritized to maximize decarbonization and economic benefits in operations specific to the region. Hydrogen's versatility as a fuel provides the ability to fundamentally transform Canada's energy landscape. Like electricity, hydrogen can serve multiple roles within the energy system from the upstream production of liquid fuels through to small-scale consumption in end-use appliances and equipment. However, unlike electricity, hydrogen can be shipped and stored in bulk quantities over extended periods. This allows it to act as a critical energy buffer between unpredictable production and end-use demand fluctuations. This temporal and geographic flexibility provides valuable redundancy and resiliency to the energy system and complements existing carriers such as electricity, natural gas, and liquid fuels. Hydrogen's ability to work as part of an integrated energy system will make it a critical part of the large-scale energy system transformation.

In the same way, road networks, railways and airlines work together to move goods from coast to coast, hydrogen, electricity, and fuel distribution networks can complement one another's strengths to make the whole system much stronger and more efficient (see, Figure 33). This is particularly important for two reasons. The first is the need to electrify as much of the economy as is technically and economically feasible. This includes most light duty forms of transportation, low-grade heat where economic (e.g. buildings), and some industrial processes. Electrification provides the most direct and effective way to decarbonize many sectors of the economy as it decouples energy use from GHG emissions at the point of use. This reduces emissions by improving overall efficiency of the process and it helps make the remaining emissions easier to manage by concentrating them at the point of production. As the electrical grid becomes cleaner, the GHG emissions for all electrified end-uses will come down. Hydrogen can play a role in supporting electrification by acting as an energy carrier for hard to electrify sectors such as high-grade heat, heavy-duty transport, and many industrial processes.

The second way hydrogen can complement wide-spread electrification is by acting as a storage medium and as an interface between the gas and electricity grids. While electricity can be stored in batteries and other chemical forms for days or weeks, the long-term, large-scale, and geographically flexible storage of electricity remains technically challenging and expensive. Hydrogen can be produced and stored when and where it is most convenient, shipped by road, rail, or water, or injected into the natural gas network for later use or reconversion back into electricity. This flexibility is critical as variable renewable energy sources make up an increasing percentage of the electricity generation mix. By providing a flexible source of demand that can ramp up and down as required throughout the day, electrolyzers can convert excess electricity from renewables into hydrogen that can used at later time. Reversing the process, fuels cells can convert hydrogen from storage back into electricity during periods of low sun and wind generation.

While *Section 3: What is Hydrogen?* and *Section 4: Canada's Production & Distribution Opportunities* discussed production pathways and end-uses independently, this section explores how hydrogen might be rolled out from a timing and regionality perspective as part of integrated energy systems. By looking at the overall projected demand for hydrogen by end-use application, possible scenarios are presented to show the range of both decarbonization and economic growth potential that hydrogen could offer in an Incremental versus Transformative Scenario.

Decisions about where hydrogen can most effectively be deployed, as the energy system transforms, will be influenced by economics, carbon abatement potential, function and performance of hydrogen in end-use applications relative to other options. With all low carbon energy vectors still undergoing rapid technology advancement and cost reduction, it is impossible to predict definitive scenarios. The cases presented should therefore not be viewed as forecasts or predictions, but rather as a set of two potential bookend scenarios. The Transformative Scenario is meant to represent the potential size of Canada's hydrogen opportunity if bold action is taken in the near term, whereas the Incremental scenario is based on a business as usual approach with lighter policy measures and a slower start to adoption.

Ultimately the timing and regionality of hydrogen's adoption in Canada is in the nascent stages, and all stakeholders can help influence what path we set ourselves on through strong leadership and initiative, and through a collaborative approach to development of the sector.

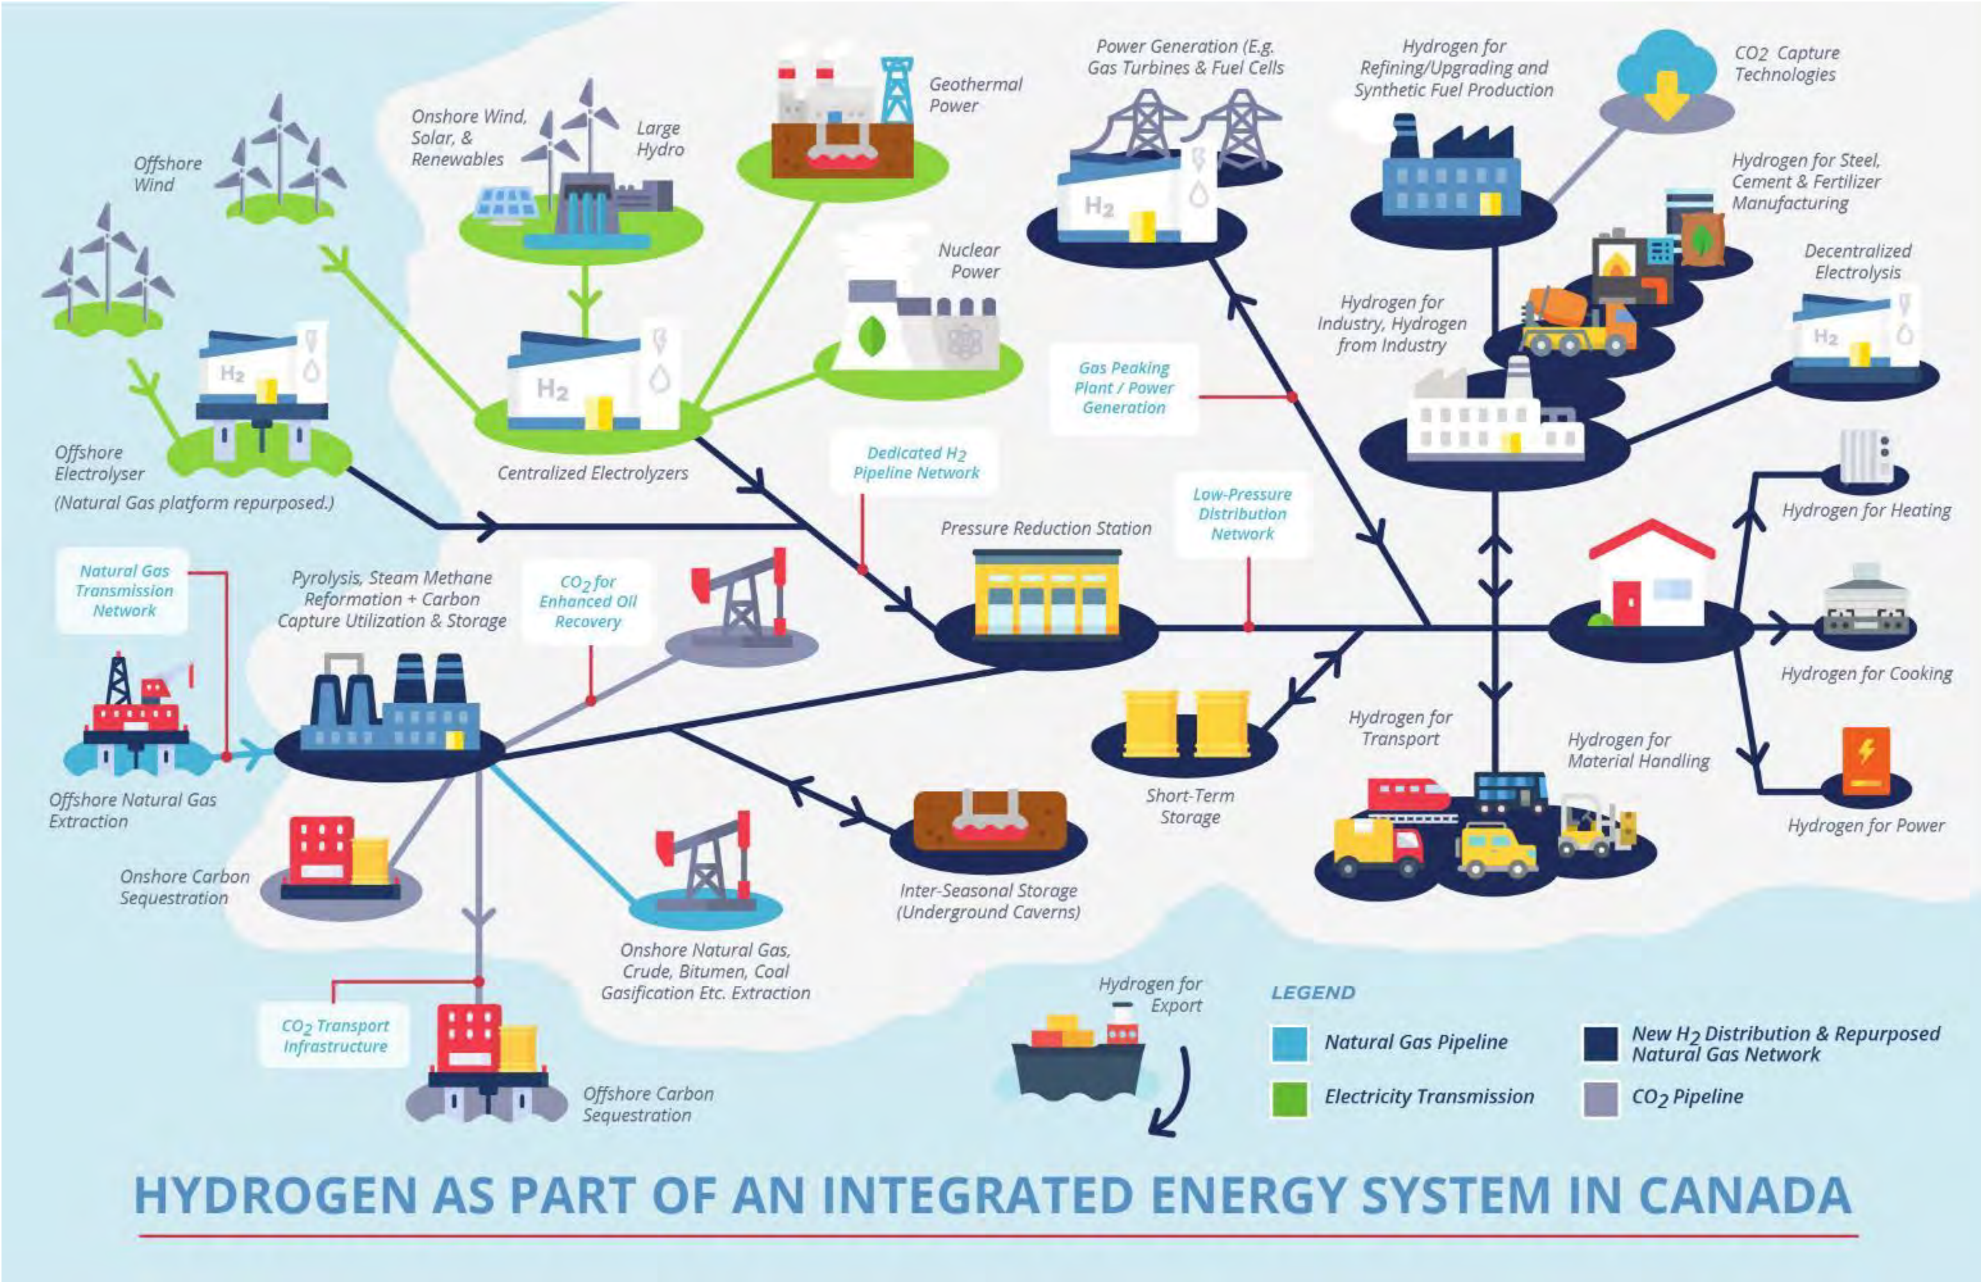


Figure 33 – Hydrogen as Part of an Integrated Energy System in Canada

ROLLOUT TIMING & REGIONALITY

Timing

Implementation in the Near-Term (2020 – 2025)

Hydrogen use in the near-term will be dominated by relatively mature market applications at or near the commercial market Technology Readiness Level (TRL) including FCEVs and FCEBs for transit operation. Pre-commercial applications such as heavy-duty trucks, seaport goods movement equipment, power generation, heat for industry and the built environment, and industrial feedstock applications will be introduced as pilot projects in regional HUBs. These regional HUBs will be strongly influenced by:

- ZEV mandates for passenger vehicles such as the existing legislation in Quebec and British Columbia;
- Carbon pricing and regulations like the Clean Fuel Standard driving low carbon hydrogen production for industrial applications including conversion of CO_2 into renewable methane at ethanol plants and biogas-to-RNG upgraders, production of renewable diesel and upgrading of transportation fuel products;
- Existing hydrogen generation, distribution and dispensing infrastructure that can be leveraged;
- Pilot results, codes, stands and regulatory approvals for blending hydrogen and natural gas to decarbonize the utility distribution system;
- Renewable gas targets for natural gas utilities where hydrogen qualifies as a pathway.

Local hydrogen production must be built concurrently with demand through end-use deployments within sub-regional HUBs in each province or region. Growing supply and demand in HUBs will bring down the cost of low-carbon intensity hydrogen pathways and spur the development of new sources of demand in several important ways. First, hydrogen production facilities can be built at scale capturing cost savings and using the diversity and longevity of demand to lower financing costs and improve project return on investment. Second, transmission and distribution costs are minimized as both supply and demand are co-located or in the same area. Finally, as many of Canada's industrial HUBs are already established users of hydrogen for refining, ammonia, and methanol, new low-volume buyers of hydrogen can scale their demand according to the timing of their needs.

There are several high potential areas to build out HUBs that have the potential to create self sustaining hydrogen economies more quickly, taking a holistic, energy system approach. These deployment HUBS bring supply and demand together but also bringing all key players together, to develop and implement regional plans that build on specific strengths and opportunities, while identifying the unique barriers and challenges, thereby improving the overall business case of each project. Specific projects and areas for early adoption include:

- The Alberta Industrial Heartland, near Edmonton, has several advantages to become one of the first hydrogen HUBs in Canada. It has access to plentiful natural gas and CCUS sites, an existing hydrogen pipeline and two CO_2 pipelines. This existing infrastructure would reduce the cost of new low-carbon hydrogen projects. It is also adjacent to the City of Edmonton, which has large potential demand for hydrogen in the transportation, space heating and electricity generation sectors.

- Coastal ports in BC, Ontario, Quebec, Manitoba and the Atlantic region are also high potential sites for hydrogen HUBs. Ports are concentrated centres of energy consumption for transportation and could also serve as the exit points for exported hydrogen.
- The transportation corridor between Montreal and Detroit is another high potential area as it connects demand for transportation with industrial and manufacturing centres. A regional hydrogen HUB along this corridor would allow supply and demand from multiple sources to be aggregated unlocking massive economies of scope and scale.
- Ethanol plants and landfill gas/biogas-to-RNG upgraders in provinces with access to hydroelectricity, such as B.C., Manitoba and Quebec, are potential sites for electrolyzers that can produce green hydrogen that can be combined with available CO_2 and produce RNG, and methanol.

Implementation in the Mid-Term (2025 – 2030)

In the mid-term, industrial clusters will serve as the starting points for expanding hydrogen use into other sectors and regions. For example, the production facilities and infrastructure built for industrial applications can be extended to supply hydrogen for residential heating, hydrogen refuelling stations or dispatchable power generation. Similarly, industrial clusters can be connected along corridors such as highways, railways, and pipelines to create larger and larger integrated networks.

As the technology matures and the full suite of end-use applications is at or near commercial TRL levels, hydrogen use in the mid-term will be focused on applications that provide the best value proposition relative to other zero-emission technologies. For example, FCEVs and FCEBs will enter the rapid expansion phase as the market for fuel cell and battery technology becomes more defined, for example where factors like range, gradeability, and fast fill times offer advantages for FCEBs.

Class 8 heavy-duty trucking in corridors that require heavy payloads and seaport goods movement equipment in regions with regulated airsheds will move into the commercial phase of deployment. New, larger scale hydrogen production in the mid-term will allow direct H_2 or H_2/NG blending for industry, the built environment and as a feedstock for chemical production and hydrocarbon upgrading to be commercialized in regional HUBs during this period.

Pre-commercial applications like Class 5-7 delivery trucks operating in urban zero-emission zones, passenger and freight rail where electrification of the line is prohibitively expensive, mining vehicles and marine vessels that require the energy density advantages that hydrogen offers, will all be piloted during this period.

Implementation in the Long-Term (2030 – 2050)

In the long-term, it is anticipated that with advances in battery and charging technology, there will be a more defined division between battery and fuel cell utilization in Canada. This is expected to result in the higher power demand applications (utility biased) predisposed toward hydrogen energy storage and the lower power demand applications (efficiency biased) using batteries for energy storage. New transportation applications will move into the commercial and rapid expansion phases during this period.

In parallel, economies of scale in the production of hydrogen and regulatory pressures could lead to accelerating growth in the blending of hydrogen in the natural gas distribution system while the Clean Fuel Standard will drive synthetic liquid fuel production for both the domestic and export markets. Power generation applications will continue to grow, albeit incrementally, lagging the transportation and industrial markets.

Regionality

Provincial regulations and policies, resource availability, geography and climate, infrastructure, and technology maturity will shape the timing and scale for hydrogen deployment across Canada. Figure 34 is a consolidated view of the most promising production and end-use applications in each Province in the mid-term. In the long-term, it is expected that most end-uses will be deployed across Canada.

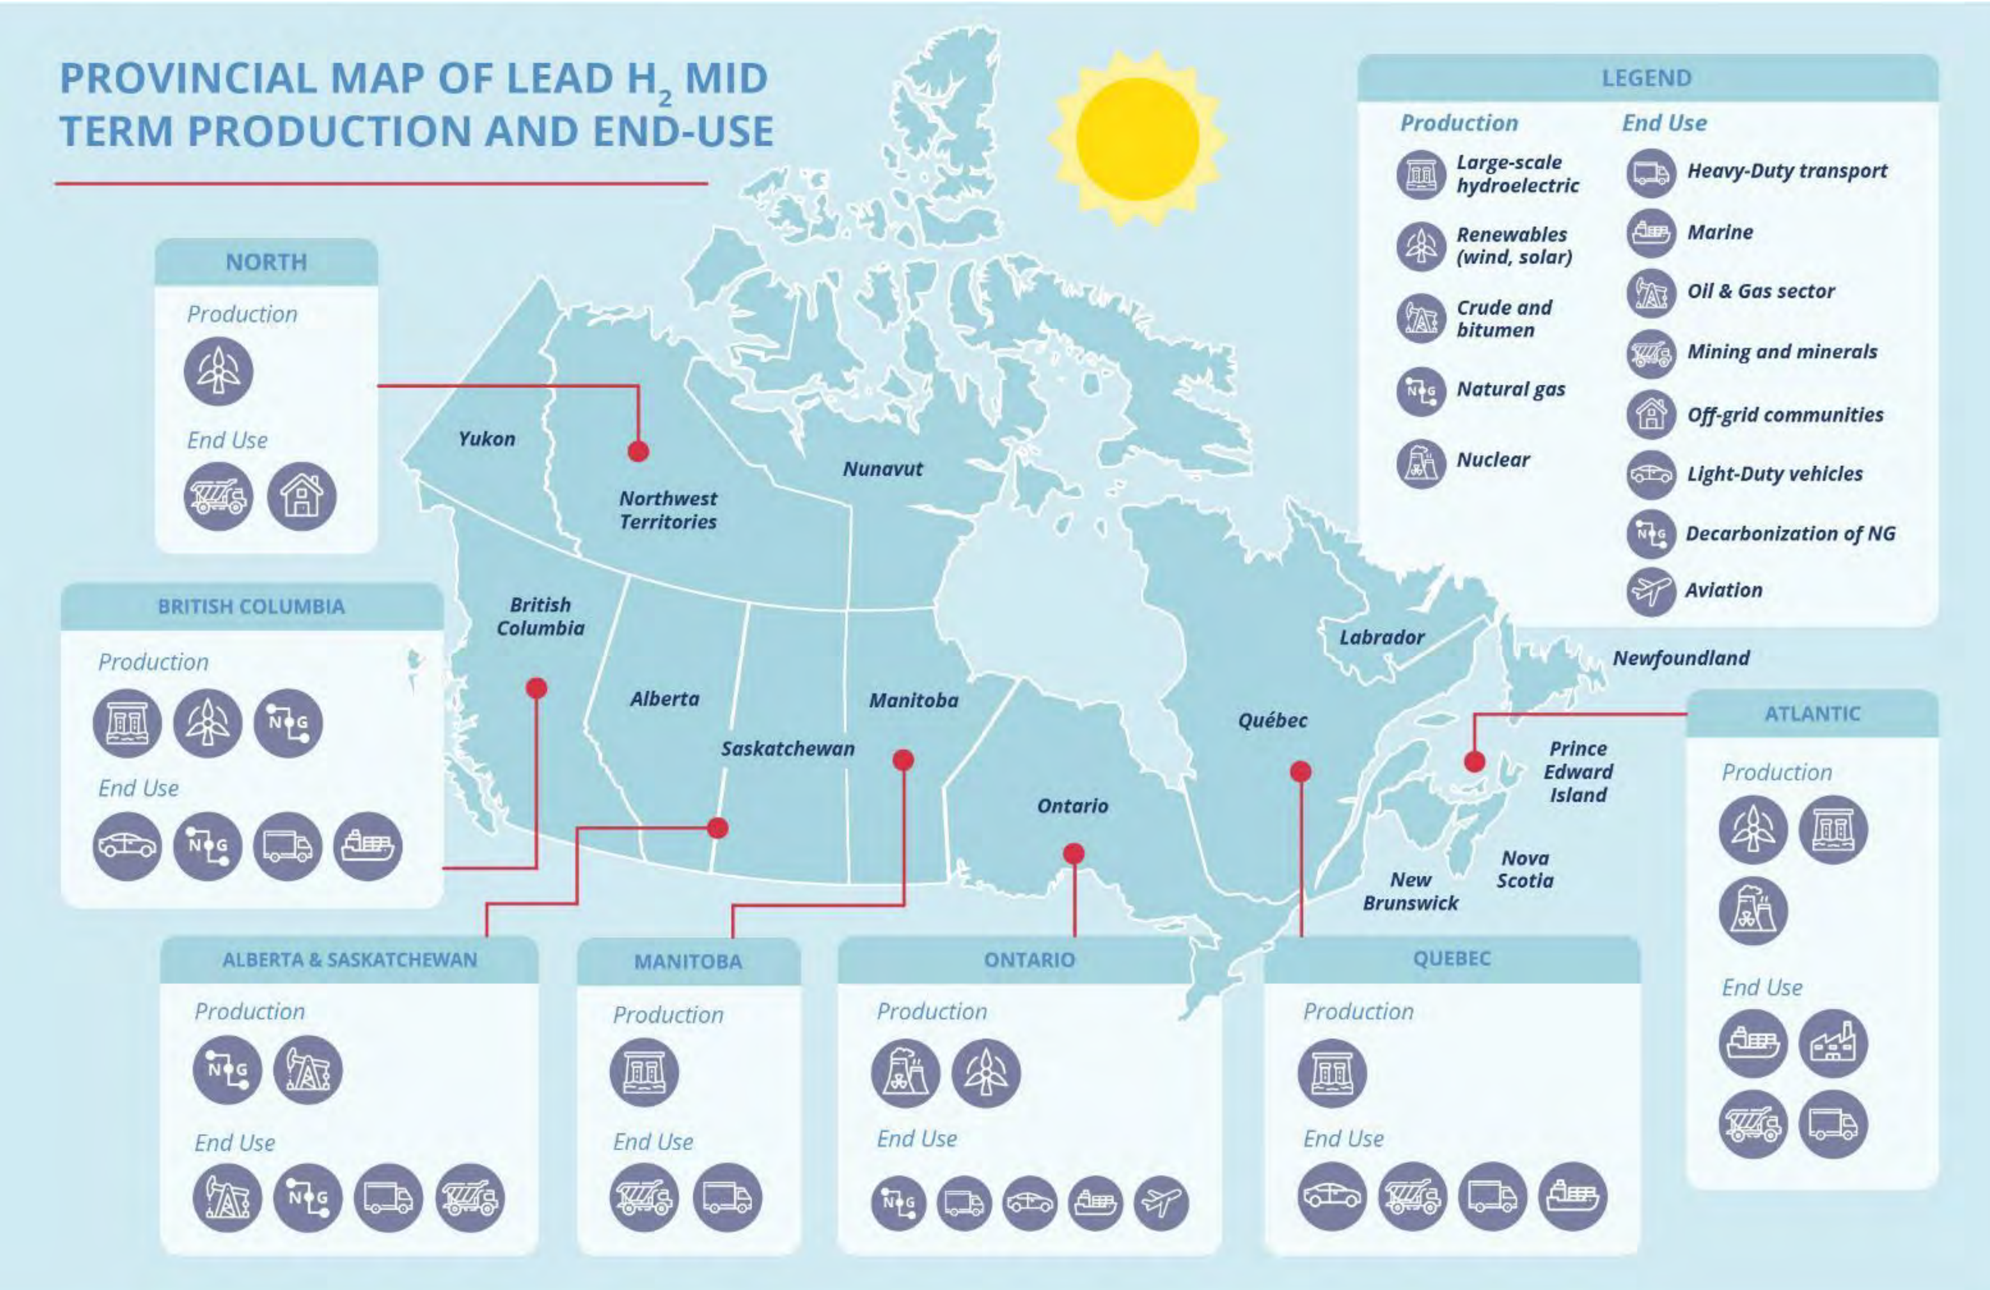

Figure 34 – Lead Mid Term Regional Production and End-Use Adoption Potential of Hydrogen Across Canada

QUANTIFYING THE OPPORTUNITY

The total primary energy supply in 2050 is expected to be delivered through several low carbon energy carriers including electrification, biofuels, hydrogen, and fossil fuels with carbon abatement. Modelling has been done to estimate potential adoption rates of hydrogen under ‘Incremental’ and ‘Transformative’ scenarios. The ‘Transformative’ scenario provides a directional estimate of the market size for hydrogen in key applications in achieving net-zero by 2050. In this ‘Transformative’ scenario, hydrogen could make up 31% of delivered energy, i.e., secondary energy use, in Canada by 2050 assuming economic and population growth are offset by efficiency improvements resulting in consistent energy consumption over time. This represents just over 20Mt of hydrogen demand per year in 2050, which is close to 3000 PJ of delivered energy. A more conservative Incremental scenario based on less aggressive policy assumptions shows opportunity for 8.3 Mt of hydrogen demand per year by 2050. Note that the Incremental scenario is not consistent with meeting net-zero targets in 2050. The demand by projected end-use application is shown in Figure 35.

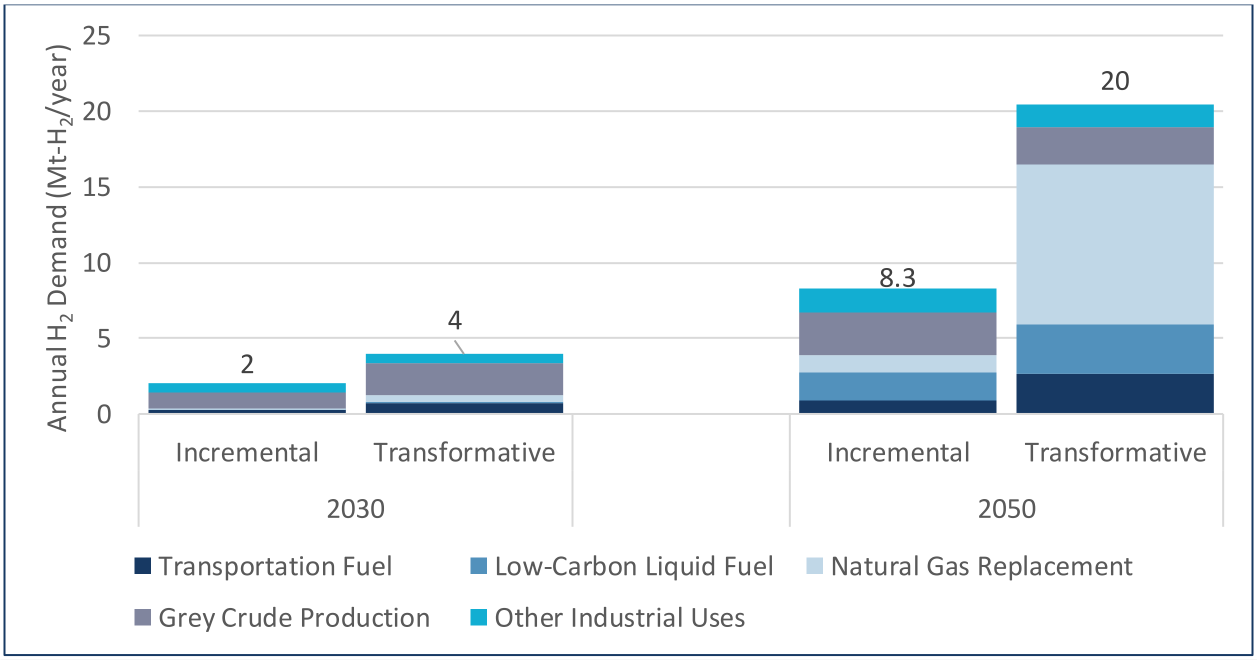

Figure 35 – Aggregate Demand Opportunity for Hydrogen in Canada

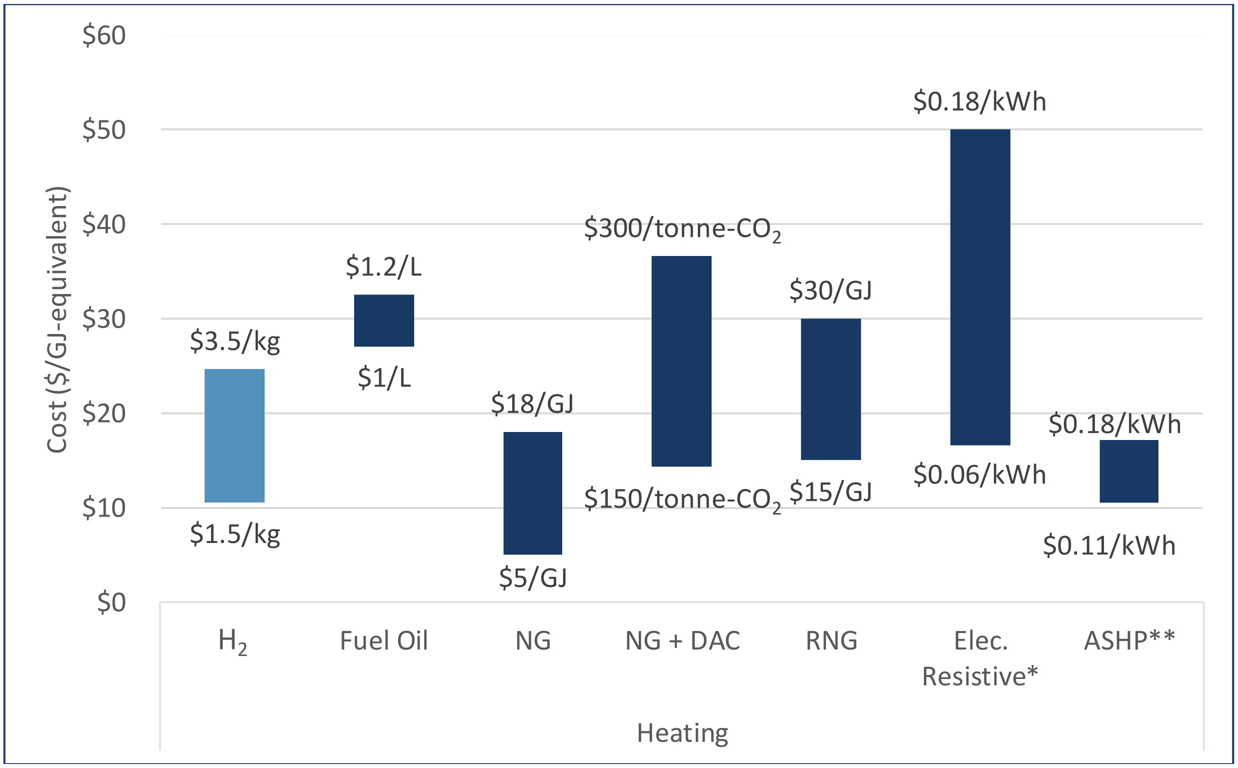
Ultimately the market will decide where best to deploy hydrogen once greater supply becomes available in Canada. The two big drivers will be cost competitiveness compared to alternative energy sources that can serve each end-use, and decarbonization potential which will ultimately be linked to the economics as carbon pollution pricing reflects the true price of emissions.

When comparing the cost of hydrogen to an incumbent fuel, it is important to consider the end-use application. For example, when used as a transportation fuel, hydrogen will be consumed in a fuel cell, which is significantly more efficient than a gasoline or diesel internal combustion engine (ICE). Therefore, the relative costs of the fuels cannot be compared on a simple $/GJ basis.

Figure 36 and Figure 37 shows the estimated cost of hydrogen relative to other fuels for heating and transportation applications. For both hydrogen and the alternative fuels, the costs shown reflect the total cost to the customer including production and distribution. The values are presented in $/GJ-equivalent, which takes into account the efficiencies of FCEVs and BEVs relative to ICE vehicles and air source heat pumps (ASHP) relative to electric resistive. As a heating fuel, hydrogen is more expensive than natural gas, but this value does not account for the increased costs of natural gas due to carbon. Over time, the delivered costs of all of the available fuels are likely to change. As a point of comparison, the figure shows the expected cost of natural gas used for heating for which the carbon emissions have been offset through direct air capture (DAC). Hydrogen for transport is cost competitive with gasoline and diesel, but will typically cost more than battery electric vehicles. Despite the additional cost, fuel cell vehicles will still be attractive in vehicle segments where operational requirements like longer range, improved performance in cold climates, and faster fueling are important.

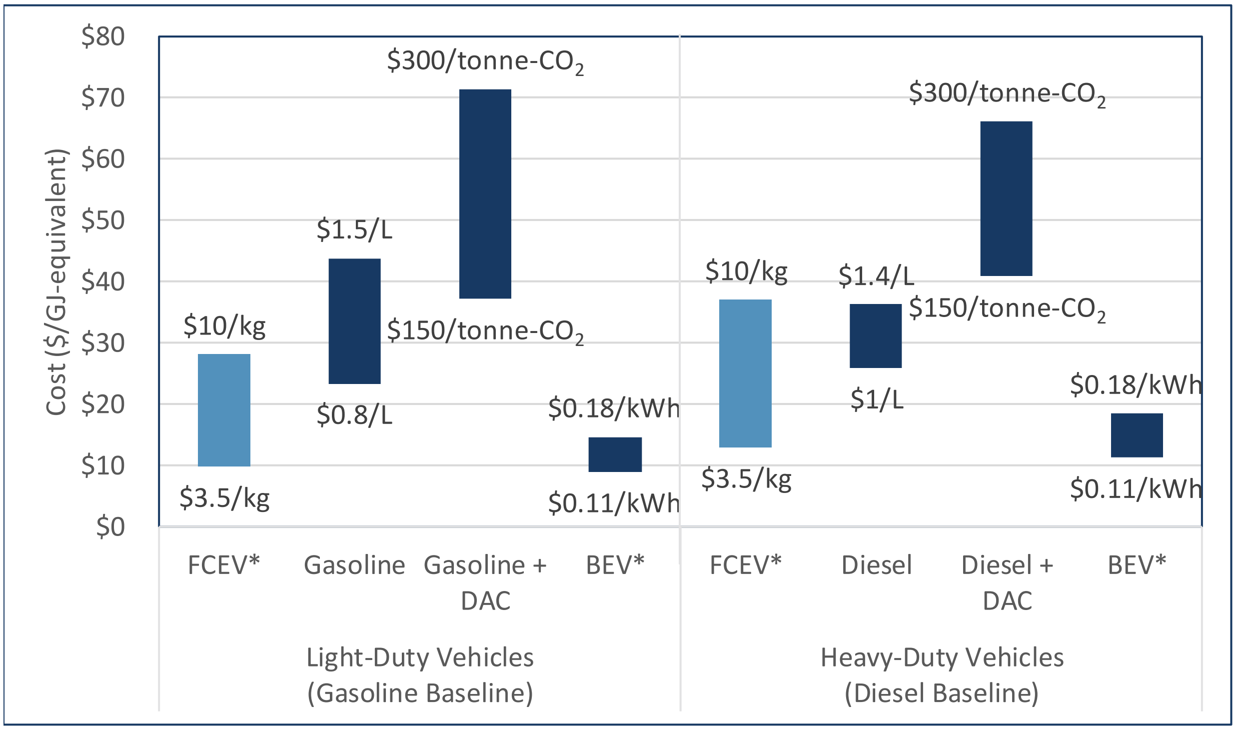


*The low price range for electric resistive heaters is less than for ASHP because resistive heaters may be used in industrial applications and therefore would be subject to rates for large scale industrial customers whereas ASHPs are typically in residential and commercial applications

**Coefficient of performance for ASHP = 2.92

Figure 36 – Hydrogen Cost Comparison as a Heating Fuel

The expected cost of hydrogen is dependent on the end-use application. As a heating fuel, it is assumed that the hydrogen will be produced in bulk and injected into the natural gas pipeline network in the short- to medium-term. The production takes place at or near the site of injection, so distribution costs are comparable to natural gas today, and the gas is only compressed to 100 bar, limiting compression costs. In the light- and heavy-duty vehicle sectors, it is assumed the fuel will be distributed via truck and compressed to 700 bar and 350 bar respectively. Comparable costs have been achieved in California for public transit applications.



*Energy efficiency ratio for light-duty vehicles: FCEV = 2.5, BEV = 3.4, energy efficiency ratio for heavy-duty vehicles: FCEV = 1.9, BEV = 2.7

Figure 37 – Hydrogen Cost Comparison as a Transportation Fuel

The emissions reduction potential of hydrogen is also dependent on the end-use application. Figure 38 and Figure 39 show the relative emissions reduction of hydrogen and electricity when used as a heating fuel or in a transportation application. The emissions reductions are compared to a natural gas baseline for the heating application, gasoline for light-duty vehicles, and diesel for heavy-duty vehicles. Negative numbers in these graphs indicate scenarios where emissions are increased relative to the baseline fuel.

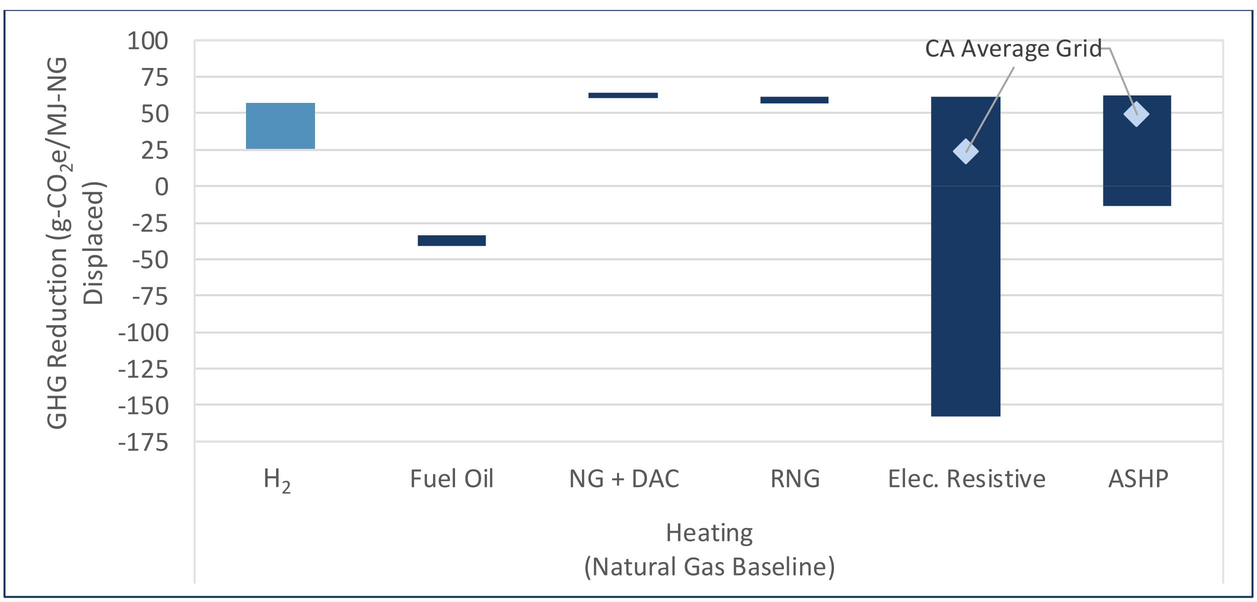


Figure 38 – GHG Emissions Reduction Potential of Hydrogen as a Heating Fuel

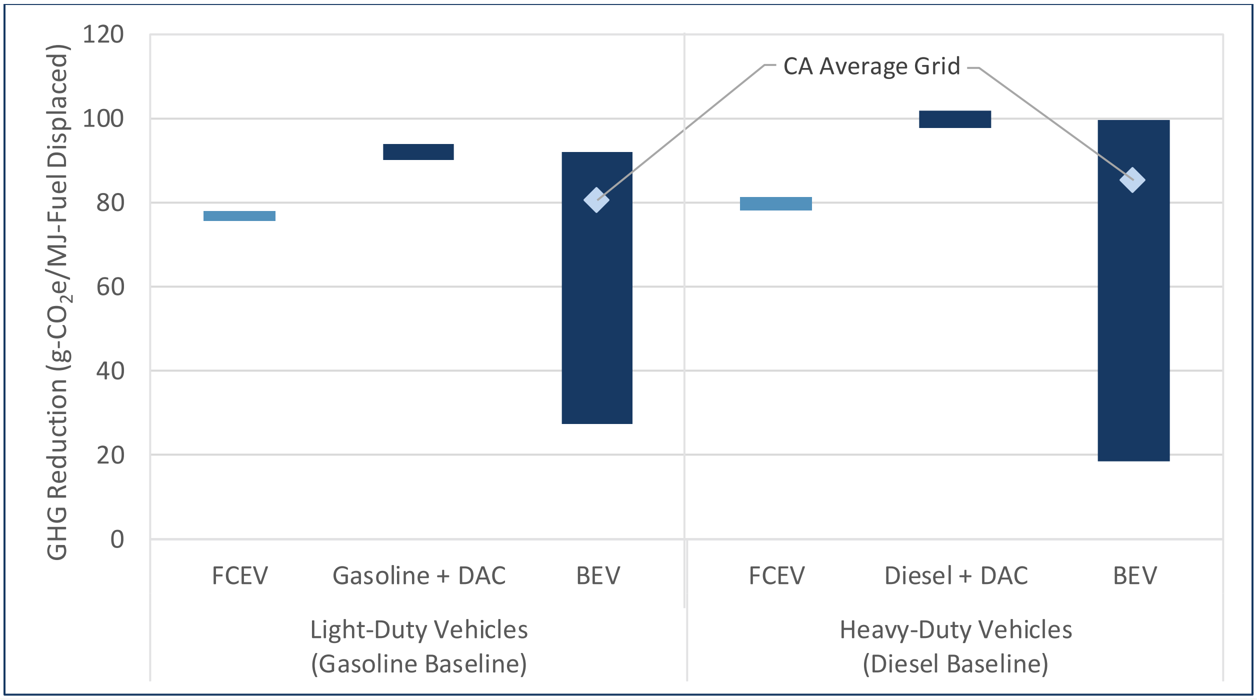

Figure 39 – GHG Emissions Reduction Potential of Hydrogen as a Transportation Fuel

The emissions reductions are dependent on the carbon intensity of the various energy sources. For hydrogen, the carbon intensity was assumed to be between 10.3-16.2 g-CO_2e/MJ when used as a heating fuel and 35.0-40.9 g-CO_2e/MJ when used as a transportation fuel to account for the additional energy required to liquify, compress, and distribute the hydrogen. These carbon intensities are consistent with large scale electrolysis and SMR with CCUS facilities, as described in the *Production Pathways' Cost & Carbon Intensity* section of this report.

The electrical emissions reduction potential is based on a carbon intensity of 140 g-CO_2e/kWh, which is the Canadian average. The lower bound (worst performing) shows the reduction potential based on Alberta's electric grid (790 g-CO_2e/kWh), which is the highest carbon intensity grid of any province in the country. The upper bound (best performing) represents Quebec's electricity grid (1.2 g-CO_2e/kWh), which is the lowest carbon intensity grid in the country.[1] In areas where the grid is particularly high-emitting, electrification will actually emit more than using natural gas or fuel oil. However, as the grid gets greener over time, the emissions reduction potential will improve.

[1] Canada Energy Regulator. (2020). Canada's Renewable Power Landscape 2017 – Energy Market Analysis. Retrieved from https://www.cer-rec.gc.ca/nrg/sttstc/lctrct/rprt/2017cndrnwblpwr/ghgmssn-eng.html

Cost and carbon intensity of each fuel are important factors that will drive adoption of the low carbon options for heating and transportation. A useful metric for comparison of different technologies is the incremental cost of hydrogen or other low carbon energy sources to the incumbent fossil fuel divided by the emissions reduction. This is often expressed in dollars per tonne of CO_2e abated ($/tonne-$CO_2e$). In transportation applications that employ fuel cells, hydrogen will cost less than gasoline or diesel resulting in a negative $/tonne-$CO_2e$ value. This provides a strong economic driver for adoption if capital costs are comparable. As a heating fuel, the cost of abatement in Canada is approximately $100-300/tonne-$CO_2e$, which is comparable to other low carbon options. While costs and carbon intensity are important factors, they are not the only limiting factors, there is also the operational differences, higher upfront capital costs and overall risk aversion (especially to new technologies). Further study is required to fully understand the costs of the entire value chain of each low carbon technology to assess the strength of each option.

The scale of aggregate demand in the 2050 Transformative scenario is significant and highlights the need for Canada to explore all low carbon intensity hydrogen production pathways. When considering pathways to satisfy future potential demand and optimize the potential for hydrogen, it is important to also consider the other changes that will be happening in the energy mix as Canada transforms all carbon emitting energy sources to carbon neutral sources . It is anticipated that direct electrification will play a significant role in reducing emissions in many sectors, from battery electric vehicles to heat pump adoption for building heat. Demand for electricity as an energy vector is expected to grow by at least 57%, and will be met through the deployment of additional renewable energy sources such as hydro, wind, and solar. Demand for bio-based liquid and gaseous fuels is also expected to grow. Natural gas on the other hand will have declining demand if not used to produce hydrogen, as any combustion related emissions in a net-zero energy system would need to be offset, for example through direct air capture. Figure 40 shows how much additional electricity generation or natural gas with CCUS capacity would be needed if all hydrogen is made though each of the pathways. The magnitude of energy feedstock needed highlights that a production strategy must be diverse, and that Canada will need to rely on fossil fuel pathways as well as the electrolysis pathway to meet decarbonization objectives.

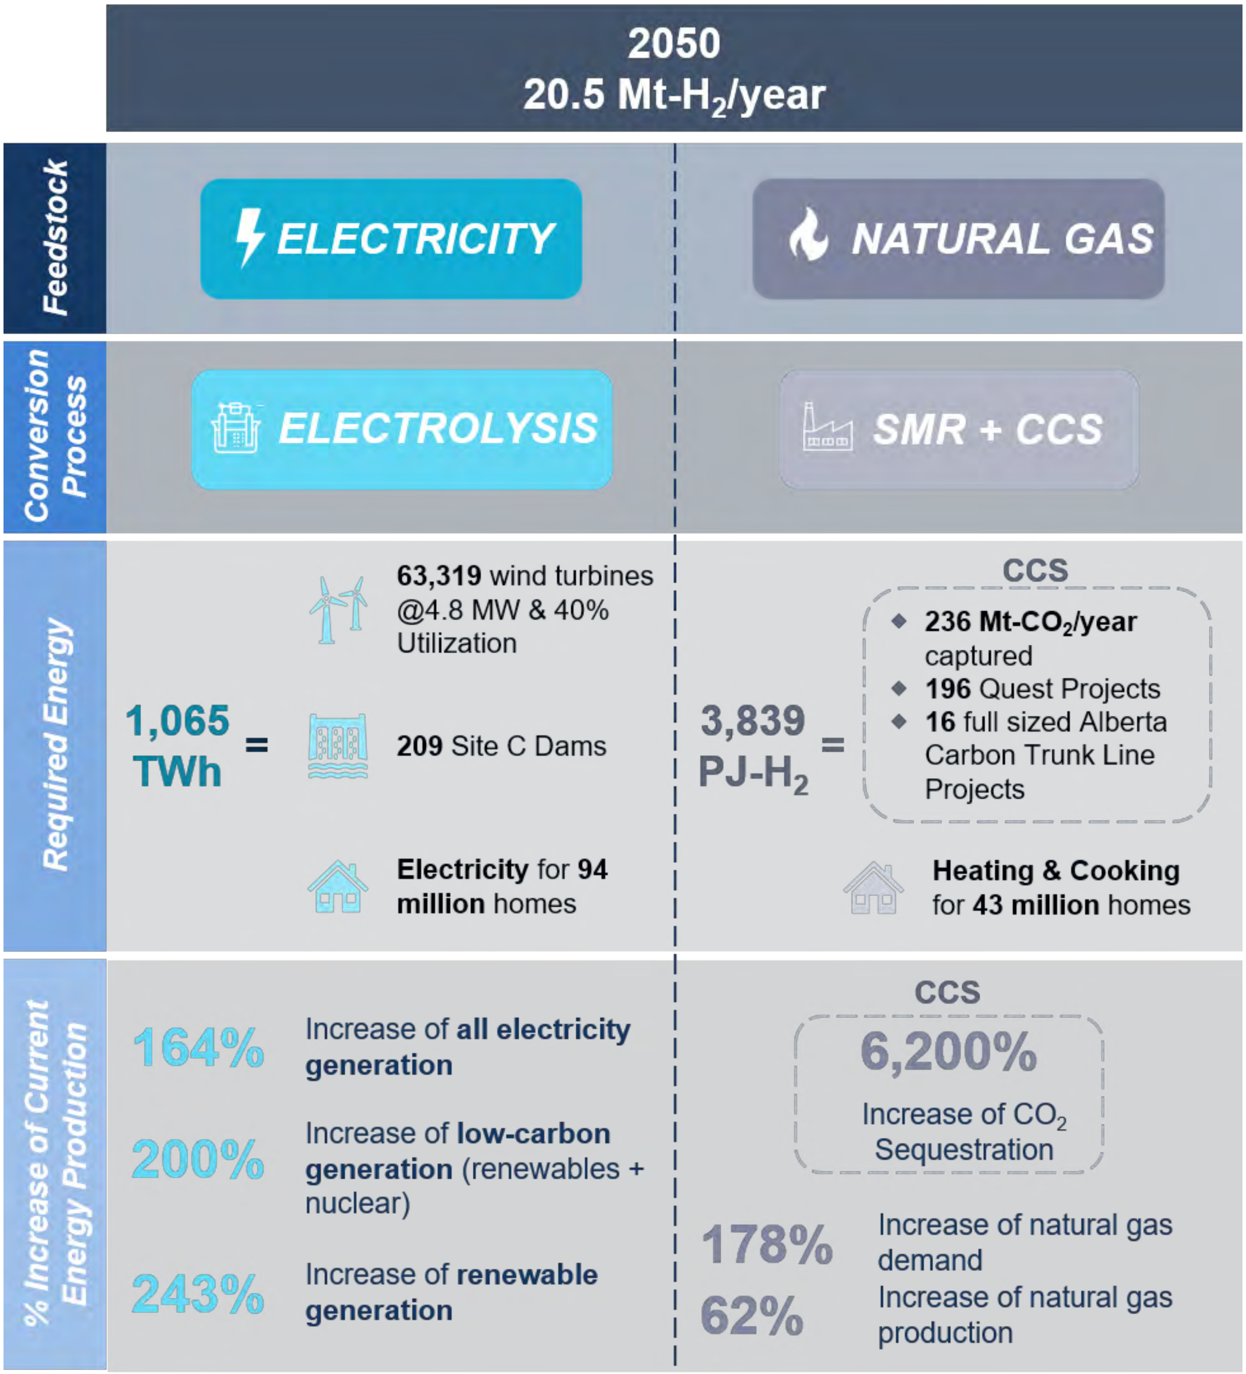

Figure 40 – 2050 Fossil Fuel vs Electrolysis Based Hydrogen Production

HYDROGEN'S DECARBONIZATION POTENTIAL

To evaluate the role hydrogen can play in reaching Canada's goal of becoming net-zero by 2050, modelling analysis was undertaken for an incremental scenario and a transformative scenario, to understand hydrogen's potential in the broader energy system, alongside electrification and other low-carbon fuels. These scenarios are more likely to be achieved with strong pricing and regulatory incentives to drive hydrogen adoption, and alignment action across government and industry.

Increased electrification with renewable and low CI power sources will play a large role in reducing emissions. It is well suited to many applications including light-duty BEVs and to provide heating when the use of heat pumps is cost effective. However, it will be impossible to grow clean electrical generation fast enough to meet demand if entire energy sectors electrify to meet climate targets. Hydrogen produced from natural gas and crude oil incorporating CCUS enables Canada to utilize its natural resources while limiting emissions as deployment of low CI electricity generating infrastructure grows. There are also end-use applications where electrification is challenging, including heavy-duty vehicles where the low energy density of batteries limits carrying capacity and where continuous operation of vehicles makes fueling time critical. In cases such as these, hydrogen is likely to become an important low CI option.

Similarly, low CI crude production, which includes traditional crude combined with indirect CCUS or enhanced oil recovery such that the net CO_2 emissions are near zero, and liquid and gaseous biofuels, will be an important part of the energy mix. These fuels serve effective substitutes for traditional crude and natural gas respectively as they can be incorporated into the current energy system without the need to replace or upgrade existing distribution and end-use infrastructure. The use of low CI crude and biofuels will be primarily limited by feedstock supply and economics. The cost to produce them will increase as the lowest hanging fruit opportunities for production are exhausted.

EVOLUTION OF THE ENERGY SECTOR

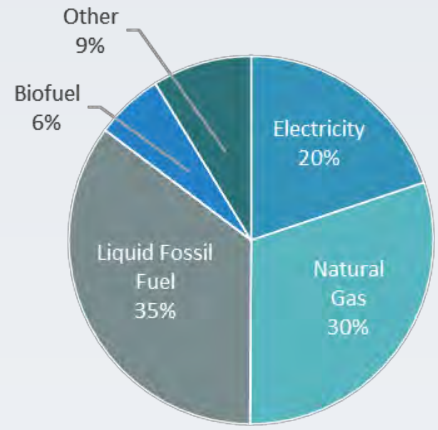

Figure 41 – Canada's 2017 Secondary Energy Demand

As demand for hydrogen grows, so will the need for other low-carbon energy sources.

Between now and 2050, high-emitting fuel sources will replaced by a combination of increased electrification, biofuels, low-carbon liquid fuels – including synthetic fuels and traditional crude offset through CCUS – and hydrogen.

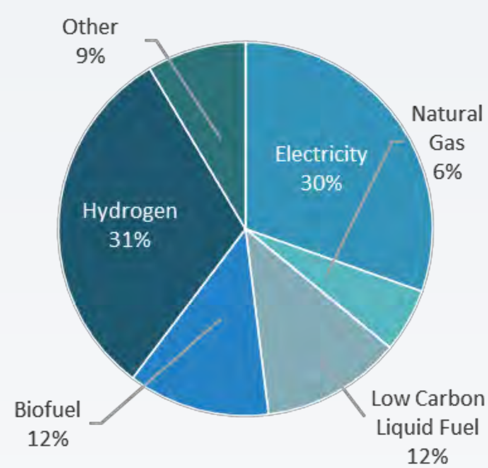

Figure 42 – Canada's 2050 Secondary Energy Demand Scenario

There are limited opportunities for cost-effective RNG production, which are likely to be maxed out on the path to net carbon neutrality. However, all low carbon fuels, including RNG will have a role in Canada's future.

Hydrogen demand was forecasted to essentially fill the gaps that electrification, and other low CI energy sources cannot reach or where they would be cost prohibitive. The analysis took into account the expected relative costs of each low CI energy source as well as the ability of technologies to meet end-use demand requirements.

The GHG emissions abatement potential was estimated by comparing hydrogen consumption to the incumbent energy source for each sector. In transportation applications, hydrogen is considered as a substitute for diesel and gasoline derived from crude oil; in the natural gas grid, hydrogen replaces natural gas; and in industrial uses, low CI hydrogen replaces either natural gas or grey hydrogen produced via SMR without CCUS depending on the specific application.

When applicable, the calculated emissions reductions account for the improved energy efficiency of fuel cells compared to internal combustion engines. In transportation applications, it was assumed that hydrogen would be used in fuel cells with energy effectiveness ratios (EER) of 1.9 for light-duty vehicles and 2.5 for medium- and heavy-duty vehicles. When used as a substitute for natural gas or as a feedstock for industrial processes, there is no efficiency gain relative to the incumbent fuel.

Figure 43 shows the transformational and incremental decarbonization potential from hydrogen in 2030 and 2050 by sector. In the Transformative case, hydrogen can reduce emissions by up to 45 Mt-CO_2e/year by 2030. In 2050, the emissions reduction increases up to 190 Mt-CO_2e /year. This simplified analysis assumes energy demand remains flat between now and 2050, with increased energy demand offset by energy efficiency improvements.

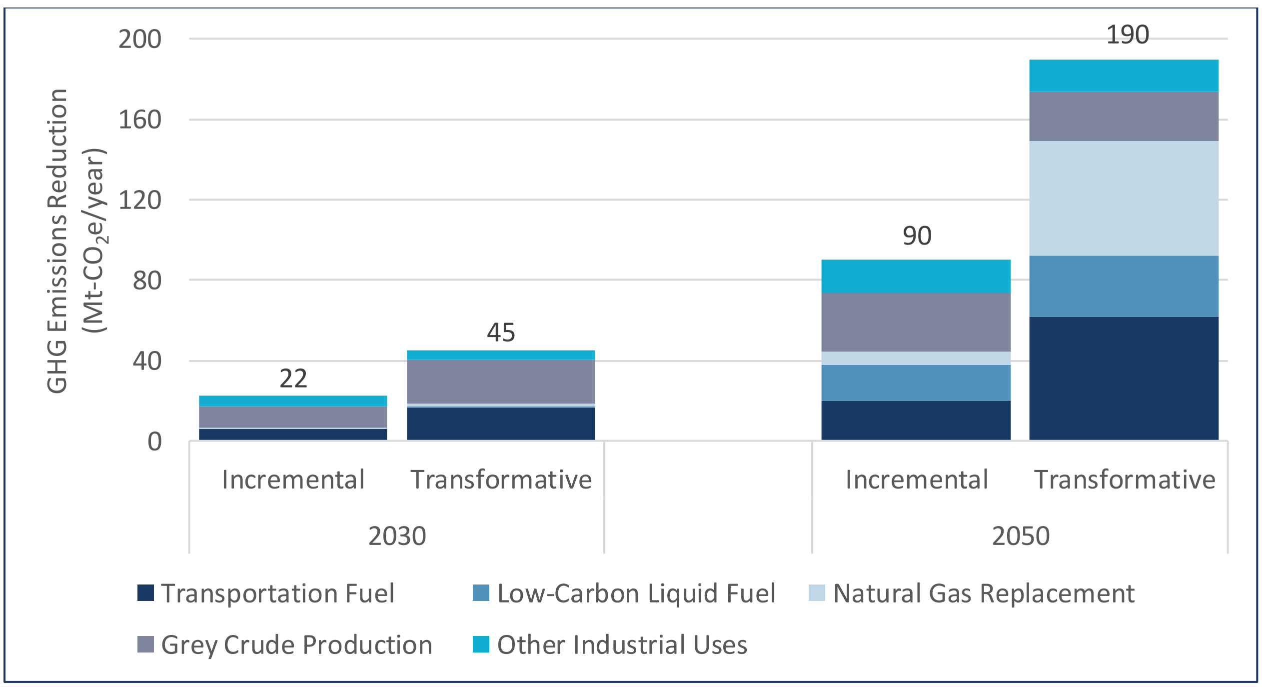

Figure 43 – Hydrogen Decarbonization Potential

Figure 44 shows the magnitude of emissions reduction from hydrogen relative to Canada's 2030 and 2050 targets.

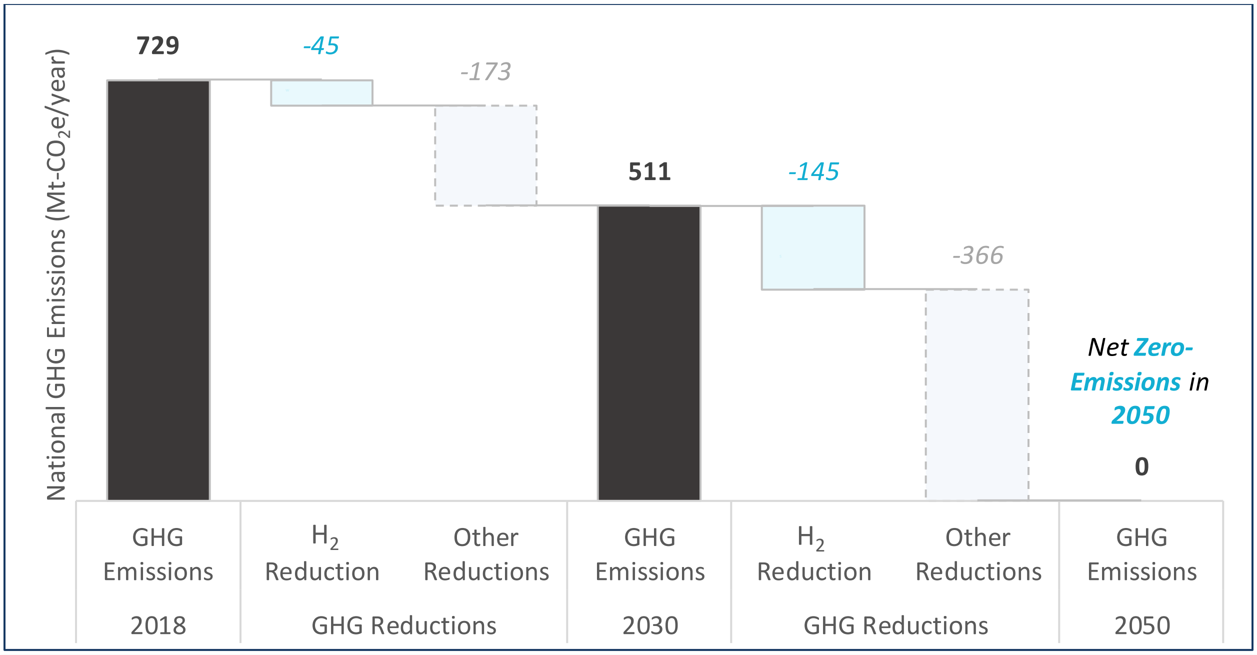

Figure 44 – Potential Role of Hydrogen in Reaching Canadian Decarbonization Targets – Transformative Scenario

ECONOMIC OPPORTUNITY

Domestic Market

Considering only the domestic demand for hydrogen production and revenues from the local manufacturing and services, the hydrogen and fuel cell sector has the potential to generate almost $50 billion in sector revenue in 2050 under the Transformative scenario (Figure 45). This figure is based on the estimated demand for hydrogen in 2030 and 2050 under the Incremental and Transformative modelling scenarios and assuming an average hydrogen sales price of CAD$2/kg. In addition, revenues from the manufacturing of electrolyzer equipment, fuel cell stacks and engineering and consulting services are estimated based on a conservative market share of 5% of the domestic market. The estimated value of the domestic market is expected to be almost **$50 billion per year** by 2050. This does not take in to account how the hydrogen market will indirectly benefit several other adjacent industries that would also contribute to economic growth and could lead to manufacturing opportunities in Canada, including SMR and CCUS facilities and equipment, H_2 pipeline development, and end-use applications in buildings, industry, and the natural gas grid.

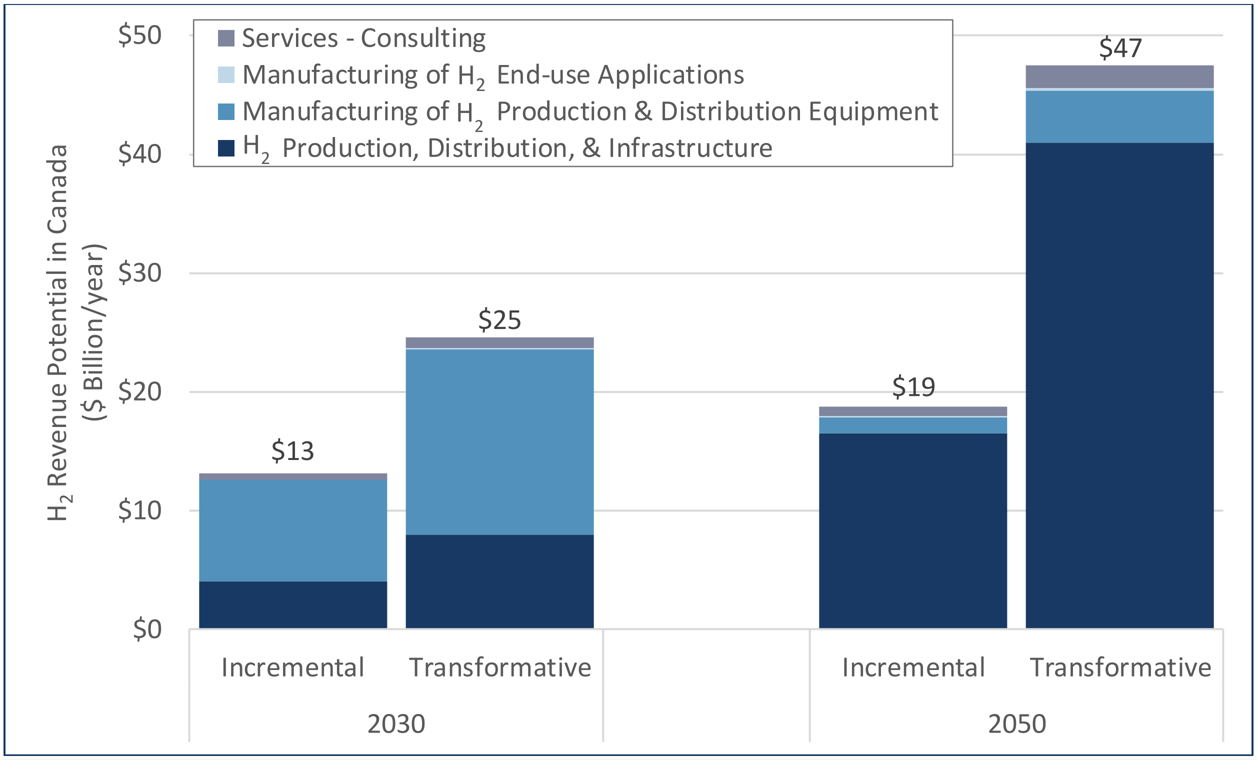

Figure 45 – Hydrogen Revenue Potential in Canada in 2030 & 2050

Based on the direct sector revenue estimates, the job creation potential for hydrogen in 2050, under the Transformation Scenario is more than **350,000** (Figure 46). This was calculated by multiplying the annual revenue for each subsector by a job multiplier based in similar industries (Table 2). For example, the number of jobs for the hydrogen production industry is based on the multiplier from the industrial gases industry. This number represents a combination of new job growth and retrained and reskilled labour.

Table 2 – Job Multipliers

Jobs per $M (jobs created each $M in revenue) [1,2]	
Jobs per revenue created in the machinery and equipment industry	12.2
Jobs per revenue created in the automotive industry	10.2
Jobs per revenue created in industrial gases	6.7
Jobs per revenue created in manufacturing of other transport equipment	14.5
Jobs multiplier –hydrogen	**6.7**
Jobs multiplier –equipment	12.3
Jobs multiplier –aftermarket	14.3

[1] These job multipliers are based on numbers from the US Fuel Cell & Hydrogen Energy Association's Road Map to a US Hydrogen Economy report (2019), adjusted to Canadian dollars. These projections should be seen as indicative of the order of magnitude of the number of jobs in the hydrogen industry and are subject to many uncertainties and unpredictable changes in economics and technologies.

[2] Source: McKinsey Global Institute Economics Research, GTAP input-output data

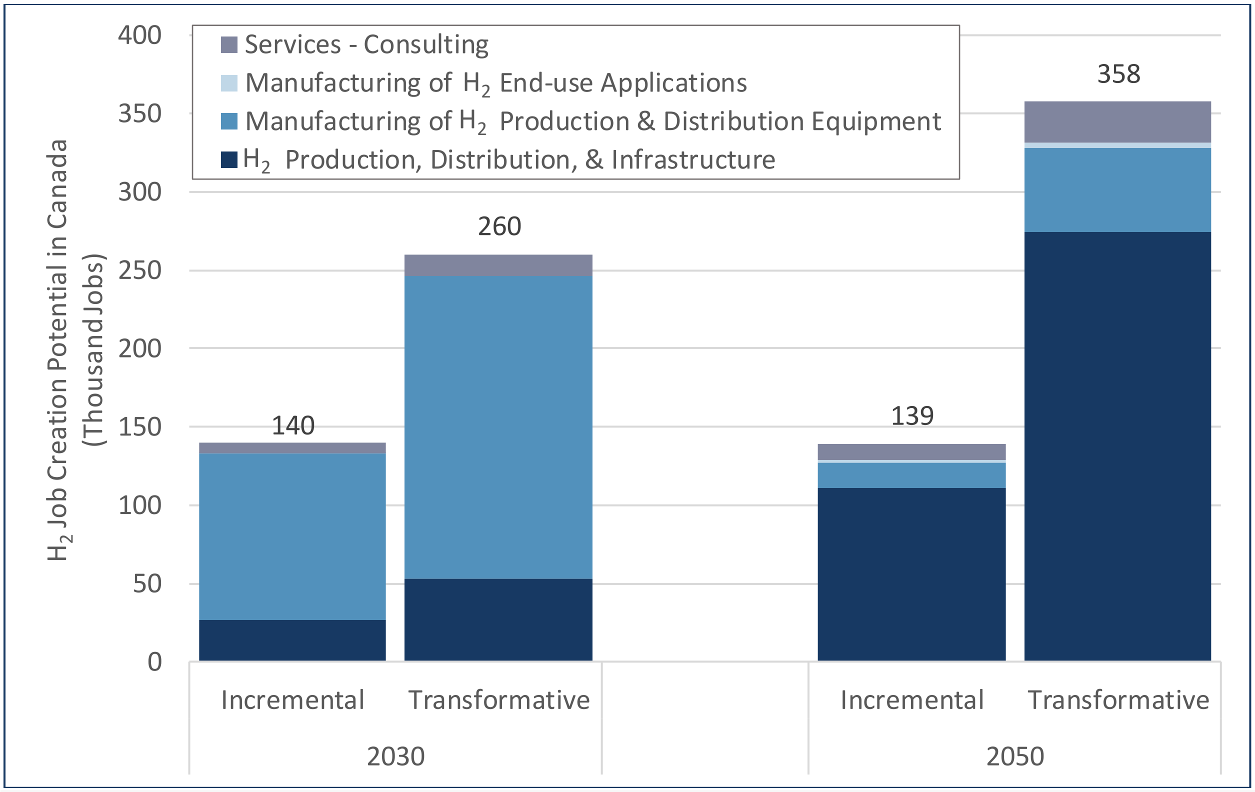

Figure 46 - Hydrogen Sector Job Creation Potential in Canada in 2030 & 2050

The energy transition will fundamentally shift the Canadian economy and alter value chains in many related sectors. One shift of particular importance is the transition away from the direct burning of fossil fuels without carbon abatement. Canada's energy sector accounted for 900,000 direct and indirect jobs as of 2017, with assets valued at $596 billion[1]. This industry's significant energy expertise and infrastructure can be leveraged to support the development of the future hydrogen economy in Canada. Hydrogen will be critical to achieving a net-zero transformation for oil and natural gas industries. It provides an opportunity to leverage our valuable energy and infrastructure assets, including fossil fuel reserves and natural gas pipelines, providing a pathway to avoid underutilizing or stranding these assets in a 2050 carbon neutral future. Leveraging these valuable assets will not only be instrumental in achieving the projected economic growth for the domestic market, but also presents the opportunity for Canada to position to become a leading global clean fuels exporter.

Opportunities for Indigenous Communities and Businesses

The energy sector is one of the largest employers of Indigenous peoples in Canada. As the energy sector transforms to adopt low carbon fuels, the emerging hydrogen economy will offer new opportunities for Indigenous communities through employment and new business creation.

The versatile production pathways of hydrogen and potential for scalable and distributed production facilities offers the potential for greater participation and ownership in the value chain than has been possible in the oil and gas and power sectors.

Hydrogen presents unique business opportunities for Indigenous communities with the capacity to take advantage of existing infrastructure, including renewable electricity, to produce, distribute and use hydrogen. These opportunities could outside of local communities as well. For example, Indigenous

[1] https://www.nrcan.gc.ca/sites/www.nrcan.gc.ca/files/energy/pdf/10-Key-Facts-on-Canada_s-Energy-Sector-2018-en%20.pdf

communities and businesses could participate in early deployment HUBS whereby they could become fuel producers and distributors both for nearby communities and adjacent industry.

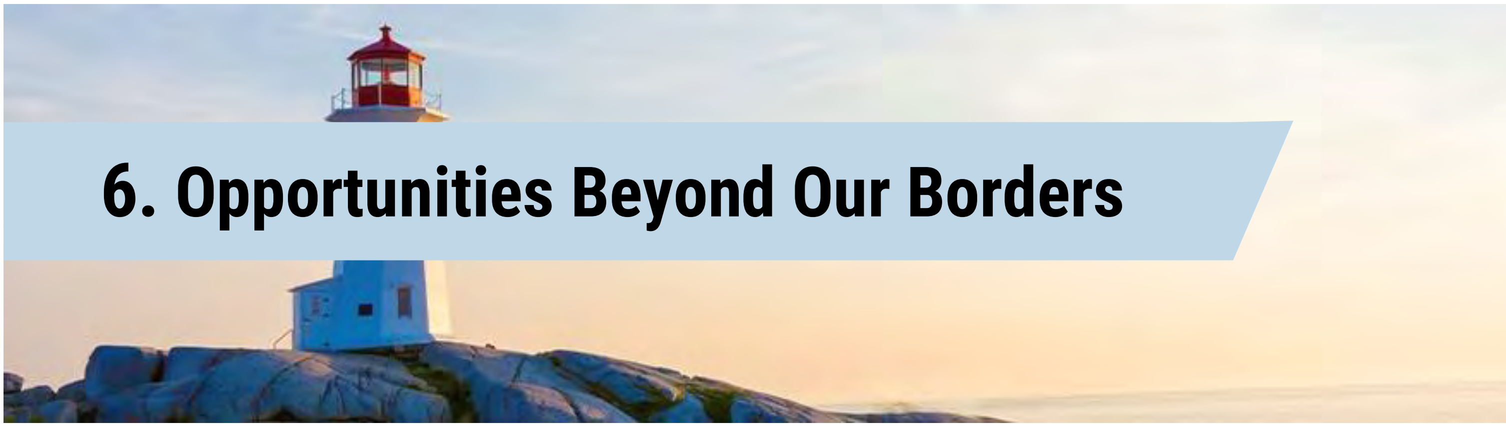
Many of Canada's remote communities house Indigenous peoples, and a large proportion of these communities are reliant on imported diesel for power generation. This leads to high operating costs and poor air quality. In the medium to longer term hydrogen can offer an opportunity for greater energy independence, as it can be made from local biomass and/or hydroelectric resources. Displacement of high-emitting diesel with hydrogen will result in improved local air quality and better health outcomes for community members.

As Canada invests in hydrogen infrastructure build-out, there is an opportunity for Indigenous peoples to participate. Some of the anticipated distribution corridors to move hydrogen from production to end-use locations will likely run through Indigenous lands. As such, skilled construction labour will be needed for build-out of production and distribution infrastructure assets, including future potential hydrogen pipelines. While there has been mixed support for traditional pipelines, hydrogen pipelines may offer a unique low environmental risk alternative to move energy within Canada, though local land disruptions through Indigenous territories will still need to be considered. Early and meaningful engagement on all aspects of hydrogen production, distribution and deployment will be essential.

Indigenous communities and businesses across Canada are already identifying hydrogen as a new opportunity for economic development, with environmental benefits. By leveraging the natural resources under their stewardship, as well as existing commercial facilities owned and operated by Indigenous-led businesses, new hydrogen opportunities are emerging. For example, the Penticton Indian Band is considering the development of a hydrogen-powered passenger railway service in the Okanagan Valley – a potential first in North America – mobilizing partners and experts throughout the region to advance a holistic vision of sustainable transport. In northeastern BC, Renewable Hydrogen Canada (RH_2C) is developing the Sundance Hydrogen project that includes Indigenous participation through operation of co-located greenhouses utilizing waste heat from electrolyzer plants that will provide fresh, local produce for the region. In Ontario, the Saugeen First Nation has formed a partnership with Bruce County to advance foundational hydrogen infrastructure, noting that the local geology can serve as a vast reservoir capable of storing hydrogen produced from local renewable resources and nuclear power. Once stored, the hydrogen can be supplied to markets as a low CI gaseous fuel; it can also be converted back to electricity to power the regional transmission grid. Similarly, Des Nedhe Development sees opportunities to include hydrogen refueling and EV chargers their existing conventional gas stations within Saskatchewan, as the next step in the transition to a lower carbon economy. They also see strong synergies between Canada's uranium mines, path to small modular reactors, and hydrogen as providing economic opportunities in the medium term.

The scale of Indigenous clean energy leadership and ownership has the capability to grow over the short and long-term. Going forward a holistic approach, to understand the potential role of hydrogen as part of broader energy pathways, in support of reconciliation, will be critical. Hydrogen deployment initiatives can be most effectively advanced through early and meaningful dialogue with Indigenous peoples.

As the Hydrogen Strategy emphasizes, collaborative, strategic partnerships are essential for growing the production and use of hydrogen across Canada. Partnerships that emphasize environmental protection, cultural recognition, community energy planning aligned with traditional values, economic development, and project participation, will be essential to maximize benefits for Indigenous peoples in the hydrogen economy.



6. Opportunities Beyond Our Borders

Momentum on hydrogen and fuel cell technology is growing globally, with market estimates ranging from \$2.5-\$11.7 trillion by 2050. Canada has the potential to produce large amounts of low-cost, clean hydrogen in excess of its domestic demand, creating an opportunity for Canada to become a supplier of choice of a new carbon-free energy export commodity. Canada, known for its leading hydrogen and fuel cell technology companies, is also well positioned to attract direct foreign investment, and continue to grow as a word-leading exporter of technology, products, and services.

EXPORT MARKET

Canadian governments, industry and academia have a long history of international collaboration to advance hydrogen production and use. These collaborations have included fundamental research, commercialization, deployment, and policy development. As a result, Canada is well positioned to continue as a global leader in both technology innovation and commercial developments. International collaborations accelerate advancements in R&D and product development, ensure codes and standards necessary for commercial rollout are harmonized, and build on policies and best-practises. They also position Canadian companies to showcase their products and expertise in international markets for export and to attract additional direct foreign investment.

With worldwide demand for hydrogen increasing, there is a significant opportunity for Canada to become a supplier of low CI hydrogen as a new carbon-free energy export commodity complementing Canada's energy exports of crude oil, natural gas, and transportation fuels. Canadian oil and natural gas exports alone totaled \$119 billion in 2019, and, with import countries looking to decarbonize their energy systems, hydrogen could take a significant portion of this share in the coming decades.[1] There is also potential to grow the export market for Canadian products, services, and intellectual property. A recent study indicated that hydrogen exports could reach \$50 billion by 2050, doubling the overall economic potential of the market projected for Canada in the same timeframe.[2] In November 2017, the Hydrogen Council estimated that the global annual sales for hydrogen and related equipment could be 2.5 trillion by 2050.[3] More recently in September 2020, the global investment bank Goldman Sachs estimated that the addressable market for hydrogen could be worth \$11.7 trillion by 2050, split between Asia, Europe and the U.S.[4]

Canada has the potential to produce large amounts of low-cost, low CI hydrogen in excess of its domestic demand. Leveraging the country's diverse range of hydrogen production feedstocks to create hydrogen for export could create substantial economic value. Canada has several strategic advantages for producing hydrogen for export including:

- Deepwater harbours and port infrastructure along both coasts, Hudson's Bay and the Great Lakes providing access to key markets in Asia, Europe and North America
- Abundant low carbon electricity, biomass, natural gas, and CCUS potential
- Integrated, country-wide natural gas and pipeline network
- Connected energy systems integrated with the large US markets, especially California and the East Coast
- A well-trained workforce with deep technical experience in the energy sector

A full analysis of the export potential for hydrogen is beyond the scope of the strategy in the near-term, but several key markets, technologies, and policies are recommended as a foundation. It is recommended that export opportunities be studied in depth following release of this *Hydrogen Strategy for Canada*, with the goal to create a specific action plan related to pursuing opportunities for export in parallel to the focus on establishing a vibrant domestic market.

TARGET MARKETS

Five key markets have been identified as potential export markets for Canada: The USA (particularly California and the Eastern US), Japan, South Korea, China, and the European Union. These have been identified based on their stated strategies, demand potential and proximity to Canada. As the global demand for hydrogen continues to evolve, new export markets in South America may also develop.

In the USA, the two main markets for hydrogen are expected to be in California and in the densely populated North Eastern states. California's estimated demand for hydrogen could be as large as 1 to 4 million tonnes by 2050. The state has strong governmental regulations and supportive funding for hydrogen infrastructure and fuel cell vehicles. The Innovative Clean Transit Regulation and Zero Emission Vehicle Mandates are expected to create significant demand for hydrogen in the transportation sector. The state also has significant renewable natural gas and energy storage requirements which could be partially addressed with imported hydrogen. For the market in the Northeastern US, there are potential opportunities to reuse elements of the LNG and other infrastructure already in place in Atlantic Canada. The ports, rail, highway and pipeline interconnections between the Maritimes and the Eastern US could provide a route to market for hydrogen generated in Central Canada and Quebec.

In Asia, Japan, South Korea, and China have ambitious hydrogen strategies. Japan and South Korea will need to rely on imports to meet the bulk of their demand. The estimated demand for hydrogen in Japan could be between 5-35 million tonnes per year in 2050 according to the Ministry of Economy, Trade and Industry. The country has already begun investigating supply options with Australia, who have, in turn, developed an aggressive and ambitious hydrogen export strategy. In South Korea's National Hydrogen Economy Roadmap, the estimated demand in 2050 is between 4 and 20 million tonnes per year, with limited domestic production potential similar to Japan. China has plans to make significant investments in hydrogen and fuel cell vehicles. The demand is expected to be between 18 to 160 million tonnes per year by 2050. China may eventually be able to become self-sufficient in its production when coupled with the large renewable and nuclear energy systems it is developing.

In Europe, Germany is leading the development of its hydrogen economy based on renewable energy and electrolysis. The German Government expects that around 2.7 to 3.3 million tonnes (90 to 110 TWh) of hydrogen will be needed by 2030, with significant upside growth in the 2030 – 2050 timeframe. To cover part of this demand, Germany plans to establish up to 5 GW of generation capacity including the offshore and onshore energy generation facilities[1]. They will also likely rely on imports of hydrogen to complement domestic production. In the rest of Europe, there are several hydrogen hubs being developed in the Netherlands, the UK, and Portugal. The Port of Rotterdam in the Netherlands is working to introduce a large-scale hydrogen network across the port complex, with the goal to make Rotterdam an international hub for hydrogen production, import, application and transport to other countries in Northwest Europe[2]. The hub will also enable Rotterdam to maintain its position as important energy port for Northwest Europe in the future, anticipating that demand for hydrogen will be growing.

British Columbia, with its proximity to East Asia, could be an export hub for Canadian hydrogen, leveraging local and Alberta production capacity provided transportation infrastructure is established to connect the two provinces. The British Columbia Hydrogen Study completed in 2019 shows export potential of $15 billion by 2050 from that province.[3] Atlantic Canada could be a potential export hub for Canadian hydrogen to serve the European market. The following image (Figure 47) highlights the international landscape for hydrogen production and demand, and identifies at a high level how Canada could explore serving these markets through export channels. Provincial and local leadership will be needed to develop identify and invest in developing strategy export hubs for Canadian hydrogen.

ENABLERS

Innovation and Intellectual Property Leadership

Canada is recognized as a global leader in the hydrogen and fuel cell sector, seen as a hub for technical expertise, intellectual property, and leading products and services. In 2018, the industry generated revenue of $207 million and was responsible for 2,177 jobs[1]. According to a survey conducted by the Canadian Hydrogen and Fuel Cell Association in 2017, 86% of respondents' hydrogen and fuel cell facilities were located in Canada with BC, Ontario, Quebec and Alberta home to some of the largest industry clusters as shown in Figure 48.

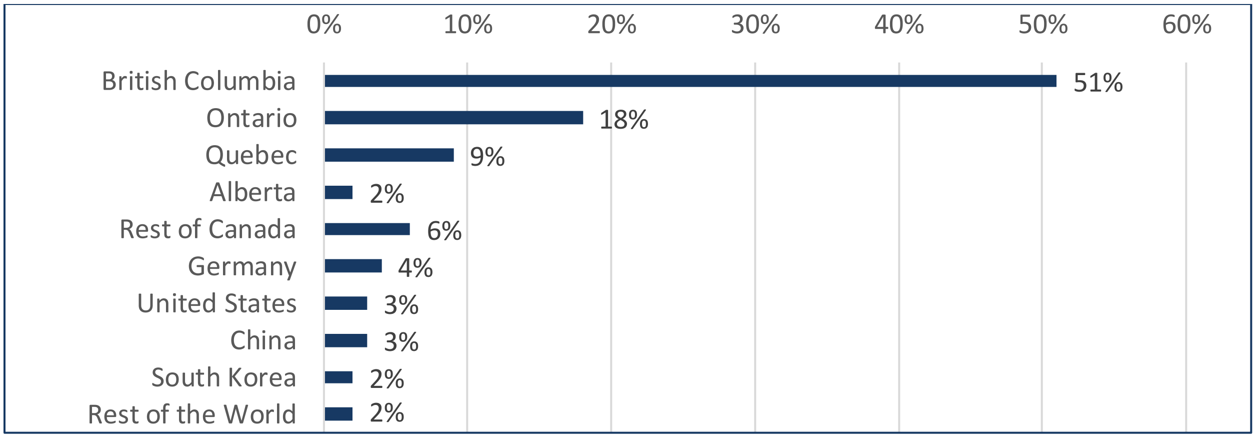

Figure 48 – Hydrogen and fuel cell facilities by region

Canadian companies, educational institutes, government agencies, and NGOs are involved with hydrogen and fuel cells across a range of sectors and areas of expertise from fundamental scientific research through to aftermarket sales and services. Many of these organizations have been involved with hydrogen and fuel cells for multiple decades and have strong interconnections and shared talent pools.

Domestic deployments will help Canadian companies across the value chain, both in providing a local market for their goods and services, and also by serving as local reference projects opportunities for Canadian companies looking to export products, services, or IP into international markets. A common theme heard from cleantech stakeholders is that international partners ask to see local reference projects to validate technology readiness and the business case.

Canadian companies in the sector are today generally relying on export markets to grow their business, given the relatively small Canadian market to date. Due to Canada's technology leadership, lead companies have attracted significant foreign investment, and international companies have set up shop in Canada to be able to leverage the local trained talent pool. This sector will continue to grow economic value for Canada, provide jobs, and attract foreign investment provided technology and innovation leadership is maintained.

Canadian companies in the hydrogen and fuel cell space are currently recognized as technology and product leaders, and today heavily rely on international sales of services and products to regions leading in hydrogen adoption. These companies will benefit from a growing domestic hydrogen economy, and can also grow from increased international sales as Canada builds on the opportunities outside our

[1] CHFCA. (2018). Canadian Hydrogen and Fuel Cell Sector Profile. Retrieved from http://www.chfca.ca/wp-content/uploads/2019/10/CHFC-Sector-Profile-2018-Final-Report.pdf

borders for the growing hydrogen sector. Canadian reference projects will validate the strengths and business case for Canadian products, facilitating international sales.

Staying at the forefront of innovation is critical to sustaining Canada's competitive advantages, and Canada is at risk of losing ground. Other countries have been heavily rapidly increasing investment in the sector whereas Canada has, in recent years, slowed investment in fundamental research. As a result, there have been examples of Canadian companies moving operations to other countries where there is more support for technology advancement. It is important for Canada to act now to prevent loss of critical IP.

Stakeholder engagement highlighted areas in which Canada can excel in hydrogen innovation. Canada already has a leading fuel cell sector with expertise ranging from fundamental materials to complete systems and vehicles. Building on these strengths to maintain leadership should be a key area of focus. As Canada transitions to deployment, there are opportunities for innovative solutions in hydrogen production technologies, as well as important complementary technologies such as CCUS and hydrogen storage unique to Canada's geology, such as use of depleted wells for both carbon storage and hydrogen storage either as a blend or pure fuel. Canada can also develop expertise in engineering and integration using deployment HUBs to strengthen local skills. Deployment HUBs also present an opportunity to nurture skills development and training, to ensure workers and communities are equipped with the skills needed to succeed in a clean energy future. In this way, Canada can showcase how, youth, women, Indigenous peoples, and other underrepresented Canadians can become the backbone of a low-carbon economy, through focused efforts from industry and governments.

Storage Technologies

Hydrogen storage and transport from production hubs to users' sites will be one of the more challenging obstacles for the large-scale global adoption of hydrogen. Liquefaction and chemical storage, in the form of chemical carriers such as ammonia or liquid organic hydrogen carriers, in particular will need to be developed to enable the safe and cost-effective transport of hydrogen from Canada to export markets around the world. Canada is currently investing in large scale Liquefied Natural Gas (LNG) infrastructure including seaports and liquefaction facilities that could potentially be adapted for hydrogen.

As countries develop hydrogen import strategies, it is expected that emissions from both production and transportation will be considered in the overall lifecycle analysis to determine decarbonization potential as an important decision metric. Canada will need to participate in international R&D related to transportation technologies if bulk export is deemed to be a strategic priority in the export roadmap.

Standards and Regulations

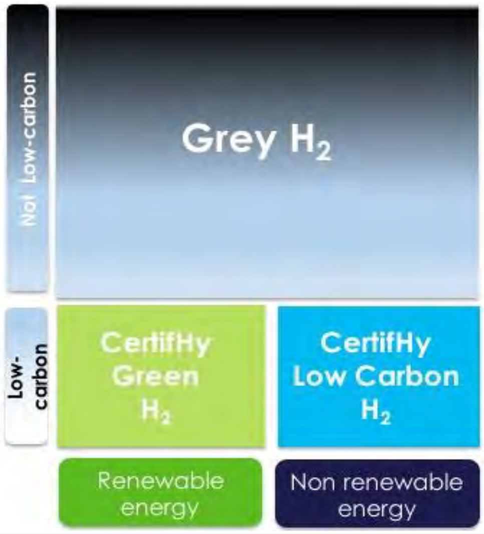

Figure 49 – CertifHy Green and Low Carbon Hydrogen Definitions

Other countries are also pursuing the same export markets and Canada will need strong policies and investments to remain competitive. The Canadian hydrogen industry will need to be integrated with export markets in terms of codes and standards, carbon intensity tracking, and renewable gas standards. Of particular importance is how other countries will value hydrogen produced from fossil fuel and non-renewable feedstocks. For example, the European CerifHy[1] Guarantee of Origin initiative label both the carbon intensity and the source of the hydrogen, distinguishing between renewable energy origins and non-renewable energy. Given Canada is focusing on all sources of low CI hydrogen, it will be important for Canada to participate in these types of activities. Branding and promoting Canada's low carbon fuels will be important to gain market acceptance. Branding and claims will need to be backed by certified lifecycle analysis.

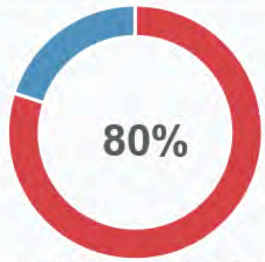
STAKEHOLDER INPUT: CLEANTECH & INNOVATION

Opportunities

- *Canada has been a pioneer in fuel cell technology for more than 40 years and is home to some the world's leading hydrogen companies*



- *Canadian fuel cell technology is used in over 80% of applications worldwide and Canada has a global IP leadership*

- *The global market for hydrogen could be worth between $2.5T and $11.7 in 2050 and employ 30M people*

Challenges

Decline in research and development has impacted Canada's early lead in innovation

Larger countries investing heavily in national research programs has pulled talent and IP away from Canada

Lack of domestic deployments means no local market and no 'living labs' to spur collaboration & innovation

Investors in Canadian companies need to be able to see examples of technology deployments domestically

Findings

- *Establish domestic deployment hubs that highlight local technology, and encourage cross sector and international collaborations*
- *Time is of the essence. Need to quickly accelerate development and support multi-year research priorities or Canada will lose innovation edge*
- *Targeted technical research in strategic areas is needed in near term to inform the development of codes and standards and commercialization of cross-cutting H_2 technology applications.*
- *Encourage mission-oriented approaches to focus research, development and demonstration (RD&D).*

7. Remaining Challenges

Canada has a strong head start in hydrogen and fuel cells and is well positioned to realize the opportunities offered by a vibrant domestic and export hydrogen economy. However, there are challenges we must work to overcome. With global competition increasing, targeted actions across the hydrogen value chain are needed to overcome these challenges and position Canada for success.

ECONOMIC & INVESTMENT

The factors limiting hydrogen use in many applications today are economic rather technological, as hydrogen is not yet cost competitive compared to conventional fuel options. For example, hydrogen used as a carbon-free heating fuel is ~5X more expensive than natural gas. While hydrogen can be cost competitive with some RNG sources, conventional natural gas is typically used as the benchmark. Hydrogen can be among the lowest cost alternatives for reducing carbon emissions on a dollar-per-tonne-abated basis. A challenge today is that GHG emissions are not always adequately reflected in the market cost of baseline fuels. Implementation of the federal Clean Fuel Standard as well as carbon pricing, will be important steps forward.

Achieving scale is also critical to economic competitiveness of the sector and to ensuring access to an affordable and abundant source of clean hydrogen. The market for low CI hydrogen in Canada is in the very early stages, and the large capital investment to scale production requires that demand grow concurrently with supply. Predictable, long-term demand is therefore critical before industry can invest in large-scale projects.

Costs of end-use applications are also a barrier to adoption, which can limit demand and associated scale. In transportation applications, FCEVs are more expensive than BEVs and PHEVs, due to low production volumes. Further work is also needed to drive down core fuel cell stack, balance-of-plant, material and manufacturing costs, as well as other vehicle speciality component costs such as hydrogen storage tanks. Investment in R&D is needed to achieve cost parity with alternatives, as is investment in manufacturing processes and facilities to achieve scale. Build out of refueling infrastructure also requires high upfront capital investment. For light duty FCEVs, multi-station refuelling networks providing accessibility and redundancy must be established before OEMs will deploy larger numbers (100s) of vehicles. This is an economic challenge for station developers who are required to make significant capital investments with uncertainty in fueling demand growth over time. For transit agencies looking to deploy FCEBs, the upfront infrastructure costs are high, and makes running early pilot deployments a challenge. While at-scale hydrogen infrastructure has been proven to be very cost effective, getting to scale is a challenge for transit agencies that are cash constrained and risk adverse.

Some applications, such as using hydrogen blended with natural gas as a heating fuel, do not require new or retrofit end-use equipment. However, the economic challenge is that, as described above, the incumbent fuel is very low cost. In addition, utilities will need to make investments in pilot projects and codes and standards development to develop this market.

While the sector must ultimately be self-sustaining, temporary support is needed in the next 5-10 years to attract and de-risk industry investment. This includes through investments in foundational infrastructure and subsidies to encourage end-use adoption and drive to scale up. Attracting investment from international sources will also be important..

TECHNOLOGY & INNOVATION

While some hydrogen and fuel cell technologies are at a level of commercial readiness, sustained support for R&D is needed to further reduce costs, develop solutions in the less mature applications, and discover new breakthrough technologies to benefit the sector. Current short term funding cycles in R&D may limit private sector investment in Canadian innovation. Commitment to support long term R&D for advanced technologies is therefore a current policy gap. Continuing to stay at the forefront of innovation is critical to sustaining Canada's competitive advantages.

Other countries have been rapidly increasing investment in the sector whereas Canada has, in recent years, slowed investment in fundamental research. Canada is also lagging other countries in starting hydrogen pilot projects. As a result, there have been examples of Canadian companies developing research centres and/or moving parts of their operations to other countries where there is more support for technology advancement. It is important for Canada to take action now to prevent loss of critical IP.

Technology development and innovation are needed for core materials, end-use products, as well as in the hydrogen production, storage and distribution value chains. Adjacent and complementary areas such as CCUS will also be critical to Canada's leadership in the sector. Technology development and innovation require local deployments to foster collaboration between industry, academia and international partners. Critical hands on experience can be gained to understand market needs and develop practical and commercially ready solutions. Canada's lack of domestic deployments is currently hampering innovation in the sector.

POLICY & REGULATION

Clean hydrogen projects around the world have primarily been in regions with a combination of supporting policies, regulations, and GHG reduction targets.

There is currently a lack of comprehensive, long-term policy and regulatory frameworks that include hydrogen in Canada. Where policies are in place they, are not consistent across regions resulting in a 'patch-work' approach that slows adoption. Achieving long-term 2050 targets represents a radical transformation of the energy sector and requires clear, coordinated efforts.

Policies and regulations that encourage the use of hydrogen technologies include low carbon fuel regulations, carbon pollution pricing, vehicle emissions regulations, zero emission vehicle mandates, creation of emission-free zones, and renewable gas mandates in natural gas networks. Mechanisms to help de-risk investments for end-users to adapt to regulations are also needed.

A more cohesive national framework with a common vision could provide a clear signal of the importance of hydrogen and avoid a patchwork of policies and regulations across jurisdictions.

HYDROGEN & INFRASTRUCTURE

Domestic supply of low CI hydrogen is limited in many parts of Canada today, and this is preventing both commercial and pilot rollout of end-use applications. For some applications, there is also a need to transport and store hydrogen from the site of production to the end-user. This includes refueling infrastructure for transportation applications. Build out of supply and distribution infrastructure must be timed concurrently with growth in demand, and this can be difficult to coordinate and requires a regionally focused development approach.

Other challenges related to infrastructure include the significant carbon storage requirements for long-term transition of the petroleum and low carbon fuels sectors, as well as the storage of high volumes of hydrogen for integration at existing nuclear sites. Geological storage, such as in depleted wells and salt caverns, will be limited to certain regions, and also require high up-front investment to be validated for hydrogen storage.

Over time, as domestic production and demand grow, there will be a need for dedicated infrastructure such as hydrogen pipelines and liquefaction plants. Ensuring that these crucial assets can be built, in a coordinated and timely manner, will be essential to ensuring low cost, low CI hydrogen can be delivered to both domestic and international markets.

CODES & STANDARDS

The deployment of hydrogen is in the early stages across many jurisdictions and sectors in Canada, and there are some gaps in existing codes & standards that need to be addressed to enable adoption.

Complex local and regional issues related to the certification of new hydrogen deployments may take significant time and effort to resolve. Harmonizing codes and standards across jurisdictions (provincial and international) will ensure that best practices are applied across the domestic and international hydrogen economy to facilitate the growth of trade and export markets.

Applications that have not yet been piloted in Canada and are in the precommercial stage represent important areas of focus. For example, blending of hydrogen into natural gas systems has been demonstrated around the world in numerous power-to-gas projects. Lack of developed and adopted codes and standards in Canada related to this end-use application is currently one of the main rate limiting steps.

Canada is also working with countries around the world to develop and align codes and standards, through efforts like the Canada/US Regulatory Cooperation Council. These efforts also include developing and aligning common methodology to determine the CI of hydrogen production pathways.

AWARENESS

There is currently a lack of awareness about the opportunities for hydrogen and around safety issues, both by the public, as well as within industry and government.

Limited domestic hydrogen deployments have further resulted in a lack of tangible case studies to increase awareness and support long-term planning and buildout. For example, mine safety and reliability must be successfully proven in the pilot stage before technology can be fully adopted.

Increased awareness about hydrogen as a viable decarbonization pathway that is safe and provides economic benefits is critical to establishing a vibrant hydrogen sector. Targeted awareness campaigns in certain industry sectors, including providing easy tools for end-users to evaluate hydrogen options, will be an important step in supporting adoption.

There is currently a lack of awareness regarding how hydrogen fits with other decarbonizing energy vectors in a net-zero future. While deployment of hydrogen and increasing electrification are in fact highly complimentary, perceived competition may limit adoption. This must be addressed with a targeted awareness campaign to show how these applications can work together.

In addition to the need for awareness of the opportunities for hydrogen and around safety issues, there is also the need for targeted awareness of the career opportunities for talented and skilled labour in the hydrogen economy. This includes the transition of mid-career workers and the training of the next generation of workers to the low carbon technology sector.

8. Seizing Canada’s Hydrogen Opportunity

Canada’s hydrogen opportunity is substantial. Canada has all the right ingredients and comparative advantages to develop a robust and thriving domestic hydrogen market. Canada’s resources are suited to producing vast amounts of clean, cost competitive hydrogen that can decarbonize our hard-to-abate end-use sectors from coast to coast. Deployment of hydrogen will lead to economic, environmental, and health benefits for Canadians, and will support Canadian companies at the forefront of the hydrogen and fuel cell sectors. While the immediate priority is on establishing at-scale domestic rollout of hydrogen, the opportunities for export of Canadian hydrogen, as well as products, services, and intellectual property also shows strong potential driven by growth in the worldwide demand for hydrogen.

The *Vision for Hydrogen in Canada in 2050* shows the magnitude of the hydrogen opportunity in Canada. If we embrace hydrogen as a strategic and necessary element of Canada's transition to a more inclusive and equitable clean energy future it can play a pivotal role in helping us achieve net zero by 2050 while maintaining the affordability, reliability and sustainability of Canada's energy supply. Aligning around a common vision is critical to setting us on the right path now.

The *Roadmap to 2050* outlines actions in the next 5 years to lay the foundation for the domestic hydrogen rollout in Canada, grow and diversify the sector in the mid-term, and achieve rapid market expansion in the long-term.

The time to act is now, and the release of this strategy is just the starting point. A set of eight recommendation pillars with specific actions are outlined as guidance for the various committees, working groups, and government and industry players who will together move this forward through the implementation plan.

VISION FOR HYDROGEN IN CANADA IN 2050
Fueling network across Canada
>5 million Fuel Cell Electric Vehicle
H_2
20 Mt H_2 and 30% of Canada's energy system
>50% H_2 in NG pipeline and dedicated H_2 pipelines
New industries enabled by low-cost hydrogen
Up to 190 Mt CO_2e annual GHG reduction
CO_2
H_2
Large distributed domestic supply of low-cost, clean hydrogen: $1.50–3.50/kg
Canadian H_2 Sector revenue > $50B
One of top 3 global clean hydrogen producers
Economic growth with > 350,000 sector jobs

ROADMAP TO 2050

Near-Term: Laying the Foundation

The focus of the next 5 years will be on laying the foundation for the hydrogen economy in Canada. This includes developing new hydrogen supply and distribution infrastructure to support early deployment HUBs in mature applications while supporting Canadian demonstrations in emerging applications. Early actions are fundamental to driving investment in the sector, as is the introduction of policies, such as carbon pricing and regulatory measures needed to move Canada forward on a path to achieve net zero targets. Regulations such as the Clean Fuel Standard will be fundamental to driving near-term investment in the sector, in addition to introducing new policy and regulatory measures that will advance Canada to achieve net-zero emissions by 2050. To achieve medium- and long-term goals, innovation investment must be made early. Early stage, 'breakthrough' R&D can take 5-10 years to realize and may require additional work to fully mature. Even later stage support for process efficiency or cost reduction can take several years, followed more time for piloting and demonstration.

Canada's petroleum sector is a major driver of investment, with $52 billion in 2019. Despite the oil price downturn and uncertainty over the COVID-19 recovery, an opportunity exists for government to partner with industry to drive commercial hydrogen projects as part of the sector's net-zero agenda. Similarly, the chemical industry can move to adopt clean hydrogen as a feedstock with government involvement.

Emerging hydrogen use in the near-term will be dominated by mature market applications at or near commercial market readiness including oil and gas upgrading, ethanol plants and landfill gas/biogas-to-RNG upgraders, forklifts, light-duty FCEVs, and FCEBs for transit operation. Pre-commercial applications such as heavy-duty trucks, seaport goods movement equipment, power generation, heat for the built environment, and industrial feedstock applications will be introduced as pilot projects in regional HUBs.

These regional HUBS will be strongly influenced by:

- Regulatory approvals for blending hydrogen and natural gas to decarbonize the utility distribution system.
- Availability of technical evidence from pilots to inform the safe integration of fuel cells into domestic regulatory regimes, i.e. Railway Safety Act, Motor Vehicle Safety Act.
- The best form of renewable gas in a regional context, i.e. the best use for hydrogen, RNG and biogas.
- Zero-Emission Vehicle mandates for passenger vehicles such as the existing legislation in Quebec and British Columbia.
- Variances in CFS compliance plans that will drive low carbon hydrogen generation for industrial applications including the upgrading of transportation fuel products.
- Existing hydrogen generation, distribution and dispensing infrastructure that can be leveraged e.g. liquefaction capacity in Quebec, or steam methane reforming with carbon sequestration in Alberta.

Mid-Term: Growth and Diversification

Activities to stimulate the sector in the next 5 years will be followed by growth and diversification of the sector in the 2025 – 2030 timeframe. Early deployment HUBs will grow and new ones will be initiated, connected by corridor infrastructure. In order to reach the opportunities outlined in the 2050 Transformative scenario, Canada should aim to be 10-20% of the way there by 2030 in terms of deployment volumes and GHG abatement.

As the technology matures and the full suite of end-use applications is at or near commercial technology readiness levels, hydrogen use in the mid-term will be focused on applications that provide the best value proposition relative to other zero-emission technologies. For example, fuel cell electric vehicles and transit buses will enter the rapid expansion phase as the market for fuel cell and battery technology becomes more defined. Fuel cells will gain traction where charging times, energy requirements, range, grade ability, and operation in extreme climates make battery technology technically challenging for specific market segments. Class 8 heavy-duty trucking in corridors that require heavy payloads and drayage equipment in regions with regulated air sheds will be commercially deploy.

New, larger scale hydrogen production in the mid-term will allow hydrogen/natural gas blending for industry, the built environment and as a feedstock for chemical production and hydrocarbon upgrading to be commercialized in regional HUBs. Clean large-scale hydrogen production in the upstream segment of the oil and gas sector will provide low cost hydrogen at volumes that can benefit other sectors.

Deployment in pre-commercial applications like Class 5-7 delivery trucks, operating in urban zero-emission zones, passenger and freight rail where gantry infrastructure needed to electrify the line is prohibitively expensive, mining vehicles and smaller domestics marine vessels continues to grow. Similarly advancement and growth in liquid synthetic fuel and methanol production, can be expected.

A regulatory framework and market ready technologies are expected to enable deployment of hydrogen in mining operations in a variety of good movement and stationary power applications. As increasing renewables are introduced into electricity grids, pilots to explore hydrogen as a utility scale energy storage medium will be required.

Long-Term: Rapid Market Expansion

In the 2030-2050 timeframe, Canada will start to realize the full benefits of a hydrogen economy as the scale of deployments increase and number of new commercial applications grows, supported by Canada's foundational backbone supply and distribution infrastructure.

In the long-term, it is anticipated that with advances in battery and charging technology there will be a more defined division between battery and fuel cell utilization in Canada for transportation purposes. This will result in the higher power demand applications (utility biased) predisposed toward hydrogen energy storage and the lower power demand applications (efficiency biased) using batteries for energy storage. New transportation applications will move into the commercial and rapid expansion phases during this period.

As the percent of hydrogen in NG systems increases, dedicated hydrogen pipelines will become an attractive alternative.

As low CI hydrogen is more widely available throughout Canada, existing heavy emitting industries will be able to adapt their operations, including, ammonia and nitrogen fertilizers, and low carbon steel.

	NEAR-TERM (2020-2025) *Laying the Foundation*	MID-TERM (2025-2030) *Growth & Diversification*	LONG-TERM (2030-2050) *Rapid Market Expansion*
HYDROGEN PRODUCTION — *Carbon Intensity*	<36.4 gCO_2e/MJ		***Decreasing*** *over time*
Renewable Threshold in Government Supported Projects	>33%		***Increasing*** *over time*
Cost of Delivered Hydrogen	$5.0 – 12.0/kg		$1.5 – 3.5/kg
DISTRIBUTION+ STORAGE — *Gaseous Hydrogen*	250 bar	450+ bar	450+ bar
Liquid Hydrogen	East Coast	Canada Wide	Canada Wide
Pipeline	H_2/NG Blended	Blended + Dedicated H_2	Blended + Dedicated H_2
Geological Storage			Salt Cavern
END-USE — *Commercial* / *Pilot*			New industry spinoffs
REGIONAL HUB	Regional high profile hub development incorporating full value chain at scale	Hub expansion, corridor connections, and new hub initiations	Full Pan–Canadian rollout and inter-provincial trade + and cooperation
RD&D	Sustained RD&D in advanced materials, hydrogen production and storage technologies, CCUS, and end-use applications		
ACHIEVEMENTS — *Hydrogen Production*	3 Mt/year (high CI)	4 Mt/year (low CI)	20 Mt/year (low CI)
% of Overall Energy Delivered by Hydrogen	1.6%	6.2%	30%
GHG Reduction		Up to 45 Mt	Up to 190 Mt

TIME TO ACT

The time for Canada to act is now. Governments around the world are developing plans for green and inclusive energy recoveries while releasing and executing hydrogen strategies that are building global momentum. In 2019 Canada seized this momentum by developing and launching a new Hydrogen Initiative under the Clean Energy Ministerial, designed to be the cornerstone for global hydrogen deployment. Now, one year later, Canada is poised to again leverage this momentum to grow the domestic opportunity for hydrogen production and end-use, while also benefitting from growth in global demand.

Although the COVID-19 pandemic has shaken all sectors of the economy, the recovery also presents a unique opportunity to build back better to advance a greener and more equitable energy future. The International Energy Agency has recommended that governments put clean energy solutions such as hydrogen at the heart of stimulus plans. Green infrastructure investments are key to achieving the post-pandemic economic recovery, clean growth, and climate change commitments of the Canadian Federal Government. Recovery from the economic impacts of COVID-19 will take many years. Stimulus funding may represent a unique and critical investment opportunity for the foundational infrastructure and skills need to support the sector. If the opportunity is wasted, Canada risks losing its competitive head start as austerity measures kick in during the anticipated recovery period.

Recommendations

Recommendations have been developed in consultation with stakeholders and represent actions needed to lay the foundation for maximizing the benefits of hydrogen in Canada's future energy system mix. These recommendations will inform development of concrete action plans in the implementation phase immediately following the release of this strategy. The recommendations in this section represent sector-wide themes. Recommendations have been proposed in eight pillar areas:

- ***Pillar 1: Strategic Partnerships*** *- Strategically use existing and new partnerships to collaborate and map out the future of hydrogen in Canada.*

- ***Pillar 2: De-Risking of Investments*** *- Establish funding programs, long-term policies, and business models to encourage industry and governments to invest in growing the hydrogen economy.*

- ***Pillar 3: Innovation*** *- Take action to support further R&D, develop research priorities, and foster collaboration between stakeholders to ensure Canada maintains its competitive edge and global leadership in hydrogen and fuel cell technologies.*

- ***Pillar 4: Codes and Standards*** *- Modernize existing and develop new codes and standards to keep pace with this rapidly changing industry and remove barriers to deployment, domestically and internationally.*

- ***Pillar 5: Enabling Policies and Regulation** - Ensure hydrogen is integrated into clean energy roadmaps and strategies at all levels of government and incentivise its application.*

- ***Pillar 6: Awareness** - Lead at the national level to ensure individuals, communities, and the private sector are aware of hydrogen's safety, uses, and benefits during a time of rapidly developing technologies.*

- ***Pillar 7: Regional Blueprints** - Implement a collaborative, multi-level, collaborative government effort to facilitate the development of regional hydrogen blueprints to identify specific opportunities and plans for hydrogen production and end use.*

- ***Pillar 8: International Markets** - Work with our international partners to ensure the global push for clean fuels includes hydrogen so Canadian industries thrive at home and abroad.*

A series of four concrete actions and rationale are provided for each of the eight pillars in the following section.

Pillar 1: Strategic Partnerships

1. *Collaborate across multiple levels of government and with Indigenous groups through Intergovernmental Working Groups to establish priority areas for deployment and to share knowledge, best practices, and lessons learned through early deployments.*
2. *Expand public/private partnerships leveraging Canada's innovative clean technology companies and world-leading hydrogen and fuel cell expertise to accelerate deployment projects across the value-chain.*
3. *Foster cross-sector collaborations within regional deployment HUBs to show the economic and operational benefits of multiple applications operating as part of an integrated ecosystem.*
4. *Leverage international collaborations and pursue synergistic international initiatives to attract direct foreign investment and to accelerate opportunities for Canada in global markets.*

Rationale

Hydrogen is an energy vector that crosses geographical boundaries, ties energy systems such as the electricity and natural gas grids together, and whose benefits are best demonstrated in integrated deployments that span multiple end-use applications. Stakeholders identified that better information sharing and collaboration across regions and sectors is needed to develop Canada's hydrogen economy. Strategic partnerships are needed across levels of government and regions, between the public and private sector, with Indigenous groups, across industry sectors and academia, and with international partners.

Coordination across all levels of government will be essential to align policies and programs and identify areas for collaboration. Coordination of this type is best carried out through an intergovernmental working group. Similarly, to ensure the unique perspectives, needs, and priorities of Indigenous groups are fully represented, a dedicated Indigenous working group could be considered.

Government and industry must work closely together, with each playing important but distinct roles and each bringing resources, expertise, and perspectives to the table. Strategic partnerships between governments and industry are also essential in successfully growing domestic hydrogen deployment. Early adoption is likely to occur in areas which bring together governments, fuel producers, end-users, and other key players, in a HUB concept, which ensures supply and demand grow together.

High profile domestic deployment HUBs or 'lighthouse projects' will be important to show the business case for hydrogen at scale. These early domestic deployment HUBs should be encouraged to include pan-Canadian participation where practical, and to include targeted outreach activities and information sharing. Initiation of these projects has already started with many 'shovel-ready' projects proposed as green stimulus recovery initiatives.

Canada cannot do this alone. While Canada demonstrated early leadership in both hydrogen and fuel cells, activity and investment in hydrogen has been accelerating around the world with other nations developing comprehensive plans for their own domestic and export markets. Canada can learn from international partners as well as help grow international trade opportunities by sharing learnings from domestic activities. International partnerships will range from government collaborations on policy approaches, to research collaborations in shared areas of interest, to participation in international codes and standards development, to the development of trade opportunities. International partnerships can be facilitated through the Hydrogen Initiative with International Energy Agency as Operating Agent, as well as Canadian Trade and Investment support channels.

Pillar 2: De-Risking Investments

5 *Implement long-term policies that create hydrogen demand certainty and de-risk the private sector investments needed to establish supply and distribution infrastructure.*

6 *Establish multi-year programming as well as a clear and long-term regulatory environment to support early production and end-use projects, including support to assess the feasibility of projects.*

7 *Develop regional deployment HUBs to demonstrate, validate, and implement business cases across the full value chain, from production and distribution to end-use.*

8 *Facilitate co-funding opportunities, leveraging multiple levels of government and the private sector.*

Rationale

It is estimated that $5B - $7B of combined public and private investment will be needed in the five years to lay the foundation of a strong national hydrogen economy that will maximize emissions reductions and provide long-term economic growth for the sector. Attracting this magnitude of investment from domestic and international sources requires actions across several fronts to de-risk investments.

Governments at all levels, as well as private sector stakeholders will all have a role to play in de-risking these investments.

Long-term policies such as the federal Clean Fuel Standard (CFS) and carbon pricing are important steps toward creating an environment of higher certainty for investors. The CFS could recognize hydrogen as a pathway to reduce the CI and resulting credit burdens on conventional fuels. The CFS could also provide credit generation and financing opportunities for projects that generate clean hydrogen. While the CFS does not preclude these pathways, there is an opportunity to be more explicit in how hydrogen can be considered as a compliance mechanism.

Long-term government climate policies like carbon pricing that reflect the externalities of climate change, air pollution, related health issues, and energy security can also provide a signal to stimulate investments. Governments can also provide market certainty by leading through example with strong procurement policies. This has been successful in Quebec where the provincial government's procurement of FCEVs in Quebec City spurred the buildout of fuelling infrastructure by industry.

Tax deductions to corporate, institutional, and individual investors made in the cleantech space is another mechanism to de-risk and attract investments, as is expanding the 100% accelerated capital cost allowance to all cleantech investments including those in hydrogen.

The market for low CI hydrogen in Canada is in the very early stages. While the sector must ultimately be self-sustaining, temporary fiscal support to de-risk investments across the value chain is needed in the next 5-10 years, while the market matures.

Canada can learn from other regions like California, where established multi-year funding commitments have been effective. For example, the California Energy Commission provides funding for hydrogen infrastructure build-out in conjunction with a Low Carbon Fuels Standard program that offers capacity payments to provide revenue certainty while demand for hydrogen grows.

Funding models should evolve over time. In the early stages resources could support projects that span the entire value-chain, both through regional deployment HUBs and large-scale projects. Considerable up-front work is required to develop complex projects of this nature, from a technical and economic perspective, before domestic projects can move into the implementation phase. Support for feasibility studies should be considered as an essential first step in project development.

Pillar 3: Innovation

9. *Develop strategic fundamental research priorities where Canada can sustainably excel and provide economic value; set technology performance and cost goals.*

10. *Establish dedicated funding for sustained RD&D to ensure Canada retains its leadership position in hydrogen and fuel cell technologies.*

11. *Leverage expertise in academia, government labs, and private sector labs to create regional research hubs and to encourage mission-oriented approaches to research, development, and pilot deployments.*

12. *Foster collaboration between Federal labs, industry, and academia as well as international partners, by supporting consortium-based projects for fundamental research and by coordinating reviews and information sharing.*

Rationale

Canada was an early leader in the hydrogen and fuel cell sector and is recognized worldwide as a region for technical expertise, intellectual property, and leading products and services. While some hydrogen and fuel cell technologies are at a level of commercial readiness, support for RD&D is needed to further reduce costs, develop solutions in the less mature applications, and discover new breakthrough technologies. Continuing to stay at the forefront of innovation is critical for sustaining Canada's competitive advantage. Other countries have been rapidly increasing investment in the sector, and Canada's leadership role is in jeopardy. As a result, there have been examples of Canadian companies developing research centres and/or moving parts of their operations to other countries where there is more support for technology advancement. It is important for Canada to act now to prevent loss of critical IP and cleantech jobs.

Canada already has a leading fuel cell sector with expertise ranging from fundamental materials to complete systems and vehicles. Building on these strengths by identifying priority areas, in consultation with industry and academic stakeholders, where Canadian researchers can excel will be essential to maintain leadership. Canada also has complementary technologies such as CCUS and hydrogen storage which are unique to Canada's geology. Canada can also leverage existing expertise in engineering and systems integration using deployment HUBs to strengthen local skills and knowledge while promoting a more diverse and inclusive workforce.

A mission-oriented approach would set a clear direction and align the efforts of participants across the energy ecosystem, while using the full range of government instruments to generate investments and innovation across the economy.

Funding for advanced research and development must come from both the public and private sector. Stakeholders identified gaps and limitations such as how much Canadian government funding can be used as "match funding" on international collaboration projects.

Collaboration across federal labs, industry, and academia is ultimately needed to both drive innovation and to develop the next generation talent pool in the sector. Canada has seen talent being recruited by other regions and efforts are needed to fight the "brain drain". Without top talent, innovation will slow. To attract new young talent to the sector, students must be able to see a linkage to industry opportunities and this can be facilitated through industry/academia collaborations, through industry sponsored student competitions, as well through internships and co-op placements. A Canadian mechanism to establish targets and priority areas modelled after the U.S. DOE's Multi-Year Research, Development, and Demonstration Plan could be used to provide guideposts to drive towards common goals. Reviews to track progress and share information could be coordinated in an annual merit review type format.

Canadian expertise in hydrogen technology development, both within academia, and in the private sector, is recognized around the world. Sustained resources to support innovation will also enable Canadian researchers to build and strengthen collaboration internationally. International collaborations will ultimately accelerate hydrogen deployment both at home and abroad.

Pillar 4: Codes and Standards

13 *Update, harmonize and recognize codes and standards (including the Canadian Hydrogen Installation Code) to enable deployments and to facilitate new technology and infrastructure adoption in early markets.*

14 *Establish a codes and standards working group, which includes inter-provincial Authorities Having Jurisdiction representatives, to share lessons learned and identify gaps in codes and standards.*

15 *Develop standards that are performance based versus prescriptive, and ensure hydrogen is not excluded from broader codes, standards, and regulations due to restrictive language.*

16 *Facilitate Canadian leadership and participation on international standard and certification efforts (e.g. development of global carbon intensity metrics, blending levels for hydrogen in natural gas systems), simplifying international trade.*

Rationale

Deployment of hydrogen technologies, including fuels cells, and refueling infrastructure, is in the early stages in many parts of Canada. It is important that codes & standards are in place that support deployment, and keep pace with new technology and innovation. Wherever possible, these standards should be performance-based rather than prescriptive to ensure that innovation is not restricted in this emerging sector.

Canada has a mature and effective standardization framework led by the Standards Council of Canada, and national standards development organizations (SDOs) like the Bureau de Normalization du Québec (BNQ) and CSA Group. However, these organizations are dependent on resources, and subject area expertise from industry and governments, to facilitate their work.

One of the foundational pieces in Canada is the Canadian Hydrogen Installation Code (CHIC) which sets the installation requirements for equipment that produces, uses or dispenses hydrogen. Although the CHIC was first of kind globally when it was developed in 2010, it has not been kept up to date, to include the most recent advancements and understanding. This has forced domestic hydrogen deployment activities to reference more recent codes from other jurisdictions internationally. This difference between established industry practices and the national code has led to inconsistencies in how Authorities Having Jurisdiction (AHJ's) recognize certify hydrogen projects across the country. While an updated version of CHIC is currently being finalized, going forward more timely updates to the code and recognition/implementation by the Provinces will be essential to facilitating the installation and operation of new hydrogen equipment in Canada.

As one of the key applications for hydrogen, the decarbonization of natural gas requires regulatory changes within the provinces to allow the use of hydrogen in natural gas distribution and transmission networks. These regulatory changes (e.g. expanding the definition of renewable gas) will be underpinned by detailed technical codes and standards, for example for material compatibility, design, testing, for key system components.

The revision, development, and adoption of key codes and standards is an essential component to enable Canada to seize the hydrogen opportunity. This work will require a coordinated effort between industry, the SDO's, national testing laboratories, and the Provincial and Federal governments, as well as Authorities Having Jurisdiction. As part of the implementation plan, it is recommended that a dedicated codes and standards working group be formed that includes industry across the value chain, SDO's, national testing laboratories, academia and the Provincial and Federal governments. Working group members should work through a Standardization Collaborative to clearly identify gaps in Canada's hydrogen codes and standards, and to develop a prioritized action plan to close gaps. As broader codes and standards are developed (e.g. definition of RNG in natural gas networks), it will be important to establish performance based standards that do not exclude hydrogen.

One of the most effective ways to accelerate domestic adoption of hydrogen is to focus on harmonizing Canadian standards with international requirements for safety, performance, and reliability, especially in jurisdictions where Canadian suppliers are working extensively. Harmonized standards allow Canadian companies to support multiple markets with the same equipment design, avoiding costly customization, unnecessary certification testing, and potential barriers to market entry.

Pillar 5: Enabling Policies and Regulations

17 *Ensure that governments at all levels consider hydrogen's essential role in Canada's energy future as they develop new policies, programs, and regulations.*

18 *Encourage governments to modernize and update existing policies, programs, and regulations to facilitate growth of domestic hydrogen production and end-use.*

19 *Ensure hydrogen is part of integrated clean energy roadmaps at national and provincial/ territorial levels.*

20 *Establish technology-neutral, performance-based standards to define a hydrogen carbon-intensity threshold. Establish tiered, time-based requirement for renewable hydrogen content in government supported projects.*

Rationale

Canada's net zero future will be powered by two things, electricity and low carbon fuels. Hydrogen shows the potential to make up to 30% of Canada's delivered energy in a net zero future, closing the gap in the toughest and most hard-to-abate energy intensive sectors. The critical role that hydrogen can play in our net-zero future should be considered as governments develop their own long-term climate policies, programs, and supporting regulation.

Similarly, there is an opportunity to lever existing policies, programs, and regulations to align with and support a path to being net-zero, which includes hydrogen.

The regions that have been most successful in stimulating the adoption of hydrogen have developed a combination of regulations and programs that work hand-in-hand, and stakeholders have indicated that this is what is needed as a cohesive pan-Canadian approach. Regulatory tools can either require adoption of alternative technologies or inhibit the use of conventional technologies. A zero-emission vehicle mandate and creation of emission-free zones or imposing high road taxes on internal combustion engine vehicles are all examples of policies which have been implemented in jurisdictions around the world. In Canada, both BC and Quebec have implemented ZEV mandates, and these are the provinces where FCEVs are being deployed and investments in infrastructure are being made.

Emissions standards are another mechanism to drive adoption of low- and zero- emission vehicles that are considered less prescriptive than ZEV mandates.

Canada has some existing policies, program, and regulations in place to drive towards decarbonization and sustainability goals. An important early activity will be to modernize and update existing policies, program, and regulations to ensure they are inclusive to hydrogen.

To meet long-term decarbonization goals, Canada will need to support all low carbon pathways, including electrification, low carbon fuels, and hydrogen. An overall integrated clean energy roadmap at the national level, and sub-national level could help identify the best role for each low carbon pathway and will identify how each pathway can be synergistic. For example, hydrogen is sometimes seen as competing with direct electrification. However, using hydrogen as a utility-scale energy storage medium can in fact enable higher penetration of variable renewables on the grid and aid in increased electrification. Roadmaps need to try to overshoot in all pathways to address the inherent uncertainty involved in the radical transformation that will need to occur in Canada's energy mix to meet carbon neutrality by 2050.

Ultimately both the CI and sustainability of feedstocks used to make hydrogen are important. In the near term, the focus needs to be on setting clear CI threshold for hydrogen. New policy should be considered to drive increasing non-emitting content in hydrogen supply to make sure that Canada develops energy sources that can be replenished in a reasonable timescale.

Pillar 6: Awareness

21 *Support community engagement and outreach where deployment HUBs are established.*

22 *Establish awareness and outreach campaigns to educate government, industry, the public, and other important influencers about hydrogen safety, uses, and benefits.*

23 *Develop a suite of tools and resources for early hydrogen markets to help end-users quantitatively evaluate hydrogen as an option for their operations. Host the tools and resources through a central, government-run website.*

24 *Support collaborations between industry and academia to develop hydrogen-specific curriculums to build awareness, interest, skills development, and training to develop the next generation talent pool and prepare the labour force for new opportunities.*

Rationale

Stakeholder engagement consistently highlighted a lack of awareness within the public, as well as within industry and government about hydrogen opportunities and safety issues. Increased awareness about hydrogen as a viable decarbonization pathway that is safe and provides economic benefits is critical to establishing a vibrant and inclusive hydrogen sector.

One of the best opportunities to drive awareness is to deploy hydrogen domestically in projects that are high profile and include awareness and outreach campaigns. Projects that provide an opportunity for the general public to interact with hydrogen as a fuel – for example fuel cell buses, hydrail or fleet vehicles such as car sharing services – provide a greater opportunity for outreach. Funded projects should require an element of outreach through program design.

A targeted hydrogen outreach campaign should be coordinated across the country and offered regionally to a range of stakeholders via different channels under a common brand and banner. This can include technical sessions and general campaigns to raise consumer awareness about hydrogen.

Governments, industry, academia, Indigenous organizations, and non-Government Organizations all can play an important role in supporting the development of tools that enable end-users to evaluate hydrogen as an alternative fuel in their operations, ensuring these materials meet their needs, and that of the general public. Examples include an online total cost of ownership tool for transit agencies, to compare lifecycle costs of a fuel cell bus to alternatives.

Sectors that are heavy users of diesel, such as the mining sector where there are multiple potential uses of hydrogen and each operation is unique, could benefit from a publicly available online tool that provides directional cost and business case assessment. There is a need for other basic tools, such as conversion factor tools and case study information, that could be shared in a centralized portal such as regularly maintained website.

As the hydrogen economy grows in Canada, the availability of a diverse and skilled workforce is essential. To attract the next generation of talent to the industry and/or encourage retraining from adjacent sectors with complementary skillsets, there needs to be a clear linkage to the growth in well-paid employment opportunities. This includes reflecting these emerging opportunities in labour market information available to Canadians to support their education and career choices. Industry/academia collaborations can support training, provide important new IP to benefit industry, and show students that there is a growing industry open to participation from all corners of society. Together, we must work to increase workforce participation from marginalized and underrepresented populations—including but not limited to women, youth, people with disabilities, and Indigenous peoples—to build a more inclusive and equitable low carbon energy sector. Early education outreach in elementary and high schools that includes hydrogen as part of Canada's overall clean energy future is also important.

Pillar 7: Regional Blueprints

25 *Facilitate the development of regional hydrogen blueprints, as a multi-level government collaborative effort, to identify specific opportunities and plans for hydrogen production and end-use. Ensure federal participation to capture synergies with the Hydrogen Strategy for Canada.*

26 *Identify opportunities for the establishment of regional HUBs, comprised of projects along the entire value-chain*

27 *Include utilities, major industry from adjacent sectors, and cleantech companies in development and implementation of blueprints.*

28 *Identify areas for alignment and replication with other provinces/regions to facilitate and accelerate overall adoption.*

Rationale

Hydrogen represents a truly pan-Canadian opportunity: from Western Canada with its abundant natural gas resources and carbon capture expertise, to Eastern Canada with its vast hydroelectricity resources. Hydrogen can be produced by a wide range of mature and emerging pathways. Local energy and feedstock resources as well as geological considerations will dictate the ultimate pathway(s) for producing hydrogen in each region. Most Canadian provinces can become producers of hydrogen for local use or export. Similarly, while there are opportunities to deploy hydrogen in a variety of end-uses across the country, these opportunities, particularly in the early deployment stages, depend on local industry interest, economic factors, as well as local policies and regulation.

For hydrogen to gain traction in Canada, projects which span the entire value chain from production, to distribution and storage, to end use will play a key role. This can be facilitated by the development of regional HUBs which can grow supply and demand concurrently. Governments at all levels will play important roles in supporting local deployment.

To seize these regionally diverse opportunities, the Hydrogen Strategy is complemented by a series of regional blueprints to guide the way. BC, Alberta, Quebec, and Atlantic Canada have already initiated activities to identify the opportunities and benefits hydrogen can offer their regions as a first step to releasing blueprints.

There is an opportunity to leverage local strengths, including research centres, major industries, and cleantech leaders, to contribute to the development and implementation of regional blueprints.

It is recommended that a diverse set of stakeholders be consulted in the development of these blueprints, including provincial and municipal governments, Indigenous groups, utilities and independent power producers, large established industrial players in adjacent sectors, end users, potential hosts for regional deployments including ports and industrial network clusters, as well as the cleantech sector and solution providers.

While local government and industry will take the lead in establishing these regional blueprints, there are benefits to having pan-Canadian coordination. This will help to avoid duplication and to identify areas for collaboration. Support will also be required to overcome common challenges across regions or for addressing issues that are critical to Canada developing and maintaining strategic advantages in the sector. There is a role for all levels of government to identify and enable the development of the pan-Canadian infrastructure assets which are needed to connect regional HUBs and support widespread adoption.

Pillar 8: International Market

29 *Develop a strong Canadian brand, positioning Canada to be a global supplier of choice for low carbon hydrogen, and the technologies to use it.*

30 *Invest in infrastructure to connect Canadian supply to international markets, such as liquefaction assets for energy dense hydrogen transport and hydrogen pipelines from western Canada to the US.*

31 *Establish domestic flagship projects that highlight Canada's expertise, attract investments into the domestic market, and that can be replicated internationally.*

32 *Leverage existing international fora (e.g. Clean Energy Ministerial Hydrogen Initiative, G20, IEA) to showcase Canada's leadership, and advance new market opportunities.*

Rationale

Momentum is growing globally, with countries around the world developing their own hydrogen strategies backed by significant investments, resulting in growing demand for hydrogen and the technologies to use it. Canada has advantages that position us to become a domestic producer and user of hydrogen as well as energy exporter, supplying clean hydrogen and hydrogen technologies into growing international markets. Important actions are required in the near term to secure the position of Canada's supply chain in global markets to fortify clean production, manufacturing, expert hydrogen sector services, and jobs in Canada.

Branding and promoting Canada's low carbon fuels, including hydrogen, will be important to gain market acceptance. This includes ensuring Canadian hydrogen production pathways are backed by certified lifecycle analysis. In considering the export of hydrogen, it is important to participate in international standards development activities underway to set thresholds and certify compliance with fuel standards.

For Canada to supply hydrogen to the European market, establishing aligned thresholds and ensuring third party certification systems are in place will be essential. Canadian natural gas pipelines cross borders into the US, and a top priority in anticipation of hydrogen blending into the pipeline is bilateral alignment on standards and certification with the US.

From the Canadian Pacific Railway to the St. Lawrence Seaway to the Trans-Canada Highway, the big projects that helped to build our country have always needed the vision and leadership of government. Now is the time to imagine a clean energy future enabled by new infrastructure assets such as hydrogen pipelines and hydrogen production and liquefaction plants that produce and move hydrogen within and across Canada and connect us to export markets. Development of infrastructure takes time, and Canada must identify enabling infrastructure for the sector.

Canadian technology is already powering a significant portion of hydrogen and fuel cell deployments globally. Over the next five years as domestic regional deployment HUBs grow and international markets develop, domestic deployments will provide reference projects that can highlight Canada's leadership. The experiences gained can be used to replicate similar projects in other countries using Canadian products, services, or intellectual property. A common theme heard from cleantech stakeholders is that international partners ask to see local reference projects to validate technology readiness and the business case.

Canada also leads and participates in several international partnerships, including the Clean Energy Ministerial, Mission Innovation, the IEA, and the International Partnership for Hydrogen and Fuel Cells in the Economy. These existing channels can be leveraged to showcase Canada's leadership in the hydrogen sector and advance new market opportunities.

Roles and Responsibilities

Development of a strong Canadian hydrogen economy requires a coordinated and collaborative effort between industry, governments, Indigenous organizations, utilities, academia, and non-government organizations driven by a common vision and strategy. The stakeholders in Table 3 were identified with roles and responsibilities in advancing he recommendations of this Strategy. For many of these activities, numerous stakeholders could play a role; however, the table aims to provide a general overview of the roles that key stakeholders could play during the early stages of hydrogen market development.

Implementation Plan

The release of this strategy is meant to serve as a catalyst for the next stages in Canada's hydrogen story. Following the release of this *Hydrogen Strategy for Canada*, there will be ongoing engagements with public, private, academia, and Indigenous partners. These engagements will be managed through a Strategic Steering Committee chaired by NRCan with committee members sourced from various sub-working groups (Figure 52). The Strategic Steering Committee and Working Groups will be tasked with building the momentum around the strategy, initiating and tracking activities related to the recommendations, following progress, and identifying new priority areas as the market evolves.

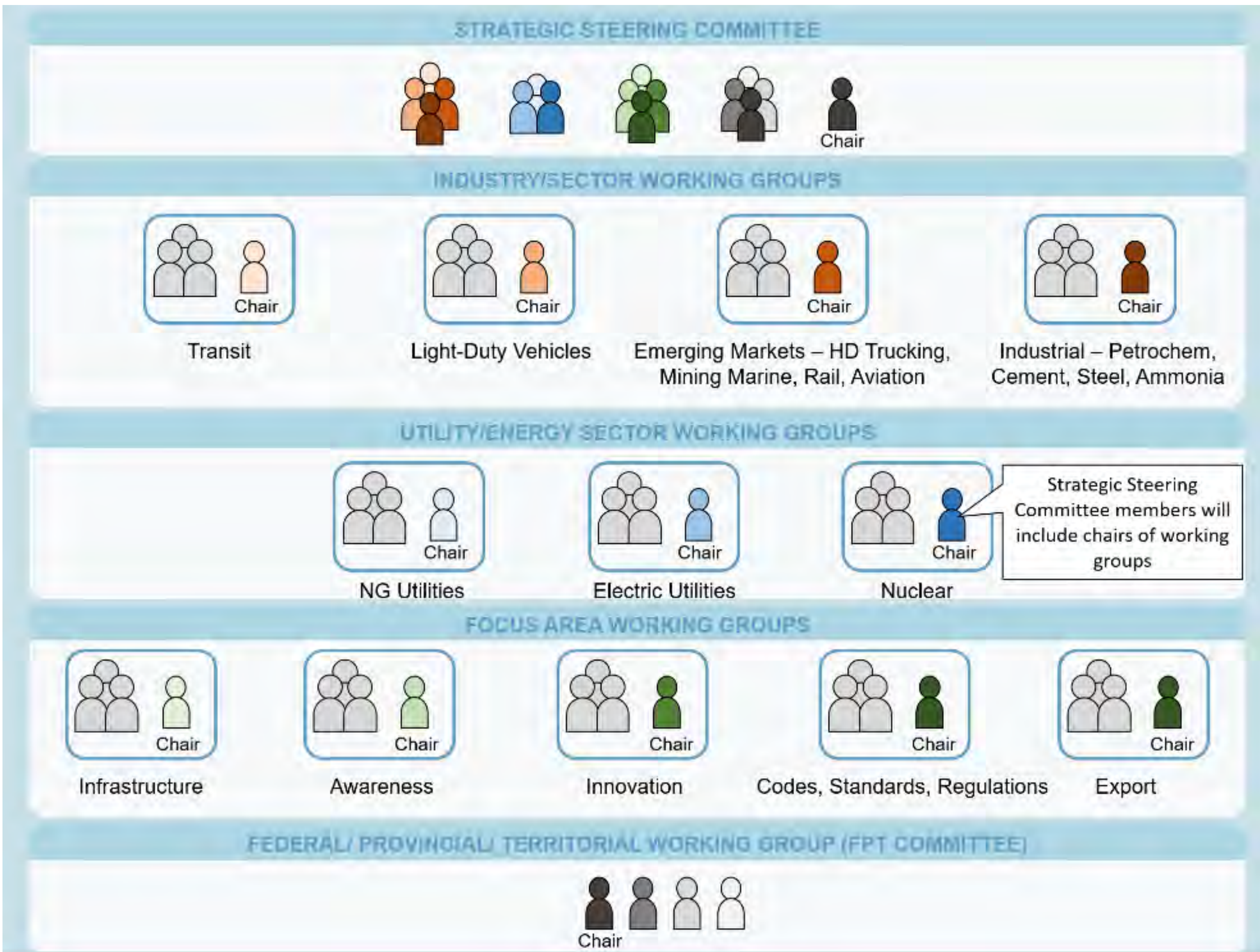

Figure 52 – Implementation Working Groups

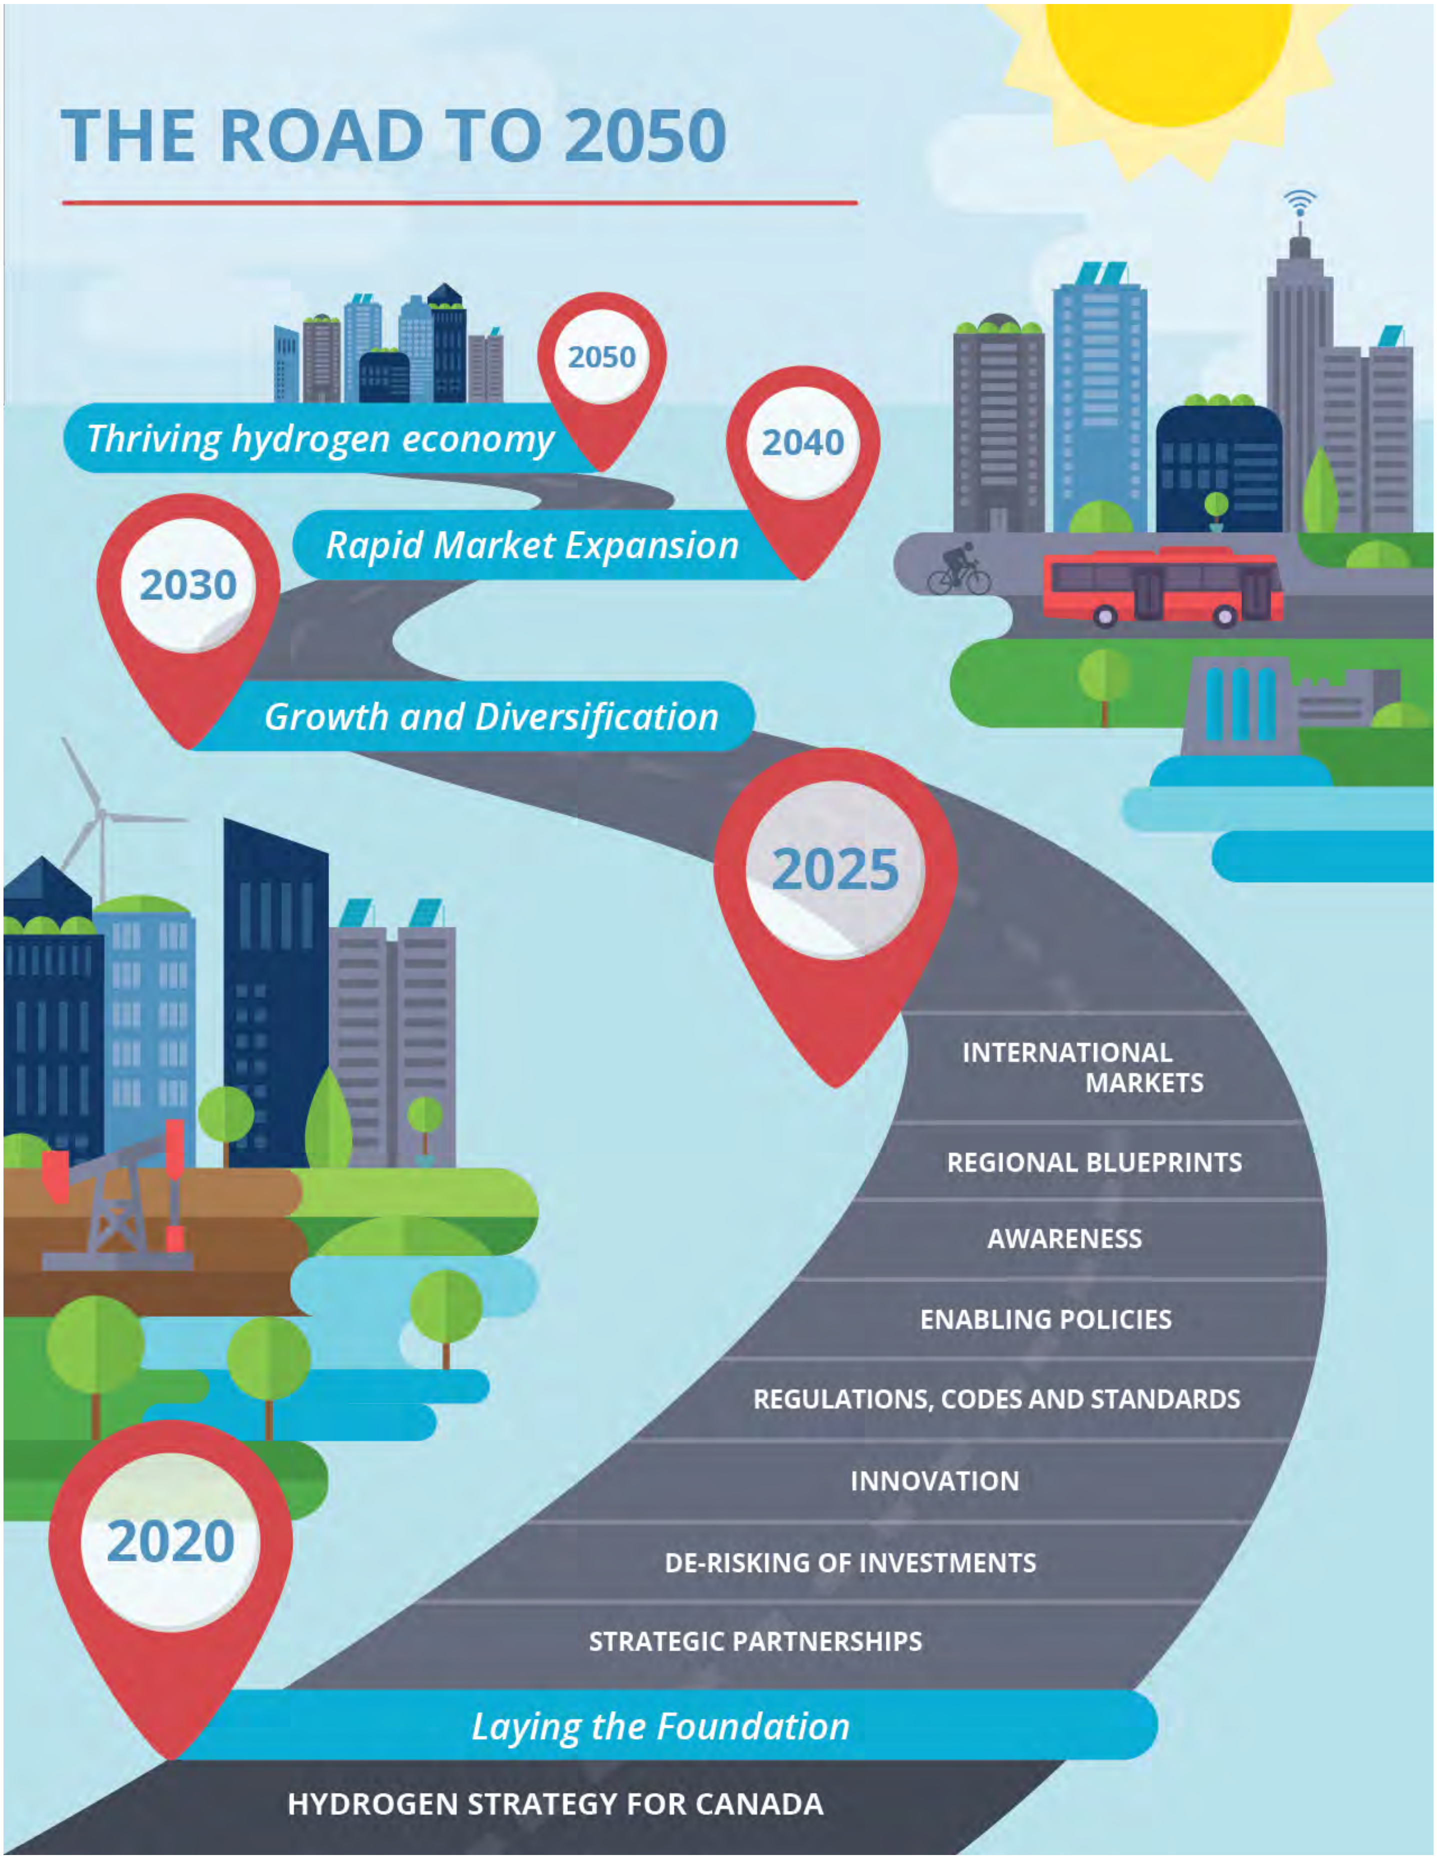

Figure 53 – Roadmap to 2050

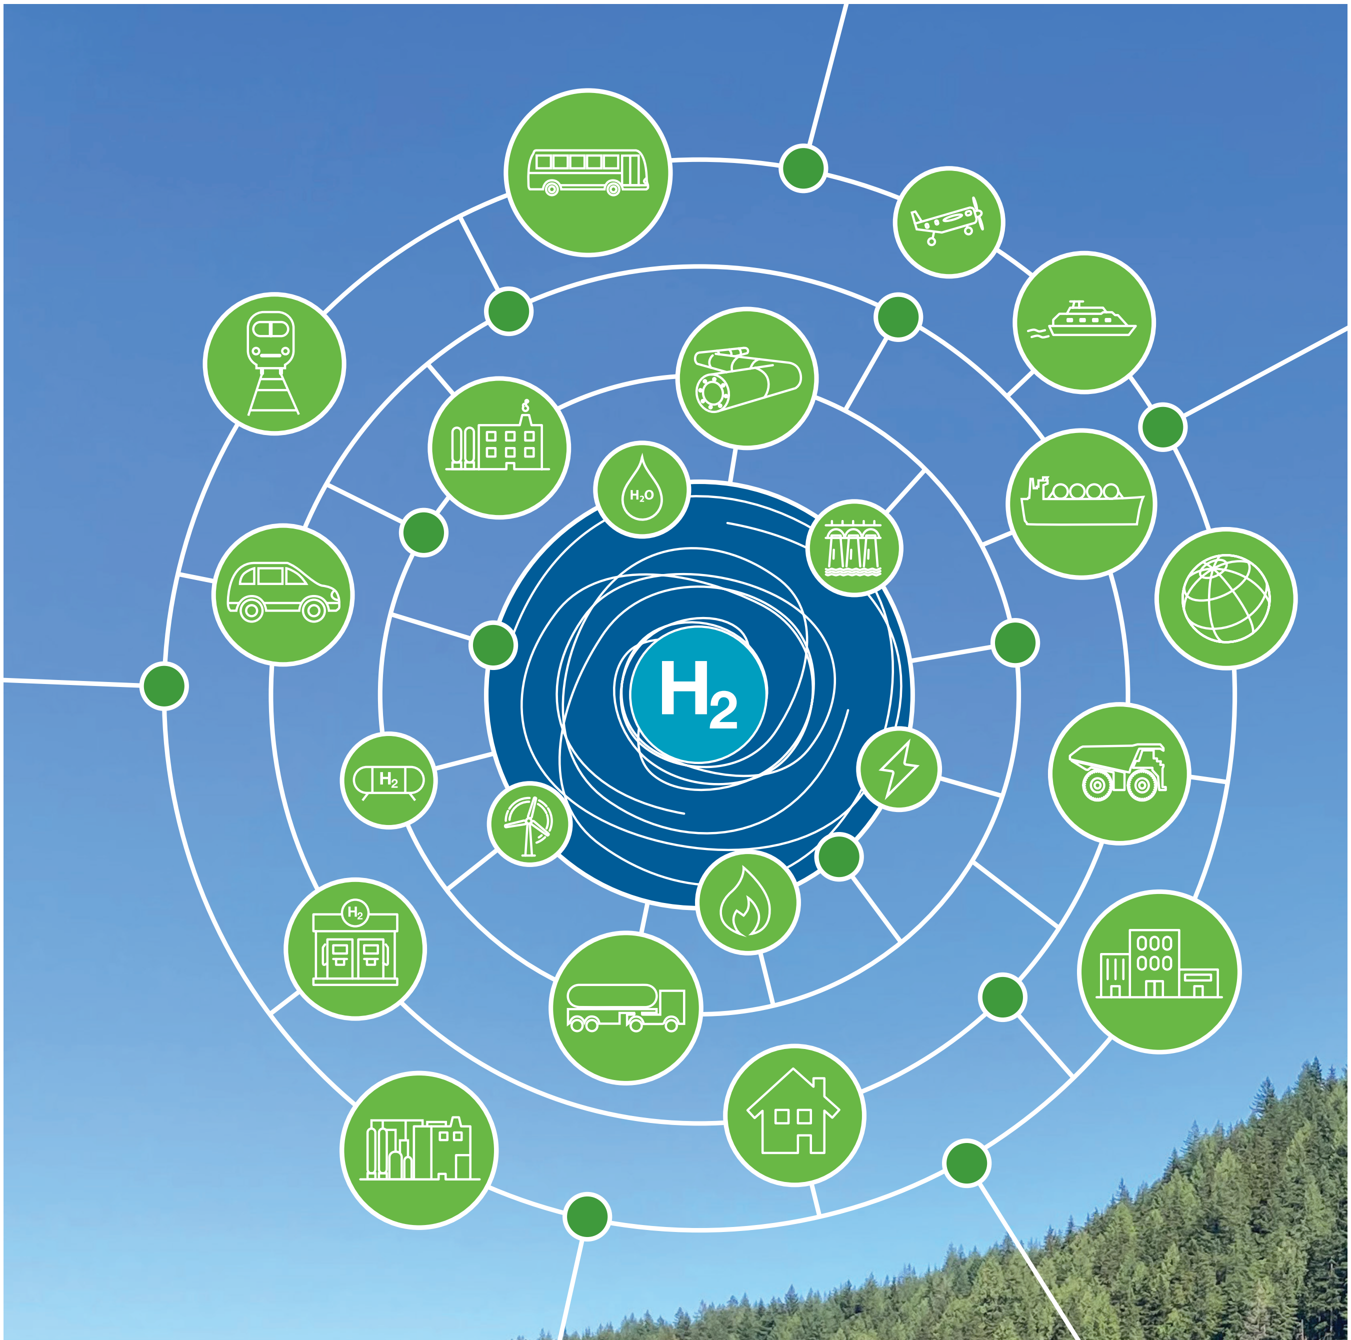
Appendix A-4

BC HYDROGEN STRATEGY – BC GOVERNMENT STUDY



B.C. Hydrogen Strategy

A sustainable pathway for B.C.'s energy transition

British Columbia
cleanBC
our nature. our power. our future.

"For British Columbia to meet its CleanBC goals, we must shift how we produce and consume energy. Renewable and low-carbon hydrogen will play a critical role in our sustainable energy future. With our clean hydroelectricity, abundant natural resources and innovative companies, B.C. can be a world leader in the growing hydrogen economy – creating new cleantech jobs and opportunities for people across the province. The B.C. Hydrogen Strategy lays out the actions we will take together to realize this vision on the path to net-zero emissions by 2050."

Honourable Bruce Ralston
Minister of Energy, Mines
and Low Carbon Innovation

H2

Powering our transition to a lower-carbon future

"Hydrogen energy is essential to achieving carbon neutrality by 2050 and limiting global warming to less than two degrees Celsius. Canada is fortunate in that we not only have a leading fuel cell sector centred in B.C., but also leading hydrogen technology and production companies. This represents a huge opportunity for B.C. to produce the significant quantities of hydrogen that will be needed at home and abroad from our abundant, low-cost renewable power and also, when coupled with CO_2 sequestration, from our natural gas resource. Hydrogen will enable B.C. industries – from ports to trucking and mining to urban transportation – to thrive in a carbon-constrained world."

– Mark Kirby, President & CEO
Canadian Hydrogen and Fuel Cell Association

"There is significant momentum building globally for the development and deployment of fuel cells and hydrogen at commercial scale. Numerous countries in Asia, the Americas, Europe and Africa have national hydrogen strategies or initiatives in place, some with medium- and long-term deployment targets – all with a view to addressing societal issues including energy security and resiliency, economic growth and innovation, and environmental goals."

– Tim Karlsson,
Executive Director of the International Partnership for Hydrogen and Fuel Cells in the Economy

"Renewable electricity can help reduce emissions in road transport, low-temperature industrial processes and in heating buildings. However, fossil fuels have a significant advantage in applications that require high energy density, industrial processes that rely on carbon as a reactant, or where demand is seasonal. To fully decarbonize the world economy, it's likely a clean molecule will be needed and hydrogen is well placed to play this role. It is versatile, reactive, storable, transportable, clean burning and can be produced with low or zero emissions."

– BloombergNEF, *Hydrogen Economy Outlook*

"Hydrogen can help overcome many difficult energy challenges. It can decarbonize hard-to-abate-sectors like steel, chemicals, trucks, ships and planes. Hydrogen can also enhance energy security by diversifying the fuel mix and providing flexibility to balance grids."

- Fatih Birol, Executive Director of the International Energy Agency

"A huge step in the fight against climate change has been taken, as both governments and investors now fully grasp the role hydrogen can play in the energy transition. Now, to bring this potential to its full fruition, governments, investors and industrial companies must work together to scale up the hydrogen ecosystem around the world. Their collaboration in the coming months will allow for many of the projects around the world to become a reality and to turn hydrogen into a new, clean, abundant and competitive energy carrier,"

- Benoît Potier, Chairman and CEO of Air Liquide
and Co-Chair of the Hydrogen Council

Contents

Executive summary

British Columbia is committed to achieve net-zero emissions by 2050. It is an ambitious target given that two-thirds of the energy we use for transportation, buildings and industry currently comes from fossil fuels. Meeting our CleanBC goals requires a determined effort to increase energy efficiency, electrify the economy and switch to low-carbon fuels such as biofuels and hydrogen.

When burned or used in a fuel cell, hydrogen produces no carbon emissions. Large-scale deployment of renewable and low-carbon hydrogen will play an essential role in reducing B.C.'s emissions. Independent estimates suggest that hydrogen has the potential to reduce annual emissions by 7.2 megatonnes by 2050 – equivalent to 11% of the province's 2018 emissions.[1]

Because of its versatility, hydrogen is one of the only solutions for decarbonizing sectors of the economy where direct electrification is not practical, such as heavy-duty transportation and industrial heat. Hydrogen can be used in fuel cells to produce energy for transportation and stationary power systems, especially important for industrial sites and remote communities powered by diesel. When blended into the natural gas grid, hydrogen can displace fossil fuels to heat and power our homes and buildings. Hydrogen can also be used for producing low-carbon synthetic fuels to reduce emissions in transportation and industry.

Realizing the potential of hydrogen requires government, industry and researchers to work together. As part of CleanBC, the B.C. Hydrogen Strategy outlines the Province's plan to accelerate the production and use of renewable and low-carbon hydrogen and be a world leader in the growing hydrogen economy.

The strategy includes 63 actions to undertake over the short term (2020-2025), medium term (2025-2030) and long term (2030-beyond). These include:

- incentivizing the production of renewable and low-carbon hydrogen;
- developing regional hydrogen hubs where production and demand are co-located;
- financial supports for deploying fuel cell electric vehicles and infrastructure;
- expanding the use of hydrogen across different industrial sectors and applications;
- promoting the adoption of hydrogen in areas where it is most cost-effective in terms of emission reductions;
- creating the B.C. Centre for Innovation and Clean Energy to drive the commercialization of new hydrogen technology; and
- establishing ambitious carbon-intensity targets and a regulatory framework for carbon capture and storage.

B.C. has already implemented robust policies to encourage hydrogen use in the transportation sector. B.C.'s carbon tax and low carbon fuel standard (LCFS) are reducing emissions while incentivizing the switch to renewable and low-carbon fuels. CleanBC committed to increasing the stringency of the LCFS by doubling the required reduction in carbon intensity of transportation fuels to 20% by 2030. Introduced in 2019, the *Zero-Emission Vehicles Act* requires automakers to meet an escalating annual percentage of new light-duty zero-emission vehicle sales, including hydrogen fuel cell electric vehicles. Hydrogen is expected to play a larger role for medium- and heavy-duty vehicles by supporting larger payloads and range.

[1] Zen and the Art of Clean Energy Solutions, *BC Hydrogen Study - Final Report* (2019).

The Province also recently introduced policies to support the production of hydrogen. In 2021, the Province and BC Hydro introduced the Clean Industry and Innovation Rate to offer discounted electricity for hydrogen production. In addition, recent amendments to the *Greenhouse Gas Reduction Regulation* enable utilities to produce or purchase hydrogen for displacing fossil fuels in the natural gas grid.

Unlike most other jurisdictions, B.C. has the resources to produce both green and blue hydrogen with low carbon intensity. More than 98% of B.C.'s electricity is renewable, allowing us to leverage our clean electricity to produce green hydrogen via electrolysis. B.C. also has low-cost natural gas reserves, significant geological storage capacity and expertise in carbon capture and storage (CCS) technology, giving us the potential to produce blue hydrogen from natural gas with adequate and permanent CCS.

Not all types of hydrogen production are equal in terms of climate benefits. To reduce emissions and decarbonize the economy, the B.C. Hydrogen Strategy must focus on advancing and providing support only for renewable and low-carbon hydrogen pathways, with long-term targets for declining carbon intensity consistent with net-zero emissions by 2050. Our immediate priorities will be to:

- scale-up green hydrogen production using B.C.'s abundant supply of clean, renewable electricity; and
- establish a regulatory framework for CCS to enable blue hydrogen production while ensuring it has similar or lower emissions.

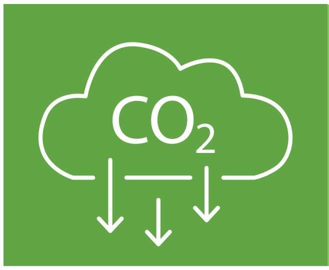
B.C. is already a world leader in hydrogen and fuel cell technology. Provincial support for innovation has led to the creation of a vibrant cluster of companies and expertise in hydrogen. More than half of Canada's companies active in the hydrogen and fuel cell sector are located in B.C. This local expertise has fuelled strong synergies between government, industry and post-secondary institutions.

B.C. is well-positioned to grow its hydrogen sector to meet the increasing demand for low-carbon solutions locally and around the world. Hydrogen is a clean energy solution for powering B.C.'s future as it presents an opportunity to reduce emissions, attract new investment and create skilled, well-paying jobs. Given our proximity to export markets, we could capture a significant portion of the global hydrogen market estimated to be greater than $305 billion by 2050.

Unlocking hydrogen's potential requires acting with urgency and working together to implement the B.C. Hydrogen Strategy. Accelerating the adoption of renewable and low-carbon hydrogen through policy, partnerships, innovation and infrastructure will help us achieve our CleanBC commitments and build a sustainable economy.

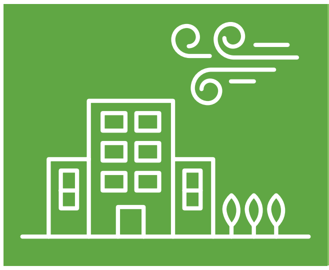
Objectives

Our vision is to become a world-leading hydrogen economy by 2050.

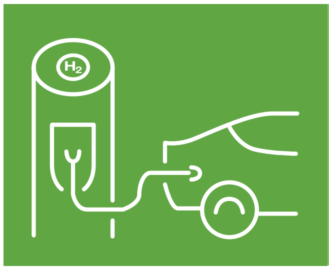


Promote innovation and investment in the production and deployment of hydrogen to achieve the energy system transformation required to meet CleanBC greenhouse gas (GHG) reduction targets

Create economic development opportunities across B.C. through increased and equitable employment in trades, cleantech and energy services



Improve air quality and reduce contamination and noise pollution in urban and remote communities



Make clean energy solutions more diverse, convenient, available and affordable for British Columbians

Fulfil our commitments under the *Declaration on the Rights of Indigenous Peoples Act*

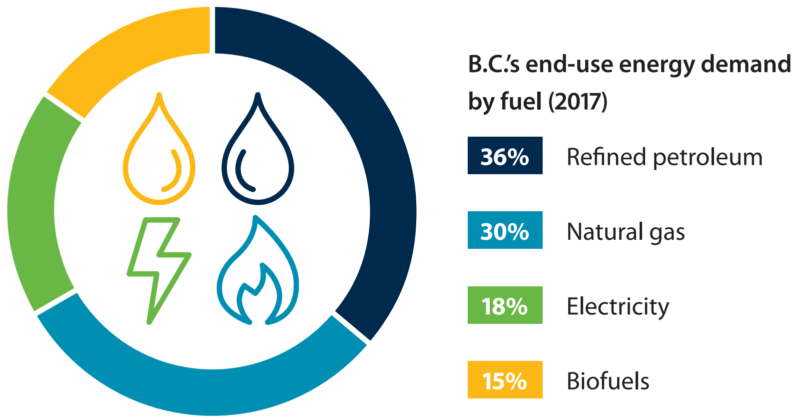
Energy and how it's used in B.C.

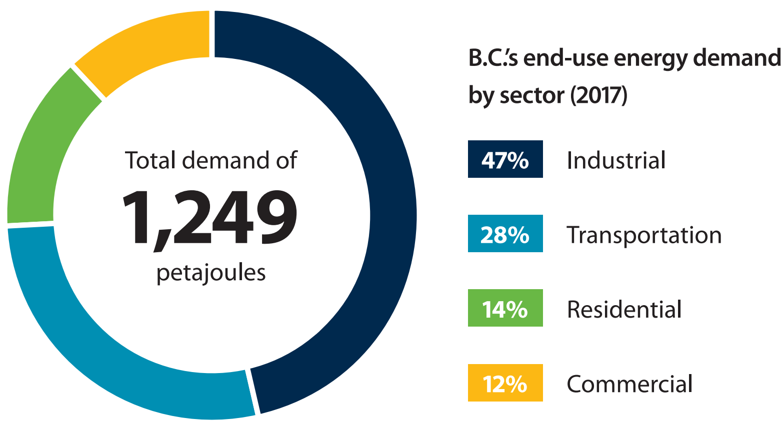
Hydrogen can help us make the essential shift away from higher-carbon fuel sources in all sectors, from industrial and transportation through to residential and commercial use.

Demand for energy in B.C. is highest in the industrial sector, followed by transportation, residential and commercial use. Hydrogen can be applied to each of these sectors in B.C. and could replace a significant percentage of demand currently met by fossil fuels.

Just under 70% of B.C.'s current energy demand is met through natural gas and refined petroleum products such as gasoline and diesel.[2] Hydrogen will play an important role in helping us transition away from these higher-carbon fuels to a cleaner, low-carbon energy system.

B.C.'s electricity is over 98% clean or renewable. Electrification of the economy is key to achieving our CleanBC goals, including fuel-switching from natural gas and diesel to electricity. But for many sectors that are dependent on these fuels, such as heavy-duty transportation and high-grade industrial heating, direct electrification is not practical. In these cases, hydrogen provides an effective solution.





2 Canada Energy Regulator, Provincial and Territorial Profiles - British Columbia (2019).

B.C.'s leadership in the hydrogen economy

B.C. is a recognized world leader in fuel cell innovation and hydrogen technologies, and the Province is committed to supporting research, development and commercialization in this sector as part of the global effort to reduce emissions.

The Government of British Columbia was an early supporter of fuel cell innovation, and today the province is home to the largest hydrogen and fuel cell sector in Canada, with 51% of companies located here. Their innovations are supported by the cutting-edge research conducted at B.C.'s universities and technical institutes, which are also training the next generation of talent working in this field.

A skilled workforce will be essential for our successful shift to cleaner energy solutions and the Province and industry both have a role to play. By helping shape programs at post-secondary institutions through program advisory committees and work-integrated learning, new graduates will be prepared to enter the workforce and contribute to the growing cleantech economy, including the hydrogen and fuel cell sector.

The synergies arising from industrial, post-secondary and governmental support for hydrogen have created the province's strong hydrogen sector. Exports of B.C. fuel cell and hydrogen technology to Asia, Europe and the US have enabled industry growth and product development. But if we are to fully benefit from the innovative technologies developed in our province, they need to be put to use here in B.C. That means we need to continue to invest and innovate across the sector. Doing so will enable us to realize our GHG reduction targets, remain a world leader in fuel cell innovation and hydrogen technology, and become a leading hydrogen economy.

Hydrogen BC (HyBC)
Fuelling hydrogen innovation in B.C.

Established in 2020 as the B.C. regional branch of the Canadian Hydrogen and Fuel Cell Association, HyBC supports the province's hydrogen energy ecosystem by co-ordinating the deployment of hydrogen infrastructure and applications province-wide. In partnership with the provincial government, HyBC has an initial mandate to promote the rollout of fuel cell electric vehicles and hydrogen fuelling stations. HyBC also works to ensure the safe operation of hydrogen infrastructure by sharing best practices developed in Canada and abroad while working across the province to build demand for low-carbon hydrogen.

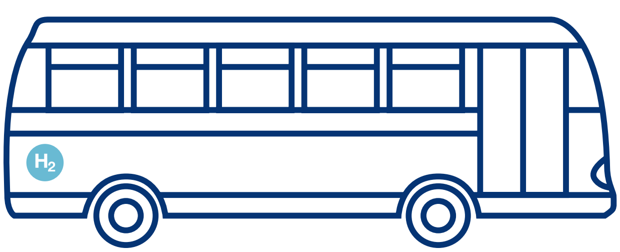
Institute for Integrated Energy Systems (IESVic)
A nexus of research and training

Since 1994, IESVic at the University of Victoria has charted feasible pathways to sustainable energy systems by developing technology and training the next generation of changemakers. IESVic was Canada's first major university-industry research partnership focused on fuel cells and hydrogen systems; with support from NSERC, Ballard Power Systems and others, an industrial research chair was created to focus on hydrogen storage and advanced liquefaction. IESVic faculty and students helped establish B.C. and Canada as world leaders in hydrogen and fuel cells, and IESVic continues to be an active research centre in fuel cell modelling, hybrid power trains, storage and techno-economics of the hydrogen economy.

Powertech Labs

Globally renowned for innovation

Wholly owned by BC Hydro, Powertech Labs is a world-renowned testing, consulting, and research and development organization that pioneered the design of turnkey hydrogen fuelling station packages. Powertech's Advanced Transportation group is a preferred partner for global industry leaders that bring hydrogen technologies to market. Powertech has amassed a profile of world firsts, including initiating a collaboration of leading automotive original equipment manufacturers that jumpstarted the development of hydrogen components used in all hydrogen fuel cell vehicles today, to designing and building the world's first fast-fill 70 MPa hydrogen station in Surrey, B.C., to its critical role in hydrogen fuelling protocols used around the world. Powertech will play a central role in the development of B.C.'s hydrogen economy and the successful implementation of the B.C. Hydrogen Strategy given its expertise in hydrogen equipment testing and design, the development of hydrogen codes and standards, hydrogen station and dispensing technology, hydrogen production and purification technologies, and materials testing. Powertech's relationship with BC Hydro and CleanBC will enable the company to maintain a leadership role as the deployment of hydrogen extends from the transportation to the energy sector.



Greenlight Innovation

The largest installed base of fuel cell and energy storage testing solutions in the world

Located in Burnaby, Greenlight Innovation is accelerating the shift towards sustainable transport and energy consumption by producing the world's best testing and development equipment for the research and manufacture of fuel cells, electric vehicles and energy storage systems. Since 1992, Greenlight has made the tools required to commercialize alternative energy technologies, and major automotive equipment manufacturers, leading universities and research institutions rely on Greenlight's advanced testing and manufacturing equipment to provide world-class results for their programs.

Ekona Power

Producing low-cost and low-carbon hydrogen from fossil fuels

Ekona is a Vancouver-based venture that is developing a novel methane pyrolysis platform for industrial-scale hydrogen production and natural gas infrastructure that delivers low-cost hydrogen while reducing GHG emissions by over 90%. Ekona's tri-generation pyrolysis solution is a unique combination of two technologies – pulse-methane pyrolysis (PMP) and direct carbon fuel cells (DCFC). Ekona's PMP produces hydrogen at costs comparable to conventional steam methane reformers, with valuable solid carbon as the principal byproduct. Ekona's DCFC efficiently converts byproduct carbon into electricity and pure CO_2, which can be sequestered or utilized.

Producing hydrogen in B.C.

Hydrogen can be produced from many different feedstocks available in B.C., including both fossil fuels and renewable resources.

Hydrogen is the lightest and most abundant element in the universe and is found in compounds such as water (H_2O) and natural gas (CH_4). When hydrogen is split from water or released from organic material, it becomes a versatile energy carrier that can be used in energy systems to generate electricity and heat.

Hydrogen can be produced from fossil fuels, biomass and clean electricity, and it is also a byproduct in some industrial processes. Several hydrogen production pathways are possible in B.C. to meet domestic and/or international demand. Determining how to produce hydrogen efficiently, cost-effectively, at scale and with minimal environmental impact is critical to building supply chains within the province.

Hydrogen production pathways are often represented by colours based on the production process used.

GREEN **hydrogen** is produced from renewable sources, such as using clean electricity (e.g., hydro or wind power) to split water into hydrogen and oxygen through a process called electrolysis. Green (or *renewable*) hydrogen has a low carbon intensity when produced using clean electricity.

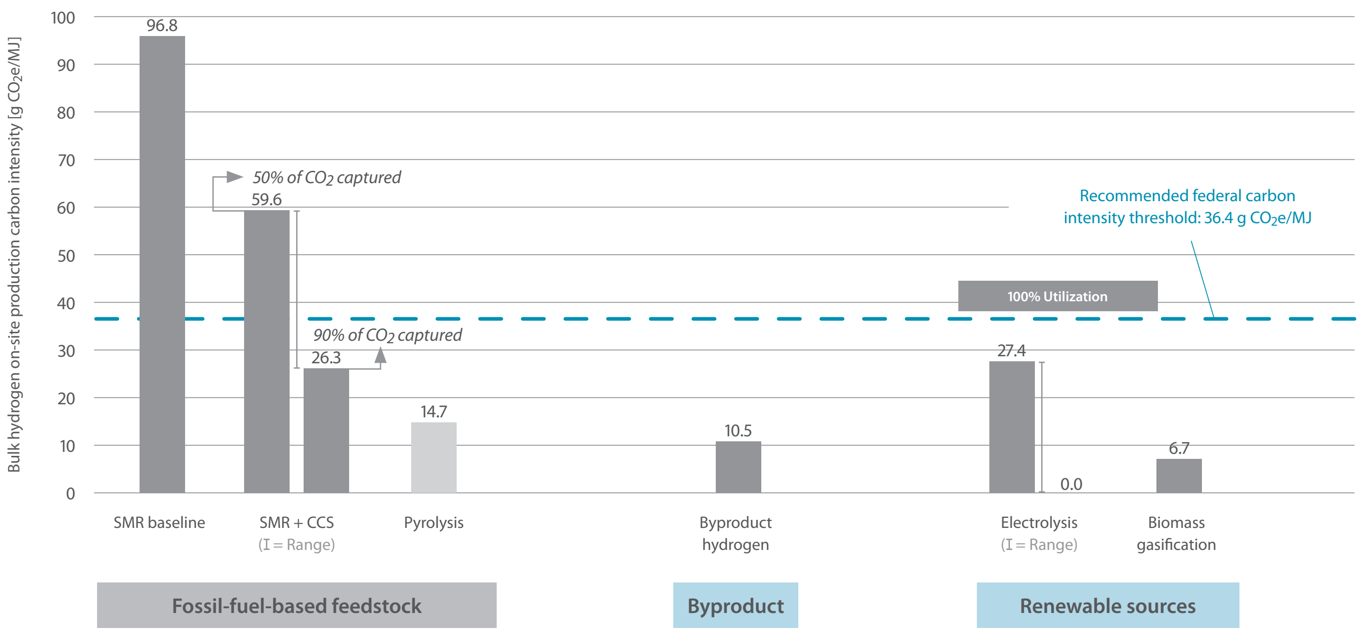
BLUE **hydrogen** is produced from non-renewable sources through steam methane reforming (SMR) with carbon capture and storage (CCS) or pyrolysis of fossil fuels, such as natural gas. With CCS, carbon dioxide is separated and sequestered underground, which reduces the carbon intensity of the produced hydrogen. With pyrolysis of natural gas, solid carbon is a byproduct. Blue hydrogen (or *hydrogen from fossil fuels with CCS*) has a low carbon intensity when produced using fossil fuel feedstock coupled with adequate and permanent CCS.

GREY **hydrogen** is produced from fossil fuel sources, but *without* CCS. Grey hydrogen does not have a low carbon intensity.

While describing hydrogen production pathways using colours is common, the terminology is not standardized and can lead to confusion around the carbon intensity of pathways and their effectiveness at reducing emissions.

In terms of climate benefits, not all hydrogen is created equal. To meet its emissions reduction targets, B.C. must focus on advancing and providing support only for renewable, low-carbon or zero-emission hydrogen pathways. The following table shows the GHG emissions intensity of different hydrogen production methods.

GHG emissions intensity of different hydrogen production methods



The carbon intensity of the production pathways shown above are modelled estimates and use a "cradle-to-gate" life-cycle analysis that includes emissions associated with feedstock production, transportation, losses, flaring, land use changes, hydrogen production and carbon capture and storage (if applicable). Data are from the B.C. low carbon fuel standard and *BC Hydrogen Study – Final Report* (2019). The actual carbon intensity of a specific hydrogen production project will depend on a number of factors.

In B.C., the carbon intensity of hydrogen will be determined using a rigorous life-cycle approach that accounts for all the emissions associated with its production. This includes emissions associated with feedstock development, transportation, hydrogen production and any CCS. The Province will work other jurisdictions to develop a common methodology for measuring and verifying the carbon intensity of hydrogen.

The federal *Hydrogen Strategy for Canada* and the European Commission recommend a carbon intensity threshold of 36.4 g CO_2e/MJ. B.C. will consider this target a starting point and will ensure that its regulatory frameworks relating to hydrogen production and use are aligned to achieve continued reductions in carbon intensity over time.

Through implementation of the B.C. Hydrogen Strategy, the Province will work to establish long-term, ambitious thresholds for declining carbon intensity consistent with ensuring that B.C. remains a world leader in hydrogen, decarbonizes the economy and achieves its goal of net-zero emissions by 2050.

Hydrogen storage and distribution

Hydrogen can be stored in either liquid or gas form for later use. It can be distributed in B.C.'s existing natural gas pipeline infrastructure or in dedicated pipelines, and it can also be compressed or liquefied for storage and distribution in tanks, convenient for delivery (generally by truck). Finally, hydrogen can also be stored in liquid chemical carriers, such as ammonia, or by bonding hydrogen to toluene, where high densities of hydrogen can be stored at lower pressures.

To overcome challenges associated with the transportation of hydrogen, B.C. is committed to reviewing hydrogen infrastructure requirements, supporting distribution trials and establishing an enabling regulatory environment for hydrogen distribution.

Hexagon Purus

Lightweight components for high-pressure vessels

Hexagon Purus is a world-leading provider of hydrogen type 4 high-pressure cylinders, complete vehicle systems and battery packs for fuel cell electric, battery electric and hybrid mobility applications. Type 4 high-pressure cylinders contain a non-metallic liner and are lightweight and cost-effective, which are important factors for high-pressure hydrogen storage across the medium- and heavy-duty commercial vehicle industry. Hexagon Purus's Global Innovation Office is in Kelowna, and the company is also investing in a new world-class engineering, prototyping and short series production factory near UBC-Okanagan for its hydrogen and battery electric products to support fuel cell vehicles, with completion planned in mid-2022.

Ionomr Innovations

Technology that improves performance and reduces environmental impact

Ionomr's innovations are enabling the ultra-high-efficiency, lowest-cost fuel cell systems of the future. The Vancouver-based company's proton-exchange membranes (PEMs) and ionomer replace the toxic materials used in most electrochemical systems without compromising on performance or chemical durability. These materials allow existing fuel cells and PEM electrolyzers to achieve higher-efficiency targets and longer lifetimes, while minimizing the use of precious metals. Ionomr's anion-exchange materials are the first to unlock high-temperature strong alkaline systems, the largest improvement in 100 years to the alkaline electrolysis systems that form most renewable hydrogen deployments today.

"Ionomr's revolutionary ion-exchange materials enable the proliferation of hydrogen to its rightful leadership position in the future of abundant renewable and sustainable energy."

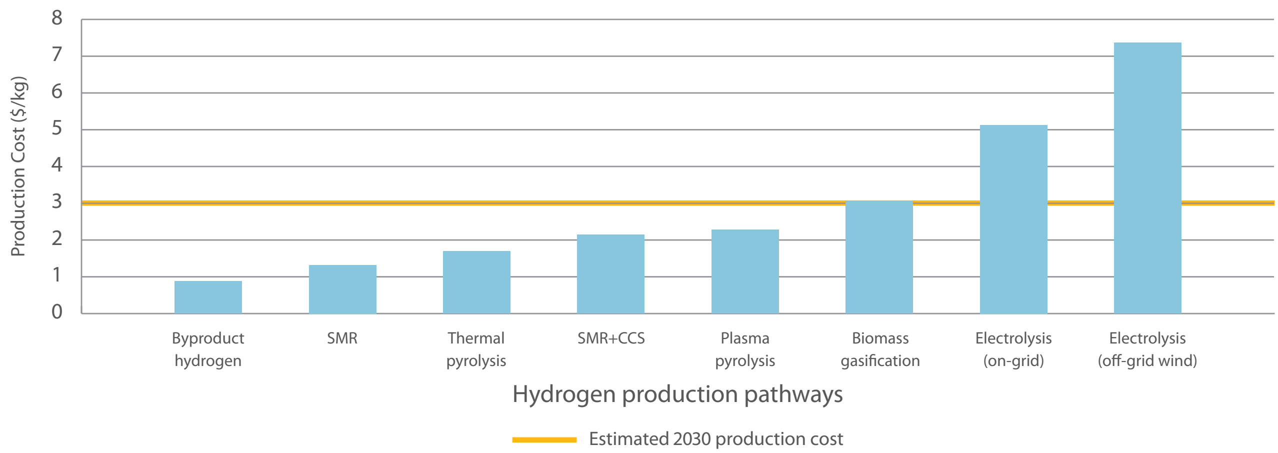
Cost of hydrogen production



Cost of bulk on-site hydrogen production by pathway in B.C. in 2020

Production costs are normalized to production scale of 100 tonnes per day.[3]

Grey hydrogen production methods, such as SMR, are currently the most cost-effective ways to produce hydrogen at scale and are the most commercially advanced technologies; however, SMR produces significant carbon emissions. CCS is one way to reduce the carbon emissions from this pathway.

Production costs for all pathways are heavily dependent on the price of inputs, such as natural gas and electricity. While B.C. has one of the lowest cost and cleanest electricity grids in North America, renewable hydrogen production at scale via electrolysis will require electricity rates in the range of $40/MWh. There is also a growing interest in dedicated electricity generation for hydrogen production using intermittent energy resources such as wind. It is expected that as the cost of these renewable electricity resources decline, so too will the cost of low-carbon hydrogen production. Building electrolyzers at locations with access to high-voltage electricity and transportation infrastructure will be necessary for renewable hydrogen production. BloombergNEF expects the levelized cost of hydrogen from large renewable-energy-powered projects will be cost-competitive with low-carbon hydrogen from natural gas via SMR + CCS by 2030.[4]

While modelling shows the costs of different hydrogen production pathways, the costs of delivered hydrogen will vary greatly depending on the location of the facility, method of production, transportation and storage requirements, and the state of the hydrogen (liquid or gaseous). The Province targets cost-parity or lower with the wholesale price of incumbent fuels for hydrogen production, such as gasoline or diesel for transportation or delivered diesel for remote communities. It is estimated that to be globally competitive, the price of hydrogen produced (excluding storage and transportation) would need to be less than $3/kg by 2030. Ensuring that hydrogen is widely available for domestic use and for export will depend on our ability to scale up the technology, keep the costs of inputs competitive within the industry, reduce transportation costs and ensure access to robust and efficient supply chains.

[4] BloombergNEF, *Hydrogen Economy Outlook* (March 20, 2020).

Making electrolysis more affordable

In January 2021, the Province and BC Hydro announced the Clean Industry and Innovation Rate to help support and attract new innovative industries, such as hydrogen production, to B.C. by making it more affordable to connect into BC Hydro's grid. The Clean Industry and Innovation Rate is a seven-year discount from BC Hydro's standard industrial rate (20% discount for the first five years, 13% discount in year six and 7% discount in year seven) and is available to new customer plants that use a process to remove GHGs from the atmosphere or produce a renewable or low-carbon fuel. The Province continues to explore ways to make B.C. more competitive with lower-cost jurisdictions by analyzing additional rate structures that will make electrolysis more affordable and, in turn, reduce the cost of low-carbon hydrogen for consumers in B.C.

How we'll grow hydrogen production

2020-2025

- Stimulate hydrogen production through direct support and incentives
- Continue to provide policy support for increasing hydrogen demand certainty and de-risking the development of hydrogen production infrastructure
- Provide policy support to utilities who choose to produce or purchase hydrogen
- Advocate for increased production and consumption of hydrogen in B.C.
- Work with industry partners to establish hydrogen deployment hubs in B.C.

2025-2030

- Consider introducing alternative electricity rate designs to support hydrogen production
- Promote hydrogen production at scale to meet domestic and/or international demand
- Determine if brownfield sites can be used for industrial parks that include hydrogen production

2030-beyond

- Support long-term self-sufficiency in hydrogen supply and with it introduce new opportunities for economic development
- Support the development of hydrogen liquefaction, distribution and transmission infrastructure

Codes and standards

Existing agencies will play an important role in regulating the hydrogen industry and ensuring the safe production and responsible use of our natural resources, such as water and natural gas. We also need to make sure that regulations and permitting requirements are clear and consistent across sectors and jurisdictions to enable sector-coupling and ensure B.C. is set up for seamless trade opportunities, both regionally and abroad.

Hydrogen projects may need to be regulated based on the specific production pathway or end use. For example, hydrogen produced by SMR has parallels with oil and gas activities due to the use of natural gas, and there may be overlap with the regulatory approval processes in place for the oil and gas industry as determined by the BC Oil and Gas Commission.

Hydrogen projects require a clear path forward, and the Province will work to remove roadblocks and harmonize regulation and permitting in B.C. Many organizations have valuable expertise to share, including the CSA Group, Canada Energy Regulator, Canadian Hydrogen and Fuel Cell Association, Measurement Canada, FortisBC, Pacific Northern Gas, Enbridge, Technical Safety BC, the BC Oil and Gas Commission and the British Columbia Utilities Commission.

Ballard Power Systems
A world leader in hydrogen fuel cells

Burnaby-based Ballard is a leading global provider of innovative hydrogen fuel cell products and services that have the Power to Change the World.® Over its 40-year history, Ballard has invested more than $1 billion in research and development to advance fuel cell technology and has produced over 850 megawatts of proton-exchange membrane fuel cell products. Today, Ballard's 900+ employees design, manufacture and sell fuel cell products that power zero-emission transit buses, trucks, trains, marine vessels and forklifts and contribute to CO_2 emission reductions. Its heavy-duty fuel cell power modules lead the industry in performance, durability and overall road experience, having operated more than 50 million kilometres, and there are currently more than 3,000 hydrogen fuel cell electric buses and trucks powered by Ballard in operation globally.

"At Ballard, we are convinced that hydrogen can offer economically viable, financially attractive and socially beneficial solutions. We believe that hydrogen is needed to achieve deep decarbonization of our economy and meet Canada's emission reduction targets. With its natural resources and a local hydrogen and fuel cell technology cluster, British Columbia is facing a unique opportunity. A comprehensive hydrogen strategy for the Province will send a strong signal to investors, boosting economic growth and local jobs while positioning B.C. as a leader in the hydrogen economy."

– Randy MacEwen, President and CEO
Ballard Power Systems

How we'll regulate hydrogen production

2020-2025

- Review provincial, federal and international codes, standards and regulations for hydrogen production and establish a compatible regulatory framework
- Amend regulations to allow the BC Oil and Gas Commission to regulate hydrogen production, storage and transportation if produced from fossil fuels
- Amend *Water Sustainability Act* related regulations to include hydrogen production as an authorized industrial water use purpose and set new water fees and rentals
- Enable hydrogen as a pathway for natural gas utilities to reduce emissions
- Ensure regulatory frameworks relating to hydrogen production and use are aligned to encourage continued reductions in carbon intensity over time
- Establish carbon-intensity targets for hydrogen production pathways
- Provide support only for renewable or low-carbon hydrogen pathways
- Establish a working group made up of representatives from the hydrogen industry, regulatory agencies and government to implement B.C. Hydrogen Strategy actions

2025-2030

- Continue to implement the Low Carbon Fuel Standard Part 3 Agreements to advance hydrogen production, fuelling infrastructure, operation and maintenance projects
- Review sectoral opportunities for hydrogen offtake
- Develop carbon management frameworks to encourage at-scale production of low-carbon hydrogen and transition policy incentives from direct support to market-based mechanisms

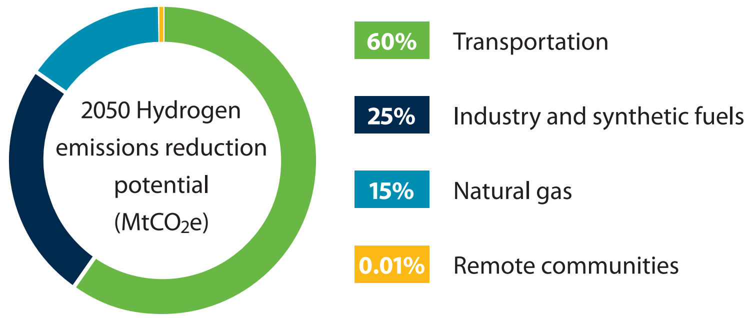
2030-beyond

- Achieve a clear and supportive regulatory environment for hydrogen production in B.C.
- Require a phased reduction in the carbon intensity of hydrogen produced and used in B.C.
- Explore policy framework mechanisms for long-duration energy storage using hydrogen

Using hydrogen in B.C.

Hydrogen will play a critical role in hard-to-decarbonize sectors where direct electrification is not practical, such as heating and power, transportation and industrial processes. The Province is committed to promoting the most cost-effective applications that result in the greatest climate benefit.

By 2050, hydrogen has the potential to reduce the province's emissions by 7.2 megatonnes of carbon dioxide equivalent (CO_2e) per year,[5] equal to 11% of B.C.'s 2018 emissions.[6] Hydrogen deployment in transportation applications is expected to account for 60% of these reductions as hydrogen fuel cells, often used in vehicles, offer greater efficiency than burning hydrogen. Applications in industry and synthetic fuels (25%) and natural gas (15%) make up the remainder of the potential reductions from hydrogen.



Blending hydrogen with natural gas to decarbonize heating and power

B.C. has an extensive network of natural gas pipelines that can be used to help meet our GHG reduction targets and grow the province's hydrogen economy. Natural gas represents the greatest source of carbon emissions in the built environment, where it is most commonly used for space and water heating in residential and commercial buildings, large multi-unit buildings, hospitals and schools. Industrial sites such as mines, pulp and paper mills, and refineries also rely on natural gas for direct heating and feedstocks.

One way to reduce emissions associated with natural gas use is by injecting hydrogen into the natural gas grid. When natural gas is blended with hydrogen, its emissions from combustion are reduced, providing a cleaner energy source. While the volume of hydrogen that can be directly injected into B.C.'s extensive pipeline distribution network depends on the point of injection and pipeline capacity, studies have shown that hydrogen by volume up to 5%-15% can be tolerated in the pipeline network with minimal disruption to appliances in homes and businesses.[7]

Blending hydrogen with natural gas is an innovative solution for natural gas utilities to meet environmental standards, including the CleanBC requirement that 15% of natural gas consumption must come from renewable gas by 2030.

It would also reduce some of the emissions associated with burning natural gas in appliances, power-generating equipment and industrial processes. More work will be done to understand the implications across the entire natural gas system. Since 80% of the natural gas produced in British Columbia is sold in the export market, injecting hydrogen in the high-pressure transmission system could have implications for downstream customers. Depending on the point of injection and volume of hydrogen injected, the Canada Energy Regulator, the BC Oil and Gas Commission or Technical Safety BC will be engaged to review the pipeline network for integrity and safety.

7 Zen and the Art of Clean Energy Solutions, *BC Hydrogen Study – Final Report* (2019).

Power-to-Gas: Integrating our electricity grid and gas infrastructure

Power-to-Gas (P2G) converts electricity into hydrogen through electrolysis, and the resulting hydrogen can then be injected into the natural gas distribution network for use in buildings, transportation or seasonal storage. P2G projects also allow utilities or communities to store surplus energy generated from intermittent renewable power, such as wind. Hydrogen can be stored in dedicated tanks for days, weeks and even months to be used when demand changes across the seasons. This stored hydrogen can also be injected into the natural gas distribution system or be used in a stationary fuel cell for electricity production when needed. P2G could be a powerful way for B.C. to integrate our clean electricity grid and our existing natural gas infrastructure to achieve our GHG reduction targets, improve system resiliency and increase energy storage.

FortisBC

Exploring how to incorporate hydrogen into the gas distribution network

An integrated gas and electric utility, FortisBC serves over 1.2 million customers across 135 communities and 57 Indigenous communities. To achieve its target of a 30% reduction in its customers' GHG emissions by 2030, FortisBC is exploring ways to increase the content of renewable and low-carbon gases like hydrogen in the gas supplied to its customers. The utility is currently progressing to pre-feasibility planning and technical analyses for introducing hydrogen into its gas distribution network and is evaluating large-scale projects for the centralized production of renewable hydrogen. Through its Clean Growth Pathway to 2050, FortisBC also plans to make significant investments in low- and zero-carbon vehicles and infrastructure and to grow renewable gas supply to achieve 15% of all gas it delivers by 2030.

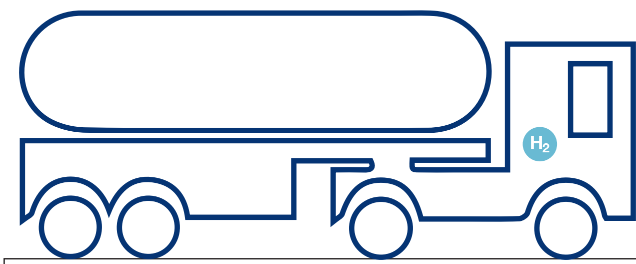
How we'll support blending hydrogen with natural gas
2020-2025
• Establish a regulatory framework for injecting hydrogen into the natural gas and propane distribution systems • Include hydrogen as a prescribed undertaking under the *Greenhouse Gas Reduction Regulation* • Partner with a utility to review the infrastructure requirements to accommodate up to 100% hydrogen in the distribution system • Support hydrogen injection trials into natural gas and/or propane distribution systems
2025-2030
• Mandate that new or modified natural gas or propane pipelines be hydrogen compatible • Support the introduction of hydrogen-tolerant equipment • Explore the role of hydrogen in meeting the CleanBC 15% renewable gas target
2030-beyond
• Support large-scale hydrogen injection into the natural gas and propane distribution systems

Fuelling our transportation sector

Transportation in B.C. emits over 25 million tonnes of CO_2e annually, accounting for approximately 41% of the province's total GHG emissions.[8] Meeting our emissions reduction goals will require a substantive change in how we choose to get around, the kilometres we travel, the vehicles we drive and how we fuel our transportation choices.

Hydrogen fuel cell electric light-duty vehicles are already being adopted by fleets in B.C., and in the near term greater opportunities for hydrogen vehicle deployment are opening up in the medium-, heavy-duty and off-road vehicle sectors. Medium- and heavy-duty hydrogen fuel cell electric vehicles are suitable for heavy payloads and can benefit from short refuelling times and greater operability range. Fuel cell vehicles can also operate in temperatures as low as -30°C with minimal impacts to engine efficiency, and the excess heat generated from the fuel cell stack keeps the engine and cabin warm.

There are currently few low-carbon solutions for planes, trains and ships that require energy-dense fuel. Here, the rapid innovation in hydrogen-powered transportation provides a promising pathway for increased hydrogen adoption in these transportation modes, which are hard to electrify. Hydrogen rail and ferry pilot projects are currently taking place in Europe with great success.

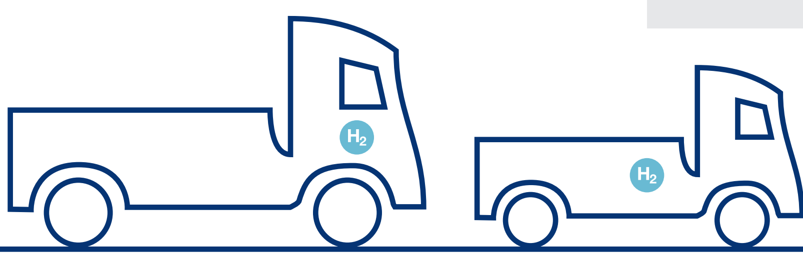


How does a fuel cell electric vehicle work?

Hydrogen fuel cell electric vehicles use hydrogen gas to power an electric motor. Hydrogen and oxygen are combined in the fuel cell to produce electricity, and the only byproducts are water and heat. These vehicles do not produce any tailpipe emissions when driven and are more efficient than conventional internal combustion engines.

Hydra Energy
Using waste hydrogen to displace diesel consumption in heavy-duty trucks

Delta-based Hydra Energy is removing barriers for hydrogen adoption in transportation and accelerating the commercial-scale deployment of hydrogen-fuelled heavy-duty vehicles. Hydra combines unprecedented innovation in hydrogen engine technology with a supply of low-carbon-intensity hydrogen fuel sourced from waste. Its Hydrogen as a Service™ model provides retrofits and fuelling infrastructure at no upfront cost to the fleet operator in exchange for an exclusive hydrogen fuel supply agreement. Heavy-duty diesel trucks can be retrofitted with Hydra technology to operate as dual-fuel, hydrogen-diesel vehicles without power, torque, range or payload loss while cutting GHG emissions and local air contaminants by 30-50%.



[8] CleanBC, *2020 Climate Change Accountability Report* (2020).

Zero-Emission Vehicles Act

The *Zero-Emission Vehicles Act* requires automakers to meet an escalating annual percentage of new light-duty zero-emission vehicle (ZEV) sales: 10% by 2025, 30% by 2030 and 100% by 2040. Although the targets start with light-duty vehicles, the legislation provides options to expand to other vehicle classes, including medium- and heavy-duty vehicles. The legislation aims to meet provincial GHG reduction targets and ensure British Columbians can benefit from a greater availability of ZEVs at more affordable prices.

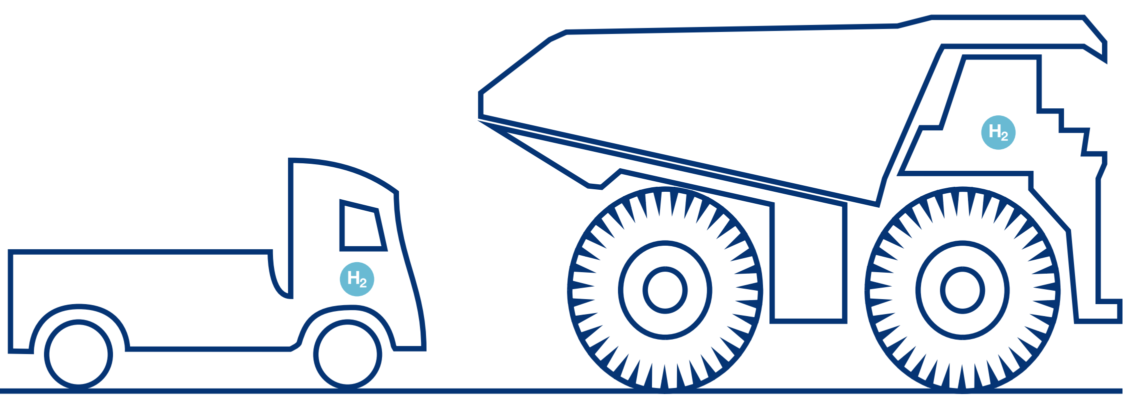
B.C.'s ZEV and FCEV Programs

The Province strives to remove barriers to adopting ZEVs, including hydrogen fuel cell electric vehicles (FCEVs). Through a comprehensive market transformation approach, the ZEV Act and Regulation, and the Go Electric program, support both the supply and demand for ZEVs in B.C. The Go Electric program provides financial support for the deployment of FCEVs, hydrogen fuelling stations and other hydrogen-powered technology and equipment through the Hydrogen Fuelling and Fleet program, Advanced Research and Commercialization program, the Commercial Vehicle Pilot program and the Speciality-Use Vehicle Incentive program. StrongerBC: BC's Economic Recovery Plan committed $30 million for a new Commercial Vehicle Innovation Challenge that will include supporting FCEV development. Additionally, the Go Electric Vehicle Rebate program supports the adoption of passenger FCEVs in B.C.

Loop Energy

More power, fewer materials

Burnaby-based Loop Energy develops world-leading zero-emission hydrogen fuel cell engines and fuel cell stacks for medium-to heavy-duty bus and truck applications. While fuel cell electric solutions have proven performance, cost remains an impediment to widespread adoption. Together with its partners, Loop Energy is commercializing zero-emission solutions that provide more power in a smaller system – with fewer materials and without compromising performance, range or economics.



Building out hydrogen fuelling infrastructure

In 2018, B.C. led the way when Canada's first retail hydrogen fuelling station opened in Vancouver with provincial government support. Since then, three more stations have been opened, two in Metro Vancouver and one in Greater Victoria. Vehicle manufacturers have targeted B.C. as a key market for the rollout of fuel cell electric vehicles in Canada thanks to the province's leadership in the fuel cell sector and the provincial government's commitment to expanding the hydrogen fuelling network as outlined in CleanBC. The Government of Canada is also supporting hydrogen fuelling stations across the country, and in 2019 Quebec's first retail hydrogen station opened for business with equipment designed and manufactured by B.C.'s Powertech Labs and Hydrogen Technology & Energy Corporation.

Hydrogen Technology & Energy Corporation (HTEC)
Experts in hydrogen fuelling infrastructure

HTEC builds, owns and operates hydrogen production facilities, distribution systems, and fuelling stations in B.C., Quebec, Alberta and California. The company began in 2005 and operates in North Vancouver. In collaboration with the Province and other partners, HTEC has opened four retail hydrogen fuelling stations in B.C., the largest network in Canada. Further, HTEC draws upon its deep industry experience, know-how and technologies to provide customized engineering services and packaged hydrogen production, processing, distribution and vehicle-fuelling solutions for its infrastructure platform and clients.

"Government policy will facilitate hydrogen's role in decarbonizing our world. Policies such as B.C.'s Zero-Emission Vehicles Act and low carbon fuel standard make it possible for fuel suppliers to deliver low-carbon-intensity fuels and give consumers the choice to drive hydrogen electric vehicles. HTEC couldn't lead the rollout of Canada's first network of hydrogen fuelling stations without the support of the Province and our other partners; we thank all for their shared commitment to fuelling the drive to hydrogen."

– Colin Armstrong, President & CEO
Hydrogen Technology & Energy Corporation

How we'll encourage the growth of hydrogen in transportation
2020-2025
• Pilot the use of hydrogen fuel cells in medium- and heavy-duty vehicles, marine, rail, aviation, off-road and other commercial transportation applications • Continue to leverage the Part 3 Agreement program to expand the public hydrogen fuelling station network across the province • Explore the roles FCEVs can play in supporting achievement of CleanBC commitments to make 10% of the BC government light-duty fleet ZEVs and reduce its emissions by 40% by 2030 • Provide monetary and non-monetary incentives for fuelling infrastructure and vehicle purchase • Allow medium- and heavy-duty vehicle sales to generate credits under the ZEV Act • Explore ZEV Act compliance targets for medium- and heavy-duty vehicle classes • ZEVs reach 10% of new light-duty vehicle sales by 2025
2025-2030
• Review and expand the pilot demonstration use of hydrogen fuel cells in medium- and heavy-duty vehicles, marine, rail, aviation, off-road and other commercial transportation applications • Include targets for medium- and heavy-duty vehicles in the ZEV Act • Support the development of hydrogen production and liquefaction infrastructure • ZEVs reach 30% of new light-duty vehicle sales by 2030
2030-beyond
• Continue to support the widespread use of hydrogen in medium- and heavy-duty vehicles, marine, rail, aviation, off-road and other commercial transportation applications • ZEVs reach 100% of new light-duty vehicle sales by 2040

Producing low-carbon and synthetic fuels

Using hydrogen to produce low-carbon and synthetic fuels is an opportunity to reduce emissions in B.C.'s transportation and refining sectors.

To increase the supply of cleaner fuels, CleanBC set out a target to ramp up production of renewable fuel in B.C. to 650 million litres by 2030. The B.C. low carbon fuel standard (LCFS) also requires fuel suppliers to progressively decrease the average carbon intensity of their fuels to achieve a 20% reduction in 2030 relative to 2010. This can be achieved by increasing the volume of biofuels blended with conventional fossil fuels or by supplying lower-carbon fuels such as hydrogen and electricity. Fuel suppliers generate credits by supplying fuels with a carbon intensity below the prescribed target. These credits can be used to comply with the LCFS or sold in the credit market to generate additional revenue. The LCFS encourages suppliers to offer lower-carbon fuels, such as hydrogen, in the B.C. fuel market.

In addition to setting annual carbon-intensity reduction requirements, the LCFS spurs growth in the clean fuels industry through the Part 3 Agreement Program. Under this program, fuel suppliers can obtain credits for undertaking projects that increase the use of low-carbon fuels sooner than would otherwise happen. The Province will continue to use existing policy mechanisms, such as the LCFS and the Part 3 Agreement Program to promote innovation while reducing GHG emissions resulting from the use of lower-carbon fuels. Since 2019, 23 projects have awarded over 800,000 credits and committed to investing over $450 million in emissions reductions in the B.C. fuels industry and the Part 3 Agreement Program to accelerate market transformation.

In the fossil fuel sector, hydrogen is used to refine crude oil into products that include gasoline, diesel and jet fuel. Since much of this hydrogen is currently produced from fossil fuels without CCS, finding ways to reduce the emissions from hydrogen production at refineries will also reduce the life-cycle emissions of these products. Hydrogen is also used in large quantities when making renewable fuels, such as co-processing biocrudes from renewable sources like canola oil or oil derived from animal fats (tallow). The Province is focusing efforts to deploy hydrogen use in low-carbon and synthetic fuel production, as these fuels can be used to decarbonize hard-to-abate sectors such as long-distance trucking, marine and aviation.

Carbon Engineering

Capturing carbon dioxide to make clean fuel

A licensed partner of Squamish-based Carbon Engineering Ltd., Huron Clean Energy is developing multiple clean fuel synthesis plants, beginning in B.C. and then deploying across Canada. Carbon Engineering's breakthrough Direct Air Capture and AIR TO FUELS™ technologies are used to create clean fuel out of air. When carbon dioxide captured from the atmosphere is combined with renewably generated hydrogen, clean fuel is produced. This clean, near-carbon-neutral fuel can be used in all existing transportation infrastructure as a replacement fuel or blended with current fuels such as gasoline, diesel or aviation Jet A to lower the carbon intensity of those fuels. Access to large quantities of low-carbon hydrogen produced in B.C. will be key in enabling these plants to deliver industrial quantities of clean fuels for the aviation and diesel markets.

Decarbonizing industrial processes

In addition to reducing the carbon intensity of fossil fuels used in hard-to-abate transportation sectors, low-carbon hydrogen can also be used to decarbonize industrial processes that are not practical to electrify or that require hydrogen as a feedstock. For example, many industrial processes require natural gas to produce process heat at temperatures that cannot be achieved through electrification. Additionally, the largest current use for hydrogen in Canada and internationally is as an essential feedstock in emissions-intensive industrial processes.

Hydrogen's decarbonization benefits and heating attributes mean that it can be used to displace natural gas and reduce the emissions from many high heat industrial processes. Industrial processes that require large amounts of high-grade heat include upstream fossil fuel extraction and downstream refining, cement manufacturing, pulp and paper processing, and other steam reliant processes.[9]

The demand for hydrogen today is driven by industries that require it as a feedstock, primarily in oil refining, ammonia production, methanol production and steel production.[10] As the vast majority of hydrogen used in these industries is produced from fossil fuels without CCS, low-carbon hydrogen presents an alternative that can reduce the carbon intensity of final products.

How we'll support industry to increase hydrogen use
2020-2025
• Evaluate the use of hydrogen across different heavy industries, such as at pulp and paper mills, cement plants, petroleum refineries and aluminum smelters to reduce emissions and create economic development • Support pilots for the use of low-carbon hydrogen for synthetic fuel production • Explore carbon-intensity targets under the low carbon fuel standard
2025-2030
• Review the success of pilot projects across B.C.'s industries • Support the use of hydrogen across industries in B.C., including refining biocrude and producing synthetic fuels • Support the use of hydrogen in small and medium-size industrial businesses • Support hydrogen's contribution to the CleanBC targets of producing 650 million litres of renewable or low-carbon fuels per year and the low carbon fuel standard reaching 20% reduction in carbon intensity by 2030
2030-beyond
• Where appropriate, support the use of low-carbon hydrogen in industrial processes, such as in pulp and paper mills, petroleum refining and aluminum smelting

9 Government of Canada, *Hydrogen Strategy for Canada* (2020).
10 International Energy Agency, *The Future of Hydrogen: Seizing Today's Opportunities* (2019).

Hydrogen hubs

One of the challenges facing hydrogen development in B.C., and around the world, is matching supply and demand. Regional hydrogen hubs overcome this challenge by co-locating hydrogen production and end-use applications. Through co-location, hydrogen hubs generate early and focussed opportunities for domestic hydrogen production and use in areas otherwise heavily dependent on fossil fuels by spurring and growing supply and demand, lowering costs and strengthening local hydrogen proficiency.

The concept of hydrogen hubs fits well with B.C.'s abundance of clean electricity and natural gas resources, established local hydrogen companies and variety of end-use applications. Supporting hydrogen hubs in B.C. is critical to accelerating domestic hydrogen supply and demand, while also realizing the significant economic opportunities in developing B.C.'s hydrogen export market. The Province is committed to identifying regions that can support and realize the greatest decarbonization benefits of hydrogen hubs, such as seaports, industrial sites and urban locations like UBC's city-scale hydrogen testbed.

Fuelling economic development

Hydrogen is both a clean energy solution and an economic development opportunity for B.C.

Hydrogen's key contribution to B.C.'s net-zero economy

Hydrogen is not only key in B.C.'s path to net-zero emissions by 2050, but also to building a prosperous low-carbon economy with new clean energy jobs. Home to Canada's largest cluster of hydrogen companies, B.C. has the unique opportunity to leverage an already successful local hydrogen sector to grow its hydrogen economy. Low-carbon hydrogen's decarbonization attributes present an opportunity for B.C. to reduce emissions and support the scale-up of B.C.-based hydrogen companies with expertise in low-carbon technologies and innovation. All of this will be in high demand as B.C. and many countries around the world pursue net-zero targets.

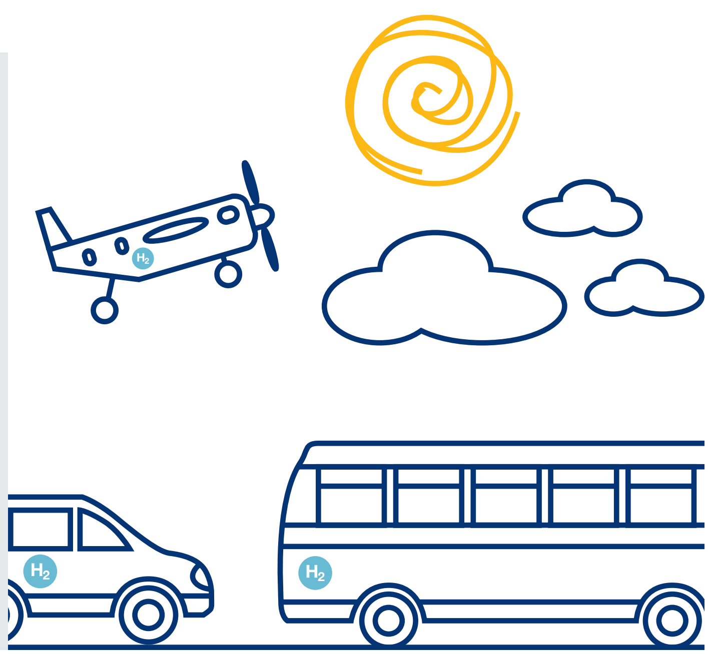
In April 2021, the Province committed $35 million to establish the Centre for Innovation and Clean Energy (CICE) as part of StrongerBC. The CICE will bring together innovators, companies, government and researchers to accelerate the commercialization of clean energy technology and products, including low-carbon hydrogen.

Zero-emission vehicles call for technicians with new skills

As zero-emission cars gain in popularity, there's a growing need for technicians and mechanics who can service these vehicles. The Province provided $325,000 in funding to the British Columbia Institute of Technology to develop a first-of its-kind training course for certified Red Seal automotive service technicians to upgrade their skills for zero-emission vehicles. The curriculum was designed in partnership with the City of Vancouver's green-fleet technicians and includes course modules for servicing battery electric, plug-in hybrid and fuel cell electric vehicles. The course will be offered throughout the province in Kelowna, Prince George and Victoria.

UBC's Hydrogen Hub
A city-scale testbed

With support from the Ministry of Energy, Mines and Low Carbon Innovation, the University of British Columbia has broken ground on a project that brings the production, distribution and end use of hydrogen together on one city block at the corner of Wesbrook Mall and Thunderbird Boulevard in Vancouver. The Integrated Energy Test Bed uses a solar array to charge electric vehicles and power a water electrolyzer. The produced hydrogen feeds a refuelling station for light- and heavy-duty fuel cell vehicles.



Hydrogen in Indigenous and remote communities

There are up to 50 remote communities in B.C. that are not connected to the natural gas or electricity distribution systems, and as a result experience energy-related challenges and opportunities that are very different from grid-connected communities. Numerous remote communities rely on diesel-powered generators to meet their power needs, and as part of CleanBC, the Province has set a target of reducing diesel generation of electricity province-wide by 80% by 2030.

Many Indigenous Nations are interested in adopting clean energy solutions that will reduce their carbon footprint, strengthen community resilience, achieve energy self-sufficiency and increase economic opportunities for their communities. Hydrogen is a potential energy resource to achieve each of these objectives, either from cleaner back-up power, fuel cell electric vehicles or increased economic activity. The Province will engage with interested Indigenous Nations to explore whether there are opportunities to be involved in developing, owning and operating hydrogen infrastructure and services.

Hydrogen-powered microgrids, which can deliver combined heat and power, have the potential to stimulate economic development opportunities. This may come in the form of employment, investment and potential for joint ownership with industry. Hydrogen-powered microgrids may also benefit communities by shifting reliance away from high-carbon-emitting generation technologies, lowering GHG emissions, improving air quality, reducing noise pollution and eliminating diesel spills.

Communities may consider building out hydrogen fuelling infrastructure to promote the uptake of fuel cell electric vehicles, which maintain high performance even during extreme cold or heat. Diesel-reliant communities may also be interested in integrating hydrogen with renewable resources to power their communities. For example, in areas where electricity can be generated from wind resources, communities could store energy using hydrogen for later use, thereby minimizing the impacts of intermittency.

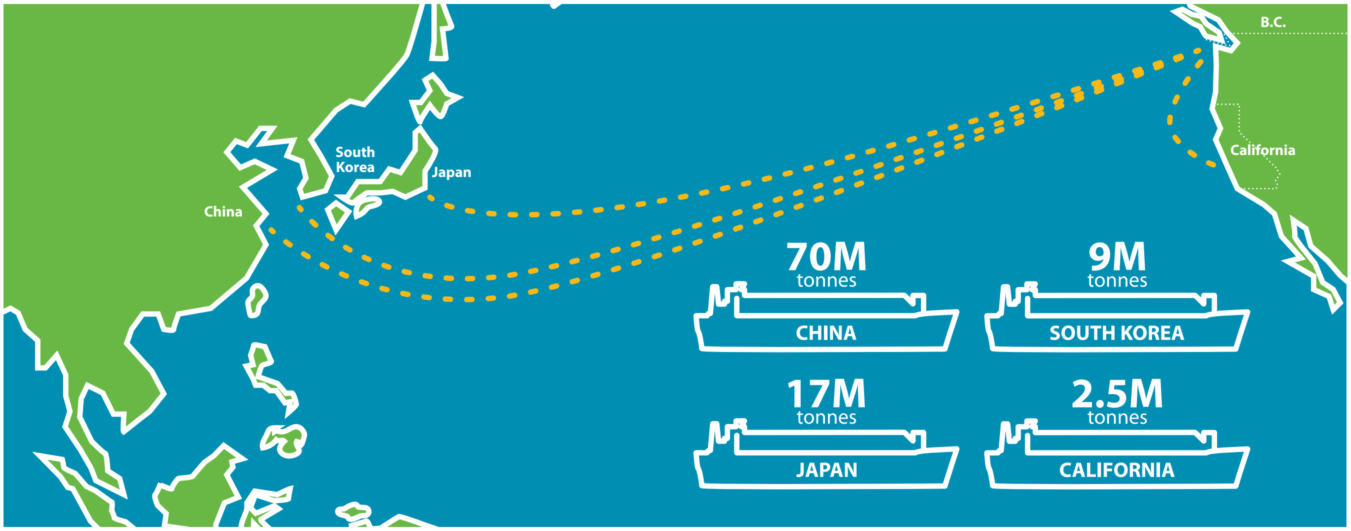
There are several potential applications for hydrogen in remote communities. The Province recognizes that a one-size-fits-all approach for hydrogen is not possible, as each community differs in size, climate, geography and energy requirements. Furthermore, production, storage and distribution costs may be a challenge depending on scale, technology and site location. The Province will look to understand the potential opportunities of hydrogen with interested communities and explore what options exist for capacity building and clean energy planning.

Declaration on the Rights of Indigenous Peoples Act

The Government of B.C. is committed to advancing reconciliation with Indigenous peoples through the implementation of the *Declaration on the Rights of Indigenous Peoples Act*. Consistent with this legislation, the Province acknowledges the need to consult and co-operate with Indigenous Nations early and in good faith to obtain their free, prior and informed consent relating to adopting and implementing hydrogen-related legislative or administrative measures that may affect them.

How we'll advance hydrogen as a source of clean energy in communities
2020-2025
Commission a comprehensive study for hydrogen in communities, including: • Education and engagement on the potential for hydrogen • Novel applications of hydrogen (e.g., phasing out propane) • Capacity-building tools for community clean energy and hydrogen projects • A case study with a small to medium-sized fossil-fuel-reliant community to investigate the feasibility of moving to 100% renewable energy with a hydrogen component
2025-2030
• Implement findings and results from the community feasibility study • Introduce capacity-building tools for community clean energy and hydrogen projects
2030-beyond
• Support the conversion of a small to medium-sized fossil-fuel-reliant community to hydrogen • Promote the installation of hydrogen to power communities

Exporting hydrogen



Demand projections by jurisdiction in 2050

Jurisdictions around the world are seeking ways to meet emissions reduction goals and are recognizing the role that hydrogen can play to help them meet ambitious targets. The global market for hydrogen is expected to reach more than 230 million tonnes in 2050. B.C. is well-positioned to meet a portion of this demand due to our extensive low-cost natural gas reserves, clean electricity, proximity to key trading partners and existing natural gas infrastructure that can be leveraged for exporting hydrogen.

The top export markets of China, Japan, South Korea and California are predicted to account for almost 50% of total global demand for hydrogen by 2050 with a combined market size of $305 billion.[11] If B.C. can capture even a fraction of this export market, it will result in significant export revenue for the province. Our proximity to these markets and their advanced plans for the adoption of hydrogen at scale further strengthens B.C.'s export potential.[12]

The *BC Hydrogen Study* estimates that B.C.'s potential production capacity could be over 2.2 million tonnes annually. Our experience and proven capabilities in producing and exporting natural resources makes for a potentially smooth transition to exporting hydrogen. This demand for hydrogen could be met through various production pathways, with transportation choices based on geography, volume, distance and end-use. The Province will continue to engage with industry stakeholders and our international partners to create export supply chains and foster support for hydrogen.

[11] Zen and the Art of Clean Energy Solutions, *BC Hydrogen Study - Final Report* (2019).
[12] ITM Power, Chiyoda Corporation, Mitsui & Co. and G&S Budd Consulting, *Centralized Renewable Hydrogen Production in BC - Final Report* (2019).

How we'll develop B.C.'s export market for hydrogen
2020-2025
• Collaborate with industry stakeholders and international partners regarding export opportunities • Promote B.C. internationally as an attractive jurisdiction for investment in hydrogen production for domestic supply and export • Continue to promote B.C.'s fuel cell technology abroad and promote the province as a supplier of low-carbon hydrogen to global markets
2025-2030
• Attract domestic and international investment for the development of supply chains to export hydrogen
2030-beyond
• Enable the construction of dedicated infrastructure for hydrogen export

Measuring our success

These Measures of Success will guide us as we continue to grow our vibrant and innovative hydrogen and fuel cell sector in B.C.

Measures of Success	
Jobs and prosperity	• B.C. maintains its position as a leader in fuel cell development with a diverse talent pool of highly qualified personnel • B.C. experiences job growth in trades as a result of a hydrogen production industry • Indigenous communities are supported in identifying possible pathways for partnerships and participation in the growing hydrogen sector
Competitive	• B.C. develops multiple hydrogen hubs that accelerate the growth of the local hydrogen economy • B.C. produces hydrogen that is a cost-effective energy resource for British Columbians • B.C. maintains its competitive position regarding the commercialization of hydrogen and fuel cell technology
Innovation	• B.C. continues to have a highly innovative hydrogen and fuel cell technology sector • B.C. has world-class hydrogen production supply chains as well as a supportive research and development environment
Clean	• The carbon intensity of hydrogen produced in B.C. declines over time • The hydrogen industry uses water sustainably and continues to look for innovative ways to maximize efficient water usage
Communities	• Benefits flow back to Indigenous and non-Indigenous communities where hydrogen production facilities are located • Hydrogen is a cost-effective option for diesel-reliant Indigenous and non-Indigenous communities to achieve their climate objectives
Hydrogen exports	• B.C. exports hydrogen to key markets and meets a portion of international demand • Hydrogen exports provide a net benefit to British Columbians • B.C. is seen as an attractive jurisdiction for domestic and international investment in hydrogen

Summary of policy actions

As outlined throughout this Strategy, the Government of British Columbia is committed to providing the policy, regulatory and infrastructure support needed to realize hydrogen's potential to help us meet our emissions reduction goals. The following actions for the next 10 years and beyond will enable us to achieve our vision to be a world-leading hydrogen economy by 2050.

How we'll grow hydrogen production
2020-2025
• Stimulate hydrogen production through direct support and incentives • Continue to provide policy support for increasing hydrogen demand certainty and de-risking the development of hydrogen production infrastructure • Provide policy support to utilities who choose to produce or purchase hydrogen • Advocate for increased production and consumption of hydrogen in B.C. • Work with industry partners to establish hydrogen deployment hubs in B.C.
2025-2030
• Consider introducing alternative electricity rate designs to support hydrogen production • Promote hydrogen production at scale to meet domestic and/or international demand • Determine if brownfield sites can be used for industrial parks that include hydrogen production
2030-beyond
• Support long-term self-sufficiency in hydrogen supply and with it introduce new opportunities for economic development • Support the development of hydrogen liquefaction, distribution and transmission infrastructure
How we'll regulate hydrogen production
2020-2025
• Review provincial, federal and international codes, standards and regulations for hydrogen production and establish a compatible regulatory framework • Amend regulations to allow the BC Oil and Gas Commission to regulate hydrogen production, storage and transportation if produced from fossil fuels • Amend *Water Sustainability Act* related regulations to include hydrogen production as an authorized industrial water use purpose and set new water fees and rentals • Enable hydrogen as a pathway for natural gas utilities to reduce emissions • Ensure regulatory frameworks relating to hydrogen production and use are aligned to encourage continued reductions in carbon intensity over time • Establish carbon-intensity targets for hydrogen production pathways • Provide support only for renewable or low-carbon hydrogen pathways • Establish a working group made up of representatives from the hydrogen industry, regulatory agencies and government to implement B.C. Hydrogen Strategy actions

2025-2030

- Continue to implement the Low Carbon Fuel Standard Part 3 Agreements to advance hydrogen production, fuelling infrastructure, operation and maintenance projects
- Review sectoral opportunities for hydrogen offtake
- Develop carbon management frameworks to encourage at-scale production of low-carbon hydrogen and transition policy incentives from direct support to market-based mechanisms

2030-beyond

- Achieve a clear and supportive regulatory environment for hydrogen production in B.C.
- Require a phased reduction in the carbon intensity of hydrogen produced and used in B.C.
- Explore policy framework mechanisms for long-duration energy storage using hydrogen

How we'll support blending hydrogen with natural gas

2020-2025

- Establish a regulatory framework for injecting hydrogen into the natural gas and propane distribution systems
- Include hydrogen as a prescribed undertaking under the *Greenhouse Gas Reduction Regulation*
- Partner with a utility to review the infrastructure requirements to accommodate up to 100% hydrogen in the distribution system
- Support hydrogen injection trials into natural gas and/or propane distribution systems

2025-2030

- Mandate that new or modified natural gas or propane pipelines be hydrogen compatible
- Support the introduction of hydrogen-tolerant equipment
- Explore the role of hydrogen in meeting the CleanBC 15% renewable gas target

2030-beyond

- Support large-scale hydrogen injection into the natural gas and propane distribution systems

How we'll encourage the growth of hydrogen in transportation

2020-2025

- Pilot the use of hydrogen fuel cells in medium- and heavy-duty vehicles, marine, rail, aviation, off-road and other commercial transportation applications
- Continue to leverage the Part 3 Agreement program to expand the public hydrogen fuelling station network across the province
- Explore the roles FCEVs can play in supporting achievement of CleanBC commitments to make 10% of the BC government light-duty fleet ZEVs and reduce its emissions by 40% by 2030
- Provide monetary and non-monetary incentives for fuelling infrastructure and vehicle purchase
- Allow medium- and heavy-duty vehicle sales to generate credits under the ZEV Act
- Explore ZEV Act compliance targets for medium- and heavy-duty vehicle classes
- ZEVs reach 10% of new light-duty vehicle sales by 2025

2025-2030
• Review and expand the pilot demonstration use of hydrogen fuel cells in medium- and heavy-duty vehicles, marine, rail, aviation, off-road and other commercial transportation applications • Include targets for medium- and heavy-duty vehicles in the ZEV Act • Support the development of hydrogen production and liquefaction infrastructure • ZEVs reach 30% of new light-duty vehicle sales by 2030
2030-beyond
• Continue to support the widespread use of hydrogen in medium- and heavy-duty vehicles, marine, rail, aviation, off-road and other commercial transportation applications • ZEVs reach 100% of new light-duty vehicle sales by 2040
How we'll support industry to increase hydrogen use
2020-2025
• Evaluate the use of hydrogen across different heavy industries, such as at pulp and paper mills, cement plants, petroleum refineries and aluminum smelters to reduce emissions and create economic development • Support pilots for the use of low-carbon hydrogen for synthetic fuel production • Explore carbon-intensity targets under the low carbon fuel standard
2025-2030
• Review the success of pilot projects across B.C.'s industries • Support the use of hydrogen across industries in B.C., including refining biocrude and producing synthetic fuels • Support the use of hydrogen in small and medium-size industrial businesses • Support hydrogen's contribution to the CleanBC targets of producing 650 million litres of renewable or low-carbon fuels per year and the low carbon fuel standard reaching 20% reduction in carbon intensity by 2030
2030-beyond
• Where appropriate, support the use of low-carbon hydrogen in industrial processes, such as in pulp and paper mills, petroleum refining and aluminum smelting

How we'll advance hydrogen as a source of clean energy in communities

2020-2025

Commission a comprehensive study for hydrogen in communities, including:

- Education and engagement on the potential for hydrogen
- Novel applications of hydrogen (e.g., phasing out propane)
- Capacity-building tools for community clean energy and hydrogen projects
- A case study with a small to medium-sized fossil-fuel-reliant community to investigate the feasibility of moving to 100% renewable energy with a hydrogen component

2025-2030

- Implement findings and results from the community feasibility study
- Introduce capacity-building tools for community clean energy and hydrogen projects

2030-beyond

- Support the conversion of a small to medium-sized fossil-fuel-reliant community to hydrogen
- Promote the installation of hydrogen to power communities

How we'll develop B.C.'s export market for hydrogen

2020-2025

- Collaborate with industry stakeholders and international partners regarding export opportunities
- Promote B.C. internationally as an attractive jurisdiction for investment in hydrogen production for domestic supply and export
- Continue to promote B.C.'s fuel cell technology abroad and promote the province as a supplier of low-carbon hydrogen to global markets

2025-2030

- Attract domestic and international investment for the development of supply chains to export hydrogen

2030-beyond

- Enable the construction of dedicated infrastructure for hydrogen export

Appendix A-5

CLEANBC ROADMAP TO 2030

BRITISH COLUMBIA

cleanBC

our nature. our power. **our future.**

Roadmap to 2030

LAND ACKNOWLEDGEMENT

We acknowledge with respect and gratitude that this report was produced on the territory of the Lək̓ʷəŋən peoples, and recognize the Songhees and Esquimalt (Xwsepsum), and W̱SÁNEĆ Nations whose deep connections with this land continue to this day.

CONTENTS

A MESSAGE FROM PREMIER JOHN HORGAN

Here in British Columbia, people share a deep connection to the clean water, abundant forests and rich farmland around us. Our province's landscape is a source of beauty, food and economic opportunities. It is a source of great pride for all of us. There is simply nothing more important than protecting this natural inheritance for future generations.

Today, the things we cherish the most in B.C. are at risk like never before.

While we are living through a time of uncertainty and overlapping crises, the greatest challenge we face now and into the future is climate change. The threat is no longer decades or even years away. The impacts are all around us – from devastating wildfires and intense heat waves to droughts and dying crops.

Three years ago, our government introduced CleanBC – North America's most progressive climate action plan. In that time, we have regulated carbon emissions from the biggest polluters, legislated strong climate targets, and made it easier for people and businesses to switch from fossil fuels to clean energy solutions.

The scale of the climate emergency we are living through demands that we act with even greater urgency.

We have accomplished a lot together, but there is so much more we need to do. As British Columbians, we know we can't afford to delay action. That's why we're taking the next big step on our continent-leading plan and introducing new measures so that we can meet our Paris emissions reduction targets for 2030 and reach net zero by 2050.

The CleanBC Roadmap builds on the progress we've made. It will help power more businesses and communities with clean, renewable hydro power. Working with large industry partners, it will ensure sector-specific plans to reduce their climate pollution. Most importantly, it will encourage innovation of clean alternatives, which will become more affordable to British Columbians.

In developing this Roadmap, we listened to input from people across British Columbia – including consultation with Indigenous leaders and expert advice from the Climate Solutions Council. As the plan is rolled out, we will seize the opportunity to build stronger partnerships with Indigenous peoples by ensuring they share in decision making and the prosperity created in the low carbon economy.

Tackling climate change is not only our greatest challenge. It's also an opportunity to build a stronger, more resilient B.C.

The world has changed since we first launched CleanBC. But our province is uniquely well-positioned to thrive in the emerging clean economy. We have abundant clean energy and renewable resources. We are strategically located as a gateway to the Asia-Pacific region and a major port to the rest of North America.

By far our biggest asset is our people. If the recent forest fires and the pandemic have taught us anything, it's that we're best when we work together. It is that same sense of common purpose that we must bring to the fight against climate change. No one person, or government, can turn things around on their own. It will take all of us doing our part to seize the opportunity in overcoming this historic challenge.

That's what this plan is all about. Working together to chart a path to a cleaner, brighter future with good jobs and opportunities – for everyone.

Honourable John Horgan
Premier of British Columbia

A MESSAGE FROM MINISTER GEORGE HEYMAN

When we launched CleanBC in 2018 we were very clear that our modelling left us with an emissions gap. We needed to intensify our focus across all sectors to hit our emissions reduction goal by 2030. We have since introduced legislatively enforced accountability measures that support the findings of recent landmark reports from the Intergovernmental Panel on Climate Change and others. In short, everyone needs to do more to address climate change.

CleanBC set out a series of actions to begin a 30-year journey to build opportunity, keep communities strong and sustain human and ecological health. In many respects it set a standard for others to reference given its comprehensive approach. The Roadmap to 2030 takes its lead from CleanBC and takes us even further. In fact, it takes us to 100 percent of the achievement of our 2030 emissions reduction target and sets the course to fulfill our net-zero commitment by 2050.

The Roadmap is a clear articulation of where we need to expand and accelerate our action to reduce greenhouse gas emissions. It takes note of where things are showing signs of early success and where renewed approaches are necessary. It creates the opportunity for new partnerships like bringing together B.C.'s burgeoning clean tech sector with traditional industries to position B.C. products and services for new and evolving markets. Increasingly global investors are recognizing climate-centred technologies as critical in how we transition to living better on the planet. British Columbia is ideally positioned to take advantage of these new opportunities and the Roadmap supports that case.

A number of the actions will show rapid results as we commit to meeting or exceeding the federal benchmark on carbon pricing, enact requirements for all new buildings to be zero carbon by 2030 and eliminate emissions from all new cars by 2035. As these new technologies come on stream we will increase clean energy and fuel efficiency to support the transition.

Like all maps, the purpose of the Roadmap is to set the direction and offer choices to guide our efforts as we continue to track progress. It will allow us to anticipate challenges and potential changes in course. It expands on the principles of fairness and equity so that costs and benefits are evenly distributed as we introduce new measures.

The plan laid out in the pages that follow is admittedly technical. The tables, charts and analysis tell a story to help decision-makers across all sectors reach our goals. They are tools to help construct that better future we all want for our children and their children. In developing this plan we have not lost sight for one moment that ultimately the Roadmap is about people. It is about our connection to place, a place that we are seeing with new eyes through the lens of reconciliation and renewed relationships with Indigenous peoples. Our success will ultimately be determined by the way our natural environment responds to our choices in this journey. I am confident that with the Roadmap focusing our efforts we will arrive at our destination and more importantly we will all arrive together.

George Heyman
Minister of Environment and Climate Change Strategy

EXECUTIVE SUMMARY

The need to take urgent action together to reduce the impacts of climate change and build a strong clean economy for everyone has never been clearer than it has this past year. Two international reports outlined the challenge ahead and called for faster action. The landmark study from the Intergovernmental Panel on Climate Change[1] provided the latest scientific consensus on climate change and was characterized as a 'code red for humanity' by leading scientific and climate experts.

In British Columbia, we saw the impacts first-hand with an unprecedented heat wave, severe droughts and dangerous wildfires this past summer. These events were a poignant example of how serious the climate crisis is and why we need to act now.

Challenges and opportunities

This spring, the International Energy Agency also released a detailed report[2] outlining the challenges and opportunities of meeting net-zero emissions globally by 2050. The report acknowledged that countries around the world are struggling to meet the moment with policies and plans to reduce emissions and create a vibrant, resilient low carbon future.

The last year saw growing recognition in the financial and business community that business-as-usual is no longer an option. Global investors like the Glasgow Financial Alliance for Net Zero – representing over $80 trillion (USD) in investment capital – have called for an accelerated transition to net-zero emissions by 2050 at the latest. Increasingly, investors are asking for detailed plans outlining how companies can prosper in a carbon-constrained world as a prerequisite for investment.

1 International Energy Agency. (May 2021). Net Zero by 2050. Available online: www.iea.org/reports/net-zero-by-2050
2 Intergovernmental Panel on Climate Change. (2021). Sixth Assessment Report. Available online: www.ipcc.ch/assessment-report/ar6

These significant developments in the global economy represent major opportunities for British Columbia. Our province's CleanBC plan includes a wide range of actions to reduce emissions, build a cleaner economy and prepare for the impacts of climate change. Launched in late-2018, CleanBC is helping improve how we get around, heat our homes and power our industry – setting us on the path to a cleaner, stronger future. It includes groundbreaking policies that are leading the way forward on climate change. For example, we were the first in the world to make it law that all new car and truck sales would be zero-emission vehicles by 2040. Since that time, we've seen the highest uptake in electric vehicle purchases on the continent, thanks in part to CleanBC incentives and investments that make 'going electric' more affordable and convenient.

Across B.C., we have seen industries and businesses respond both to CleanBC actions and to the new global economic environment. At least half of all emissions from large operators in B.C. are now covered by a corporate commitment to reach net zero by 2050. We've worked with industry to accelerate this transition by investing in new technologies that reduce emissions and support good jobs for people. And we are accelerating industrial decarbonization by utilizing one of B.C.'s strongest assets in the fight against climate change – our supply of clean, abundant, and affordable hydro-electricity.

While we have made enormous progress in a few short years, we know there is much more to do. B.C. has not been immune to the challenges faced by other jurisdictions trying to reach their targets.

As required by our climate accountability legislation, government presents the latest information every year on progress to our emissions targets. New emissions projections show the road ahead is significantly more challenging than when CleanBC was originally launched in 2018.

While there are several reasons for this shift – including revised emissions methodology from the federal government – it's clear that substantial new and sustained action is required to meet our commitments.

The CleanBC Roadmap to 2030 is our plan to achieve 100% of our emissions target while building a cleaner economy that benefits everyone. It includes a range of accelerated and expanded actions across eight pathways.

- Low Carbon Energy
- Transportation
- Buildings
- Communities
- Industry, including Oil and Gas
- Forest Bioeconomy
- Agriculture, Aquaculture and Fisheries
- Negative Emissions Technologies

The Roadmap will strengthen action in areas already showing positive results, as well as those at the earlier stages of transition. Each action is based on how affordable and available clean solutions are in each market – known as 'market readiness'. If low-carbon technologies are already available and affordable, for example, the

Roadmap will help increase their adoption on a wider scale through targeted supports, regulations and other policies. If technologies are limited in their availability and expensive, actions instead focus on supporting research, development, and commercialization to create affordable, clean options. This approach will help minimize costs and maximize benefits in the long run.

Foundational Roadmap actions include:

- A stronger price on carbon pollution, aligned with or exceeding federal requirements, with built in supports for people and businesses
- Increased clean fuel requirements and doubling the target for renewable fuels produced in B.C. to 1.3 billion litres by 2030
- An accelerated zero-emission vehicle (ZEV) law (26% of new light-duty vehicles by 2026, 90% by 2030, 100% by 2035)
- New ZEV targets for medium- and heavy-duty vehicles aligned with California
- Complete B.C.'s Electric Highway by 2024 and a target of the province having 10,000 public EV charging stations by 2030
- Actions to support mode-shift towards active transportation and public transit
- Stronger methane policies that will reduce methane emissions from the oil and gas sector by 75% by 2030 and nearly eliminate all industrial methane emissions by 2035
- Requirements for new large industrial facilities to work with government to demonstrate how they align with B.C.'s legislated targets and submit plans to achieve net-zero emissions by 2050
- Enhancing the CleanBC Program for Industry to reduce emissions while supporting a strong economy
- Implement programs and policies so that oil and gas emissions are reduced in line with sectoral targets
- A cap on emissions for natural gas utilities with a variety of pathways to achieve it

- New requirements for all new buildings to be zero carbon and new space and water heating equipment to be highest efficiency by 2030
- Implement a 100% Clean Electricity Delivery Standard for the BC Hydro grid
- A new program to support local government climate and resiliency goals with predictable funding
- Support for innovation in areas like low carbon hydrogen, the forest-based bioeconomy and negative emissions technologies
- Household affordability will continue to be a key focus, especially for those who need it most.

British Columbia's plan will be aligned with actions being taken at the federal, municipal and Crown corporation levels. When emissions reductions from these actions are considered, we expect B.C. to further surpass our 2030 emissions target.

These actions and others included in the Roadmap will help drive deeper emissions reductions at a faster pace and support clean economic opportunities.

In less than a decade, people across our province will live, work and play in a cleaner and more prosperous B.C. Almost all new vehicles sold in the province will be zero emissions. We'll see more people walking, biking and taking transit.

Our communities will be more comfortable with less pollution. New homes and buildings will no longer emit carbon pollution and will use energy much more efficiently, saving people money on their energy bills. They will be built using materials that are less carbon intensive. People will have more affordable options to retrofit their homes. The system that delivers natural gas to heat homes and businesses today will transition to also deliver cleaner fuels like renewable natural gas and hydrogen. And more of us will find jobs in the clean economy working to reduce pollution with innovative advanced technologies that are exported beyond our borders.

A central pillar of the Roadmap focuses on our abundant supply of clean and affordable hydroelectric power as an alternative to fossil fuels. B.C. is one of the few jurisdictions in the world with an electricity grid that can deliver close to 100% zero-emissions electricity to power our homes, businesses and vehicles. Further, by pairing this resource with our commitment to innovation and partnership between B.C.'s clean tech sector and traditional industries, we're ensuring B.C. is ideally positioned for a world that is increasingly focused on near-term emissions reductions and reaching net-zero emissions by mid-century.

The Roadmap recognizes that we are at a defining moment of change and need to make sure we're ready for a global economy that is rapidly moving towards a future defined by net-zero emissions. It also builds on other efforts across government including the upcoming Climate Preparedness and Adaptation Strategy and economic plan, as well as work to modernize the forest sector and implement the recommendations of the Old Growth Strategic Review.

Nature often offers the best solutions to strengthening our response to climate change. In British Columbia, we are blessed to have a natural environment that sustains our health, strengthens our communities and builds hope for the future. The Roadmap demonstrates that at the core of our approach to climate change is a foundational commitment to protecting and preserving our environment now and for future generations.

CHAPTER 1: CLEANBC AND THE ROAD TO 2030

1.1 Accelerating Climate Impacts, Accelerating Climate Action

Climate change is often called the defining issue of our time. It demands simultaneous action on two fronts: reducing greenhouse gas emissions and making sure our homes, communities, businesses and infrastructure can withstand the impacts of a changing climate in the years to come.

It's hard work, but British Columbians are rising to the challenge – changing our behavior (what we buy, how we get around, how we heat and cool our homes), our economy (what we produce and how we produce it), and our energy system (how much and what kinds of energy we use, as well as how often we use them). More and more people are choosing electric vehicles, installing heat pumps in their homes and buildings, and investing in low carbon technologies and approaches.

These trends are encouraging. At the same time, we know we need to do much more. The pace and scale of climate change are accelerating, threatening so much of what we hold dear.

B.C.'S NET-ZERO COMMITMENT

Like our current emission reduction targets, B.C.'s commitment to a net-zero future will be backed by legislation. We'll engage with Indigenous communities, local governments, business, industry and others in 2022 to ensure the legislation is consistent with the targets, and the paths to reach them.

Net zero means that any greenhouse gas (GHG) emissions from our economy are balanced by equivalent amounts of GHG removals from the atmosphere. Working to achieve this balance will advance our economy, create good jobs and help to keep us competitive.

Net zero and the new global economic context

On top of these changes, international markets are shifting and demand is growing quickly for new climate-friendly technologies and services, renewable energy and low carbon products. Dozens of countries, accounting for roughly 70% of global GDP, have now adopted net-zero-by-2050 targets. Our neighbours and partners in the Pacific Coast Collaborative – Washington, Oregon and California – are significantly ramping up their own climate actions. And almost 20% of the world's biggest companies – representing annual sales of nearly $14 trillion – now have plans to achieve net-zero emissions by 2050.[3]

During 2020, even with the global downturn created by COVID-19, investment in clean energy and climate solutions grew significantly. Companies and governments around the world put half a trillion dollars into renewable energy, electrified transport, electrified heat, energy storage, hydrogen production, and carbon capture and storage.[4] And B.C. clean tech companies are at the forefront of this transition – with four on the 2021 Global Cleantech 100 list.

GLASGOW ALLIANCE

Over 250 firms with more than $88 trillion in assets have joined forces to steer the global economy towards net-zero emissions. The Glasgow Financial Alliance for Net Zero, chaired by Mark Carney, UN Special Envoy on Climate Action and Finance and former Bank of Canada governor, brings together leading net-zero initiatives from across the financial system to accelerate the transition to net-zero emissions by 2050 at the latest.

Members include major asset owners and managers as well as banks with the power to mobilize trillions of dollars behind the transition to net zero.

Closer to home, the B.C. based Catalyst Business Alliance – a network of companies focused on clean growth – believes that climate change is the greatest risk to jobs and the economy. It champions strong climate and energy policy, and the creation of a resilient economy that benefits customers, employees, communities and the environment.

There's also a growing global movement to ensure that solutions are responsibly sourced and conform to high environmental, social and governance (ESG) standards. Investors with more than $120 trillion worth of assets under management have signed on to the United Nations Principles for Responsible Investment, which advocates a greater focus on ESG investing.

These developments support the business case for increasing our climate ambition. B.C. is well positioned to meet the interests of ESG investors with abundant clean energy, a vibrant clean tech sector, clean industries and a rich, diverse and growing bioeconomy.

3 Taking stock: A global assessment of net zero targets. (23 March 2021). Available online: www.eciu.net/analysis/reports/2021/taking-stock-assessment-net-zero-targets

4 BloombergNEF 2021 Executive Factbook. (March 2 2021). Available online: www.about.bnef.com/blog/bloombergnef-2021-executive-factbook

We're also making progress in partnership with Indigenous peoples, as part of our commitment to implement the Declaration on the Rights of Indigenous Peoples Act. The Province and Indigenous peoples are working together to develop a province-wide, whole-of-government action plan, setting out a path towards reconciliation. The plan will describe the long-term actions needed to meet the objectives of the UN Declaration, along with specific actions the Province will take in the next five years.

We've shown that working together with Indigenous peoples creates more opportunities for everyone. As the plan is implemented, we will have renewed opportunities to build stronger partnerships and better incorporate Indigenous rights, perspectives and interests into provincial climate plans and policies. We have heard clearly from Indigenous peoples about the importance of early and meaningful engagement, and that more can be done to increase capacity to ensure Indigenous peoples can participate most effectively. There is also enormous opportunity that comes with mobilizing Indigenous resources to build new economic opportunities while protecting the environment. We will further strengthen our consultation and engagement work on climate action, including with First Nations Economic Development Officers (EDOs) or similar leadership groups from Nations that don't have EDOs.

Ongoing engagement with Indigenous peoples has informed and shaped this Roadmap, the Climate Preparedness and Adaptation Strategy and our continued partnership on shared climate objectives. This includes work with the First Nations Leadership Council, which is developing a B.C. First Nations Climate Strategy and Action Plan.

These actions are consistent with our commitment to address our greatest challenges in ways that benefit people, communities and the environment, along with the economy. This Roadmap provides another set of opportunities to make our society more inclusive and sustainable – by putting people first and ensuring we consider and mitigate impacts to B.C.'s diverse populations.

> *"I would say with a pretty high degree of confidence that in the next three years a net-zero commitment and a plan to achieve it will be the norm for public companies"*
>
> – Mark Carney, UN Special Envoy on Climate Action and Finance and former Bank of Canada governor[5]

5 Financial Post. (September 21, 2021). Mark Carney says net-zero plan to be 'norm' for public firms in coming years. Available online: https://financialpost.com/news/economy/mark-carney-says-net-zero-plan-to-be-norm-for-public-firms-in-coming-years

1.2 How Does the Roadmap Work?

As we continue to implement the long-term actions in CleanBC, the Roadmap builds on our progress to date with an expanded and accelerated approach to meeting our targets and transforming markets for clean solutions. The Roadmap:

- Examines the eight key areas of our economy that generate emissions or can create solutions
- Assesses our progress in developing and deploying low- and zero-carbon products, approaches and technologies
- Sets out a series of pathways to support innovation in sectors where low carbon solutions are emerging, and drive deployment in sectors where they're already mature – helping to deliver more clean solutions, faster.

Some of the pathways are specific to economic sectors. Others cut across sectors to advance key objectives, such as developing our bioeconomy and exploring the potential of negative emissions technologies. Each pathway describes where we need to be by 2030 and maps out the most promising routes to get there – recognizing that some of these routes break new ground and will only reveal their strengths and weaknesses with time.

Foundational pathway actions to achieve our targets and advance market readiness for decarbonization include:

- Beginning in 2023, B.C.'s carbon tax will meet or exceed federal carbon price requirements, while considering impacts to household affordability. We'll also improve our industry programs to help meet our climate targets by supporting the adoption of new technologies while keeping our businesses competitive.
- New regulations will enhance the Low Carbon Fuel Standard, one of our most successful climate action measures. It requires fuel suppliers to make continuous reductions in their products' carbon intensity. We will double the target for renewable fuels produced in B.C. to 1.3 billion litres by 2030.
- We're accelerating our targets for zero-emission vehicles and we will set new standards for medium- and heavy-duty vehicles aligned with leading jurisdictions. By 2030, ZEVs will account for 90% of all new light-duty vehicle sales in the province (and targets of 26% by 2026 and 100% by 2035).

- We'll complete B.C.'s Electric Highway by 2024 and target having 10,000 public EV charging stations by 2030.
- A comprehensive Clean Transportation Action Plan in 2023 will support emission reductions by focusing on efficiency-first transportation options.
- A reduction of methane emissions from the oil and gas sector will lower emissions by 75% below 2014 levels by 2030, equivalent with the federal commitment. We'll also aim to eliminate methane emissions from oil and gas, mining, forestry and industrial wood waste by 2035.
- New large industrial facilities will be required to work with government to demonstrate how they align with government's 2030 and 2040 targets and submit plans to achieve net-zero emissions by 2050.
- The CleanBC Program for Industry will be enhanced to reduce emissions while supporting a strong economy.
- We'll implement programs and policies so that oil and gas emissions are reduced in line with sectoral targets.
- A greenhouse gas (GHG) cap for natural gas utilities – limiting emissions from the gas used to heat our homes and buildings and power some of our industries – will encourage new investment in low-carbon technologies and fuels (including renewable natural gas and hydrogen) and energy efficiency.
- By 2030, all new buildings will be zero carbon, and all new space and water heating equipment will meet the highest standards for efficiency.
- We'll implement a 100% Clean Electricity Delivery Standard for the BC Hydro grid.
- A new program will support local governments to continue taking climate action.
- We'll support innovation in areas like low-carbon hydrogen, the forest-based bioeconomy and negative emissions technologies.
- Household affordability will continue to be a key focus, especially for those who need it most.

Together, these measures will deliver significant reductions in GHG emissions. But the actions in this Roadmap are not just about climate change. Transforming our economy provides an opportunity to implement solutions that will also build on our broader social, environmental and fiscal priorities. These include:

- Advancing reconciliation with Indigenous peoples
- Improving people's health and well-being
- Spurring innovation in clean technologies that we can use and export to build a stronger economy and drive clean job creation
- Reducing inequalities so everyone has the opportunity to participate in, and benefit from, our growing clean economy
- Attracting investment based on sound ESG credentials.

This Roadmap will serve as an evolving plan to get us to our targets. Climate policy doesn't work if you set it and forget it, so the Roadmap will be updated as we move forward, learn from our experience and craft new solutions to meet our goals.

In the months and years ahead, we will continue to work with Indigenous peoples, recognizing their essential role as climate action partners. Many of the solutions we're developing and pursuing together will affect their territories, creating new opportunities for joint decision-making to advance self-government, self-determination and sustainable economic development in support of the Province's commitment to the *Declaration on the Rights of Indigenous Peoples Act*.

We will also continue working closely with local governments, industry, civil society partners and the independent Climate Solutions Council to further shape our pathways and hone our approaches to meet our targets for 2030 and beyond.

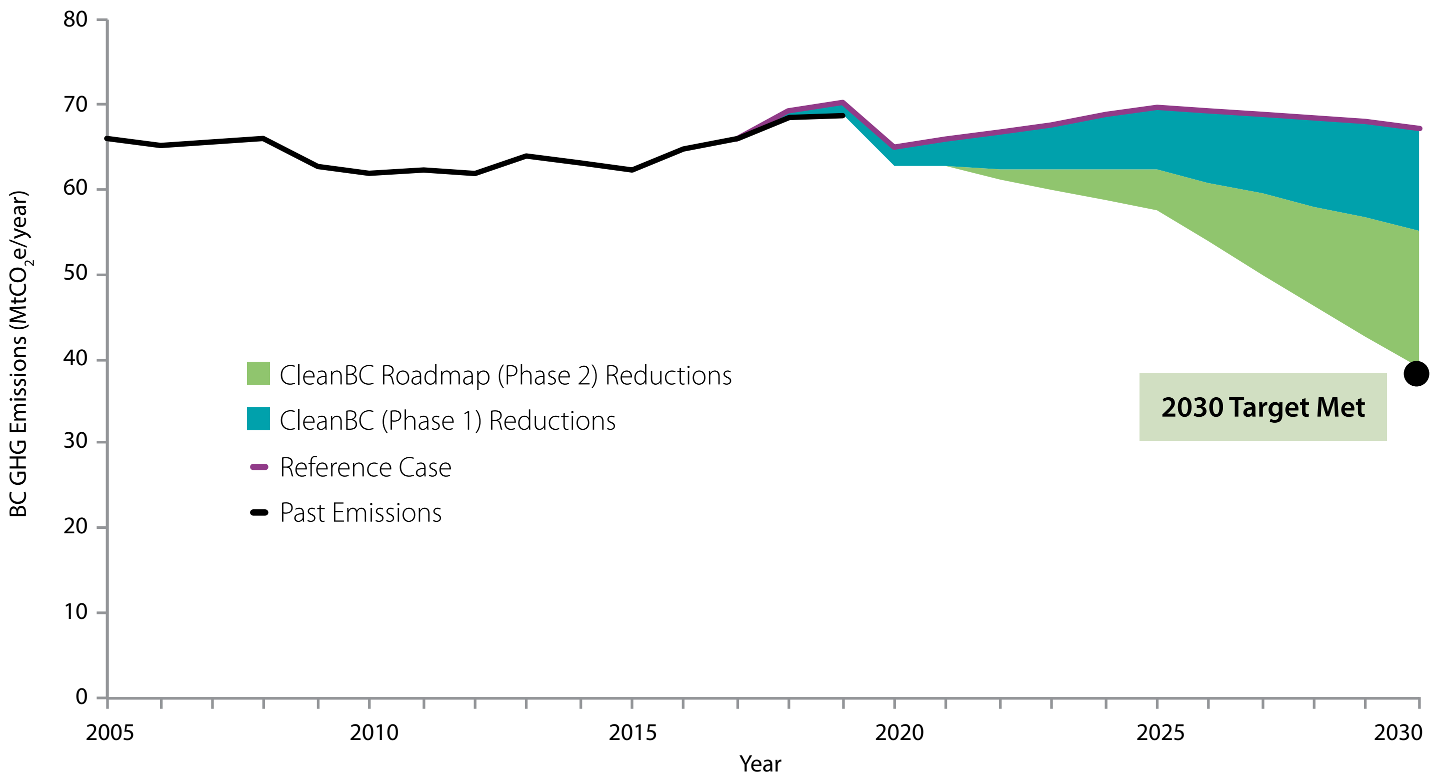
ENGAGEMENT WITH INDIGENOUS PEOPLES

Indigenous peoples across British Columbia were invited to contribute their knowledge and experience during engagements in 2021. The interests, opportunities, ideas and perspectives shared by Indigenous leaders and community members have helped shape the Roadmap to 2030. For example, through these conversations Indigenous peoples:

- Expressed interest in low carbon economic opportunities in their communities
- Affirmed the need for greater affordability and accessibility of CleanBC programs, leading to the commitment to a single-window access for all CleanBC incentives and programs and a renewed focus on affordability in program design
- Emphasized public climate education as key to support community decision making, understanding priorities and the importance of climate action, which influenced the Roadmap commitment to implement public awareness and education campaigns with a dedicated youth strategy
- Highlighted the importance of expanding clean transportation beyond ZEVs to ensure safe and reliable public transportation, which the Clean Transportation Action Plan's "efficiency first" approach will work to address
- Shared the need for cleaner transportation options suited to rural and remote living, contributing to the expansion of the Low Carbon Fuel Standard
- Expressed a desire for skills training to ensure participation in clean growth opportunities, as will be the focus in the upcoming workforce readiness framework
- Noted the high cost of transporting recycling and waste, leading to the commitment to a circular economy strategy.

In each pathway you'll find 'What we heard' boxes that provide examples of the perspectives of Indigenous peoples we worked with in the development of this Roadmap.

CleanBC Emissions Reductions



CLIMATE SOLUTIONS COUNCIL

B.C.'s Climate Solutions Council provides strategic advice on climate action and clean economic growth. It includes members representing Indigenous peoples, environmental organizations, industry, academia, youth, labour and local government. This Roadmap responds to many of the Council's recommendations, including:

- Increasing carbon tax in line with the federal benchmark while providing additional supports for emissions-intensive, trade-exposed industry
- Increasing the zero-emission vehicle standard for light-duty vehicles to between 80 and 100% by 2030
- Implementing medium- and heavy-duty, zero-emission vehicle regulations
- Supporting local governments
- Strengthening the Low Carbon Fuel Standard and implementing a new emissions cap for natural gas utilities.

By increasing the pace and scale of these and other CleanBC initiatives, the council says, "B.C. can both create more stable employment opportunities and achieve additional emission reductions that assist in getting the province on track for our 2030 climate change targets."

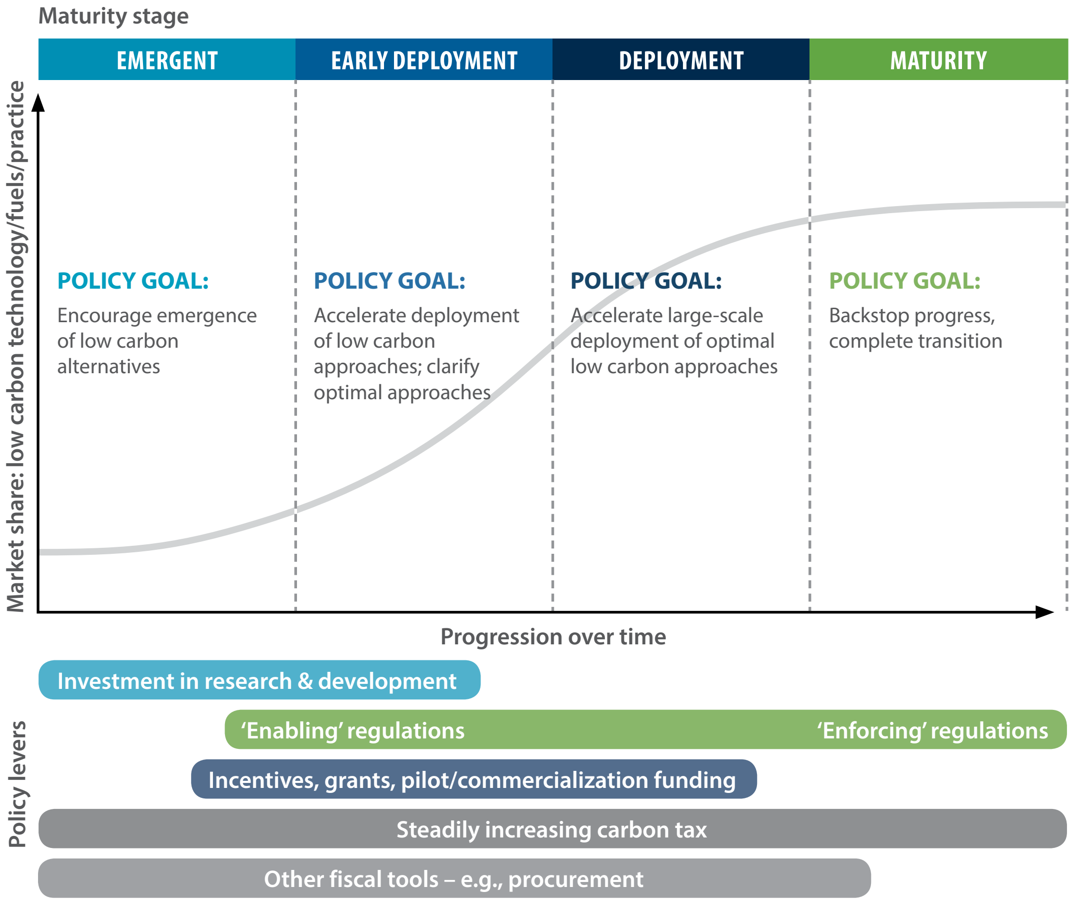
1.3 Climate Solutions – from Innovation to Wide-Scale Implementation

With CleanBC, our province began a set of bold, ambitious actions to transform our economy by shifting away from fossil fuels and towards clean, renewable energy and innovative technology. This Roadmap builds on our work to date and sets the stage for a broader, deeper transformation of large-scale societal systems – from how we produce and use energy to how we build low carbon, climate-resilient communities that keep us safe as the climate changes.

To reach this goal, we're focusing on tailoring approaches for each sector – recognizing that we need different tools for different market stages. Our actions will focus on growing markets for, and speeding up the adoption of, technologies we know are ready for deployment, such as zero-emission vehicles and heat pumps, while supporting research and development in areas where alternative solutions are still emerging.

In all cases, we will prioritize actions that solve unique problems or unlock co-benefits, such as improving people's health or achieving equity outcomes.

Stages of Market Readiness



Adapted from: Victor, D.G. et al. 2019. Accelerating the Low Carbon Transition: The case for stronger, more targeted, and coordinated international action. The Brookings Institution; and Meadowcroft, J. et al. 2021. Pathways to Net Zero: A decision support tool. Transition Accelerator Reports

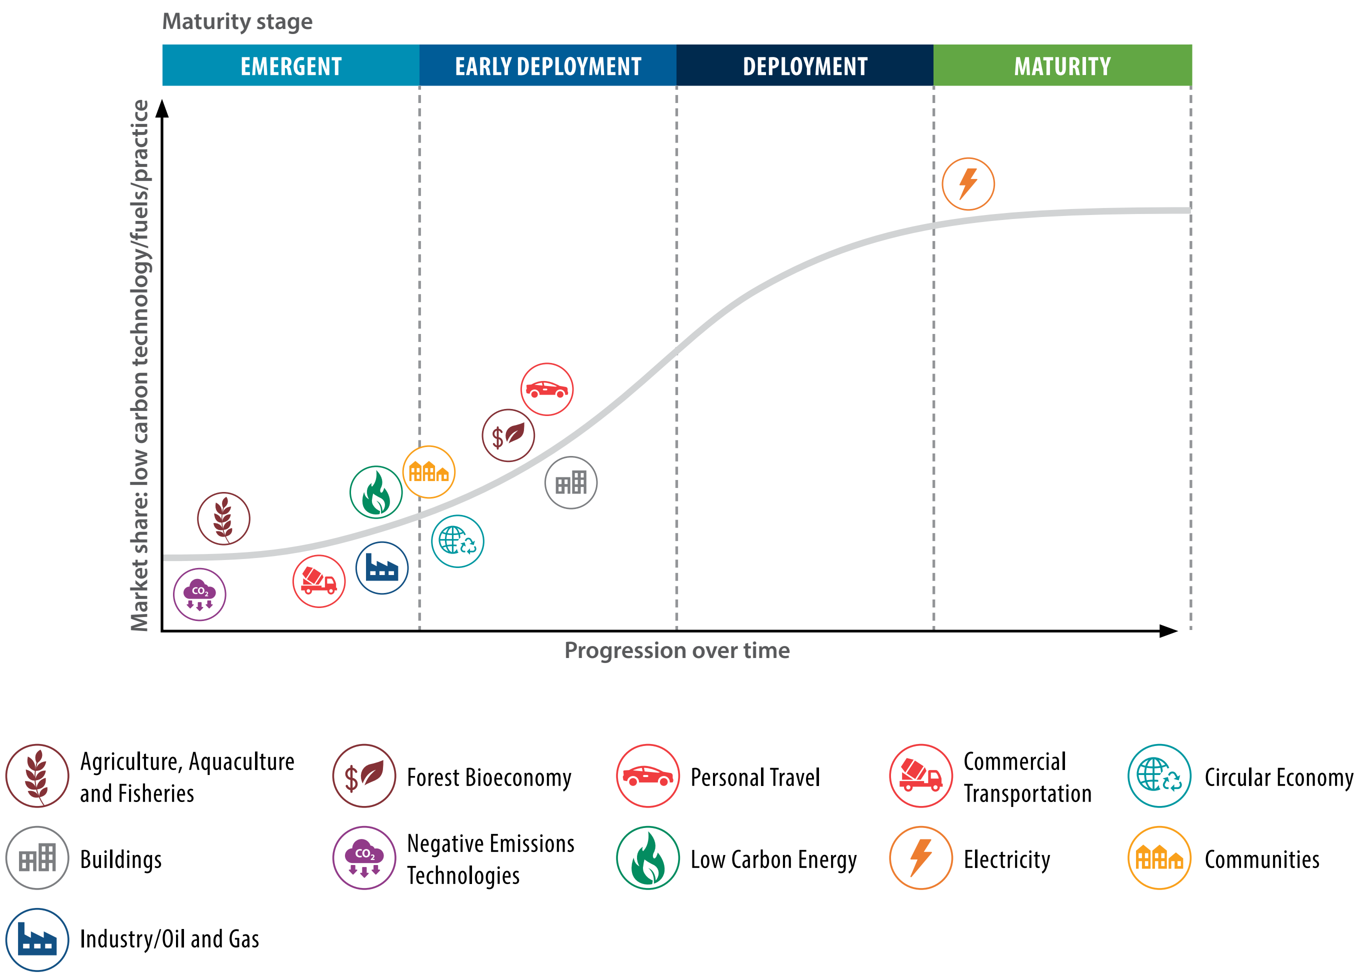
Market readiness indicators

To inform the types of actions needed to drive decarbonization, and to help us track our progress, we're developing a series of readiness indicators, which will be applied across the pathways. The indicators address key issues including:

- Market share of technologies, reflecting the extent to which low-emission solutions are being adopted
- Cost of transitioning to low-emission solutions
- Workforce and skills readiness, reflecting our capacity to adopt new approaches
- Economic and social opportunities, pointing to important co-benefits in areas such as reducing inequality and advancing reconciliation with Indigenous peoples.

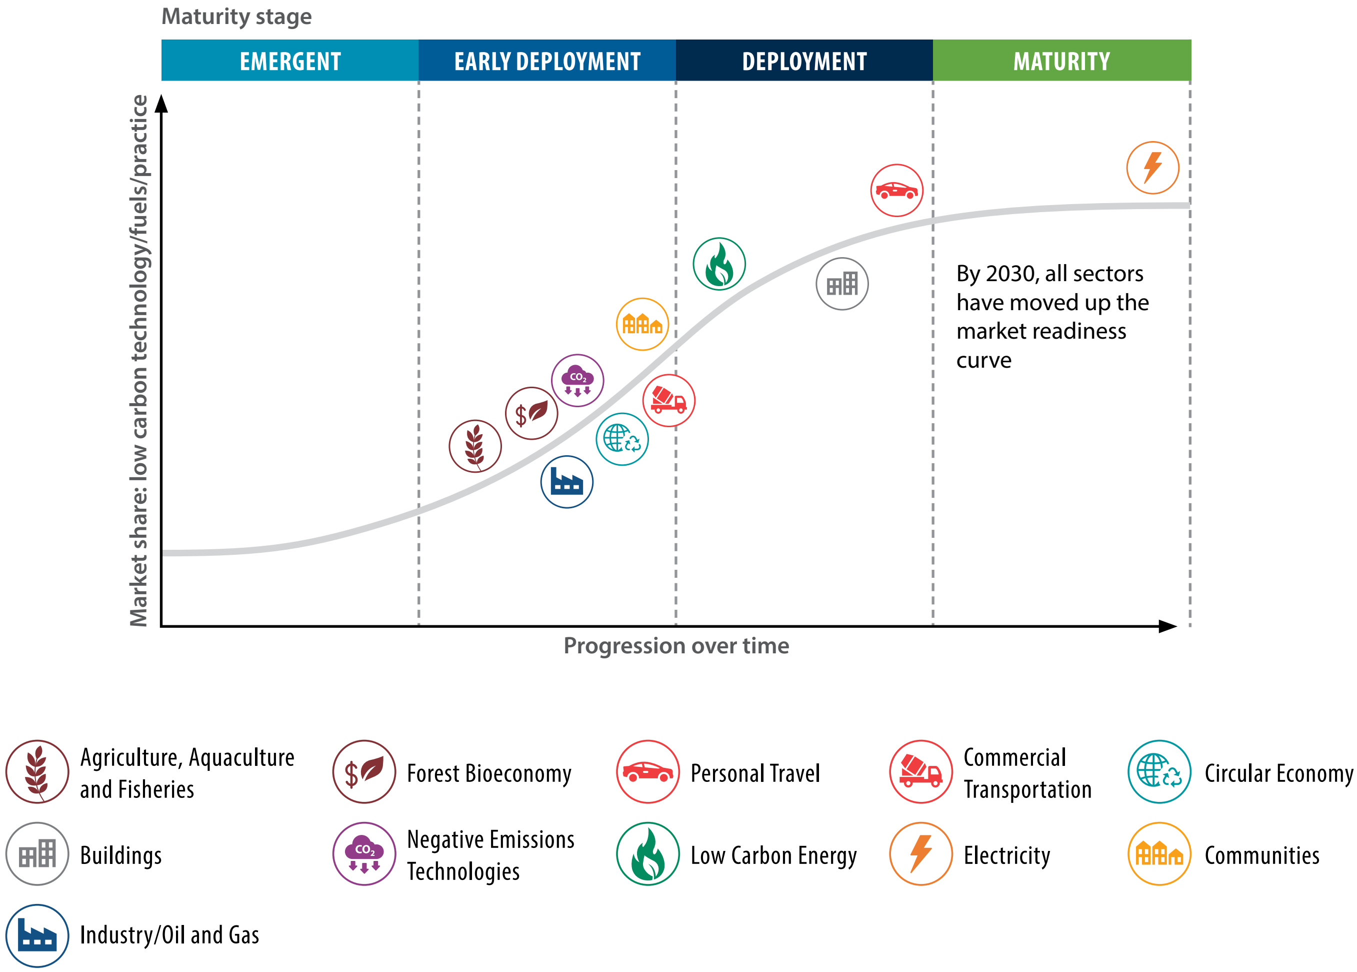
Based on these indicators, we've developed a baseline (below) showing where each of the pathways or Roadmap elements is starting from.

Current State of Market Readiness



By 2030, we will achieve the following advances in market readiness:

State of Market Readiness by 2030 with Roadmap



1.4 Modelling and Economic Analysis

To forecast the impacts of our climate actions, B.C. follows well-established best practices, using the best available data and sophisticated computer modeling. However, projections change over time as new information becomes available and methodologies are updated and it can be challenging predicting specific outcomes a decade or more away. As noted earlier, we now expect the measures in CleanBC (not including Roadmap actions) to achieve 32 to 48% of our 2030 targets – compared to the original estimate of 75%. The increased gap is due to several factors, including:

- Updated modelling: for example, new data on natural gas and electricity have lowered projected GHG reductions from industrial electrification
- Higher than expected emissions in sectors such as transportation and pulp and paper
- Changes in the federal approach to measuring emissions from sectors such as waste.

Detailed information on model updates and estimates are available as part of the 2021 Climate Change Accountability Report.

Through the measures in this Roadmap we expect to reach 100% of the 2030 emissions target.

Impacts on jobs and GDP

In today's economy, citizens and the global financial community are insisting that governments and companies have credible, long-term plans to reduce climate pollution – making this Roadmap an economic necessity.

Based on provincial data, we expect investment in Roadmap initiatives to generate approximately 18,000 direct and spinoff jobs with:

- GDP increases of 19% by 2030 and 89% by 2050 from 2020 levels
- Job growth of 7% and 37% by 2030 and 2050 respectively from 2020 levels.

These are conservative estimates; the economic benefits could be even greater if, for example, new clean technologies turn out to cost less than we expect. The Roadmap, like any credible climate plan, will increase the cost of fossil fuels. Government will minimize the impacts by continuing the Climate Action Tax Credit and providing increased support to help people and businesses reduce emissions and costs.

CHAPTER 2: PATHWAYS

The pathways presented here are not unlike a road network, intersecting in various places and offering multiple routes to reach our destination. They're also affected by a number of broader, overarching initiatives that provide a foundation for ongoing climate action in British Columbia.

Carbon pricing

A price on carbon pollution is one of the most effective and economically efficient ways to reduce GHG emissions. Consistent with the recommendations of the Climate Solutions Council, B.C.'s carbon tax will continue to meet or exceed any federal carbon price requirements for 2023 and beyond.

What we heard

In the consultations that informed this Roadmap, we heard from many local governments, the Climate Solutions Council, and others that the carbon tax needs to be raised and in line with the federal benchmark. From industry, we heard there is overall support for carbon pricing, along with concerns about competitiveness and carbon leakage.

Between now and 2030, we'll analyze the price and program options that best support meeting our climate targets while protecting affordability and competitiveness for people and businesses. We are working to develop mechanisms to support long-term funding for climate action in B.C., including preparing for the impacts of climate change.

The federal government has announced a carbon price of $170 per tonne in 2030, with annual $15 increases beginning in 2023. B.C.'s current price is $45 per tonne – already the strongest, most comprehensive carbon-pricing policy in Canada. Increasing the tax will support greater emissions reductions while encouraging sustainable growth and investment in new low carbon innovations.

At the same time, a higher carbon price can create challenges. For example, it can impact people who still depend on fossil fuels to get to work and heat their homes. It can also affect industries that sell their products in global markets, competing with producers who don't pay a carbon tax, or don't pay as much. Where carbon tax represents a significant operating cost that can't be addressed through investments in cleaner technologies, this can lead to carbon leakage – the movement of business, industry and jobs to places with lower carbon prices.

We'll explore other approaches to help make low-carbon options more affordable for low- and middle-income people in British Columbia. To promote greater fairness, we'll work with the federal government to explore ideas such as carbon border adjustments – ensuring that goods from places without strong climate policies face similar costs to those produced domestically. Through the CleanBC Program for Industry, B.C. uses carbon tax revenue to support emission performance improvements and competitiveness.

Government leadership

Every year since 2010, B.C. has achieved net-zero (carbon neutral) operations across the public sector, including health authorities, school districts, universities, and Crown corporations. As part of this Roadmap, we're building on our progress with the following new measures:

- Factoring climate considerations into government decision making, ensuring a focus on climate-resilient, zero- or low carbon projects. This priority will be delivered through capital projects as they include an assessment of these factors in their planning and approval processes
- Making zero-emission vehicles the default option for B.C. public sector fleets, with ZEVs accounting for 100% of light-duty vehicle acquisitions by 2027
- Requiring all new public sector buildings to align with our climate goals beginning with performance standards (2023) and moving to zero-carbon new buildings (2027)
- Developing and implementing a comprehensive strategy (2024) to transform our existing buildings portfolio to a low carbon and resiliency standard
- Implementing a public awareness and education campaign; this will include a dedicated strategy for connecting with youth and involving them in climate action
- Providing single-window access to all CleanBC incentives and programs.

Climate preparedness and adaptation

B.C.'s Climate Preparedness and Adaptation Strategy will be released in 2022, strengthening our capacity to anticipate and respond to the impacts of climate change in every part of B.C. These include sudden events like wildfires, floods and heat waves, as well as changes that happen more slowly like habitat loss, sea level rise and changes in growing seasons.

The strategy builds on the substantial work already underway in B.C. to adapt to climate change, lower long-term costs of impacts and help keep our communities safe, ensuring government programs and policies continue to achieve their goals as the climate changes. The strategy draws on a 2019 assessment of the greatest climate risks to B.C. and outlines actions to prepare for them in ways that respect and respond to the diverse needs of people and communities across B.C.

Circular economy

A circular economy refers to a system where, by design, there is no waste – in contrast to the traditional Western model, which can be described as take-make-waste: we take raw materials, make them into products, use them and throw them away. The circular approach emphasizes sharing, reusing, repairing and recycling – eliminating waste and reducing GHG emissions while making better use of our resources.

What we heard

In the consultations that informed this Roadmap, people from Indigenous and remote communities said they face significant challenges and expenses to transport recycling and waste, especially when they have to use barges, forest service roads, or planes. There is support for developing a circular economy, including expanding B.C.'s continent-leading extended producer responsibility recycling system.

Circular economy in action: B.C. is keeping plastics in use and out of the environment

Learn more at: **CleanBC.gov.bc.ca/success-stories**

With this Roadmap, we're taking more steps to advance the circular economy, especially in sectors such as agriculture and forestry. They generate byproducts that can be used to create low carbon building materials, renewable energy and other clean products – generating value and new opportunities while shrinking our carbon footprint.

We will develop a Circular Economy Strategy in 2022, supporting both our climate goals and our economy. Key components will include advancing the Plastics Action Plan and requiring more manufacturers to take responsibility for their products' eventual recycling, reuse or safe disposal.

The strategy will build on recent actions we've taken to expand our continent-leading recycling system, which will include electric vehicle batteries and chargers, mattresses, and electronic products such as solar panels, lithium-ion batteries and e-cigarettes.

A Workforce Readiness Framework: Preparing for a cleaner economy

The global transition to a low-carbon future will create new jobs in a range of sectors, and we want to make sure those jobs benefit people across B.C. A workforce readiness framework is being developed to ensure people are positioned for good jobs in a future, cleaner economy and that B.C. has the workers needed for sustainable economic growth and innovation.

Some jobs will be new. In other cases, existing jobs will evolve to incorporate new technologies, approaches and innovations. Some areas will see immediate changes while others will experience smaller shifts over time as we build a future workforce that is more inclusive, resilient and adaptable – in partnership with Indigenous peoples, industry, post-secondary institutions and others.

The framework will include measures to ensure B.C. has the number and diversity of workers to meet employers' needs; ensure there are opportunities for workers to upgrade their skills to adapt to changing jobs; and new training programs, standards and credentials that workers and employers are increasingly looking for as we transition to a low carbon economy.

The framework will guide work with industry, stakeholders, and Indigenous peoples to understand developing job growth opportunities and the skills needed for the current and future clean economy, and to identify barriers to train, attract and retain workers to support the just transition to a low-carbon economy.

EXTENDED PRODUCER RESPONSIBILITY (EPR) AND THE CLEANBC PLASTICS ACTION PLAN

B.C. has one of the strongest, most comprehensive recycling systems in North America known as Extended Producer Responsibility (EPR). EPR requires producers to take responsibility for the lifecycle of their products, including collection and recycling. B.C.'s EPR strategy recovers $46 million worth of materials annually and reduces greenhouse gas emissions by more than 200,000 tonnes of carbon dioxide equivalent. It generates an estimated $500 million annually through recycling programs, and collects approximately 315,000 tonnes of plastic from bottles, packaging and electronics. We're expanding this system to include electric vehicle batteries and chargers, solar panels, more types of lithium-ion batteries, mattresses and e-cigarettes.

B.C. is building on this leadership in EPR and developing the circular economy on plastics supported by the CleanBC Plastics Action Plan, which identifies actions to ban single-use items and reclaim more materials. These aims are bolstered by the CleanBC Plastics Action Fund that encourages innovation to turn used plastics into new products, as well as the Clean Coast Clean Waters initiative that supported the largest shoreline clean-up in the province's history. This initiative partnered with Indigenous and coastal communities, as well as local tourism operators and environmental groups. More than 550 tonnes of marine debris has been removed to date, with the majority of the material being reused and recycled.

2.1 Low Carbon Energy

Whether it's for producing food, lighting and heating our homes, moving people and goods or supporting industrial growth – energy underpins almost every aspect of our lives and economy in British Columbia.

To decarbonize our economy and accelerate the shift to clean technologies in the buildings, transportation and industrial sectors, we need to use energy more efficiently and replace fossil fuels with clean energy, including more clean electricity, renewable natural gas, low carbon hydrogen and liquid biofuels.

What we heard

In the consultations that informed this Roadmap, industrial operators said low carbon fuels can provide short-term flexibility as a substitute for natural gas but to ramp up production we need to address barriers, such as:

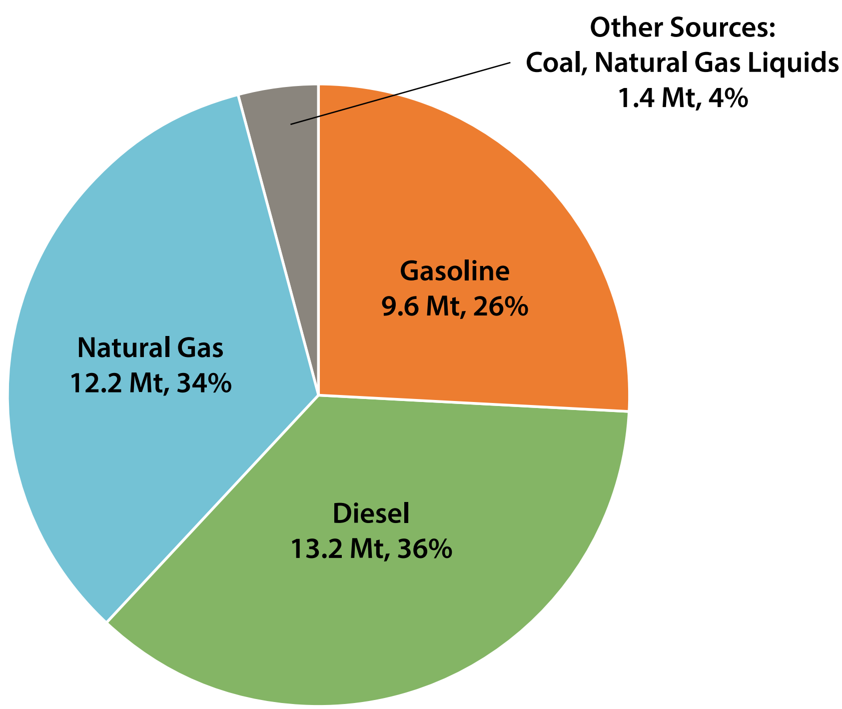
- *Biomass supply and uncertainties related to technology/capital purchases*
- *The impact of increasing transportation fuel costs on final production for certain industries*
- *The need for partnerships to implement the B.C. Hydrogen Strategy*

Indigenous peoples pointed to potential job creation opportunities through wood waste transfer facilities to create biofuel, as well as a waste collection program to support biofuel creation. There was also interest in more solar and wind power including cost sharing agreements.

Where we're starting from

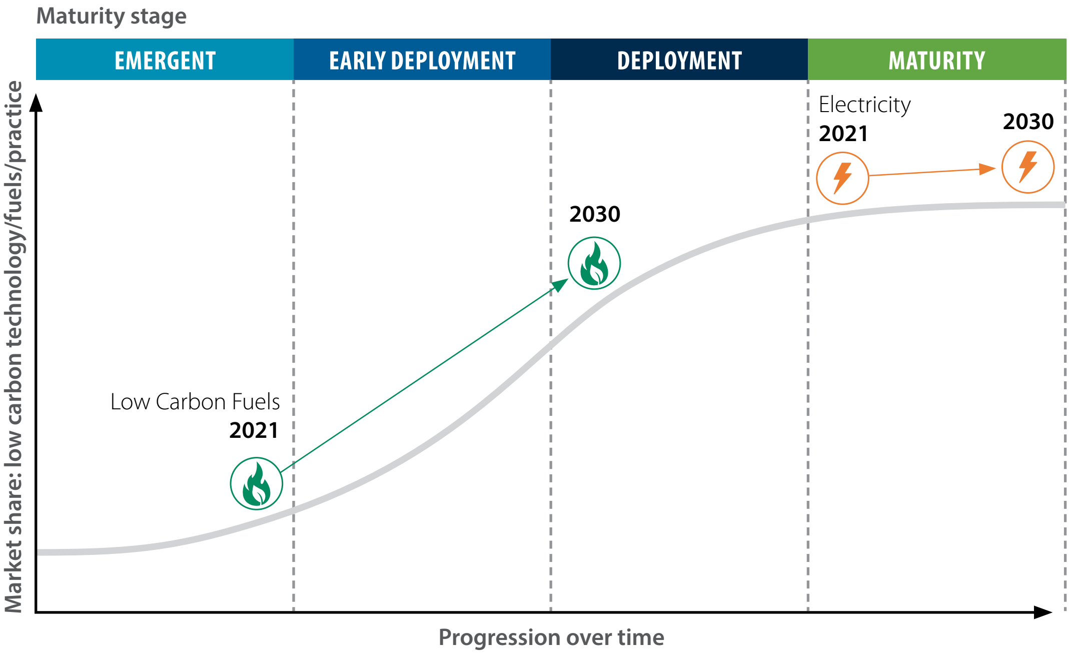
B.C. uses a diverse mix of energy types to meet demands from our transportation, industry and building sectors. Clean electricity currently accounts for only 19% of the total. Low carbon biomass and biofuels meet an additional 11%, and that proportion will rise in the future. However, most of our energy needs – the remaining 69% – are still met by fossil fuels, mainly in the form of refined petroleum products and natural gas. Fossil fuel production and consumption accounts for approximately 80% of B.C. emissions, underlining the need to move to cleaner fuels, faster. The pie chart below shows a breakdown of emissions by energy source.

2020 Emissions by Energy Source for Transportation, Buildings and Industry (Excluding Oil and Gas Sector)



Most of our electricity is clean and renewable, putting its market readiness stage at early maturity. Liquid biofuels are available but emergent, limited by a number of factors including the availability of feedstock, such as vegetable oils and tallow for products like renewable diesel. Low carbon gaseous fuels such as biomethane and hydrogen are also emergent, limited by factors such as capital investment, feedstocks and access to commercial-ready technologies.

Low Carbon Energy



KEY ACTIONS

- Expanding the Low Carbon Fuel Standard (LCFS)
- Implementing a GHG emissions cap for natural gas utilities
- Adopting a 100% Clean Electricity Delivery Standard
- Advancing BC Hydro's Electrification Plan
- Implementing the B.C. Hydrogen Strategy
- Indigenous clean energy opportunities review

THE PATH TO TRANSFORMATION – 2030 AND BEYOND

To maximize production of low carbon energy, we need a suite of regulatory and program initiatives that build on approaches we know work well and create incentives for new innovation.

Expanding the Low Carbon Fuel Standard (LCFS)

B.C.'s Low Carbon Fuel Standard is one of our most successful approaches to reducing GHGs from transportation. It requires fuel suppliers to progressively decrease the average carbon intensity of the fuels they supply to users in B.C.

With CleanBC, we increased its stringency by doubling the carbon-intensity reduction for gasoline and diesel from 10% to 20% by 2030. As part of this Roadmap, we intend to modernize the legislation governing the Low Carbon Fuel Standard, including to expand it to cover marine and aviation fuels beginning in 2023.We'll also consider new compliance options such as negative emissions technologies, while increasing the financial implications of failing to comply.

After careful assessment of impacts, we will raise our target beyond the current 20%, consistent with advice from the Climate Solutions Council, using 30% by 2030 as a starting point for further analysis and consultations. We will also double our commitment to develop production capacity for made-in-B.C. renewable fuels to 1.3 billion litres per year by 2030, creating new jobs and economic opportunities across the province.

Implementing a GHG emissions cap for natural gas utilities

B.C.'s existing pipeline infrastructure can play an important role in reducing greenhouse gases by transitioning away from delivering fossil natural gas to delivering renewable gas. B.C.'s gas utilities have been leaders in enabling this transition.

To help drive this transition, we will introduce a GHG emissions cap that will require gas utilities to undertake activities and invest in technologies to further lower GHG emissions from the fossil natural gas used to heat homes and buildings and power some of our industries.

Following further modelling and analysis, the cap will be set at approximately 6 Mt of CO_2e per year for 2030, which is approximately 47% lower than 2007 levels. Since emissions from gas consumption are linked to industry (excluding oil and gas) and the built environment, the cap is consistent with emissions targets for those sectors.

From waste to clean energy: B.C. companies are making the fuels of the future

Learn more at: **CleanBC.gov.bc.ca/success-stories**

Utilities will determine how best to meet the target, which could include acquiring more renewable gases as well as supporting greater energy efficiency. Measures in CleanBC allow gas utilities to use renewables such as synthetic gas, biomethane, green and waste hydrogen and lignin to achieve this.

The B.C. Utilities Commission will have a mandate to review gas utilities' plans, investments and expenditures to ensure they're aligned with the GHG emissions cap and cost effective, helping to keep rates affordable for people and businesses.

Adopting a 100% Clean Electricity Delivery Standard

B.C.'s abundant supply of clean electricity is one of our greatest allies in the fight against climate change. Currently, an average of 98% is from renewable sources, mostly hydro power.

As part of this Roadmap, we are committing to increase this to 100% – making our power even cleaner; creating new opportunities in areas such as the bioeconomy; and helping to attract new businesses by supporting their sustainability strategies. BC Hydro will meet the new standard by ensuring it has produced or acquired sufficient clean electricity to meet the needs of its domestic customers and phasing out remaining gas-fired facilities on its integrated grid by 2030.

Micro-hydropower provides clean energy and jobs for Kitasoo Xai'xais Nation

Learn more at: **CleanBC.gov.bc.ca/success-stories**

Advancing BC Hydro's Electrification Plan

BC Hydro will advance its Electrification Plan by offering customers incentives, tools and business-to-business support to help them run their homes and businesses with clean electricity – and to reduce the time it takes to connect to the grid.

Subject to the approval of the BC Utilities Commission, over the next five years, the Crown corporation plans to invest over $260 million to advance electrification, including more than $190 million to promote fuel switching in buildings, transportation and industry and more than $50 million to attract new customers – such as data centres and hydrogen producers – who can locate anywhere but see the advantages of B.C.'s clean, reliable, affordable hydroelectric power.

To help support and drive BC Hydro's focus on GHG reductions, we will add electrification and fuel-switching to its mandate, introduce an internal carbon price to evaluate electrification initiatives in regulatory applications, and enable investments in green hydrogen production and commercial vehicle incentives and infrastructure.

BC HYDRO'S INTEGRATED RESOURCE PLAN

BC Hydro is preparing an Integrated Resource Plan (IRP), which outlines how BC Hydro plans to provide reliable, affordable and clean electricity to meet customer demand now and into the future. It considers BC Hydro's 20-year projections of electricity demand in B.C. The IRP includes high and low load ranges and scenarios to account for a range of potential impacts, including support of CleanBC as policies and regulations are implemented and electrification ramps up to help achieve 2030 emissions reduction targets.

Implementing the B.C. Hydrogen Strategy

When burned or used in a fuel cell, hydrogen produces no carbon emissions. Hydrogen is one of the only solutions for decarbonizing sectors of the economy where direct electrification is not practical, such as heavy-duty transportation or industrial heating. When injected into the natural-gas grid, renewable hydrogen can displace fossil fuels for heating homes and businesses. Hydrogen can also be used for producing low carbon, synthetic fuels to reduce emissions in transportation and industry.

B.C.'s hydrogen sector is fueling green jobs

Learn more at: **CleanBC.gov.bc.ca/success-stories**

B.C. is the first province in Canada to release a comprehensive hydrogen strategy. The B.C. Hydrogen Strategy outlines how the Province will support the development of production, use and export of renewable and low carbon hydrogen for the next 10 years and beyond. It complements the federal hydrogen strategy, serving as a blueprint for regional development with 63 actions for the short term (2020-2025), medium term (2025-2030) and long term (2030-beyond).

Implementing the B.C. Hydrogen Strategy and developing our hydrogen economy will generate more clean economic opportunities, help reduce emissions and contribute to meeting our climate targets. The strategy's immediate priorities include scaling up production of renewable hydrogen, establishing regional hydrogen hubs and deploying medium- and heavy-duty fuel-cell vehicles.

OPENING THE B.C. CENTRE FOR INNOVATION AND CLEAN ENERGY (CICE)

With an initial $35 million provincial investment leveraging an additional $70 million from federal and private sources, the Centre for Innovation and Clean Energy will be a member-based, non-profit corporation, independent from government and private entities. The Centre will bring together innovators, industry, governments and academics to accelerate the commercialization and scale-up of B.C. based clean energy technologies. It will also be a catalyst for new partnerships and world-leading innovation to deliver near- and longer-term carbon emission reductions.

The Centre's initial focus areas for funding and project delivery will include:

- Carbon capture, utilization and storage
- Production, use and distribution of low-carbon hydrogen
- Biofuels and synthetic fuels (including marine and aviation fuels)
- Renewable natural gas
- Battery technology, storage and energy management systems.

The Centre will also initiate new technology pathways to accelerate larger reductions on the path to net-zero emissions by 2050.

Indigenous clean energy opportunities review

The actions in the Roadmap will open up a wide range of economic opportunities in B.C.'s low carbon energy sector. The Province is committed to working with First Nations to maximize the benefits for Indigenous communities. As a key step, the Ministry of Energy, Mines and Low Carbon Innovation and the First Nations Leadership Council, through their designate, the BC First Nations Energy and Mining Council, are launching a co-designed and co-led Indigenous Clean Energy Opportunities engagement process. Through the process, the Ministry and the Council will jointly engage First Nations to identify and support clean energy opportunities. They will also seek to collaborate with First Nations rights holders on the development of strategic clean energy policy and legislation, and meaningfully explore and develop policy, regulatory and program support to enable Indigenous participation within the growing and diverse clean energy sector.

2.2 Transportation

Transportation plays a major role in all our lives, connecting us to each other and the world. It's also our largest single source of GHG emissions, accounting for approximately 40% of our annual total in British Columbia. Actions that reduce these emissions have a wide range of benefits, from cleaner air and less congestion to better health, more clean jobs and economic development – benefits we'll see more of as we implement this Roadmap.

What we heard

In the consultations that informed this Roadmap, many groups supported accelerating and expanding zero-emission vehicle targets and enhancing funding and supports for active transportation. People in commercial transportation supported measures to predictably reduce emissions from medium- and heavy-duty fleets. In engagements with Indigenous peoples, we heard suggestions to expand clean transportation supports such as charging infrastructure, electric buses and public transportation, especially in the North.

Where we're starting from

The B.C. market for decarbonizing personal travel is at the early deployment stage. People can choose from more than 50 models of light-duty, zero-emission vehicles (ZEVs). However, these still cost about 20-40% more than equivalent non-ZEVs (before considering government rebates and lower maintenance and fuel costs). And more work is needed to build out the infrastructure for ZEV charging and hydrogen fueling. For active transportation, many communities still have significant gaps to fill to complete their networks for people of all ages and abilities.

The market for commercial travel is in the emergent stage, with ZEV solutions for medium- and heavy-duty vehicles starting to be deployed. Costs remain high and the commercial market is behind the personal market.

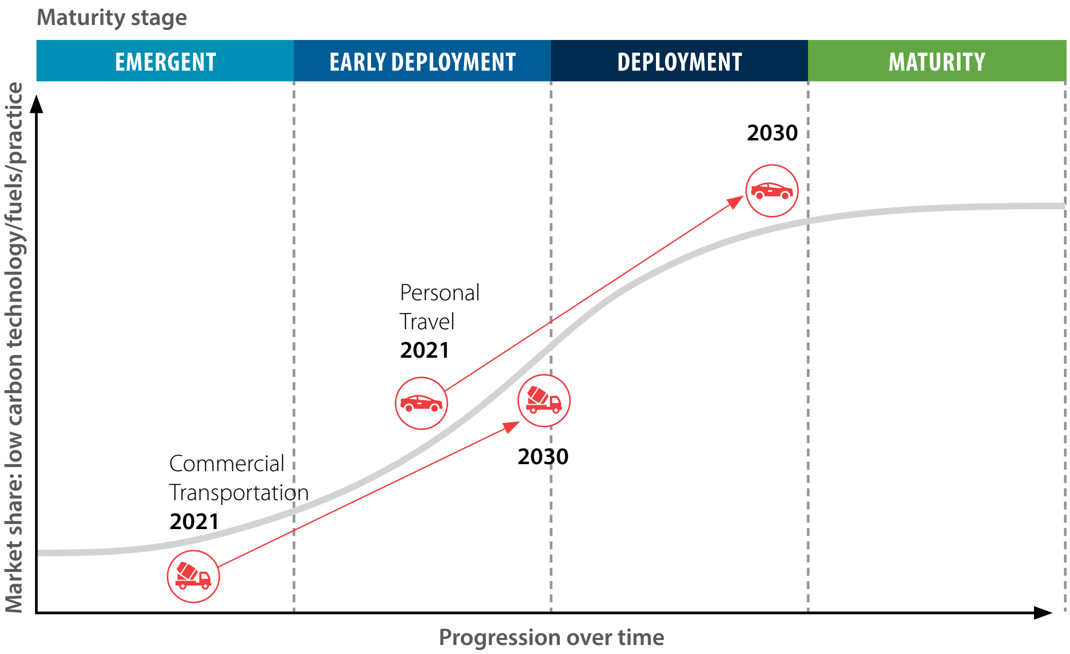
CLEANBC GO ELECTRIC COMMERCIAL VEHICLE PILOTS

The CleanBC Go Electric Commercial Vehicle Pilots program, launched in 2021, supports the switch to zero-emission commercial vehicles of all types, including trains, ships, trucks, construction and agricultural equipment, along with the necessary charging and fueling infrastructure.

The companion CleanBC Go Electric Specialty Use Vehicle Incentive program is supporting the transition for specialty vehicles, such as delivery trucks, passenger shuttles and a variety of other vehicles. Purolator is among the companies using the program to advance cleaner choices, running battery-electric trucks from its facility in Richmond.

More work is also needed to explore opportunities to move more goods by rail and shipping. This includes short sea shipping – using barges and waterways to get goods from ports to regional facilities. Ultimately, we expect there will be no single solution but a range of cleaner options for commercial transportation, reflecting the diversity of needs and opportunities.

Transportation



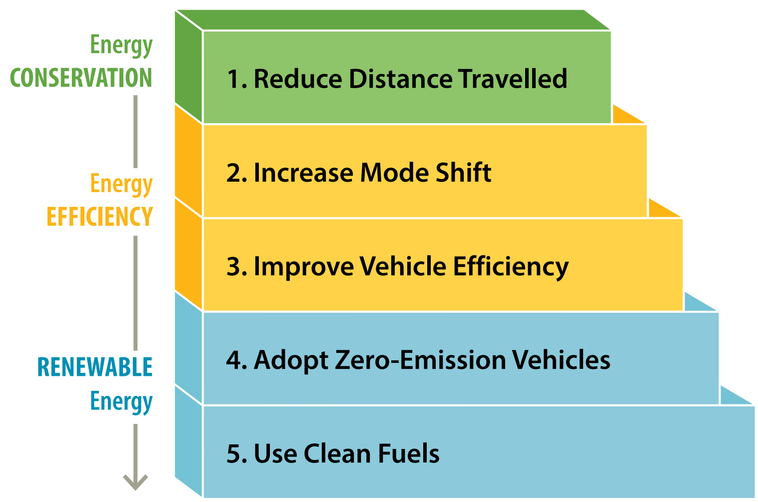
KEY ACTIONS

- Reducing distance travelled
- Encouraging "mode shifting" to more energy efficient forms of transport
- Accelerating the switch to ZEVs
- Expanding B.C.'s public charging network
- Making commercial transportation more energy efficient
- Improving vehicle efficiency
- Expanding the Low Carbon Fuel Standard (LCFS)
- Completing the Clean Transportation Action Plan

THE ROAD TO TRANSFORMATION - 2030 AND BEYOND

Meeting our targets in the transportation sector demands aggressive action in addition to our world-leading ZEV and fuel standards. With this Roadmap, we're working across five areas, from encouraging more walking and cycling to reducing the carbon intensity of fuels. This approach, illustrated below, is based on an efficiency-first model, consistent with energy conservation principles.

In 2023, the actions in this Roadmap will be complemented by a new Clean Transportation Action Plan, setting out our next set of actions to reduce transportation emissions by 27-32% (from 2007) by 2030. Specific actions will be consistent with advice from the Climate Solutions Council.



Reducing distance travelled

As part of this Roadmap, we will work to reduce the distances travelled in light-duty vehicles by 25% by 2030, compared to 2020. This can be achieved in part by supporting more compact urban planning in partnership with municipalities to increase active transportation and public transit. We will also provide continued support for digital access and remote work where feasible, building on the lessons learned during the COVID-19 pandemic. In addition, we will work with ICBC to monitor vehicle kilometres travelled and develop additional ways to bring them down, helping to reduce emissions, transportation costs, collision risk, and wear and tear on our roads.

To help inform future decisions, we'll continue to collect and share transportation data, supporting both provincial goals and planning and analysis by partners, such as local governments and Indigenous communities.

Encouraging "mode shifting" to more energy efficient forms of transport

One of the surest ways to reduce our GHG emissions from transport is to choose the least energy-intensive and polluting ways to get around. For personal travel that generally means walking, cycling or taking transit. For commercial travel, it means moving more goods by rail, water or cargo bike where possible instead of using heavy-duty, on-road vehicles.

To encourage these shifts, we will establish energy intensity targets for personal and commercial transportation and work with key partners to:

- Increase the share of trips (e.g., commuting for work and personal activities) made by walking, cycling, transit to 30% by 2030, 40% by 2040 and 50% by 2050. In a 2019 survey, 24% of people in B.C. said they primarily used sustainable transportation (walking, cycling or public transit) to get to work.
- Reduce the energy intensity of goods movement (tonne-kilometres) by at least 10% by 2030, 30% by 2040, and 50% by 2050, relative to 2020.

Accelerating the switch to ZEVs

B.C.'s Zero-Emission Vehicles Act, passed in 2019, has already helped to transform the marketplace. Thanks in part to government rebates, we're close to achieving our 2025 target, with ZEVs accounting for 9.4% of all new light-duty vehicle sales in 2020. To build on that momentum, we're accelerating our targets in alignment with automakers' published deployment plans. Our new light-duty ZEV sales targets are 26% by 2026, 90% by 2030 and 100% by 2035.

To support these targets, we will bring in "right-to-charge" legislation, allowing more people to install EV charging infrastructure in strata and apartment buildings. We will also introduce new ZEV targets for medium- and heavy-duty vehicles, in consultation with automakers, businesses and industry in alignment with the state of California.

Heavy-duty vehicles account for a large part of transportation emissions and modelling suggests the new targets will have a significant impact. Given the time required for research and engagement, we expect these targets will be in place by 2023.

Making cleaner models more affordable will help get more of them on our roads. And rising demand for cleaner vehicles will act as a further incentive for automakers, driving further improvements in efficiency and generating high-value jobs in ZEV research and development. We will explore other fiscal measures to broaden consumer access to ZEVs, accelerate market transformation and create a more sustainable fiscal framework for the ZEV transition.

Expanding B.C.'s public charging network

We will also ensure it's easy to charge your ZEV, wherever you are in the province. We will work with the private sector, utilities, Indigenous communities, the federal and local governments and others to achieve an overall target of B.C. having 10,000 public EV charging stations by 2030. This will include completing B.C.'s Electric Highway by ensuring broad geographic coverage across the Province for fast-charger EV sites by Summer 2024. BC Transit, TransLink and BC Ferries are also moving increasingly to zero-emission vehicles.

Making commercial transportation more energy efficient

Delivery trucks are getting cleaner – and bikes are sharing the load

Learn more at: **CleanBC.gov.bc.ca/success-stories**

In partnership with industry and other key stakeholders, we will work to make our commercial transportation systems more competitive while accelerating innovation and driving the adoption of clean B.C. technologies to support and advance climate change goals. As noted above, we're committed to reducing the energy intensity of goods movements by 10% in 2030, 30% by 2040 and 50% by 2050. We'll also use better data technology to make our transportation systems more efficient, intelligent and competitive.

Having one of the cleanest, greenest transportation networks in the world will add to our competitive advantages, supporting economic growth along with GHG reductions.

Improving vehicle efficiency

When you need to use a vehicle, it makes sense to choose the most efficient one. And this is another place where government can help move the market through regulations, standards and incentives.

To help drive improvements in vehicle efficiency, we'll work with business and industry to encourage faster fleet turnover for the oldest vehicles, work with the federal government to strengthen emissions standards, and develop new equipment regulations for air, rail, marine and off-road vehicles. We'll also identify how the CleanBC Heavy Duty Vehicle Efficiency Program can drive further improvements. For example, the Province could offer higher incentives for tires that reduce fuel consumption on specific types of commercial heavy-duty vehicles and encourage the use of speed-limiting technology and electronic tracking to improve safety while continuing to reduce GHG emissions.

Expanding the Low Carbon Fuel Standard (LCFS)

As noted in the Low Carbon Energy pathway, the Low Carbon Fuel Standard is one of our most successful approaches to reducing GHGs from transportation. It requires fuel suppliers to progressively decrease the average carbon intensity of the fuels they supply to users in B.C.

As part of this Roadmap, we will increase its stringency, consider expanding it to apply to marine and aviation fuels, and consider allowing new compliance options such as negative emissions technologies.

Completing the Clean Transportation Action Plan

In addition to the specific actions in this Roadmap, we will develop a comprehensive Clean Transportation Action Plan in 2023. The Plan will highlight additional steps government will take to reduce emissions in the transportation sector, including ports and airports, to meet our 2030 targets and align with the development of complete, compact, connected communities to reduce vehicle travel.

Electric ferries are the wave of the future

Learn more at: **CleanBC.gov.bc.ca/success-stories**

2.3 Buildings

Buildings – the places where we live, work, learn and play, and a vital component of B.C.'s economy – account for about 10% of the province's GHG emissions, mainly from the energy we use to heat them and provide hot water.

Our building sector has been getting steadily cleaner and greener in recent years, but current emissions reductions are not at the scale needed to meet our 2030 targets.

INVESTING IN AFFORDABLE HOUSING ACROSS B.C.

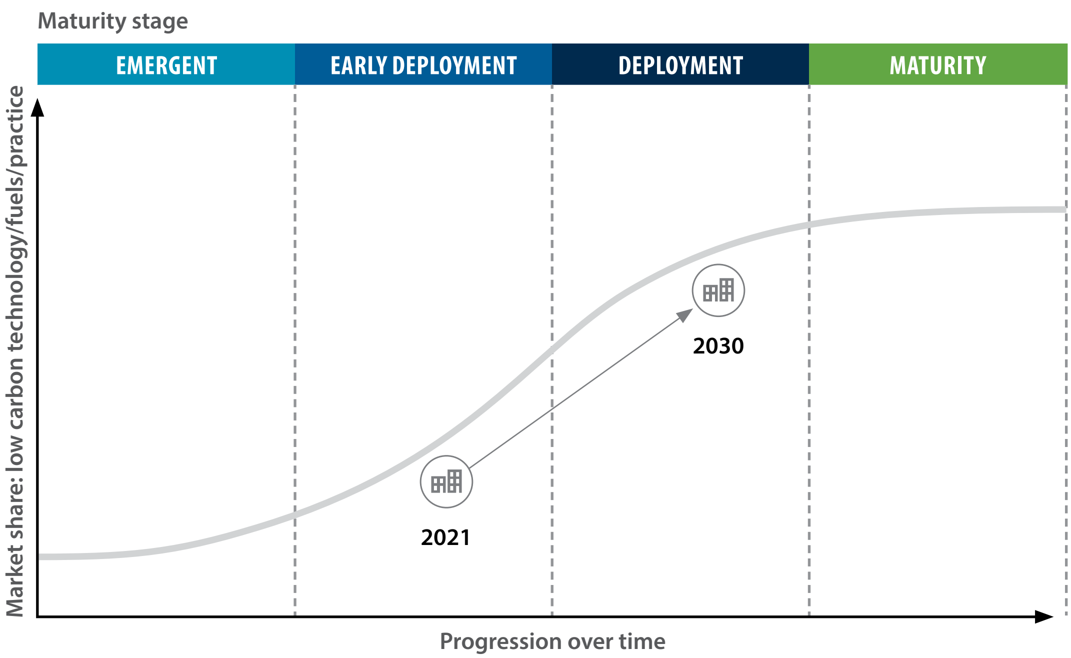
The Province is working to make housing more affordable for everyone in B.C. With $7 billion dedicated over 10 years, we're making the largest investment in housing in B.C.'s history. By working with partners, including local governments, we're delivering 114,000 affordable homes over this time period. In just over three years, more than 30,000 new affordable homes are already complete or underway in more than 100 communities across the province. And we continue to make progress on our plan to retrofit 51,000 units of publicly owned social housing over ten years, making them more energy efficient, less polluting and safer, while significantly reducing heating costs for residents.

Where we're starting from

The decarbonization of buildings is at an early deployment phase. Households and businesses can choose from a range of low carbon solutions and B.C. is already a leader in this space. New construction is steadily moving towards the highest efficiency levels and builders are growing their capacity to make new buildings cleaner, supported by increasing adoption of the Energy Step Code, which sets higher energy-efficiency standards than the base BC Building Code. However, we still rely on fossil fuels to meet more than half our energy needs in buildings.

Low carbon electric technologies like baseboard heaters are commonplace, but not the most efficient options available. Heat pump technologies are more than twice as efficient and cost less to operate. Plus, they double as air conditioners in increasingly hotter summers and can include air filtration, protecting people from wildfire smoke, pollen and pollution. Heat pumps are gaining in market share, with options available for all major building types and climates. However, costs are still a barrier for many households and businesses.

Buildings



KEY ACTIONS

- Zero-carbon new construction by 2030
- Highest efficiency standards for new space and water heating equipment
- Enhancing energy efficiency programs
- Introducing home energy labelling
- More low carbon building materials

What we heard

In the consultations that informed this Roadmap, a wide range of groups including local governments, utilities, Indigenous peoples, professionals and organizations, shared their views on decarbonizing buildings, such as:

- *Regulating carbon as well as energy efficiency in the BC Building Code for new buildings*
- *Accelerating highest efficiency heating equipment standards for existing buildings*
- *Addressing affordability impacts especially for those who need it most*
- *Integrating climate resilience, for example, to address heat waves and air quality issues*
- *Considering unique Indigenous geographic and cultural needs*
- *Ensuring program incentives support and align with future building codes and standards.*

THE PATH TO TRANSFORMATION – 2030 AND BEYOND

Zero-carbon new construction by 2030

Current requirements for new construction focus on energy efficiency without directly addressing the issue of GHG emissions. Since natural gas is still a dominant, low-cost energy source for buildings, efficiency requirements alone are not enough to meet our climate targets.

That's why we're adding a new carbon pollution standard to the BC Building Code, supporting a transition to zero-carbon new buildings by 2030. We're already working with local governments to develop voluntary carbon pollution standards. Those communities will serve as pilots for future province-wide requirements. The standard will be performance-based, allowing for a variety of options including electrification, low carbon fuels like renewable natural gas, and low carbon district energy.

In 2023, we'll review our progress and, based on what we've learned, we'll start phasing in provincial regulations over time (2024, 2027, 2030). We'll also incorporate energy-efficiency standards for existing buildings into the BC Building Code starting in 2024.

Highest efficiency standards for new space and water heating equipment

Space and water heating are the primary drivers of GHG emissions from buildings. To meet our targets, we need to ensure these functions are super-efficient, improve resilience and, wherever possible, run on clean electricity or other renewable fuels. To help accelerate this transition, we're committing to highest-efficiency standards for new space and water heating equipment by 2030, and earlier where feasible.

After 2030, all new space and water heating equipment sold and installed in B.C. will be at least 100% efficient, significantly reducing emissions compared to current combustion technology. Electric resistance technologies like baseboard and electric water heaters are 100% efficient: they convert all the energy they use into heat. But heat pump technologies exceed 100% efficiency by capturing and moving ambient heat, without having to produce it. The new requirements will encourage more people to install electric heat pumps while continuing to allow the use of electric resistance technologies. They will also allow hybrid electric heat pump gas systems and high-efficiency gas heat pumps.

As building owners, professionals, tradespeople and supply chains prepare for these significant shifts in how we build in B.C., the Province will continue to support market readiness and affordability through CleanBC Better Homes and Better Buildings rebates and financing, innovation funding, technical guidance and ongoing industry training.

CLEANBC BETTER HOMES INCOME QUALIFIED PROGRAM

CleanBC Better Homes is B.C.'s online hub for homeowners to access information, rebates and support to reduce energy use and greenhouse gas emissions in their homes.

The CleanBC Better Homes Income Qualified Program is a new, time limited, efficiency and electrification offer that provides high-value incentives to low- and moderate-income households. It complements existing residential energy efficiency programs to help make life more affordable while improving the quality, comfort and resiliency of homes, saving energy, and reducing GHG emissions.

Enhancing energy efficiency programs

Energy companies like BC Hydro and FortisBC have been working for years to encourage efficiency, offering information, tools and support and partnering with the Province to provide incentives and rebates. Utility-funded programs have been effective in reducing emissions, but like so many aspects of our climate-change response, they need to go further, building on initiatives in CleanBC to support the deep reductions needed to meet our long-term targets.

We'll achieve that, in part, with updated regulations to shift the focus of utility-funded efficiency programs to support market readiness for future standards and codes, place more emphasis on electrification, and to ensure affordability for households and businesses. Instead of seeing incentives for conventional gas-fired heating equipment such as furnaces and boilers, consumers will see more support for building-envelope improvements such as insulation and better windows, and all kinds of high efficiency heat pumps – electric, gas and hybrid. We'll also look for ways to further coordinate and integrate energy efficiency programs to make them more effective and easier to access.

We will proceed with the next steps on a Property Assessed Clean Energy (PACE) program, which is a form of financing for energy retrofits designed to help building owners save on energy costs and reduce greenhouse gas emissions. PACE programs link an energy improvement loan to a specific property through a municipal tax lien. The annual payments for the improvements are tied to the property, not an individual, and paid through local government property taxes. This allows for longer terms, helping to reduce upfront loan repayment costs for building improvements. If the property changes hands to a new owner, the outstanding balance of the PACE loan is also transferred over to the new owner.

Introducing home energy labelling

We've done it for years with appliances and vehicles. Now we're putting tools in place to show people how energy efficient their next home could be. B.C. home sale listings will include an energy efficiency rating or label, letting buyers know what their energy costs and carbon footprint will be. Along with raising public awareness, home energy labelling can motivate owners to invest in retrofits that save energy and cut GHG emissions, knowing it will impact future salability.

As a first step, we will introduce a user-friendly, web-based, virtual home-energy rating tool to let people see how efficient their homes are. The tool will be linked to the Better Homes web hub, helping to make CleanBC and utility program offers more accessible. In-home EnerGuide assessments will continue to play a role where homeowners want a more in-depth evaluation, or where homes are too unique for virtual energy ratings to be accurate.

Hartley Bay heats up (and cools down) with energy saving heat pumps

Learn more at: **CleanBC.gov.bc.ca/success-stories**

More low carbon building materials

Much of our work to date around cleaner buildings has focused on the amount and types of energy they use. The next bold step is to reduce embodied carbon, which refers to the total GHG emissions created through a building's lifecycle – from material extraction through manufacturing, transportation, construction, maintenance, and end-of-life disposal or reuse.

One approach is to use low carbon building materials, such as mass timber, wood-based insulation, carbon-absorbing concrete, and concrete made with lignin fibres from trees and other plants. Along with reducing embodied carbon, choosing cleaner materials can support a waste-free, circular economy while creating new opportunities in sectors such as forestry where the emphasis is shifting from high-volume to high-value products.

To help build the market for these cleaner materials, we will develop a Low Carbon Building Materials Strategy by 2023 that includes a holistic approach to decarbonizing buildings, initially emphasizing public sector buildings, supporting the development and implementation of embodied carbon targets for public sector buildings by 2030. We're also developing methods for quantifying and analyzing the total embodied carbon of our built environment and identifying pathways to reduce it.

2.4 Communities

B.C.'s local governments play a vital role in meeting provincial climate targets. Along with directly controlling emissions from their own facilities, operations and vehicle fleets, municipalities and regional districts have the capacity to influence about 50% of our GHG emissions through decisions on land use, transportation and infrastructure that affect where people live and work, how they get around, and how their communities grow and change with time.

This puts local governments on the front lines of climate action, where all these policies converge.

Local Government Relative Influence over GHG Emissions

High ← → **Low**

Municipal infrastructure, buildings and fleet	Transportation network Land use patterns Solid waste Building efficiency standards	Transportation mode share Residential and business energy efficiency Food security	Air travel Industrial energy efficiency Vehicle standards Energy utilities

Adapted from: Options to Accelerate Climate Action. Available online: https://kelownapublishing.escribemeetings.com/filestream.ashx?DocumentId=29429

What we heard

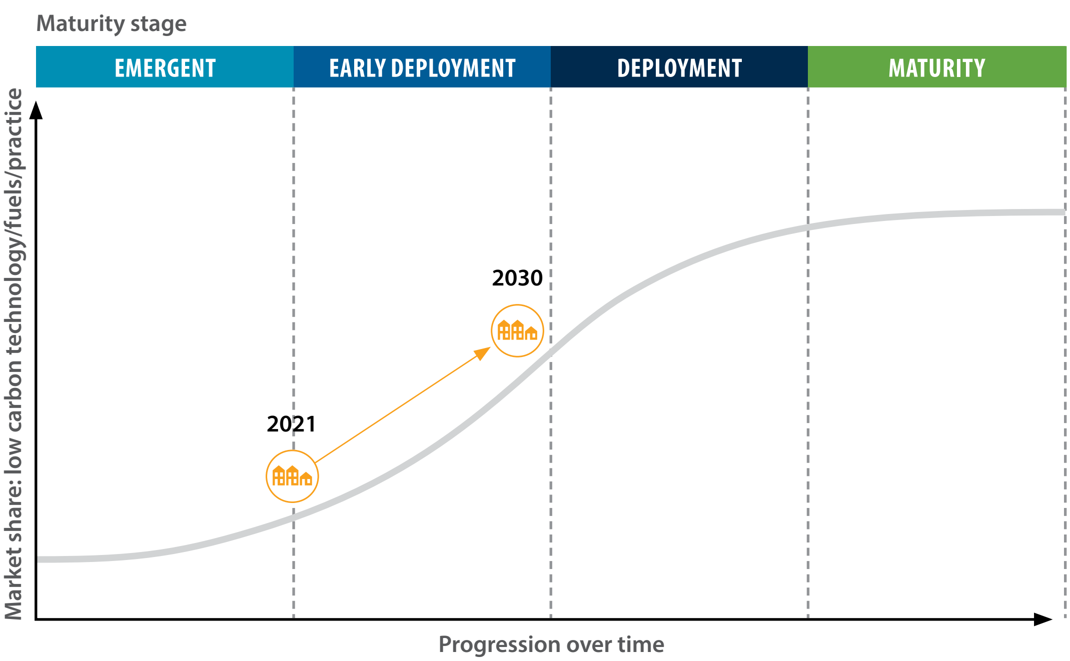
In the consultations that informed this Roadmap, many local governments shared their views regarding the need to:

- *Provide sufficient, flexible and guaranteed climate action funding*
- *Enable local governments to regulate via opt-in legislation and expanded authority*
- *Target capacity constraints through coordination, funding and tailored support*
- *Consider legislative changes to better integrate climate action into Official Community Plans and take a more holistic approach to integrate climate resilience*
- *Increase ZEV targets, carbon tax and the Low Carbon Fuel Standard.*

Where we're starting from

Since 2008, virtually all of B.C.'s local governments have signed the B.C. Climate Action Charter, a voluntary agreement to work toward corporate carbon neutrality, measure community-wide emissions and create complete, compact, more energy-efficient rural and urban communities. Many have ambitious targets and much has been achieved. However, within communities – especially in smaller and rural areas – capacity, environment, geography and size can add to the challenges of taking climate action.

Communities



KEY ACTIONS

- Supporting better land-use planning
- Supporting local climate action
- Improving local governance
- Supporting natural asset infrastructure

THE PATH TO TRANSFORMATION – 2030 AND BEYOND

Transformation for this sector is closely tied to actions in the other Roadmap pathways, including transportation, buildings and low carbon energy, all of which have significant impacts on communities' GHG emissions and will require local government leadership to implement. In this pathway, our work addresses land-use planning, infrastructure and governance – key elements contributing to the larger climate action picture.

Supporting better land-use planning

Land-use planning links communities to the environment and the economy. It's multi-faceted, complex work that affects people's daily lives and plays a large role in shaping how communities will look, feel and function in the future. As part of this Roadmap, we'll work with municipalities and regional districts to enhance their work on land-use planning by:

- Providing better supports, tools and guidance
- Making data available to help inform decisions and assess progress
- Using a climate lens to review provisions in areas such as Regional Growth Strategies, Official Community Plans and zoning.

INTEGRATING TRANSPORTATION AND LAND-USE PLANNING

The Province is developing an integrated planning approach to better align transportation and land-use planning. The goal is to integrate future transportation investments with local and regional development plans, supporting the seamless movement of people and goods, enabling trade, preparing for future growth, and encouraging the development of diverse, affordable, resilient connected communities that provide the amenities, housing and quality of life people value.

As communities grow, we will support them to better align land-use and transportation planning to build connected, mixed-use communities where more people can live closer to jobs, services and transportation choices, helping to reduce commute times and greenhouse gas emissions. Climate sensitive land-use planning can also reduce emissions from deforestation by reducing urban sprawl.

Supporting local climate action

Local governments are climate action leaders and we want to make sure they maintain their momentum. The Province will partner with local governments to find new ways to support their work. This will include establishing a new program in 2022 to support local government climate actions through flexible, predictable funding. And we will continue to work with federal partners to enable local governments, Indigenous communities and stakeholders to apply a climate and resilience lens for all major infrastructure funding applications. This will help ensure that B.C.'s future infrastructure is clean, low carbon and able to withstand the impacts of a changing climate.

Improving local governance

B.C.'s *Community Charter*, the *Local Government Act* (LGA) and the *Vancouver Charter* define the core authorities of local governments and guide their decision making across a range of areas including land-use planning. Because better land use is essential to climate action, we will evaluate opportunities to strengthen the local government legislative framework – working with municipalities, regional districts, Indigenous communities and other key partners to identify where improvements may be needed.

We're also taking steps to re-invigorate and refresh the Province's partnership with local governments and the Union of BC Municipalities (UBCM) through the Green Communities Committee, established under the Climate Action Charter. Committee members support the development of strategies, actions, supports and incentives to advance climate action in all of our communities. They also work with local governments to build their capacity to plan and implement climate change initiatives.

Other actions in this pathway will include:

- Supporting access to GHG emissions data related to buildings, transportation and waste
- Enhancing the existing Community Energy Emissions Database for local governments and Indigenous communities
- Working to develop regionally specific adaptation and resilience strategies as part of B.C.'s Climate Preparedness and Adaptation Strategy; this includes supporting access to data needed for hazard and land-use risk reduction.

Supporting natural asset infrastructure

Natural assets such as aquifers, forests, streams, wetlands and foreshores provide important environmental services equivalent to those from many engineered assets. When we keep them healthy, they're also inherently resilient and adaptable to climate change. With effective monitoring, maintenance and rehabilitation, natural assets can provide services and add value for decades in ways that many engineered assets cannot match. Supporting natural assets can also reduce deforestation, leading to lower emissions.

As part of this Roadmap, we will support the development of natural asset infrastructure for local governments and Indigenous communities, aligned with local government climate initiatives.

2.5 Industry, Including Oil and Gas

B.C.'s industries are making great strides in low carbon innovation, delivering some of the cleanest industrial products of their kind in the world. Keeping them competitive is both an economic and environmental imperative. We produce resources the world needs, and we can make them with a smaller carbon footprint than most of our competitors, helping to address the impacts of climate change worldwide. If production moves to places with less environmentally friendly practices, the planet will be worse off and so will our economy.

To meet our climate targets, B.C. companies will need to continue investing in low carbon technologies and practices. In some cases, they will need support to further reduce emissions so they can stay competitive, attract new investment and showcase their successes to the world.

Where we're starting from

The market for fully decarbonizing large industry in B.C. is at the emergent stage, with a number of solutions and technologies being piloted or demonstrated. Because each industrial facility is different, there is no one-size-fits-all solution, and some operators are farther along the low carbon continuum.

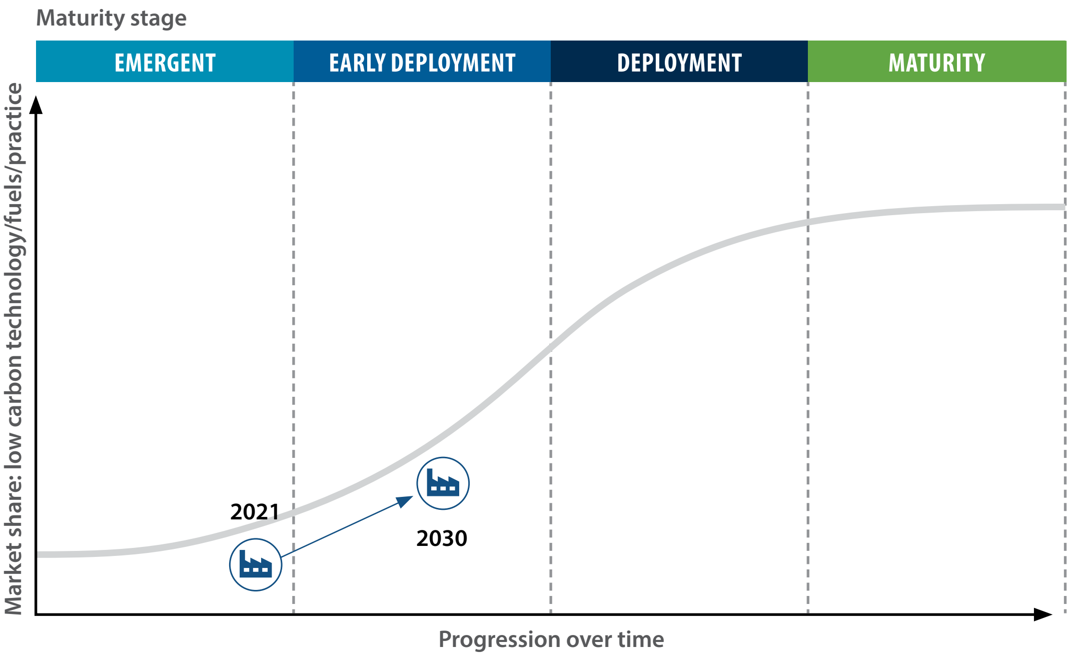
Commercial deployments are also at different stages, largely due to economic factors including cost, scale and regulatory considerations. Promising technologies such as carbon capture and storage are still in early development. And, while we're making progress towards reducing methane emissions in some sectors, we still have work to do on measuring and managing them in others.

What we heard

In the consultations that informed this Roadmap, industry leaders stressed the need to leverage their low carbon advantage while building on our natural resources to create opportunities for low carbon growth, including:

- *Providing a predictable and forward-looking policy landscape that allows for long-term emissions reduction planning and investment*
- *Increasing protection for emissions-intensive trade-exposed industry and considering flexible options, such as offsets or credit generating systems, to help address competitiveness concerns*
- *Providing clarity on how to advance carbon capture, utilization and storage projects, including through regulatory certainty and fiscal measures*
- *Tackling major barriers to electrification such as high initial investment and operating costs and timing uncertainty*
- *Advancing low carbon fuel production and use to fill specific niches within industry.*

Industry, Including Oil and Gas



KEY ACTIONS

- Enhancing the CleanBC Program for Industry
- Making new industrial operations 'net-zero ready'
- Aiming to eliminate industrial methane emissions by 2035
- Reducing emissions from the oil and gas sector
- Integrating emissions goals into the oil and gas royalty system
- Advancing a provincial approach to carbon capture, utilization and storage (CCUS) and negative emissions technologies

THE PATH TO TRANSFORMATION – 2030 AND BEYOND

To help meet our climate targets and keep B.C. industry at the forefront of low carbon innovation and production, we need to work together to reduce industrial emissions as quickly as possible, including continuing to invest in low carbon technologies and practices and implementing more circular processes.

As part of this Roadmap, we'll encourage more facilities to connect to clean electricity, use more low carbon fuels such as hydrogen, explore how best to capture and safely store or use carbon, and reduce industrial methane emissions. We're also moving forward with a suite of new initiatives to help keep our industries competitive as we move to a net-zero future.

Enhancing the CleanBC Program for Industry

The CleanBC Program for Industry supports GHG reductions and competitiveness by investing carbon tax revenue in projects that reduce emissions and costs across B.C. In 2022, we will work with industry, the Government of Canada and Indigenous peoples to redesign the program to align with new federal carbon pricing rules while continuing to promote a competitive business environment and significant GHG reductions.

Our work will include determining how best to support common infrastructure needs through projects such as transmission grids and access to low carbon fuels. We will also explore ways of structuring projects to include and further benefit Indigenous communities.

Making new industrial operations 'net-zero ready'

Electric fleet reduces costs and improves productivity at this B.C. mine

Learn more at: CleanBC.gov.bc.ca/success-stories

Some of B.C.'s largest industrial operators – accounting for almost 50% of industrial GHG emissions – have already committed to reaching net-zero emissions by 2050. Building on that progress, we're introducing a new requirement: all new large industrial facilities must have a plan to achieve net-zero emissions by 2050. New facilities will also have to show how they align with B.C.'s interim 2030 and 2040 targets.

This means facilities will have to be designed to minimize emissions as much as possible. Where emissions can't be reduced, companies will have to assess the use of new technologies such as carbon capture or consider the purchase of high-quality offsets from projects offering long-term carbon sequestration, such as through the use of negative emissions technologies. New net-zero plans will be required and assessed at different stages of development, subject to review, revision and enforcement over time. Government will work with facility proponents to align new policies and compliance mechanisms to support net-zero-emission plans.

This type of planning will future proof our newest industrial facilities, ensuring they can meet the needs of investors and purchasers adhering to a stringent definition of net zero. This approach will also help to drive investments in new, clean B.C. technologies while providing the certainty industry needs to thrive in a global net-zero economy. Government will work with stakeholders and First Nations as these requirements are further developed.

Aiming to eliminate industrial methane emissions by 2035

Methane is a powerful greenhouse gas, with more than 80 times the warming power of carbon dioxide during its first 20 years in the atmosphere. Clearly, we need to reduce its emissions – but measuring them and identifying where they're from has long been a major challenge.

New solutions are becoming available and we're learning more about them, thanks to the work we've been doing with research organizations, the oil and gas sector, the federal government and non-profits. Through the BC Methane Emissions Research Collaborative, we've demonstrated that methane emissions from oil and gas can be detected, attributed and quantified at specific sites, likely in a more cost-effective way than traditional methods.

With this Roadmap, we are committed to building on that research and applying it across the industrial sector to achieve our goal of zero emissions from methane – or as close to zero as possible – by 2035, and to reduce methane emissions in the oil and gas sector by 75% (compared to 2014) by 2030, consistent with the federal commitment. Methane from industrial wood waste landfills can be converted to less-harmful greenhouse gases through landfill management.

Reducing emissions from the oil and gas sector

Currently responsible for 20% of B.C.'s emissions and 50% of industrial emissions, the oil and gas sector will be required to make a meaningful contribution to BC's climate targets. B.C. is the first jurisdiction in Canada to set a specific sectoral target for reducing emissions from the oil and gas industry.

The Province will work to implement policies and programs to reduce emissions in line with its sectoral target of a 33-38% reduction below 2007 levels. In addition to strengthening B.C.'s methane regulations and modernizing B.C.'s royalty system, our new industrial climate program, to be released in 2023, will be designed to ensure the oil and gas sectoral target is met.

We will also commit to cleaning up 100% of current orphan wells in B.C. before 2030 through the industry-funded Orphan Site Reclamation Fund.

Integrating emissions goals into the oil and gas royalty system

B.C.'s royalty system was set up nearly 30 years ago in the 1992 Petroleum and Natural Gas Royalty and Freehold Production Tax Regulation. The way natural gas is produced has changed significantly since then, as have market conditions, drilling technology and costs, and global concerns on the need to address climate change.

As part of this Roadmap, the Province will review the rules for oil and gas royalties to ensure they support our goals for economic development, environmental protection and a fair return on the resource for the people of B.C. It's part of our commitment to reduce emissions from oil and gas by 33-38% by 2030, compared to 2007 levels.

The review will examine ways to adjust the royalty system to help meet provincial emission reduction targets and will consider recommendations from the independent panel currently reviewing B.C.'s royalty system. Policy tools will be considered to encourage further emissions reductions from the sector, and to support the other pathways in this Roadmap.

Advancing a provincial approach to carbon capture, utilization and storage and negative emissions technologies

The full decarbonization of B.C. industry will require widespread electrification; the use of low carbon fuels like lignin, renewable gas and hydrogen; and the use of carbon capture, utilization and storage (CCUS) and other negative emissions technologies across different sectors.

The cleanest cement plant in Canada might be right here in B.C.

Learn more at: **CleanBC.gov.bc.ca/success-stories**

CCUS technologies can reduce emissions in hard-to-abate industrial sectors such as oil and gas, pulp and paper, and cement, where emissions associated with chemical processes cannot be eliminated in any other way. Since they are still in the emergent phase, we will develop a coordinated, comprehensive provincial approach to guide their deployment.

2.6 Forest Bioeconomy

B.C.'s expansive forests are central to our bioeconomy – the part of our economy that uses renewable resources to produce things we use every day like textiles and packaging. By using the residuals from conventional forestry, our forest bioeconomy supports the sector's shift from high volume to high value and contributes to a waste-free, circular economy while helping in the fight against climate change.

INDIGENOUS PEOPLES AND FOREST MANAGEMENT

Forests are, and have been, central to many Indigenous communities whose inherent rights are connected to their respective territories. They provide food, shelter, economic opportunities, tools and medicine along with materials for arts, culture and spiritual activities. For example, some Indigenous peoples see cedar as the tree of life, using it for homes, clothing, canoes, baskets and traditional ceremonies.[6] As the original stewards of the land we now call British Columbia, Indigenous peoples are essential partners in transforming our forest sector from high-volume to high-value, and keeping it sustainable.

What we heard

The Province engages regularly with industry, academia, Indigenous peoples and governments to advance forest sector innovation and build a broader bioeconomy in support of sustainable forest use. Key themes discussed in the consultations informing this Roadmap were:

- *Need for a competitive carbon policy that incentivizes GHG reduction practices and investments in the forest sector*
- *Investments and further engagement to support commercialization of new bioproducts that can replace more GHG intensive products; this includes using lignin in asphalt instead of bitumen and cellulose foams instead of Styrofoam.*

Indigenous peoples we engaged with emphasized the need to balance environmental and economic benefits, noting the alignment between bioeconomy opportunities and their traditional knowledge principles. Some also expressed interest in pursuing carbon offset projects.

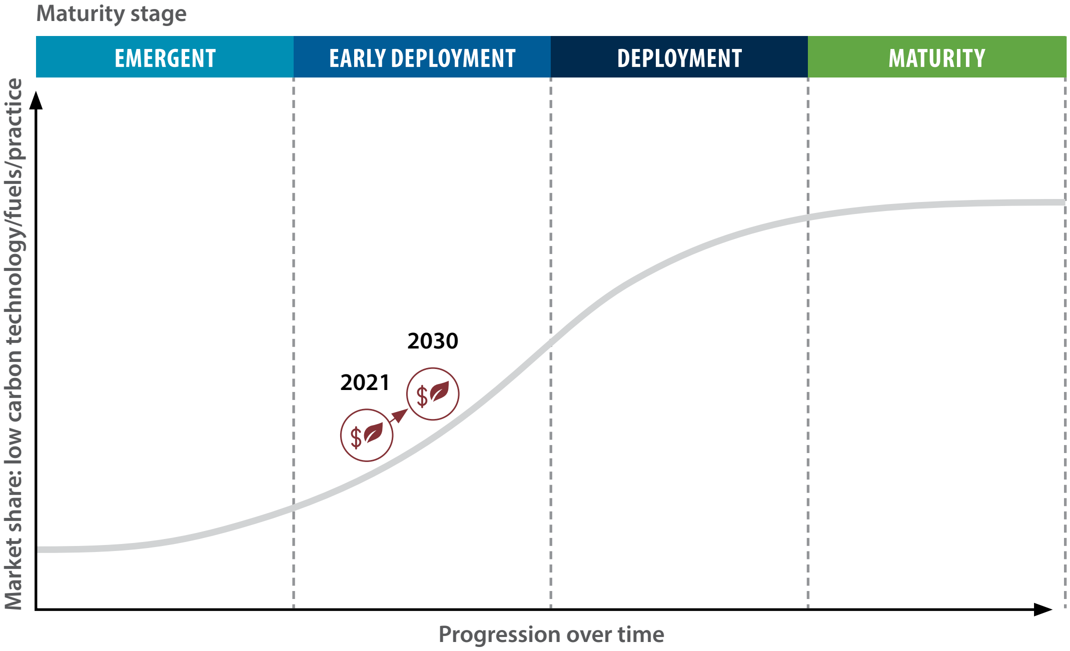
Where we're starting from

The B.C. bioeconomy is currently in early deployment, supported by partnerships with Indigenous peoples and private companies throughout the province. For example, the Indigenous Forest Bioeconomy Program has supported the production of a wide range of innovative high-value bioproducts – from essential oils extracted from conifer needles, to new health beverages from trees, to biochemicals extracted from bark.

There's also a growing market for forest carbon offsets – tradable credits used to offset or counterbalance greenhouse gas emissions. They provide a pathway to meeting climate targets for sectors whose emissions are particularly tough to abate.

6 "The Tree of Life". https://umistapotlatch.ca/enseignants-education/cours_4_partie_2-lesson_4_part_2-eng.php

Forest Bioeconomy



KEY ACTIONS

- Growing and caring for B.C.'s carbon sinks
- Supporting investment in bioproduct development
- Supporting integrated bioproduct manufacturing
- Minimizing slash pile burning/ encouraging fibre utilization

THE PATH TO TRANSFORMATION – 2030 AND BEYOND

The global market for bioproducts is expected to undergo a major transition over the next 10 years, with advanced biomaterials and biochemicals making up the largest market segments.

By 2030, the province should be producing bioproducts at scale and providing high-quality jobs in the bioproducts sector. We'll reach these goals through the following actions.

Old Growth Strategy

Old growth forests – those containing trees that are more than 250 years old – make up nearly one quarter of B.C.'s total forested area. Old growth has a range of benefits, on top of protecting biodiversity, watershed protection and helping the Province adapt to the effects of climate change, they also store large amounts of carbon. Because trees store carbon as they grow, old growth seems like a natural ally in the fight against climate change.

Consistent with the recommendations from the Old Growth Strategic Review, we're integrating climate mitigation into forest management and undertaking research to improve our understanding of old growth forests and their impacts on greenhouse gases. B.C. uses many mitigation options in our forests, including reforestation, fertilization, managing forest health, reducing slash pile burning and using more fibre in longer lived products. Conserving old growth forests as carbon sinks is one of those strategies.

Growing and caring for B.C.'s carbon sinks

B.C. will explore opportunities to partner with the federal government to plant more trees, creating larger carbon sinks and rehabilitating wildfire impacted lands – areas that absorb more carbon than they emit into the atmosphere. We'll also evaluate additional reforestation and forest management activities that sequester carbon and foster climate resilience – including through fertilization, forest health improvements and wildfire mitigation – ensuring opportunities for Indigenous businesses.

A new B.C. Forest Carbon Offset Protocol will expand access to the carbon-offset market for Indigenous communities and forest companies, supporting them to generate revenue while helping others meet their climate commitments. The Protocol will also help to focus attention on the value of non-timber forest benefits, including biodiversity protection and carbon sequestration.

Offset projects will include afforestation (planting trees in areas where there is no forest), reforestation, and improved forest management through practices such as letting trees grow longer before they're harvested. The Province will also explore updating policy and laws to allow the use of Crown land for offset purposes.

Supporting investment in bioproduct development

The Province will partner with Indigenous peoples and industry to build the market for high-value wood products that store carbon or displace products made with fossil fuels. This will include:

- Exploring policy actions, such as biomass content requirements, to increase the use of biomaterials in carbon-intensive products such as concrete, asphalt and plastic components used in finishing cabinets, flooring and other materials
- Encouraging the use of biomaterials in the packaging, consumer goods and biochemical sectors; this could include replacing single-use plastic packaging with biobased materials
- Exploring opportunities to support sector growth through measures such as market and supply chain studies, capacity building, technology assessments and pilot projects for scale-up opportunities
- Advancing mass timber production and use through a Mass Timber Action Plan; work to develop the plan is being guided by a steering committee representing Indigenous communities, industry and government
- Exploring the potential for regional bio-hubs to help ensure communities have access to fibre for diversified manufacturing, and to enhance the number of well-paying forest sector jobs across the province.

Supporting integrated bioproduct manufacturing

One of the potential downsides of forest-based bioproduct manufacturing is having to move material from one site to another. Integrating manufacturing with existing pulp and paper facilities and pellet mills eliminates that issue, creating significant logistical and cost advantages. As part of this Roadmap, we will explore ways to streamline regulations and generate investment for bioproducts facilities at pulp mill sites, allowing producers to make full use of B.C.'s forest resources.

Minimizing slash pile burning and encouraging fibre utilization

Slash piles – the residue from conventional forest harvesting– have long been burned as a way to help reduce the risk of wildfires, and to enhance habitat for wildlife and replanting. The Province will work towards near elimination of slash pile burning by 2030 and will increasingly divert materials away from slash piles and into bioproduct development, reducing both air pollution and GHG emissions while creating new economic opportunities.

In the months ahead, we will partner with forest licensees and Indigenous communities to explore ways to make this feasible, taking into account any impact on wildfire risks. We'll also continue to invest in projects that encourage greater use of forest fibre that would otherwise be burned.

2.7 Agriculture, Aquaculture and Fisheries

The agriculture sector directly accounts for just under 4% of B.C.'s GHG emissions. The largest source is from enteric fermentation, a digestive process of cattle and other ruminants that produces methane, a powerful greenhouse gas. The next largest sources of agricultural emissions are on-farm energy, agricultural soils and manure management.

AGRICULTURE, FISHERIES AND ADAPTATION

Adaptation to climate change has been, and continues to be, a key focus of climate action for agriculture, fisheries and aquaculture. These industries are extremely vulnerable to the impacts of changing weather patterns and severe weather events, including high intensity rainfall, heat waves, drought, wildfire and changing marine conditions. Industry and Indigenous partners are acutely aware that the changing climate affects their productivity and livelihoods, and that building resilience is critical. New measures to support the sector's adaptation will be included in the Climate Preparedness and Adaptation Strategy, due for release in 2022.

What we heard

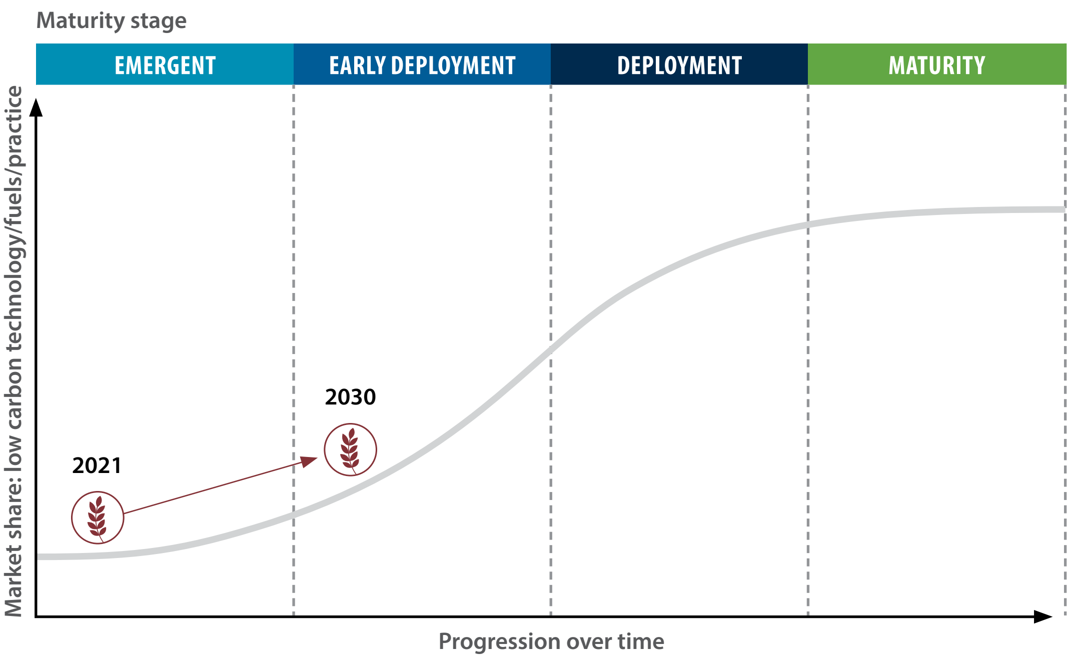
In the consultations that informed this Roadmap, people in the agriculture and aquaculture sectors said they want to continue being informed and consulted as programs and policies are developed and implemented, and want to see their roles and expected contributions more clearly defined. They also highlighted the importance of:

- *Providing financial support to help sectors transition practices and technology*
- *A high-level of buy-in from producers who will readily take up practices that are economically viable*
- *Undertaking research and development and developing monitoring and measurement frameworks to establish benchmarks and track GHG reductions.*

Where we're starting from

The market for decarbonizing agriculture, aquaculture and fisheries is in the emergent phase. Stakeholders have emphasized the need to be realistic about what can be achieved by 2030, noting that cost and economic viability present significant barriers to adopting new solutions.

Agriculture, Aquaculture and Fisheries



KEY ACTIONS

- Supporting GHG efficient practices
- Enhancing agricultural carbon sequestration
- Seizing the potential of regenerative agriculture
- Exploring the potential for seaweed aquaculture to sequester carbon
- Supporting increased on-farm efficiencies and fuel switching, and anaerobic digesters for biogas production

THE PATH TO TRANSFORMATION – 2030 AND BEYOND

To help move the market to early deployment by 2030, we're supporting producers to increase GHG efficient practices and exploring several measures to enhance carbon sequestration.

Supporting GHG efficient practices

As part of this Roadmap, the Province will continue to support the transition to technologies and practices that reduce both net GHG emissions and operating costs for producers. This includes encouraging fuel switching and electrification to reduce emissions from equipment in agriculture, aquaculture and fisheries, along with increased efficiency in manure and nutrient management. We'll encourage the development and piloting of new clean solutions such as electric tractors and technologies to further improve energy efficiency in greenhouses. And, we'll encourage more local, sustainable food production, which has the potential to reduce greenhouse gas emissions in B.C.

Waste management will be supported by growing opportunities to capture biogas, turning farm waste into a valuable resource. Pathway strategies related to biogas will contribute to our goal for renewable energy to make up at least 15% of the content of B.C.'s natural gas by 2030.

Enhancing agricultural carbon sequestration

We will work with the agriculture sector to determine beneficial management practices to maximize carbon sequestration and its benefits to biodiversity, soil and water quality, and farm profitability. Our primary focus in this area is supporting research and monitoring to fill in critical knowledge gaps. We will support applied research, explore piloting promising ideas, monitor results and work to improve local technical knowledge of climate adaptation.

Seaweed aquaculture reduces climate pollution

Learn more at: CleanBC.gov.bc.ca/success-stories

We will also encourage producers to implement regenerative agricultural practices and technologies that improve soil health and biodiversity, allowing farmland to store more carbon. And we'll work with Indigenous communities and the aquaculture sector to explore the carbon-storage potential of seaweed cultivation.

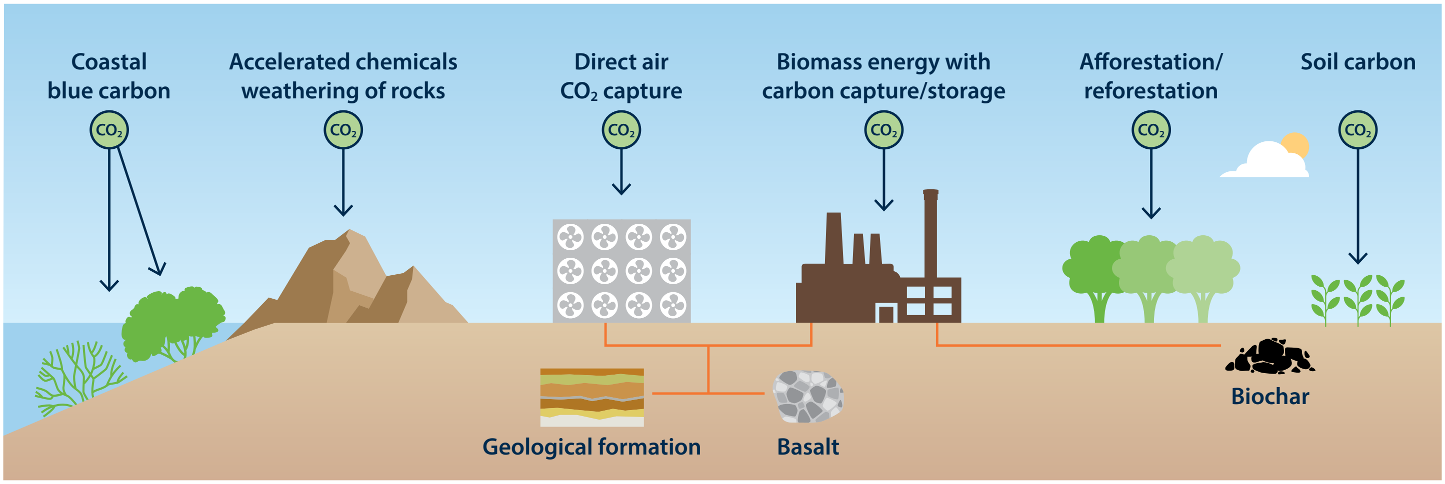
2.8 Negative Emissions Technologies

THE NEED FOR NEGATIVE EMISSIONS TECHNOLOGIES

According to the International Energy Agency, almost half the GHG reductions targeted worldwide for 2050 will come from technologies currently in the demonstration phase. Expert groups like the Canadian Institute for Climate Choices agree on the need for high-risk, high-reward technologies, projecting that solutions such as negative emissions technologies (NETs) could deliver two thirds of the reductions needed to meet our 2050 targets.

Negative emissions technologies can play an important role in meeting our climate targets, especially the long-range commitment to reach net-zero by 2050. They remove CO_2 from the atmosphere, offsetting emissions that have already occurred. NETs range from biological options, such as forest and soil ecosystems, to novel engineered technologies. This pathway is focused on the latter.

Negative Emissions Technologies



Adapted from: National Academies of Sciences, Engineering, and Medicine. 2019. Negative Emissions Technologies and Reliable Sequestration: A Research Agenda. Available online: www.nap.edu/download/25259

What we heard

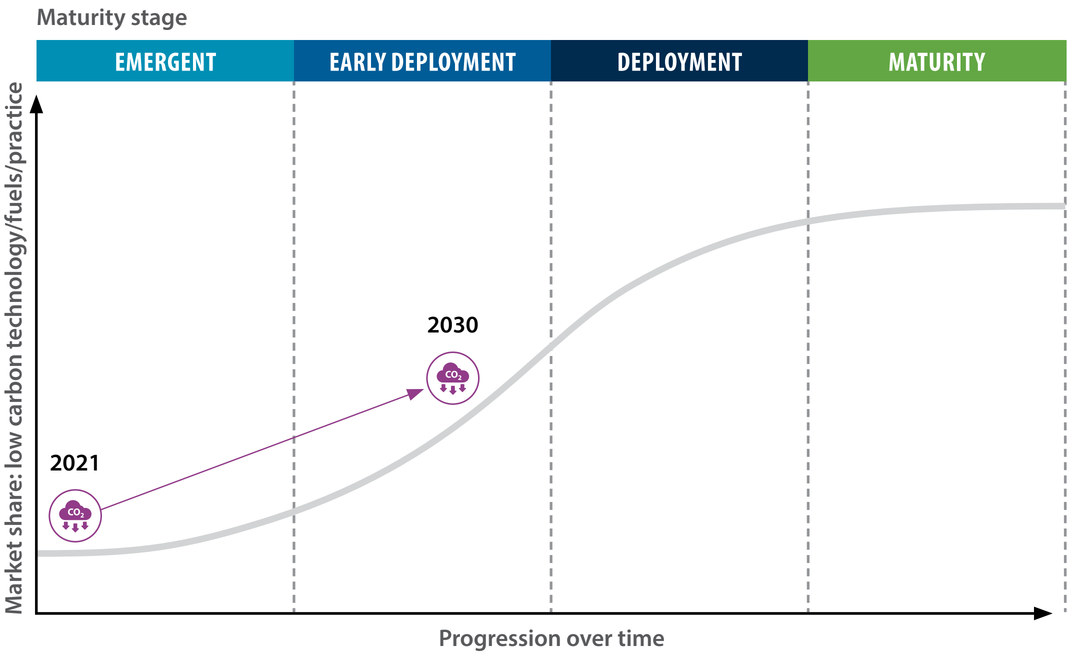
In the consultations that informed this Roadmap, industry, Indigenous peoples, businesses, clean tech companies and others encouraged the Province to explore the potential of NETs. Key themes discussed were:

- *Continuing engagement to develop a policy framework including a clear definition of NETs, especially as many technologies are in development or in early stages*
- *Encouraging NETs as part of a global solution, and considering equity and affordability implications*
- *Targeting NETs to offset emissions in hard-to-decarbonize industries, not as a replacement for decarbonization*
- *Providing adequate funding supports for technology development and to scale technologies for adoption*

Where we're starting from

The market for NETs is still in the emergent stage but B.C. has the capacity and potential advantage to play a lead role in moving it forward. We're home to a rich ecosystem of innovation and clean tech companies with NET solutions at various stages of development. Because of their novelty and complexity, it will take significant time and investment to determine whether their large-scale deployment is cost-effective and functional.

Negative Emissions Technologies



KEY ACTIONS

- Considering NETs as compliance pathways for the Low Carbon Fuel Standard (LCFS)
- Building an accounting framework for NETs
- Investing in research, development and deployment

THE PATH TO TRANSFORMATION – 2030 AND BEYOND

To support the scale-up of NETs by 2030, B.C. needs an enabling environment that supports innovation, incentivizes public-private involvement and is flexible enough to adapt to change. That could include a supportive regulatory and policy climate, economic incentives, measures to reduce costs or new business models to achieve economies of scale.

To achieve these goals and move the market, we will provide investments through InBC to help small- and medium-sized B.C. companies scale up and reach their highest potential. InBC investments will help foster a low carbon economy by anchoring talent, innovation, intellectual property and high-quality, family-supporting jobs throughout the province. We'll also take the following actions.

Considering NETs as compliance pathways for the Low Carbon Fuel Standard (LCFS)

The LCFS requires fuel suppliers to progressively decrease the average carbon intensity of the fuels they supply to users in B.C. By 2030, they'll have to deliver a reduction of more than 20%, with the target continuing to rise in the coming years.

Recognizing the challenges inherent in reducing carbon intensity, we will consider allowing NETs as an option for compliance. This could attract significant new investment to B.C., along with new jobs in clean technology. A final decision on the LCFS will be based on consultations and assessments of recent program changes affecting costs and emissions.

Building an accounting framework for NETs

Currently, our GHG accounting used to measure progress to targets only captures emission reductions from forest-offset projects, since they are the only NET that currently meets our rigorous standards for planning, implementation and monitoring. As more engineered solutions come online, B.C. will build an accounting framework by 2025 to define how other types of NET projects may impact emissions reductions, and how they can be brought into the inventory's scope. This will ensure they're evaluated on a lifecycle basis so we don't adopt technologies that ultimately require more materials and energy, and produce more GHGs, than what they're capturing and storing.

Once we're able to reliably quantify the impacts of NETs, we will clarify their role in carbon offsets. We will also advocate for international collaboration to ensure national inventories can account for NETs consistently.

Investing in research, development and deployment

As noted in the industry pathway, B.C. will develop a comprehensive provincial approach to carbon capture, utilization and storage (CCUS) technologies, leveraging supports such as the federal investment tax credit for CCUS. We'll also consider additional grants and incentives for research and development, pilot projects and commercial scale deployment.

Negative emissions technologies are breathing fresh air into emissions reductions

Learn more at: CleanBC.gov.bc.ca/success-stories

Some of this support will be delivered through the new B.C. Centre for Innovation and Clean Energy. Its mandate is to bring together innovators, industry, academics and government to accelerate the commercialization and scale-up of B.C. based, clean energy technologies. We will also assess the need for new provincial tools to encourage private-sector investment in NETs. And we will assess the potential of research developed through the University of British Columbia and University of Victoria to mineralize CO_2 from the atmosphere to store it in rock and in other materials.

CHAPTER 3: NEXT STEPS AND IMPLEMENTATION

The CleanBC Roadmap to 2030 is designed to be a living document, to be revisited and updated as we move forward to ensure we stay on track to meet our targets. In the months ahead, we will engage with partners and stakeholders to work out the details of major new measures and find the best ways to put them into practice.

Many of the actions in this Roadmap will expand and accelerate CleanBC policies and programs already in place. Others will require close monitoring and adjustments as we learn from experience. Where policies are working, we'll act quickly to ramp up our efforts. Where they're not as effective, we'll change course, in close collaboration with affected sectors.

As we chart our progress, we will continue to provide detailed reporting to the public through the annual Climate Change Accountability Report, which includes progress indicators for CleanBC programs. In future years, we will also report on the following indicators specific to the Roadmap:

- Market share of technologies, reflecting the extent to which low-emission solutions are being adopted
- Cost of transformation for each sector
- Workforce and skills readiness, reflecting our capacity to adopt new approaches
- Economic and social opportunities, pointing to important co-benefits such as reducing inequality and advancing reconciliation with Indigenous peoples.

The work ahead will be challenging. Transforming British Columbia's economy will require determination, particularly as many of these changes will be made in less than a decade. Achieving our targets will demand an unprecedented level of commitment. It will also offer unprecedented opportunities for the future as we work towards net zero by 2050.

Successful implementation of this plan will require a focused, all of government approach. To support this, the Premier has instructed all Ministers, via mandate letters, to ensure their work continues to achieve CleanBC's goals.

Business and industry will have new opportunities to innovate and build on the CleanBC actions and supports, as well as our global reputation as a place for environmental, social and governance investments and net-zero focused business. Local governments will have new opportunities to build more liveable, compact and energy-efficient communities. Indigenous peoples will have new opportunities to advance their self-determination and participate more fully in every sector of our economy. And everyone in B.C. will have the opportunity to look forward to a cleaner, better future.

We're building a British Columbia where no one's left behind; where innovation drives new advances and keeps us competitive; where we all enjoy improvements in our quality of life and prosper along with – not at the expense of – our natural environment. Meeting our climate targets and building a cleaner economy is fundamental to making this future a reality.

APPENDICES

Roadmap to 2030 Greenhouse Gas Reductions by Initiative

Economy-Wide Initiatives		
Increase the price of carbon pollution	Meet or exceed the federal benchmark of $170 by 2030	
	Revise industrial carbon pricing in 2023	
Reduction of GHGs in 2030 for Economy-Wide Initiatives		**Subtotal 2.4**
Low Carbon Energy		
Enhance the Low Carbon Fuel Standard	Increase the carbon intensity reduction requirement	
	Expand to include marine and aviation fuel	
	Double production capacity for made-in-B.C. renewable fuels to 1.3bn litres	
Increase benefits of electrification	Implement 100% Clean Electricity Delivery Standard	
Reduce emissions from natural gas	New GHG cap for natural gas utilities with a variety of compliance options	
Reduction of GHGs in 2030 for Low Carbon Energy		**Subtotal 5.0**
Transportation		
Accelerate zero-emission vehicle (ZEV) law	By 2030, ZEVs will account for 90% of all new light-duty vehicle sales in the province	
	New ZEV targets for medium- and heavy-duty vehicles to be developed in alignment with California	
Reduce light-duty vehicle travel	Reduce distances travelled by vehicle by 25% relative to 2020	
	Encourage increase in mode shift to walking, cycling and transit to 30% by 2030	
Reduce goods movement emissions	Reduce the energy intensity of goods movement by 10% relative to 2020	
Reduction of GHGs in 2030 for Transportation		**Subtotal 4.9**
Buildings		
New carbon pollution standard in BC Building Code	Carbon pollution standards introduced for new buildings in 2024, with zero-carbon new construction by 2030	
Highest efficiency standards	After 2030, all new space and water heating equipment sold and installed in B.C. will be at least 100% efficient (i.e. electric resistance heating, heat pumps, and hybrid electric heat pump-gas systems)	
Reduction of GHGs in 2030 for Buildings		**Subtotal 1.3**
Industry		
Enhance CleanBC Program for Industry	Enhance industry program to reduce GHGs and support a strong economy	
Reduce methane emissions	Near elimination of methane emissions by 2035 in oil and gas, mining, industrial wood waste and other sectors	
Make new industrial operations 'net-zero ready'	New large industrial development to submit plans to achieve net-zero emissions by 2050 and show how they align with interim 2030 and 2040 targets	
Reduce oil and gas sector emissions	Implement programs and policies so that oil and gas emissions are reduced in line with sectoral targets (reduction of 33-38% by 2030)	
Reduction of GHGs in 2030 for Industry		**Subtotal 2.6**
Other Measures Including: reducing agricultural emissions, supporting compact and resilient communities, and aligning with federal, municipal and Crown Corporation plans.		
Reduction of GHGs in 2030 for Other Measures		**Subtotal 0.9**
Note: Individual pathway reductions do not add up to the totals because of interaction effects between policies that target the same emissions		
Roadmap to 2030		16.2 $MtCO_2e$
CleanBC Phase 1		10.5 $MtCO_2e$
Total GHG $MtCO_2e$ reduced by 2030		**26.7 $MtCO_2e$**
The legislated target for 2030 is 39.4 $MtCO_2e$ (or a reduction of 26.3 $MtCO_2e$ from a 2007 baseline), which we are exceeding by 0.4 $MtCO_2e$.		

Roadmap Portfolio of Measures

Near-term

- Evaluate additional reforestation and forest management activities
- Support carbon sequestration, on-farm efficiencies, fuel switching and anaerobic digesters for biogas production
  Support investment in bioproduct development
- Phase out utility gas equipment incentives
- Implementation of BC Hydro Electrification Plan
- Local government climate action program
- Enhanced CleanBC Program for Industry
- Develop province-wide Circular Economy Strategy
- Establish energy intensity targets
  Implement Clean Transportation Action Plan
  ZEV targets for medium- and heavy-duty vehicles in place
- BC Hydro 100% Clean Electricity Delivery Standard
- Establish requirement for net-zero 2050 plans for industry
  Decision on industrial (including oil and gas) methane approach
  Advance provincial approach to CCUS
- Establish emissions cap for natural gas utilities (GHG Reduction Standard) for 2030
  Enhance LCFS including increasing stringency for 2030 and expanding to aviation/marine fuels
- Public sector new building and light-duty, ZEV-first requirements
  Revised carbon pricing system, including for Industry, that meets or exceeds federal benchmark and protects affordability

Mid-term

- Ensure broad geographic coverage of fast-charger sites
- Introduce carbon pollution standards in the BC Building Code for new buildings
  Energy-efficiency standards for existing buildings in the BC Building Code
- Requirement for low-carbon and resiliency standards for existing public sector buildings
- Implement energy intensity targets/policies for movement of goods
- Develop accounting framework for NETs
- Evaluate opportunities to strengthen local government legislative framework
- Public sector medium- and heavy-duty ZEV-first requirement
- ZEV targets to 26% for new light-duty vehicles
- Public sector 100% light-duty ZEV fleet acquisitions
  Zero-carbon new public sector buildings
- Near elimination of slash pile burning

2030

- ZEV targets to 90% for new light-duty vehicles
  10,000 public EV charging stations
- Highest efficiency standards for new space and water heating equipment and zero-carbon new construction
- Oil and gas sector achieves sectoral target and 75% reduction in methane
  Clean up 100% of current orphan wells
- Increase stringency of LCFS and double production of renewable fuels produced in B.C.
  Phase out gas-fired facilities
- Embodied carbon targets for public sector buildings

Agriculture, Aquaculture and Fisheries
Forest Bioeconomy
Personal Travel
Commercial Transportation
Circular Economy
Buildings
Negative Emissions Technologies
Low Carbon Energy
Electricity
Communities
Industry/Oil and Gas

The Roadmap is an iterative document subject to change on the basis of emerging technologies and changing social, economic and business environments.

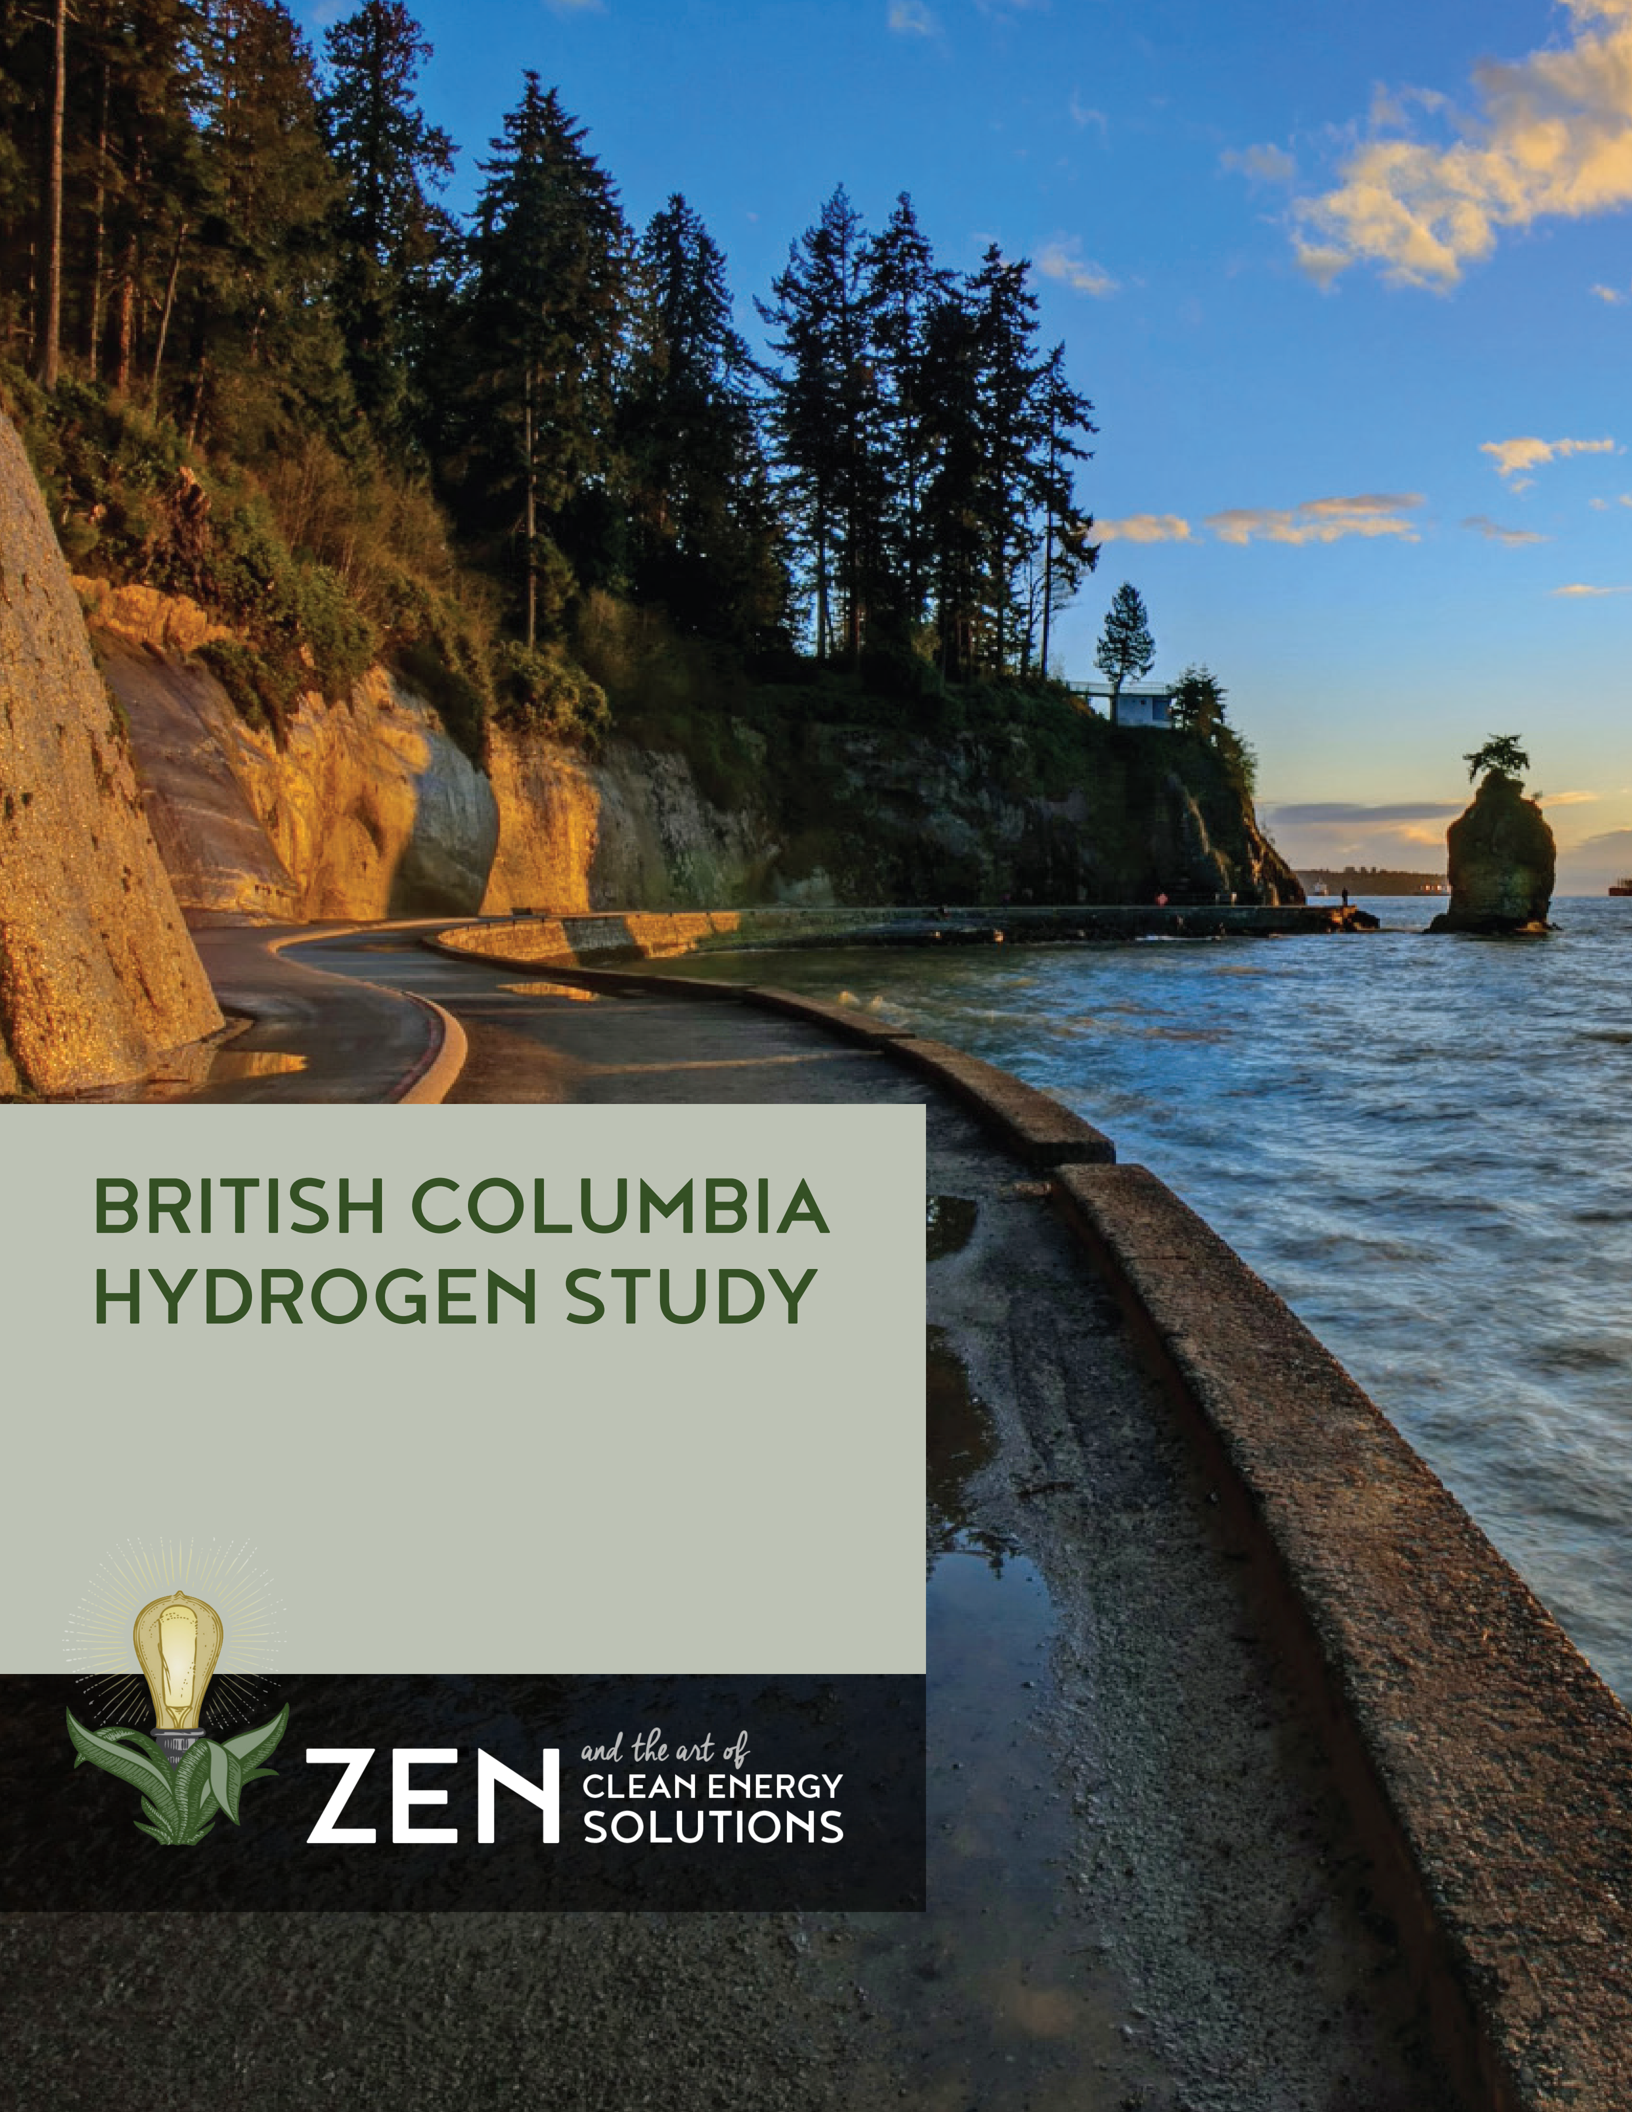
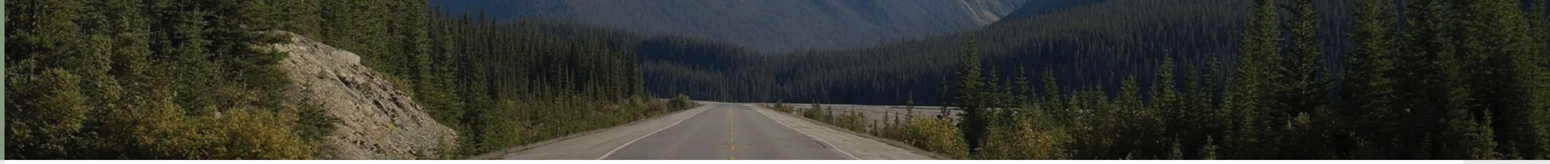
BRITISH COLUMBIA HYDROGEN STUDY – BC BIOENERGY NETWORK



BRITISH COLUMBIA HYDROGEN STUDY

ZEN and the art of CLEAN ENERGY SOLUTIONS



ACKNOWLEDGEMENTS

The BC Hydrogen Study was conducted by Zen and the Art of Clean Energy Solutions and project partners the Institute for Breakthrough Energy and Emission Technologies and G&S Budd Consulting Services. Work on the study ran from February 2019 to June 2019.

The project team would like to thank the many individuals and organizations that provided input to the study through participation in workshops, surveys, and individual interviews. The team would also like to thank the BC Ministry of Energy, Mines and Petroleum Resources, BC Bioenergy Network, and FortisBC for support and guidance throughout the study.

FORTIS BC™

EXECUTIVE SUMMARY

Why Hydrogen in BC?

Deployment of hydrogen in British Columbia (BC) will be required for the Province to meet 2030 and 2050 decarbonization goals and emissions reduction commitments. End use energy demand in BC was 1,165 petajoules (PJ) in 2016, with 68% of demand met through refined petroleum products and natural gas. Direct electrification and increased supply of renewable natural gas will not be able to displace all this energy to transition the Province to lower carbon and ultimately renewable energy sources. Hydrogen will play a critical role, particularly in energy intensive applications that are most reliant on fossil fuels today such as long-range transportation and heating.

Hydrogen is a versatile energy carrier that can be made from a range of feedstocks that are abundant in our Province, and it has the advantage of being carbon free at the point of use. BC has a distinct comparative advantage because of its clean electricity and low-cost natural gas resources, both of which can be leveraged to produce hydrogen. Hydrogen can be:

- *Blended with BC's rich natural gas reserves to create a cleaner burning fuel and increase the renewable content of the gas delivered through our extensive natural gas infrastructure;*
- *Used directly in fuel cells to produce zero emission electricity in electric vehicles, stationary power systems, and off-road industrial vehicles; and*
- *Utilized as a feedstock in industrial applications, including to produce renewable synthetic liquid fuels that allow existing combustion engines to be used in a cleaner and more sustainable way.*

Use of hydrogen in BC is in the nascent stages, while the pace of worldwide deployment is clearly accelerating. For BC to realize 2030 emissions reductions goals as set out in the CleanBC plan, it is important for government to work with industry now to establish supply and infrastructure necessary to stimulate adoption in the Province. Export opportunities can help to bring international investment to the development of our hydrogen energy systems and provide strong revenue generation potential.

Building of a vibrant and robust hydrogen economy in the Province will result in:

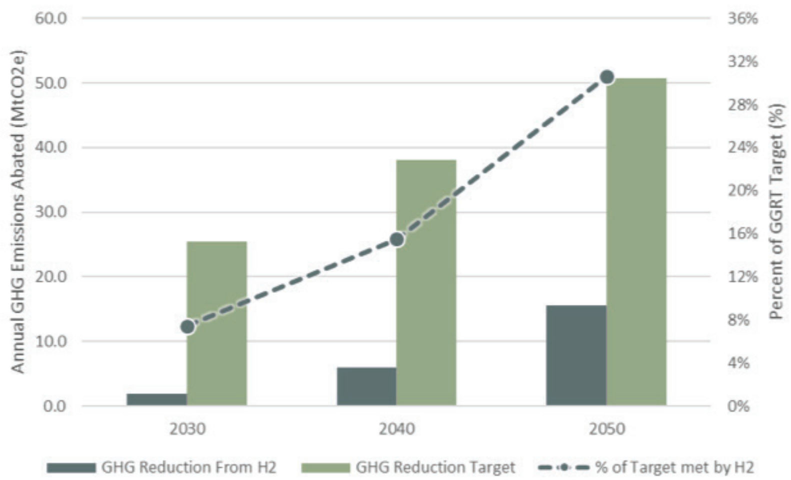
- *Decarbonization of hard-to-abate sectors of the economy such as heating and cooling, long-range transportation applications, and energy intensive industries;*
- *Economic growth and job creation through the development of BC's hydrogen supply chain and infrastructure, and supply to emerging export markets; and*
- *Leveraging BC's natural gas reserves and infrastructure to meet emissions reductions goals in the mid-term while transitioning to renewable energy sources in the long-term.*

Large-scale deployment of hydrogen in BC can close the gap in current plans to balance both emissions reduction and optimal utilization of BC's natural resources and infrastructure assets. It will also benefit the Province's world-class hydrogen and fuel cell sector which is increasingly facing pressures to develop new intellectual property (IP) abroad, in regions where governments support both deployment and development of hydrogen and fuel cell technologies.

Decarbonization of Economic Sectors

CleanBC is the Government of British Columbia's plan for achieving its greenhouse gas (GHG) emissions reductions commitments from the May 2018 Climate Change Accountability Act, formerly titled Greenhouse Gas Reduction Targets (GGRT) Act.

To meet its commitments, provincial emissions will have to fall 40% from the 2007 baseline by 2030 and 80% by 2050. Hydrogen is needed to meet those decarbonization objectives, with study findings demonstrating that hydrogen can contribute up to 31% of the 2050 carbon reduction target, at 15.6 Mt CO_2e/year reductions. The benefits of hydrogen will be strongest in the 2030 – 2050 timeframe, after other high-yield opportunities outlined in the CleanBC plan have been implemented and exhausted. In this period, hydrogen can reduce emissions by 13.7 Mt CO_2e, which represents 54% of the Province's goal during that timeframe.

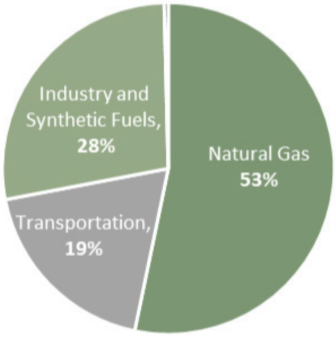


The opportunities where the greatest decarbonization impacts can be realized are: 1) through injection of low carbon hydrogen into the natural gas grid, which will have benefits in the built environment, transportation, and industry economic sectors in the Province; 2) through using low carbon hydrogen directly as a transportation fuel; and 3) through the production of low carbon synthetic fuels that can be used as drop in replacement for current combustion engines and are an important enabler in meeting the Renewable and Low Carbon Fuel Requirements Regulation in BC.

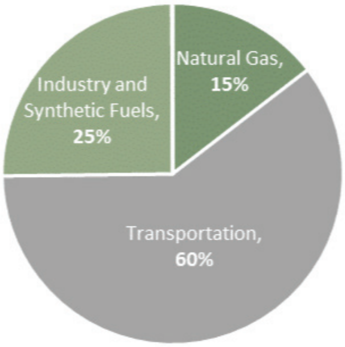
The relative benefits in these applications will shift over time. In the near-term, the easiest and lowest cost way to use hydrogen which will have the highest emission reduction potential in the Province is to inject it into the natural gas grid, and directly reduce emissions by utilizing the lower carbon hydrogen/natural gas blend. Ultimately directly using hydrogen as a transportation fuel will dominate in emissions reduction potential.

The deployment of both battery electric and fuel cell electric vehicles (FCEVs) is critical to reducing emissions in BC. The higher range and faster refueling times of FCEVs will lead to meaningful market share in the Province, particularly in larger passenger vehicles and in medium and heavy-duty vans, buses, and trucks. Utilizing hydrogen directly as a transportation fuel offers the greatest advantages for emissions reduction, as electrochemical conversion of hydrogen in fuel cells is twice as efficient as combustion. Regulation and financial support for infrastructure build out will be critical to achieving the adoption potential of FCEVs. As the transition to FCEVs is evolving, hydrogen can offer emissions reduction benefits in transportation applications through enabling higher use of renewable natural gas (RNG), in co-combustion retrofit engines, and as a low carbon feedstock for synthetic fuels.

2030 GHG Reduction Opportunities
1.9 Mt CO_2e/year



2050 GHG Reduction Opportunities
15.6 Mt CO_2e/year



In these graphs, 'Natural Gas' includes all end use applications that would benefit from the lower carbon H_2/NG blend, including heating in the built environment and industry, and transportation applications running on compressed natural gas (CNG). 'Transportation' refers to applications where pure hydrogen is used as a transportation fuel, either in fuel cell electric vehicles or hydrogen/diesel co-combustion engines.

Economic Growth and Job Creation

Since Geoffrey Ballard first set up shop in North Vancouver in 1979, Canada's hydrogen and fuel cell sector has been recognized as a global leader, with BC hosting Canada's largest industry cluster. BC has pioneered new technologies and industry expertise in areas such as hydrogen production and processing, fuel cell stack and system development, components and systems testing and test infrastructure development, technology research and development (R&D) and commercialization, and standards development. BC is also home to world class academic institutions with specialized programs and R&D supporting the clean tech sector. Local deployment of hydrogen technology will help to maintain a healthy economic cluster in the Province, and will help to develop technical expertise, job opportunities and IP, and will also contribute to continued growth of the sector by ensuring BC maintains a strong competitive advantage.

BC's economy is heavily dependent on the extraction, consumption, and export of natural resources, and hydrogen fits as a value-added future export resource that can support both local and international decarbonization efforts. Hydrogen is expected to become increasingly important in the world's energy systems as countries around the world develop roadmaps to achieve decarbonization goals and to improve local air quality. BC's coastal access and relative proximity to leading markets such as California, Japan, China and South Korea position BC to become an exporter of clean hydrogen. By 2050, demand in those target regions is projected to reach 100 million tonnes/year under moderate forecast assumptions, with significant upside potential. If BC were to capture 5% market share in those regions, the export market could be $15 billion annually. International investment for large-scale hydrogen production would benefit local markets while generating significant revenue and should be considered as a significant opportunity for the Province.

The Intergovernmental Panel on Climate Change (IPCC) estimates that USD $2.4 trillion will need to be invested through 2035 in clean technology deployments.[1] A portion of that investment will be made in the hydrogen sector, and BC can benefit from that through its leadership in the development and deployment of hydrogen technologies. BC is well positioned to reinvigorate its leadership position in innovation and venture creation. Build-out in the Province will benefit professional, trades, and manufacturing employment.

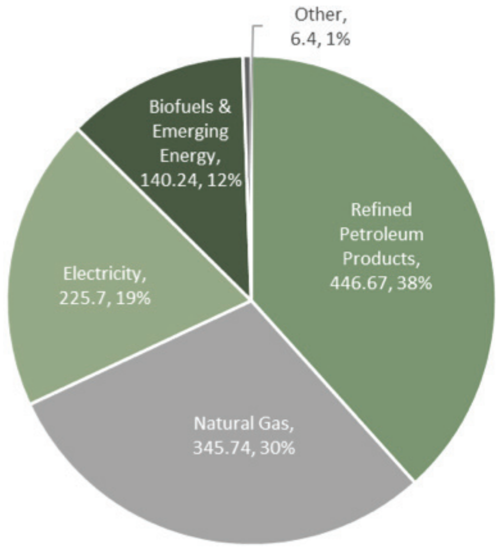
Low Carbon Use of Natural Gas Reserves and Infrastructure

BC is fortunate to have an abundance of clean, renewable hydroelectric power. In 2016 electricity supplied 19% of the Province's end use energy requirements. Electrification is a major theme in CleanBC to meet the Province's emissions reductions goals. While electrification will play an important role, it has limitations in generation capacity and transmission and distribution. Some applications are better served by gas as an energy carrier, such as high-grade heat production and long-range transportation. BC has abundant low-cost natural gas reserves that will play a role in meeting energy needs of the Province far out into the future. The National Energy Board (NEB) forecast shows increasing demand for both natural gas and refined petroleum products in BC out to 2040. This is at odds with the Province's emissions reduction goals unless we can find ways to decarbonize those energy sources. Hydrogen can play a key role in this through the decarbonization of natural gas at the source of extraction, and as a renewable feedstock for refined petroleum products and lower carbon intensity synthetic fuels to replace conventional refined petroleum products.



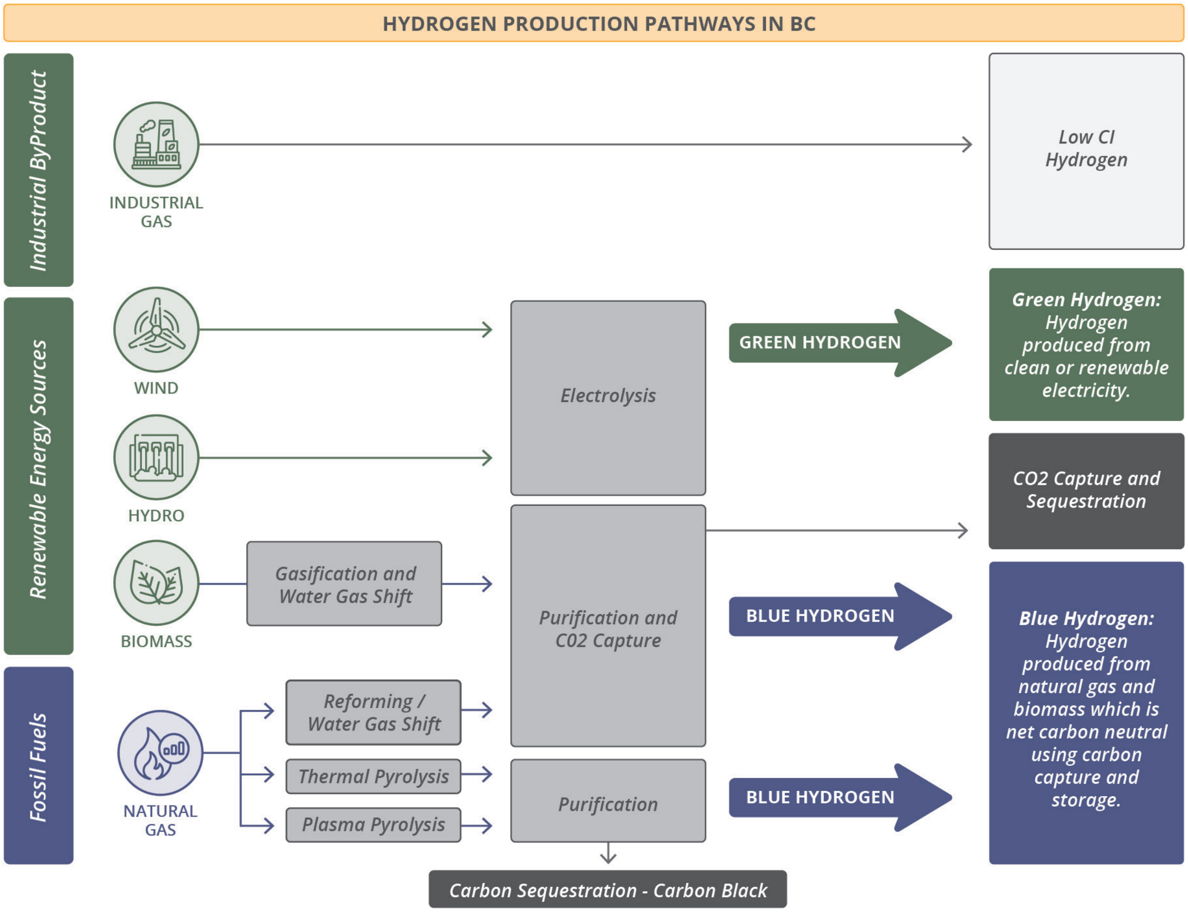
2016 BC End Use Energy Demand[2]

The natural gas infrastructure is a strategic asset for BC. Repurposing that asset for both the transportation and storage of hydrogen presents a cost-effective pathway for the large-scale deployment of hydrogen in the Province. The existing natural gas infrastructure can act as storage for low carbon hydrogen, initially as a hydrogen/natural gas blend and transitioning to 100% hydrogen in some regions of the Province over the longer-term. Hydrogen produced via electrolysis can also foster greater integration of our electricity and gas energy system, optimizing the Province's overall energy systems to achieve optimal efficiency and economic return on critical infrastructure assets.

Hydrogen Production Pathways in BC

Hydrogen can be produced via different pathways using a range of feedstocks. Hydrogen can be made via renewable and fossil fuel resources and is a by-product of some industrial processes. In this study, only 'Green Hydrogen' produced from clean and renewable electricity, 'Blue Hydrogen' produced from natural gas or biomass coupled with carbon capture and storage (CCS), and low carbon intensity (CI) industrial by-product hydrogen are considered.

2 *Canada National Energy Board (2017). Canada's Energy Future 2018: Energy Supply and Demand Projections to 2040. Retrieved from https://apps.neb-one.gc.ca/ftrppndc/dflt.aspx?GoCTemplateCulture=en-CA*

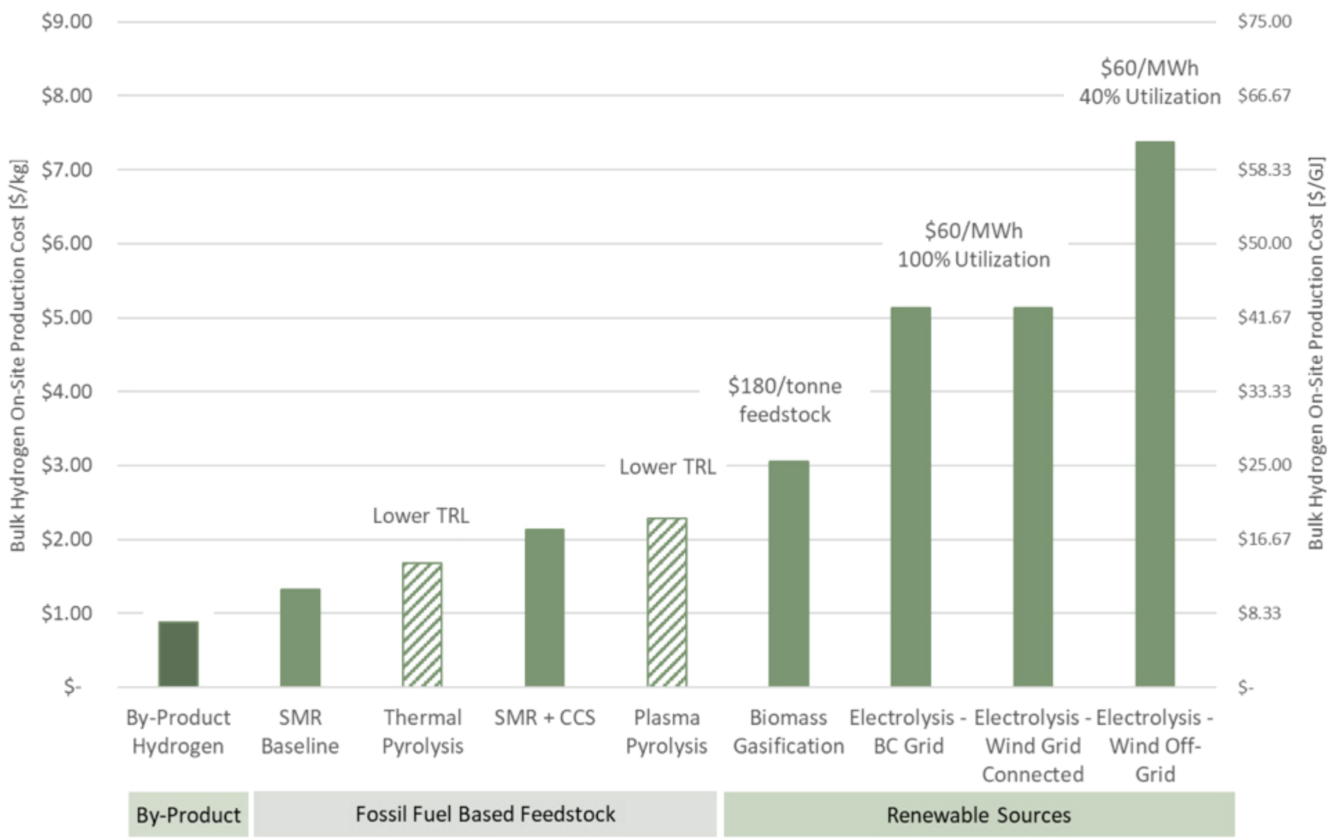


Hydrogen produced at scale from natural gas offers the lowest cost source of low carbon intensity hydrogen when coupled with carbon capture and storage technology. BC has substantial natural gas reserves in the Northeast of the Province, estimated at 525 trillion cubic feet and sufficient to meet 315 years of BC natural gas demand at current levels. The Province also has depleted gas reservoirs and saline aquifers that enable large volumes of CO_2 sequestration. Steam methane reforming (SMR) coupled with carbon capture and storage at the point of extraction is a mature commercial process, whereas pyrolysis with carbon black as a byproduct shows strong potential but is at lower technology readiness level (TRL).

Renewable sources of hydrogen in the Province are currently more expensive than fossil pathways. Production of hydrogen via electrolysis enables a distributed model of hydrogen production that is inherently scalable. While offering many advantages, the electrolysis pathway is currently the most expensive for at-scale hydrogen production in the Province. Flexible, low-cost electricity rates are essential to promoting the growth and adoption of Green Hydrogen.

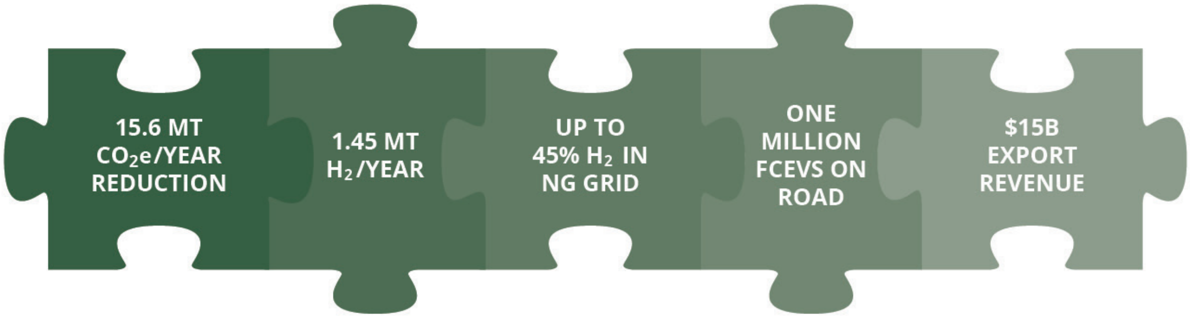
There is an immediate urgency to decarbonize BC's energy supply across all industry sectors, and low carbon intensity hydrogen from fossil fuels is seen as a key enabler to cost effective deployment of hydrogen in the intermediate period. The Province needs policy to drive adoption of multiple energy pathways to ensure both decarbonization and sustainability goals are met. Our policies should set BC as the global leader in hydrogen production with a clear understanding of how their inherent cost structure will drive market adoption of the lower cost natural gas sourced hydrogen to the more expensive fully renewable hydrogen as the finite hydrocarbon sources are depleted over time.

A key pillar to the successful introduction of hydrogen in BC is government support for infrastructure development for the production, distribution, and dispensing of hydrogen. Establishment of low-cost supply channels must lead large-scale adoption in the Province. Development of a robust hydrogen supply chain is also expected to attract new industry to the Province that relies on hydrogen as a feedstock.



Vision for 2050

BC can be a global leader by adopting policies that promote and support all sides of an emerging hydrogen economy including demand, supply and technology development. Through a combination of policy and investment, hydrogen can play a major role in the Province by 2050.



Recommendations

The report outlines a comprehensive list of 38 instrument and policy recommendations to support development of a vibrant hydrogen economy in BC.

The top ten recommendation themes for the 2020 – 2025 timeframe are to:

1. *Identify and communicate hydrogen as priority sector for the Province.*
2. *Prioritize development of large-scale, low carbon intensity hydrogen supply infrastructure and strategic hydrogen liquefaction and distribution assets in the Province.*
3. *Adopt policy that specifies the carbon intensity of hydrogen, rather than limiting to renewable only. This includes updating the definition of renewable natural gas in BC's Greenhouse Gas Reduction Regulation to include low carbon intensity hydrogen.*
4. *Set longer-term objectives for transition to renewable hydrogen supplies through establishing tiered thresholds of required renewable content over time.*
5. *Develop flexible, lower cost electricity rate schedule to encourage production of Green Hydrogen.*
6. *Support lighthouse projects that will demonstrate the potential of hydrogen in critical end use applications.*
7. *Adopt recommended policies and regulatory framework for light and heavy-duty FCEVs and support the build out of hydrogen refueling infrastructure.*
8. *Support research, development and deployment in the Province to ensure the local hydrogen cluster maintains competitive global advantages and remains an important economic sector within the Province.*
9. *Support initiatives related to developing an export market for hydrogen, particularly those that can leverage international investment to develop local supply of hydrogen.*
10. *Prioritize a strategic investment fund to support the above recommendations.*

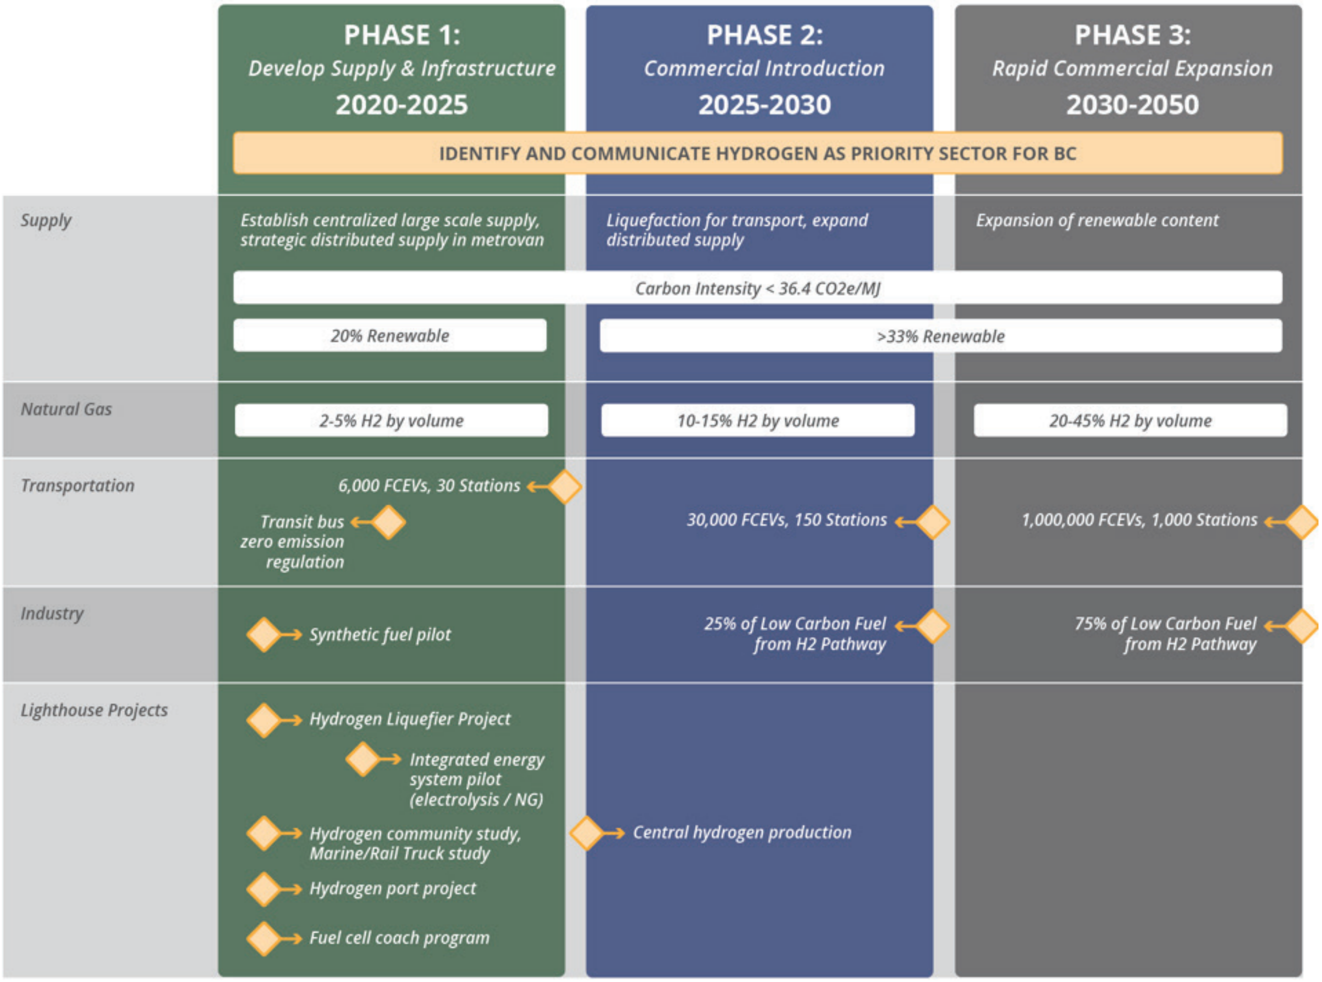
Recommended Investment, 2020-2025

Government investment is needed to establish a robust hydrogen economy in BC. That investment will provide the necessary infrastructure and sector support to allow industry to establish a foundation from which to grow commercial deployments. Government investment will yield necessary decarbonization benefits for the Province, economic growth potential, and long-term diversity and security of our energy systems.

Our analysis recommends a total spend from the Province in the order of $176,000,000 over the next five years, which is approximately $35,200,000 per year. This funding would be focused primarily on supporting lighthouse projects and studies, funding critical infrastructure development, providing subsidies for the rollout of light-duty FCEVs, and supporting the sector through establishing dedicated R&D funding. It is anticipated that this Provincial funding would be leveraged with Federal and Industry match funding, thereby amplifying the benefits of this investment in the Province.

Hydrogen in BC – A Phased Approach

For hydrogen to play a critical role in BC's energy systems in the mid and long-term, it is important to set goals and start developing supporting infrastructure and policies now. Over the next 5 years, the focus needs to be on establishing supply and distribution infrastructure for hydrogen, with lighthouse projects supported to initiate the rollout of end use applications in the Province. The following schematic summarizes the phases of hydrogen rollout and opportunities in the various applications over time.



GLOSSARY

TERM	DEFINITION
AANDC	*Aboriginal Affairs and Northern Development Canada.*
AZETEC	*Alberta Zero-Emissions Truck Electrification Collaboration.*
BC	*British Columbia.*
Ballard	*Ballard Power Systems.*
Bbl/d	*Barrels per day. Measure of production capacity for fuel.*
BCBN	*BC Bioenergy Network.*
Bcf	*Billion cubic feet. A measure of the energy content of one billion cubic feet of natural gas.*
Bcfd	*Billion cubic feet per day. A measure of natural gas production.*
BEB	*Battery Electric Bus.*
BECCS	*Bioenergy with Carbon Capture and Storage.*
BEV	*Battery Electric Vehicle.*
Blue hydrogen	*Hydrogen produced from natural gas or biomass which is net carbon neutral through carbon capture and storage.*
C	*Carbon.*
CAPEX	*Capital Expenditure.*
CCS	*Carbon Capture and Sequestration (or Storage). A process by which carbon dioxide is separated from a gas stream ("captured") and buried underground ("sequestered").* *Though industry prefers the term Carbon Capture and Utilization or Storage (CCU/S) this is less commonly used in a hydrogen context, so the convention of CCS will be maintained.*
CEV	*Clean Energy Vehicles. BC's incentive program designed to make clean energy vehicles more affordable for British Columbians.*
CHP	*Combined Heat and Power. Also called cogeneration (or cogen); it is the simultaneous production of electricity with the recovery and utilisation heat.*
CH_4	*Methane.*

TERM	DEFINITION
CI	*Carbon intensity.*
CNG	*Compressed Natural Gas.*
CO	*Carbon monoxide.*
CO_2	*Carbon dioxide.*
CO_2e	*Carbon dioxide equivalent. A measure of greenhouse gas warming potential expressed in terms of the equivalent amount of carbon dioxide.*
DAC	*Direct Air Capture.*
DCFC	*DC Fast Charger.*
DNV GL	*DNV GL is an international accredited registrar and classification society headquartered in Høvik, Norway. It provides services for several industries including maritime, renewable energy, oil & gas, electrification, food & beverage and healthcare.*
EER	*Energy efficiency ratio.*
EJ	*ExaJoule; a unit of energy equivalent to 10^{18} Joules.*
FCEB	*Fuel Cell Electric Bus.*
FCEV	*Fuel Cell Electric Vehicle.*
FCH JU	*Fuel Cells and Hydrogen Joint Undertaking. A public private partnership supporting research, technological development and demonstration activities in fuel cell and hydrogen energy technologies in Europe.*
FF	*Fossil Fuel.*
FF Gen	*Fossil Fuel Generation.*
g CO_2e	*Grams of CO_2 equivalent. A measure of GHG emissions intensity.*
Green hydrogen	*Hydrogen produced from clean or renewable electricity.*
GGRT	*Greenhouse Gas Reductions Target.*
GHG	*Greenhouse gas.*
GJ	*GigaJoule. One billion joules of energy.*
GWh	*Gigawatt-hour. One billion watt-hours, or one million kilowatt-hours.*
H_2	*Hydrogen.*
HARP	*Hydrogen Assisted Renewable Power.*

TERM	DEFINITION
HCl	*Hydrochloric acid.*
HDV	*Heavy-duty Vehicle, encompassing commercial trucks and buses.*
HOV	*High-Occupancy Vehicle.*
Hydrail	*Hydrogen fuel cell powered train.*
ICE	*Internal Combustion Engine.*
ICT	*Innovative Clean Transit.*
IEA	*International Energy Agency.*
IESO	*Independent Electricity System Operator*
IP	*Intellectual Property.*
IPCC	*Intergovernmental Panel on Climate Change.*
IPP	*Independent Power Producers.*
IRAP	*Industrial Research Assistance Program.*
IWHUP	*Integrated Waste Hydrogen Utilization Project.*
JIVE	*Joint Initiative for hydrogen Vehicles across Europe.*
JIVE 2	*Joint Initiative for hydrogen Vehicles across Europe (second project).*
JV	*Joint Venture.*
kWh	*Kilowatt-hour. One thousand watt-hours. A watt-hour is the amount of energy generated if one watt of power is sustained for one hour.*
LCFR	*Low Carbon Fuel Regulation.*
LCFS	*Low Carbon Fuel Standard, a market-based regulation designed to reduce the carbon intensity of the fuel mix.*
LDV	*Light-Duty Vehicle, encompassing the category known colloquially as passenger vehicles, from sedans to pickup trucks.*
LH_2	*Liquid hydrogen.*
LNG	*Liquefied Natural Gas.*
LPG	*Liquefied Petroleum Gas or Liquid Petroleum Gas.*
MCH	*Methylcyclohexane.*

TERM	DEFINITION
MDV	*Medium-duty Vehicle.*
METI	*Ministry of Economy, Trade and Industry from Japanese Government.*
MJ	*MegaJoule. One million joules of energy.*
Mt	*Megatonne; one million metric tonnes.*
MVRD	*Metro Vancouver Regional District.*
MW	*Megawatt.*
MWh	*Megawatt-hour. One million watt-hours, or one thousand kilowatt-hours. A price of $60/MWh is equivalent to a price of $0.06/kWh.*
NEB	*National Energy Board.*
NG	*Natural Gas.*
NGO	*Non-Governmental Organization.*
NGTL	*Nova Gas Transmission Limited.*
NRCan	*Natural Resources Canada.*
OCH	*Organic Chemical Hydride.*
OEM	*Original Equipment Manufacturer. An abbreviation generally used in reference to auto manufacturers.*
OGC	*Oil and Gas Commission.*
OPEX	*Operational Expenditure.*
P2G	*Power to Gas. Process of converting surplus renewable electricity into hydrogen gas through electrolysis.*
PE	*Polyethylene.*
PEM	*Proton Exchange Membrane.*
pH	*A figure expressing the acidity or alkalinity of a solution on a logarithmic scale on which 7 is neutral, lower values are more acid and higher values more alkaline.*
PJ	*PetaJoule; a unit of energy equivalent to 10^{15} Joules.*
PNG	*Pacific Natural Gas.*
PSA	*Pressure swing absorption.*
PUD	*Public Utility District.*

TERM	DEFINITION
PVC	*Polyvinylchloride.*
R&D	*Research & Development.*
RFP	*Request for Proposal.*
RG	*Renewable Gas*
RNG	*Renewable Natural Gas.*
SME	*Small to Medium-sized Enterprise. Industry Canada defines SMEs as enterprises with fewer than 500 employees.*
SMR	*Steam Methane Reforming. A process by which natural gas (chemical formula CH_4) is reacted at high temperature with water vapour (H_2O) resulting in the production of hydrogen (H_2) and carbon dioxide (CO_2).*
SNG	*Synthetic Natural Gas.*
SWOT	*Strengths, Weaknesses, Opportunities and Threats. A SWOT analysis is a strategic planning technique used to help a person or organization identify strengths, weaknesses, opportunities, and threats related to business competition or project planning.*
Syngas	*Syngas, or synthesis gas, is a fuel gas mixture consisting primarily of hydrogen, carbon monoxide, and very often some carbon dioxide.*
tcf	*Trillion cubic feet of gas. A measure of the energy content of one trillion cubic feet of natural gas.*
TPD	*Tonnes per day.*
TRL	*Technology Readiness Level.*
TWh	*Terawatt-hour. One-thousand Gigawatt-hours. 10^{12} watt-hours.*
VRE	*Variable Renewable Electricity.*
WCBS	*Western Canadian Sedimentary Basin.*
ZEV	*Zero Emission Vehicle.*

1.0 : INTRODUCTION

1.1 : Objectives and Scope

The British Columbia Hydrogen Study was commissioned by the British Columbia Ministry of Energy, Mines and Petroleum Resources, the BC Bioenergy Network, and FortisBC with the aim of building a vibrant and robust hydrogen economy in the province.

At a high level the goals of the Hydrogen Study are to identify roles hydrogen can play in BC in the mid-term (2030) and long-term (2050) and to provide recommendations for instruments and policies to enable hydrogen to play an important role in the decarbonization of BC's economy.

Specific questions to be answered in the study are:

Q1	What role(s) should hydrogen play in decarbonizing the energy system and sectors of the economy in BC? Including, but not limited to, explicit consideration of the following: natural gas (NG), transportation, industry, the built environment, feedstock for low carbon energy and fuel production, and remote and off-grid communities.
Q2	What is the anticipated global demand and market potential for hydrogen and what is the export opportunity for BC to meet a portion of that demand?
Q3	What are BC's existing and potential competitive advantages in the hydrogen and fuel cell sector? How can BC maintain and improve its advantages?
Q4	What are BC's competitive disadvantages in the hydrogen and fuel cell sector? How can BC address them?
Q5	What are the instruments and policies necessary to develop hydrogen supply chains in BC?
Q6	What are the existing and potential competitive advantages and disadvantages specific to using hydrogen in the BC natural gas grid as a drop-in fuel, or as a replacement for natural gas?
Q7	What are the opportunities, challenges and costs specific to incorporating hydrogen as storage for intermittent renewable energy in BC?

The specific desired outputs of the study are:

R1	A mid-term (to 2030) and long-term (to 2050) cost curve of potential hydrogen supply in BC by quantifying the amount available at progressively higher price points.
R2	A jurisdictional scan of international commitments, financial incentives and regulatory instruments for green and blue hydrogen development/deployment.
R3	Recommendations for policies, regulations and legislation to facilitate the development of the hydrogen sector in BC.

The scope specifically excluded:

- *Technology Readiness Level (TRL) and Commercial Readiness Index analysis for hydrogen and fuel cell technologies;*
- *Hydrogen pathways that would result in increased greenhouse gas (GHG) emissions.*

1.2 : Project Methodology

The project team used a collaborative, integrative approach in conducting this study.

Data underpinning the study were collected through a combination of stakeholder engagement, online surveys, market and technology reports, internet research, and through leveraging the project team's expertise in the field.

A broad base of stakeholders was consulted throughout the project to ensure a balanced view of the hydrogen sector and to develop aggressive but achievable recommendations supporting the goals of the Province's CleanBC plan. Participants in stakeholder engagement spanned the private sector, non-governmental organizations (NGOs), public utilities, academia and government. Follow-up interviews were also conducted with selected participants.

The project team conducted three workshops, with the following themes:

- *Large Centralized Production of Hydrogen in BC for Decarbonization of BC's NG Industry, Synthetic & Low Carbon Fuel Production, and Export (Workshop 1, March 14, 2019, hosted by FortisBC);*
- *Opportunities for Hydrogen in Transportation Applications in BC (Workshop 2, April 5, 2019, hosted by LGM Financial Services); and*
- *BC's Competitive Advantages in Hydrogen and Fuel Cells (Workshop 3, April 11, 2018, hosted by Ballard Power Systems).*

In advance of each workshop, an online survey was developed and sent to workshop invitees. The project sponsors provided input to the survey questions. Survey responses were used to help guide discussion at the workshop, and to provide input to the study.

A complete list of stakeholders that provided input to the study, along with a summary of select survey responses, and notes from the workshops are included in APPENDIX A: Summary of Stakeholder Engagements.

To assess where hydrogen could decarbonize BC's economic sectors, the team first developed a baseline of provincial energy use and emissions. Baseline data were drawn from reputable public references such as Canada's National Inventory Report and the National Energy Board (NEB). Industry sectors were broken down as: Natural Gas, Transportation, Industry, Built Environment, and Remote Communities. For natural gas, opportunities for injecting hydrogen into natural gas infrastructure and its use to reduce the carbon intensity of the Liquefied Natural Gas (LNG) export market were both evaluated. Hydrogen injection into the natural gas grid impacts both the industry and built environment sectors.

Opportunities for hydrogen to reduce GHG emissions in each sector were identified through an analysis of activities in leading jurisdictions, input from stakeholders, a review of technology options and technology readiness levels, and modeling to understand specific opportunities and constraints related to British Columbia.

For each economic sector, two scenarios were modeled:

- *A conservative scenario incorporating the lowest cost, lowest risk opportunities for hydrogen deployment, generally aligned with existing policy goals and/or regulation;*
- *An aggressive scenario incorporating ambitious targets to realize greater emissions reductions through hydrogen, reliant on increased investment for the development of supply and distribution infrastructure, new policies, and in some cases more ambitious assumptions for technology development.*

The team also met with representatives from the local hydrogen and fuel cell sector to understand BC's competitive advantages and disadvantages, to understand how the Province can benefit from cost-effectively supporting and growing the sector, and to provide reference cases to help support the development of provincial exports.

The global market for hydrogen was assessed by referencing previously published studies forecasting hydrogen demand. Where available, goals for hydrogen use by region announced by local governments were also assessed and rolled into the overall global forecast for hydrogen out to 2050. The BC target markets and opportunity size for export of hydrogen were projected based on market penetration rates in order to size the potential opportunity for export of hydrogen.

Notable initiatives in other jurisdictions are highlighted in the report in sidebars. The team has also identified several "Big Bold Goals" with which to take a leadership position in hydrogen deployment, over and above the aggressive scenarios. These goals are the construction of a hydrogen "backbone" pipeline, decarbonizing of LNG Canada, and the planning of a hydrogen community. If these seem ambitious, or even unreasonable, the climate commitments and climate action of recent years have demonstrated that the ambitious is attainable.

The study findings were synthesized to create hydrogen demand curves based on the opportunities in the examined economic sectors. Policy recommendations were also made to support the development of a vibrant, profitable, emissions reducing hydrogen economy in the Province in the coming decades.

1.3 : Alignment with CleanBC goals

CleanBC is the Government of British Columbia's plan for achieving the GHG emissions reductions commitments from the May 2018 Climate Change Accountability Act of:

- *40% GHG emissions reductions by 2030 (from 2007 levels);*
- *60% reductions by 2040;*
- *80% reductions by 2050.*

For British Columbia to meet its 2030 commitment, provincial emissions will have to fall 40% from 63.6 million tonnes of CO_2 equivalent (Mt CO_2e) in the baseline year of 2007, to 38.2 Mt CO_2e in 2030. Consequently, the province is targeting GHG reductions of 25.4 Mt CO_2e from the 2007 baseline provincial emissions profile, by 2030.

The province's gross GHG emissions in 2016, the most recent year for which data are available, were 62.3 Mt CO_2e, but economic development is expected to increase provincial emissions in the interim.

The CleanBC plan identifies 18.9 Mt CO_2e of emissions reductions; additional opportunities are being evaluated to meet the Climate Change Accountability Act commitments.

Hydrogen's versatility allows it to contribute to CleanBC's GHG emissions reductions goals in several capacities:

1. *For **cleaner transportation**, hydrogen is expected to play a supporting role in helping BC achieve its light-duty vehicle Zero Emission Vehicle (ZEV) mandate targets, and a stronger role reducing emissions from larger vehicles, through fuel cell and co-combustion technologies. Renewable or low carbon hydrogen will also be required for fuel suppliers to meet the low carbon fuel standard. Hydrogen can also enable larger quantities of renewable natural gas to be available to fuel Compressed Natural Gas (CNG) vehicles.*
2. *To **improve where British Columbians live and work**, hydrogen can help achieve the goal of renewable gas comprising 15% of the Province's natural gas consumption. Hydrogen technologies can also help BC's many remote communities reduce their dependence on diesel.*
3. *For **cleaner industry**, renewable and low carbon hydrogen can serve as emissions-free alternatives to natural gas for heat.*
4. *To **reduce waste**, the production of hydrogen-rich synthetic gas (syngas) could up-cycle wood and crop residues and agricultural wastes. Such efforts would also align with the BC Bioenergy Strategy.*

Hydrogen can also play an important role connecting BC's electric and natural gas energy systems together via power-to-gas systems where hydrogen can be used for bulk energy storage. Hydrogen's versatility enables it to provide benefits greater than the sum of each discrete opportunity.

This report evaluates how hydrogen can be harnessed, as a clean energy fuel and feedstock, to grow British Columbia's economy while reducing its GHG emissions, in line with the CleanBC plan.

1.4 : Energy Consumption and GHG Emissions in BC

1.4.1 : Energy Consumption in BC

To understand how hydrogen can reduce the Province's GHG emissions and build its energy economy, an understanding of BC's energy sources and consumption is necessary. Figure 1 shows the NEB's assessment of the Province's primary energy demand by end use in 2016 and 2040.[3]

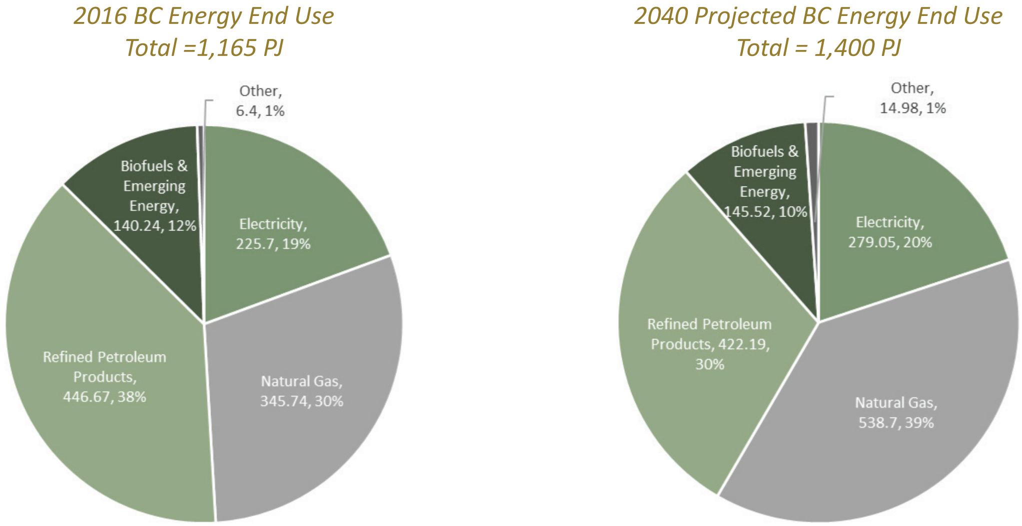

Figure 1. BC Historical and Projected Energy End Use by Energy Currency (2016 and 2040) [3]

The majority of primary energy consumption in the Province derives from fossil fuels: 68% in 2016 and a projected 69% in 2040.

Each energy source has a different GHG intensity, and the Province has provided guidance for quantifying GHG emissions from different energy sources.[4]

Electrification can improve energy efficiency and reduce primary energy demand – for example through the replacement of furnaces and boilers with heat pumps – but can only meet some of the Province's energy needs. A complementary strategy of using hydrogen to replace fossil fuels in other applications will be necessary for the Province to meet its longer-term climate goals. This includes contributing to increased use of renewable gas, which accounts for 75% of the GHG reductions attributed to the built environment in the CleanBC plan. Hydrogen blending in the NG pipeline will be required to meet the 15% renewable gas goal by 2030, which is needed to achieve the associated GHG reductions outlined in CleanBC.

1.4.2 : GHG Emissions in BC

BC's Climate Change Accountability Act sets GHG emission reduction targets of 40% by 2030, 60% by 2040, and 80% by 2050 compared to a 2007 baseline.[5] Figure 2 shows BC's GHG emissions from 1990 to 2016 and a linear path from 2007 GHG emissions levels to the 2030, 2040, and 2050 targets.

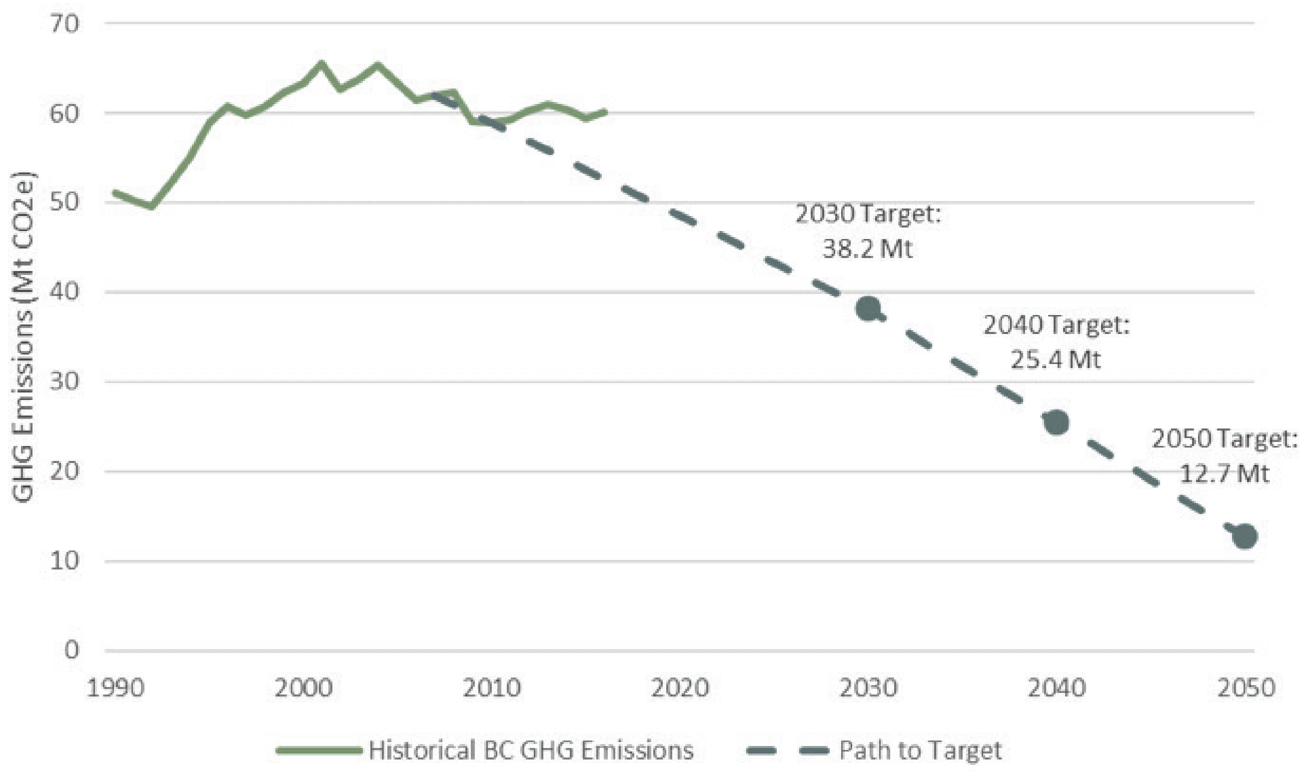

Figure 2. BC's Historical GHG Emissions and Path to Targets[5, 6]

From 2007 to 2016, the Province experienced a moderate reduction in emissions of 3%.[6] To meet its GHG emissions targets, the Province needs to rapidly accelerate its decarbonization efforts. Over the same period, the GDP rose by 19%, demonstrating that economic growth can be decoupled from emissions growth.[7]

Figure 3 shows BC's 2016 GHG emissions by economic sector. Transportation made up the greatest share of total GHG emissions, followed by the oil and gas sector and the built environment.[6]

Figure 3. BC GHG Emissions by Economic Sector (2016)[6]

Inexpensive, energy-dense fossil fuels lend themselves well to transportation and the built environment, which is a reason for these two sectors' large share of the Province's GHG emissions profile. Hydrogen is well-suited to decarbonize these hard-to-abate sectors.

1.5 : Current Uses and Applications of Hydrogen in BC

BC has a strong history of developing hydrogen and fuel cell technologies and is known as the "cradle" of the modern fuel cell industry. Paradoxically, there are relatively few ongoing hydrogen or fuel cell deployments in the Province, forcing the sector to export technology with limited home-province or home-country reference cases. The sector is instead supported by exports to regions such as China, Europe and California, where governments recognize the benefits of hydrogen and fuel cell technologies for their GHG emissions reduction, air quality improvement and energy security objectives.

Without local deployments of hydrogen and fuel cell technology, these regions stand to become the true "centre of gravity" for the sector, eclipsing the Province's early leadership in deploying hydrogen technology. Some notable projects in BC related to hydrogen, starting with the most recent, include:

- *Shell opening Canada's first retail hydrogen filling station in 2018 in Vancouver.*
- *Demonstration of a hydrogen-diesel co-combustion class 8 truck by Hydra Energy in 2017.*
- *BC being selected as Hyundai's first market for its Fuel Cell Electric Vehicles (FCEVs) in Canada in 2015, leasing 10 Tucson FCEVs.*
- *The deployment of 20 fuel cell electric buses (FCEBs) with Ballard Power Systems fuel cells in Whistler from 2009 to 2014. The FCEBs made up almost the entire Whistler bus fleet, which comprised 23 buses (26 buses during peak season).*
- *The Integrated Waste Hydrogen Utilization Project (IWHUP), a six-year project led by Hydrogen Technology & Energy Corporation (HTEC) that included the processing of by-product hydrogen from a sodium chlorate plant, distribution to end users, hydrogen station development, and transportation and stationary fuel cell power system deployment. The Project ran from 2006-2011.*

- *The world's first deployment of fuel cells in a material handling application by Cellex Power at London Drugs in Richmond in 2003.*
- *The world's first 700 bar (10,000 psi) hydrogen refueling station at Powertech Labs in Surrey in 2002.*

There are currently a small number of light-duty FCEVs on-the-road in BC, with growing numbers expected in 2019. No hydrogen powered heavy-duty vehicles, marine vessels, railway locomotives, or aircraft are currently deployed in the Province.

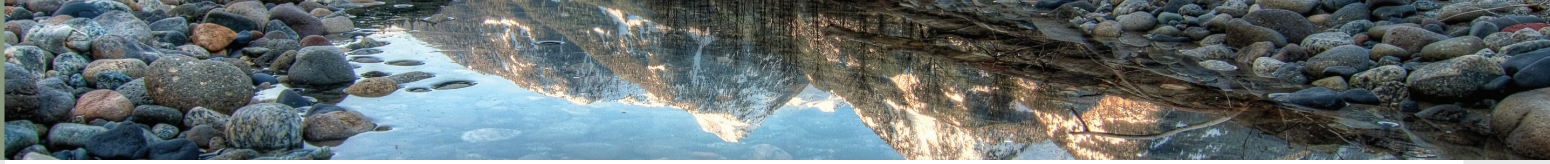
To support the rollout of vehicles, the Provincial and Federal governments have supported early development of hydrogen infrastructure. In addition to the first retail hydrogen fueling station that opened in Vancouver in June 2018, five more stations are in development as of May 2019.

BC industries using hydrogen include the hydrocarbon fuel refining, sodium chlorate, and chlor-alkali industries. The two refineries in BC, located in Burnaby (Parkland) and Prince George (Husky), use hydrogen as part of the refining process. Both produce hydrogen on site through naphtha as an internal part of the refining process and steam methane reformation respectively. There are also sodium chlorate plants in North Vancouver and Prince George and a chlor-alkali plant in North Vancouver. These plants produce hydrogen as a by-product. Some is currently captured for use in refineries, some is used to produce hydrochloric acid (HCl), some is used for process heat, and some is vented to the atmosphere. Vented hydrogen presents a potential hydrogen supply opportunity in the Province, discussed further in Section 3.0.

BC's Renewable and Low Carbon Fuel Requirements Regulation (LCFR), a form of Low Carbon Fuel Standard (LCFS), is driving demand for hydrogen in BC. The LCFR is made up of two components - the renewable content requirement for diesel and gasoline, and the decreasing carbon intensity of fossil fuels. Both of these are driving renewed interest in hydrogen.

Finally, there is strong hydrogen demand emerging from the Province and FortisBC as a means of meeting the CleanBC requirement that 15% of natural gas consumed in the Province comes from a renewable source, but at time of writing no Provincial regulation exists to enable the injection of hydrogen into the natural gas system and account for it as a feedstock for renewable gas.

Deployment of hydrogen within the Province has strong potential in the coming years, and early projects have helped to demonstrate the viability and benefits in various applications. The goal of this report is to recommend opportunities that will significantly assist the Province's decarbonization objectives, will support the goals for economic development in the province, and show the most promise for commercial and technical viability to ensure they can be sustained over the long-term.



2.0 : HYDROGEN PRODUCTION, STORAGE AND USE

2.1 : Hydrogen Production Technologies

Worldwide annual hydrogen production is approximately 55 million tonnes (Mt) or 6.6 ExaJoules (EJ) of energy.[8] The Hydrogen Council proposes that production could increase tenfold through 2050. The Council is a global initiative of leading energy, transportation and industry companies with a shared vision for hydrogen's role in the energy transition; at time of writing it comprised a 33-member Steering Group and 20 Supporting Members.[9]

Hydrogen can be produced via a number of different pathways using a range of feedstocks. Hydrogen can be made via renewable and fossil fuel resources and is a by-product of some industrial processes. Most hydrogen is made today from fossil fuels without carbon capture and sequestration. The majority is used in industrial processes and is produced at the site where it is used.

BC is focused on low carbon intensity hydrogen pathways, sometimes classified as "Green Hydrogen" or "Blue Hydrogen". Definitions for the two terms vary internationally. In this study Green Hydrogen is defined as hydrogen produced from clean or renewable electricity, and Blue Hydrogen as hydrogen produced from natural gas and biomass which is net carbon neutral using carbon capture and storage. The pathways that relate to BC are described in Section 3.1.

2.2 : Hydrogen Storage and Transport

There are several methods for storing and transporting hydrogen, illustrated in Figure 4 below. These include physical-based storage such as compressing or cryogenically liquefying the hydrogen. Hydrogen can also be stored in a range of material-based solid and liquid compounds. Storage methods are typically chosen based on end use requirements such as weight and volume available for energy storage. The natural gas pipeline can also be used to store and transport hydrogen using existing infrastructure. When the NG pipeline is used, a blend of H_2/NG is the result. In most cases this blend will be used directly, although it is possible to separate the H_2 and NG at the point of use once concentrations of hydrogen are high enough to cost effectively separate the gases.

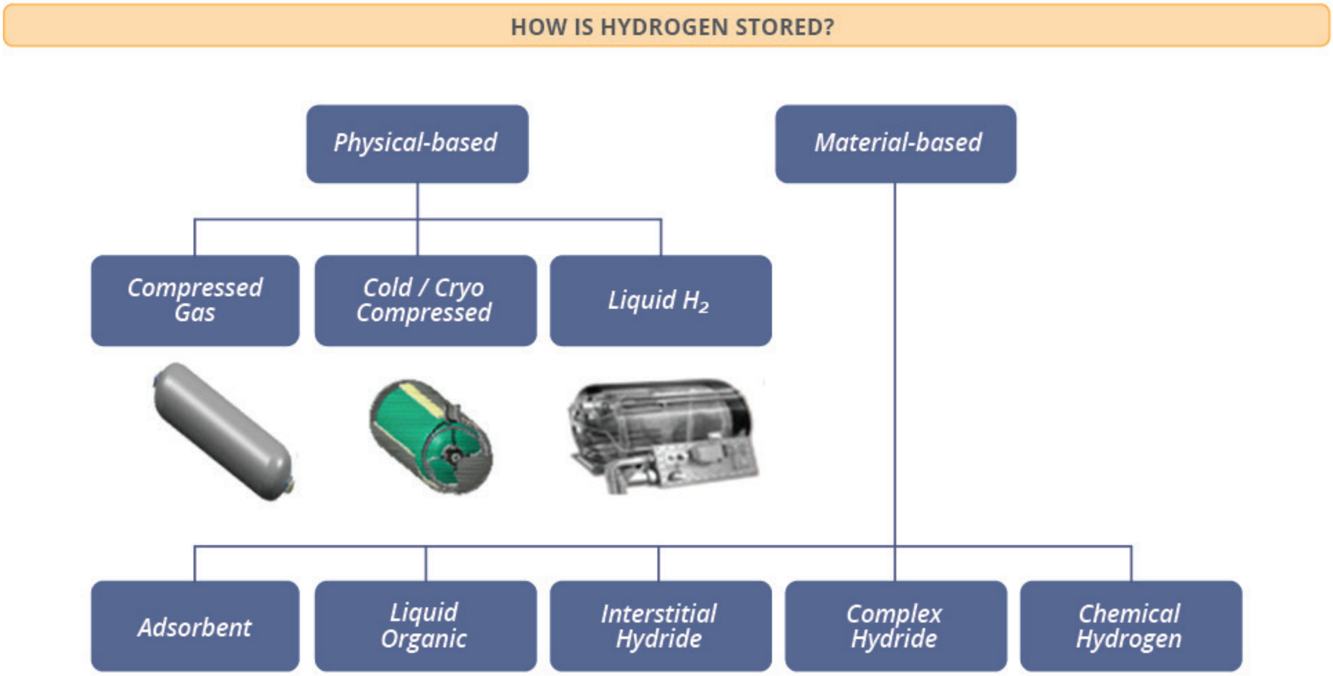

Figure 4. Methods of Hydrogen Storage. Source: US Department of Energy.[10]

2.2.1 : Compression

As a gas under atmospheric conditions, hydrogen must often be compressed, liquefied, or stored in an otherwise dense manner prior to use.

Hydrogen tanks for forklift and public transit applications often use hydrogen compressed to a pressure of 350 bar (5,000 psi) or 345 times as dense as it would be under atmospheric conditions. (Standard atmospheric pressure is 1.01 bar.)

This is somewhat higher than the 250 bar (3,600 psi) pressure in compressed natural gas, or CNG cylinders. The energy loss from having to compress the hydrogen to 350 bar was estimated by UC Davis to be on the order of 8.5 percent.[11] The results are consistent with a recent International Energy Agency (IEA) report.[12]

2.2.2 : Liquefaction

Where hydrogen must be made denser – such as for rail, marine, power plant or space applications -- it is likely to be liquefied, providing an 800-fold increase in density. Hydrogen liquefaction is performed in a series of compression and cooling steps, much as is done when producing liquefied natural gas. Liquid hydrogen (LH_2) is considerably more energy intensive to produce; natural gas liquefies at -160°C while hydrogen liquefies at -253°C. As a result, while the energy loss to liquefy natural gas is on the order of 10 percent, the energy loss to liquefy hydrogen is generally estimated to be on the order of 20 to 30 percent, though an energy loss of as little as 13 percent may be possible. [13, 14]

Organizations evaluating hydrogen export options such as Japan's Kawasaki Heavy Industries and Norway SINTEF favour liquid hydrogen for long-distance transport.

2.2.3 : Chemical Storage

Another means of storing hydrogen is in the form of compounds called chemical carriers. Liquid chemical carriers are relatively easily handled and can contain large quantities of hydrogen by volume: there is more hydrogen in a litre of gasoline (116 g H_2) than in a litre of liquid hydrogen (71 g H_2).

The two chemical carriers currently receiving the most development are methylcyclohexane (MCH) and ammonia. MCH is a liquid at atmospheric pressure with the chemical formula C_7H1_4 and can be handled by oceanic chemical tankers. Three hydrogen molecules (H_2) can be liberated from the MCH, transforming it into toluene, also a liquid. When hydrogen is added to toluene, it is transformed back into MCH. The business model consists of bonding hydrogen into toluene, forming MCH at the point of hydrogen supply, and then releasing the hydrogen from the MCH, forming toluene, at the point of hydrogen demand.

An illustrative diagram from Chiyoda Corporation is shown in Figure 5. A consortium is currently evaluating the export of hydrogen from the coast of British Columbia to Japan in the form of MCH.[15]

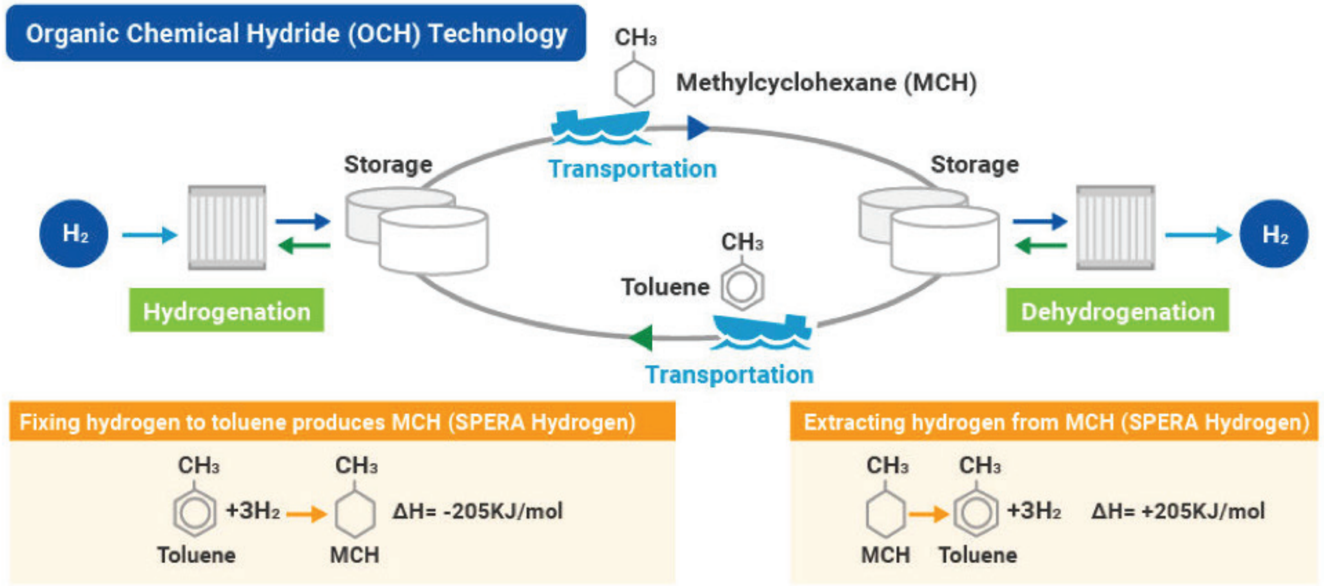

Figure 5. Methylcyclohexane as Hydrogen Carrier. Source: Chiyoda Corporation.[15]

Ammonia (NH_3) is also being evaluated as a chemical carrier for hydrogen, particularly for jurisdictions wishing to export electrolyzed hydrogen in the form of ammonia for fertilizer production. Ammonia is a common industrial chemical already produced and transported on a global scale; it is also the largest global consumer of steam methane reformed hydrogen. Once transported to the point of demand, the ammonia can be dehydrogenated, yielding 0.176 tonnes of hydrogen per tonne of ammonia.

2.2.4 : Adsorbent Storage

Hydrogen can also be stored by adsorbing the gas on powders. One advantage of this method is that the amounts of energy required to adsorb (bind) the hydrogen to the powder should be less than required to form chemical bonds, as per the chemical storage methods above. Adsorbent storage may make it possible to store relatively high densities of hydrogen – comparable to compressed gases – at lower pressures. BC's Hydrogen In Motion is developing a hydrogen storage technology by engineering a powder for this purpose.

2.2.5 : Transport

In gaseous form, hydrogen can be transported in existing natural gas pipeline networks. Small percentages of hydrogen could be blended into existing natural gas streams without requiring infrastructure retrofits. The blending of larger quantities, or of 100% hydrogen, could necessitate retrofits to pipeline equipment, though the pipe segments themselves are not expected to require replacement. This concept is discussed further in Section 4.1.

Smaller volumes of compressed hydrogen are also transported by truck in tube trailers, in much the manner done for other industrial gases.

Hydrogen can also be transported by truck in liquefied form, again in the manner of industrial gases. Kawasaki Heavy Industries, which built Japan's first LNG carrier vessel, plans to build the world's first liquid hydrogen (LH_2) carrier as part of its Hydrogen Energy Supply Chain project in Australia.

When stored in the form of a chemical carrier, hydrogen transportation would follow chemical industry practice for transporting the carrier.

2.3 : Hydrogen Applications

Demonstrating hydrogen's versatility, the Hydrogen Council enumerated seven separate supportive roles it could play in global decarbonization efforts, as shown in Figure 6 below.[16]

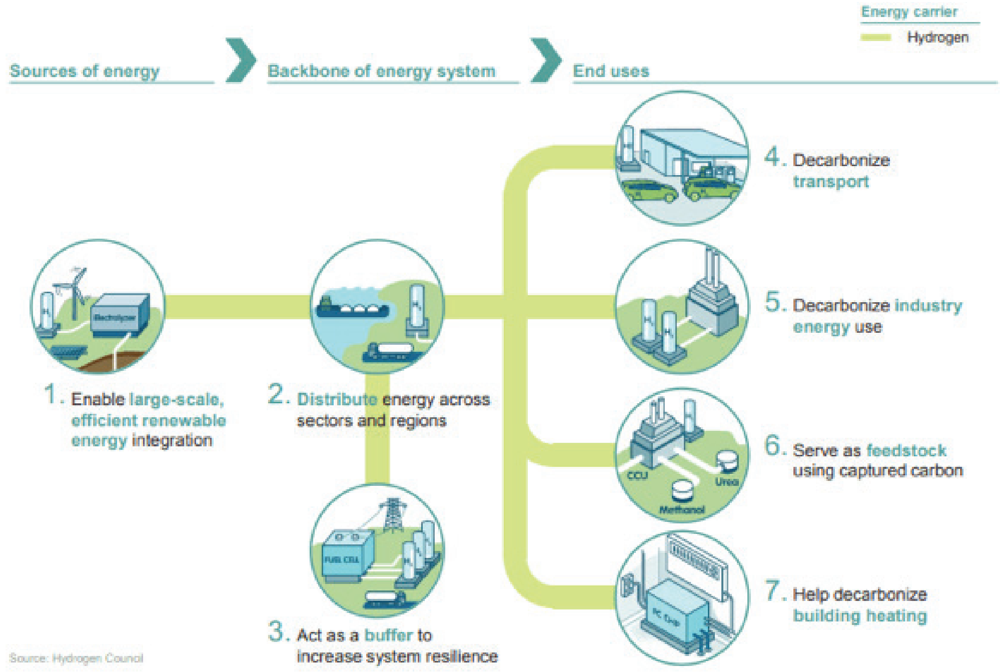

Figure 6. Roles for Hydrogen in Decarbonization. Source: Hydrogen Council.[16]

This report focuses how hydrogen can be deployed in support of the Province's CleanBC plan and broader climate targets. Consideration is given to hydrogen's potential in BC related to:

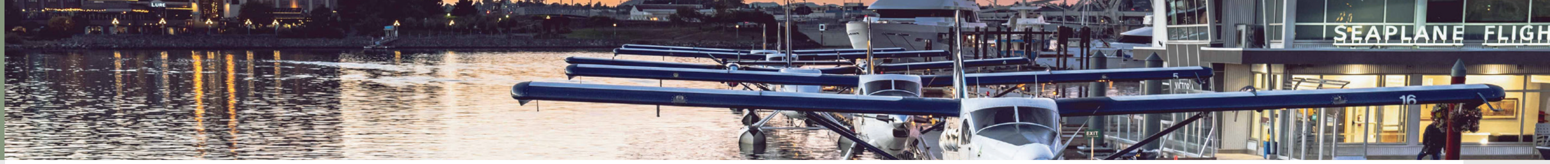
- *BC's Natural Gas sector (section 4.1)*
- *BC's Transportation sector (section 4.2)*
- *BC's Industrial sector (section 4.3)*
- *BC's Built Environment (section 4.4)*
- *BC's Remote and Off-Grid Communities (section 4.5)*
- *Energy Storage through Power to Gas opportunities (section 5.2)*

Hydrogen can be combusted as a cleaner burning substitute for fossil fuels such as natural gas or oil. This is one use case for end users of natural gas in the industrial and built environment sectors. Hydrogen combustion equipment and technology are also being pursued in jurisdictions where natural gas is combusted for power generation. In the transportation sector, BC company Hydra Energy has developed technology allowing for hydrogen-diesel co-combustion.

16 *The Hydrogen Council. (2017). How Hydrogen Empowers the Energy Transition. Retrieved from http://hydrogencouncil.com/wp-content/uploads/2017/06/Hydrogen-Council-Vision-Document.pdf*

Hydrogen can also be reacted electrochemically -- without combustion – in fuel cells, generating an electric current. Fuel cell technology is being developed across the transportation sector, from light-duty and heavy-duty vehicles up to rail and marine vessels. Fuel cells are increasingly being deployed for utility-scale power generation (South Korea) and to provide guaranteed on-site power, and sometimes hot water, at commercial facilities (California) or in residential homes (Japan, Europe). Proton Exchange Membrane (PEM) stationary fuel cell systems can run on both natural gas (with a reformer) or on pure hydrogen fuel.

During times of overproduction of renewable electricity, hydrogen can also be generated via electrolysis and used for long-term energy storage, a highly valuable characteristic for BC's remote and off-grid communities.



3.0 : HYDROGEN PRODUCTION IN BRITISH COLUMBIA

3.1 : BC Production Pathways

Hydrogen molecules do not generally exist on their own in a free state in nature but are found in many abundant compounds. Hydrogen must be produced from feedstocks using energy inputs. When investigating viable local hydrogen pathways, the availability of both feedstocks and energy sources must be considered. For energy sources, point source emissions and upstream emissions must both be considered; a fuller treatment is provided in APPENDIX B: Upstream GHG emissions In BC.

Feedstocks are the chemical sources of the hydrogen. BC is fortunate to have an abundance of three hydrogen feedstocks: water, biomass (predominantly carbon, hydrogen and oxygen) and natural gas (primarily methane). Crude oil and coal could also be used as hydrogen feedstocks, but they have a lower ratio of hydrogen to carbon, making them less attractive than natural gas. BC is a minor producer of crude oil and produces significant quantities of coal. The vast majority (80-90%) of this coal however is low hydrogen-content metallurgical grade coal used for high-value steel manufacture.

This report considers the three most likely energy inputs for large-scale hydrogen production in British Columbia: electricity, biomass, and natural gas. In the case of electricity, electricity generated from hydroelectricity and wind are considered, since these are the most abundant sources of electricity in the Province.

BC generates by-product hydrogen from two sodium chlorate plants operating in the Province, located in North Vancouver and Prince George, and one chlor-alkali plant in North Vancouver. Chemtrade operates the chlor-alkali plant in North Vancouver and the sodium chlorate plant in Prince George. While some of the by-product hydrogen is currently used as feedstock in chemical production, approximately 18,500 kg/day of hydrogen is vented. This represents an important near-term hydrogen source for the Province.

Considering feedstock and energy sources in tandem, the following pathways have been identified as primary options for producing large quantities of hydrogen in the Province:

- *Industrial by-product hydrogen;*
- *Electrolysis via hydroelectric or wind (grid connected or non-grid connected);*
- *Biomass gasification with water gas shift and reforming;*
- *Steam methane reforming with carbon capture and storage; and*
- *Methane pyrolysis (thermal and plasma) with carbon capture and storage.*

With hydroelectricity representing 86% of the electricity generated in BC the assumption has been made that grid connected electrolysis is primarily powered by hydroelectricity. Hydroelectricity, wind and biomass together account for approximately 95% of the province's electricity production.[17]

17 *National Energy Board. (2018). Canada's Renewable Power Landscape 2016 – Energy Market Analysis. Retrieved from* https://www.neb-one.gc.ca/nrg/sttstc/lctrct/rprt/2016cndrnwblpwr/prvnc/bc-eng.html

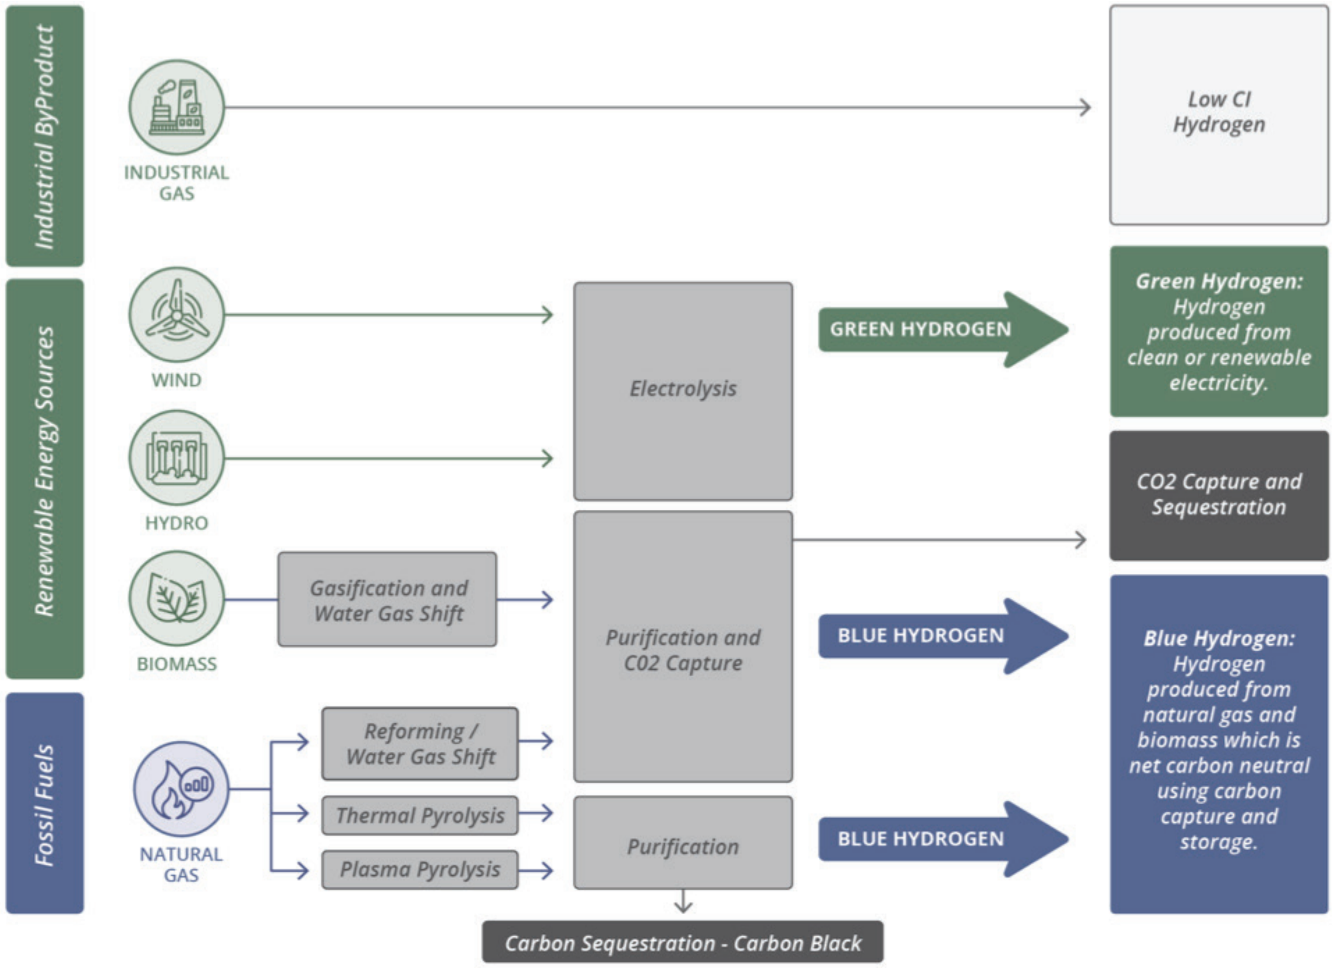


Figure 7. Hydrogen Production Pathways in BC

BC is focused on low carbon intensity hydrogen pathways, or Green and Blue Hydrogen as it is commonly called. The report focuses on low carbon intensity hydrogen, without the use of Green and Blue terminology. It is recommended that all pathways shown in Figure 7 above be evaluated based on production cost, carbon intensity, and availability in the Province.

Given the Province's interest in transitioning to sustainable energy in the longer-term, it is recommended that hydrogen produced from renewable resources including hydroelectric, wind, and biomass resources be given special consideration as identified in the policy recommendations of this report. By-product hydrogen currently produced in BC can also be considered renewable, as the primary energy source used in the brine electrolysis in the sodium chlorate and chlor-alkali plants comes from the electric grid.

The technology fundamentals for each production pathway is described in the following sections. A large production scale of 100 tonnes of hydrogen per day is assumed given that some technologies, such as steam methane reforming (SMR) followed by carbon capture and sequestration (CCS) are only expected to be feasible at large scale. Cost sensitivities have also been provided, where estimates could be made. Cost figures refer to bulk centralized production and do not include transportation costs, which can vary significantly by location. Costs also do not include any profit.

GHG intensities are also presented for each pathway. The analysis looks at both upstream and direct emissions, projected for 2030 which account for potential changes in upstream emissions per year. The assumptions and analysis for calculating carbon intensity are described in Appendix B.

3.1.1 : Industrial By-product Hydrogen

Approximately 18.5 tonnes of relatively pure hydrogen is currently vented to atmosphere every day in the Province. The by-product hydrogen requires minimal cleanup to remove traces of chlorine gas, and represents a low-cost, low carbon intensity hydrogen supply. It would have to be pressurized prior to purification and transportation to distributors (in the case of fuel stations) or end users. The cost of recovering this industrial by-product hydrogen is based on hydrogen's heating value, as it is often burned for process heat, and the amortized capital costs. These costs are estimated to be $0.88/kg as shown in Figure 8.

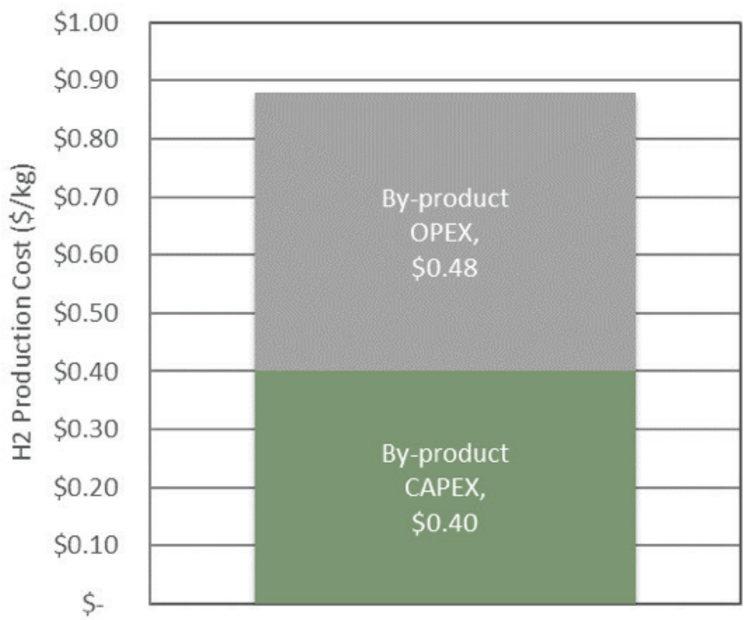

Figure 8. Cost breakdown for by-product hydrogen

Hydra Energy is looking to secure by-product hydrogen supply in the Province to operate trucks retrofitted with their hydrogen co-combustion technology. They have recently evaluated the carbon intensity from this pathway and have determined it to be 1.43 g CO_2e/MJ at the point of dispensing. This has been used in the pathway comparison in this report.

3.1.2 : Electrolysis

Water electrolysis is a hydrogen production pathway attractive in BC given the relatively low cost of electricity from the Province's low carbon intensity electric grid. In addition to existing hydroelectric dams, the Province also possesses significant wind energy resources.

Electrolysis is the process by which electricity is used to split water into hydrogen and oxygen. The chemical transformations are described in reaction (1).

(1) $H_2O + \text{electricity} \rightarrow H_2 + \frac{1}{2}O_2$

The ideal or minimum amount of electricity required to produce 1 kg of hydrogen is 39 kWh.

The equipment in which this reaction takes place is called an electrolyzer. Electrolyzers are modular, and their sizes vary widely depending on the chosen technology and required production capacity. They can range from appliance-sized equipment for small-scale hydrogen production to large-scale, central production facilities. Their modular nature makes electrolyzers attractive when relatively small quantities of hydrogen are required; higher per-kg production costs may be offset by reduced transportation costs.

Electrolyzers consist of an anode and a cathode separated by an electrolyte, as in Figure 9. The two major types of electrolyzers in current use are Proton Exchange Membrane (PEM) electrolyzers, and Alkaline electrolyzers.

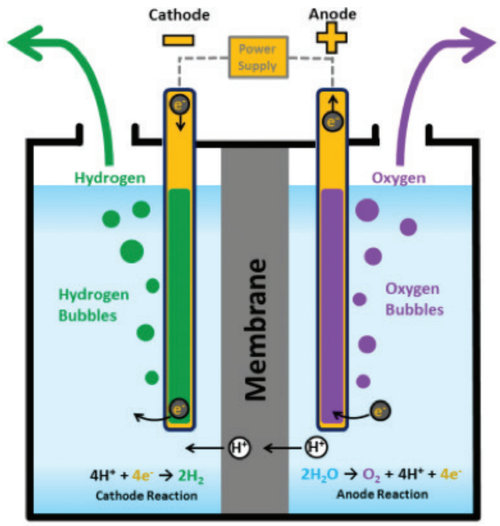

Figure 9. Electrolysis in a PEM Electrolyzer. Source: US Department of Energy.[18]

3.1.2.1 : PEM Electrolyzers

In a PEM electrolyzer, the electrolyte is a solid polymer, or plastic. At the anode, water is split into oxygen, positively charged hydrogen ions (protons) and negatively charged electrons. The protons migrate across the proton exchange membrane while the electrons flow through an external circuit. The protons and electrons recombine on the cathode to form hydrogen gas.

PEM electrolyzers have received heightened attention in recent years. This is due in part to breakthroughs allowing for significantly higher hydrogen production density. It is also due to PEM electrolyzers' flexibility; they can operate when the incoming current fluctuates, producing variable rates of hydrogen from second to second, depending on the power supplied. This "load-following" capability makes them a highly complementary technology to variable solar photovoltaic and intermittent wind energy. Curtailment of renewable electricity currently occurs during periods of excess production; more curtailment is expected to occur as renewable electricity is added to electrical grids. PEM electrolyzers provide a responsive electrical load, which can reduce the amount of curtailment while producing valuable hydrogen. Some PEM electrolyzer deployments have also generated additional revenue by providing grid services, being compensated for helping to buffer and stabilize the grid when solar or wind power suddenly ramps up or down.

3.1.2.2 : Alkaline and Solid Oxide Electrolyzers

While PEM electrolyzers transport protons (H^+) through a membrane, Alkaline electrolyzers transport hydroxide ions (OH-) through their electrolyte, which is generally sodium or potassium hydroxide. Both compounds are alkaline – in chemical terms they have a high pH – hence the term Alkaline electrolyzer.

A third electrolyzer technology, the Solid Oxide electrolyzer, is under development but has not yet been commercially deployed. These electrolyzers operate at high temperatures and hold the promise of being more efficient than PEM or Alkaline electrolyzers.

....

18 U.S. Department of Energy Office of Energy Efficiency & Renewable Energy. Hydrogen Production: Electrolysis. Retrieved from https://www.energy.gov/eere/fuelcells/hydrogen-production-electrolysis

3.1.2.3 : Hydrogen Production Cost

The price of electricity is the dominant factor determining the cost of hydrogen produced via electrolysis. Whereas ideal specific efficiencies for water electrolysis is 39 kWh/kg H_2, actual demonstrated specific efficiencies are between 50-60 kWh/kg H_2. Where an electrolyzer is run 24/7, operating costs account for approximately 80% of the cost of hydrogen, and the bulk of operating costs consist of the sourced electricity.

As shown in Figure 10 below, hydrogen production in BC via electrolysis is expected to be $5-7/kg H_2 based on an industrial electricity rate of $60/MWh (Megawatt-hour), representative of current industrial rate tariffs.[19]

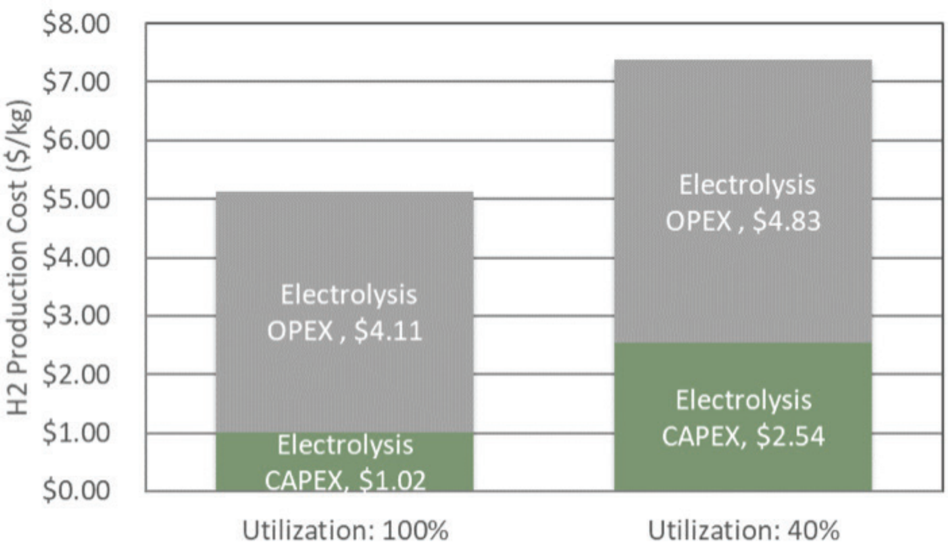

Figure 10. Cost breakdown for hydrogen produced via Electrolyzer

Figure 11 shows a sensitivity analysis of hydrogen production costs based on the cost of electricity and the size of the electrolyzer. As would be expected, larger electrolyzers drive economies of scale in capital equipment and installation cost.

For hydrogen to be produced at scale in BC using electrolysis, it is estimated that the cost of electricity must be <$40/MWh. If the cost of electricity is higher, other hydrogen production processes will have a cost advantage. This report provides recommendations by which to decrease the cost of this production pathway, which has potential to be strategic for the Province.

19 *$0.0606/kWh equates to $60.60/MWh. Source: BC Hydro. (2019). General Service Business Rates. Retrieved from* https://app.bchydro.com/accounts-billing/rates-energy-use/electricity-rates/business-rates.html

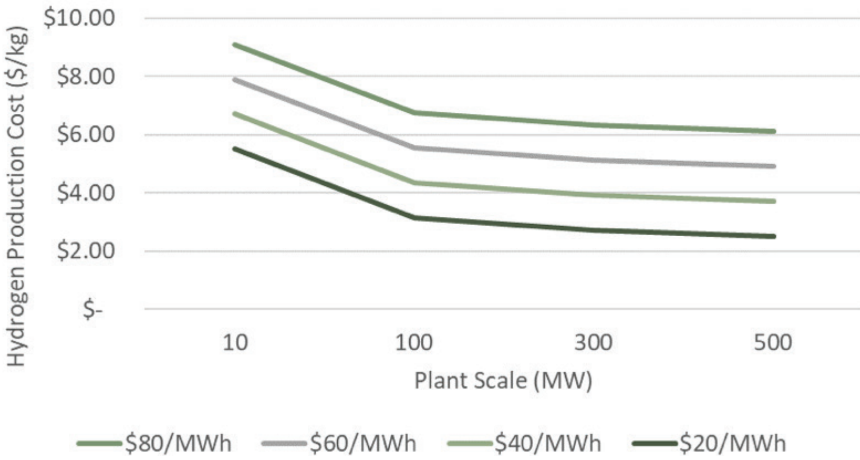

Figure 11. Impact of Scale and Electricity Feedstock Price for Electrolysis Pathway

In addition to rich hydroelectric resources in the Province, BC has significant wind reserves that can be leveraged to produce hydrogen. It is estimated that there are >5.4 GW of high-quality wind reserves with high utilization potential (40-70%) in areas that can be readily developed.

BC's Renewable Hydrogen Canada (RH_2C) is developing large-scale projects to produce hydrogen from renewable power, primarily wind augmented by hydroelectric power. They are in the stages of developing a project in Northeastern BC in the heart of the Montney gas formation. In the first phase of the project, a 120 MW electrolyzer farm will produce pure hydrogen and inject in into the natural gas grid. Longer-term, additional projects will be developed to use the hydrogen to produce methanol (Canadian Methanol) and low carbon gasoline (Blue Fuel Energy).

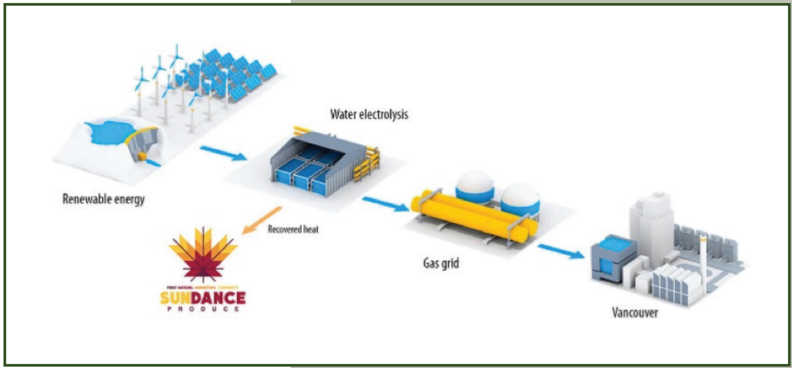
3.1.3 : Biomass Gasification and Purification

Biomass is a renewable organic resource predominantly comprised of carbon, hydrogen and oxygen, encompassing crop and forest residues, specialty crops, and even waste streams. Biomass gasification is a mature technology that uses the controlled application of heat (generally >700°C), steam, and oxygen (from air) to convert biomass to hydrogen and other products without combustion. Biomass gasification is generally undertaken in two stages, with an initial gasification stage (reaction 1) followed by a water-gas shift reaction (reaction 2) in which carbon monoxide (CO) is converted to carbon dioxide (CO_2), generating additional H_2.

(1) $C_6H_{12}O_6 + O_2 + H_2O + \text{heat} \rightarrow CO + CO_2 + H_2$ + other species

(2) $CO + H_2O \rightarrow CO_2 + H_2 + \text{heat}$

The products of gasification are H_2 and CO_2, along with other species; pressure swing absorption is then used to purify the hydrogen. Though carbon dioxide is produced, biomass is considered a GHG-neutral fuel because biomass sequesters carbon dioxide during its life. Some biomass facilities may sequester the resulting CO_2, effectively making this pathway carbon negative. Such technology pathways are sometimes referred to in climate science literature as Bioenergy with Carbon Capture and Storage (BECCS).



The cost of hydrogen from biomass gasification for this study was modeled without CCS. Feedstock costs of $80/dry tonne of biomass were assumed, with $100/tonne of processing costs. For a facility producing 100 tonnes of hydrogen per day the cost of hydrogen is modelled to be approximately $3/kg H_2 as shown in Figure 12.

A facility producing 100 tonnes of hydrogen per day would be very large, requiring 1,350 dry tonnes of biomass feedstock per day, and thus may or may not be feasible based on constraints for regional supplies. Smaller facilities would be more feasible from a feedstock availability perspective but would drive up the capex portion of the cost.

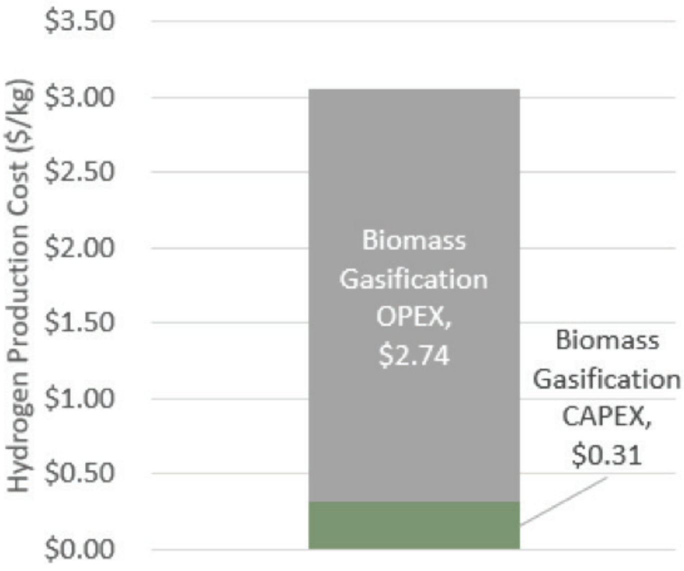


Figure 12. Cost breakdown for hydrogen produced via biomass gasification

3.1.4 : Steam Methane Reforming with CCS

Steam methane reforming (SMR) is the most common bulk hydrogen production pathway; fossil fuel reforming accounted for approximately 95% of worldwide hydrogen production in the year 2000 timeframe with natural gas representing about one-half the total.[20]

SMR involves reacting natural gas (primarily methane, CH_4) with steam (H_2O) to produce H_2 and CO_2. The efficiency of SMR is greater than 80% as measured by the higher heating value of the energy content of the hydrogen produced, compared to that of the natural gas consumed.[21] Higher heating value is a measure of the energy liberated from a compound if, after being combusted, all the combustion products are brought back to pre-reaction temperatures.

The overall chemical reaction for steam methane reforming process is shown in reaction (1) below. Reaction (2) describes the water gas shift reaction, which is used in SMR as well as in biomass gasification.

(1) $CH_4 + H_2O + \text{heat} \rightarrow CO + 3H_2$

(2) $CO + H_2O \rightarrow CO_2 + H_2 + \text{heat}$

21 *Peng, X. D. (2012). Analysis of the Thermal Efficiency Limit of the Steam Methane Reforming Process. Ind. Eng. Chem. Res., 51 (50), pp 16385–16392. Retrieved from http://www.airproducts.com/~/media/Files/PDF/industries/en-analysis-of-thermal-efficiency-limit-of-steam-methane-reforming-process.pdf*

A process diagram for steam methane reforming is provided in Figure 13 below.

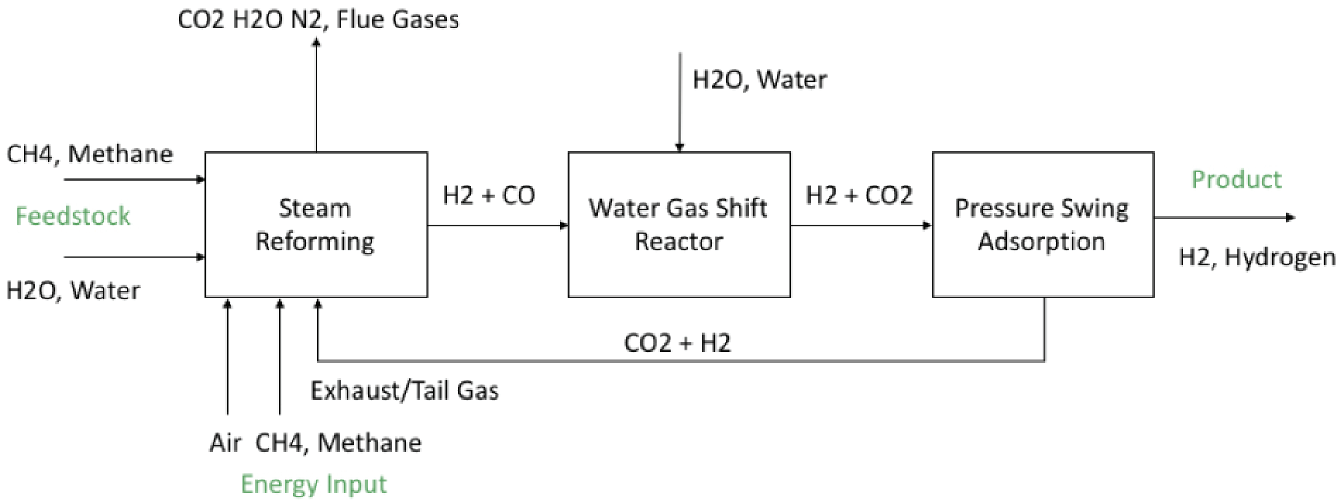

Figure 13. Steam Methane Reforming Process

Using a conservative 75% efficiency, applying SMR to 1 GigaJoule (GJ) of natural gas would result in 0.75 GJ of hydrogen, or approximately 5.3 kg.[22] SMR plants can produce hydrogen at very large scale; a recent plant announcement exceeded 300 tonnes H_2/day.[23]

SMR generates approximately 8-10 kg CO_2e per kg of H_2 produced (CO_2e/kg H_2). The report will use 10 kg CO_2e/kg H_2. Existing technology such as amine scrubbers and vacuum swing adsorption can be deployed within the SMR process to capture up to 56-90% of the generated CO_2 resulting in net emissions of 2 kg CO_2e/kg H_2.[24]

Factoring in upstream natural gas GHG emissions, total GHG emissions from SMR with CO_2 capture and storage comprise 2.7 t CO_2e/t H_2.[25, 26]

In SMR processes, hydrogen production costs are driven by feedstock costs and amount to 2 to 3 times the cost of natural gas on a $/GJ basis. For example, for a natural gas price of $4/GJ (approximately $4.20/MMBTU) hydrogen production costs can be expected to range from $8-12/GJ H_2. Our analysis of SMR production costs yielded a per-kilogram cost of $1.32/kg H_2.

CCS is estimated to add approximately $0.82/kg H_2 to base SMR costs. The hydrogen production cost of SMR + CCS is then estimated to be approximately $2.14/kg H_2. The cost breakdown is shown in Figure 14, with the sensitivity to natural gas feedstock price shown in Figure 15.

22 *Based on higher heating value of hydrogen at 0.142 GJ/kg*

23 *Bailey, M.P. (2018). Air Products Inaugurates Steam-Methane Reformer at Covestro's Baytown Site. Chemical Engineering. Retrieved from https://www.chemengonline.com/air-products-inaugurates-steam-methane-reformer-at-covestros-baytown-site/*

25 *Upstream emissions = 3.3 kg CO_2/GJ NG ÷ 5.3 kg H_2/GJ NG = 0.62 kg CO_2e/kg H_2*

26 *This analysis assumes the 2030 upstream natural gas business as usual emissions in 2030 are equal to 2016/2017 emissions. This is supported by the figure on page 10 of the CleanBC plan. Retrieved from https://blog.gov.bc.ca/app/uploads/sites/436/2019/02/CleanBC_Full_Report_Updated_Mar2019.pdf See APPENDIX B: Upstream GHG emissions In BC for full details.*

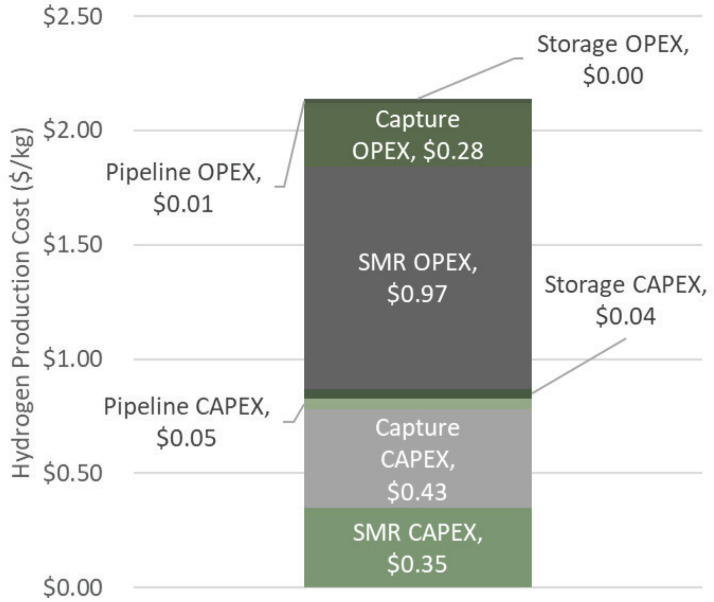

Figure 14. Cost breakdown for hydrogen produced via SMR + CCS

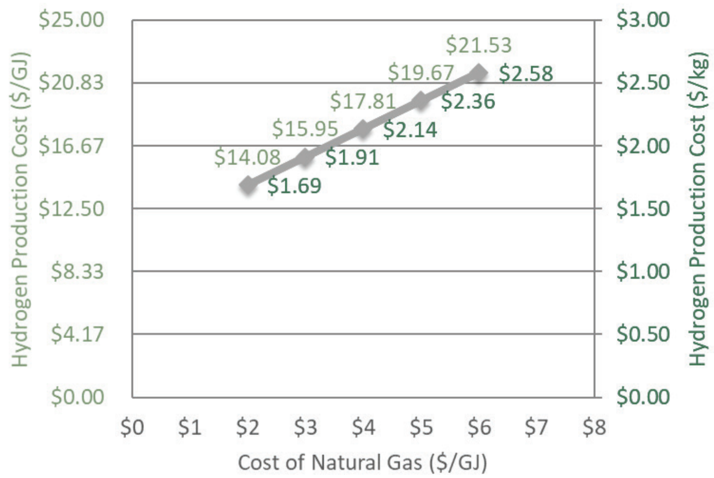

Figure 15. Impact of natural gas feedstock cost on hydrogen cost from SMR + CCS

Assuming that CCS processes cost approximately \$0.82/kg H_2 and remove 8 kg of the 10 kg CO_2e produced per kg H_2 in the SMR process, the equivalent cost of carbon capture and storage can be calculated as \$0.82/8 kg CO_2e, or \$0.102/kg CO_2e. This is equivalent to \$102/tonne CO_2e.

3.1.5 : Methane Pyrolysis

Methane pyrolysis is the decomposition of natural gas without oxygen into its two main elements; gaseous H_2 and solid carbon (C). CO_2 is not produced, as the reaction takes place in the absence of oxygen. Thermal pyrolysis of natural gas has been commercially operated at scale by Cancarb of Alberta since the early 1900s.

The pyrolysis process is described in reaction (1) and a process diagram is shown in Figure 16 below.

(1) $CH4 + \text{energy} \rightarrow C + 2H_2$

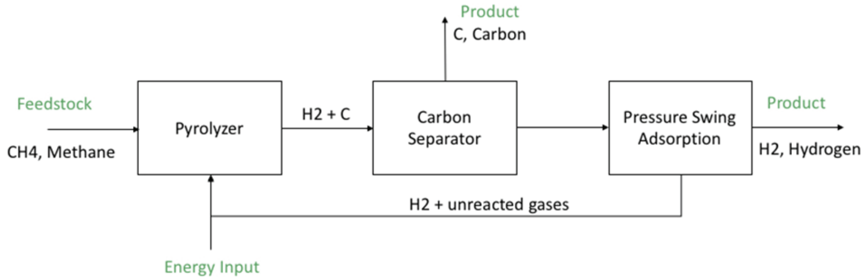

Figure 16. Methane Pyrolysis Process

Thermal pyrolysis and plasma pyrolysis are two technologies under development.

Carbon powder, sometimes called carbon black, commands a price of \$50 to \$500/tonne in a market of approximately 12 million tonnes per year.[28] Methane pyrolysis will generate approximately 3.75 kg of carbon black per kg of hydrogen, so large-scale pyrolysis could saturate BC carbon black markets and reduce the powder's market price.

3.1.5.1 : Thermal Pyrolysis

In thermal pyrolysis, complete conversion of methane to hydrogen and carbon is difficult to achieve; hydrogen leaving the reactor will contain unreacted methane. Pressure swing absorption is likely to be used to separate the hydrogen from the methane, with the latter recirculated and combusted to provide the heat for the reaction. A novel type of thermal pyrolysis, using a liquid or molten metal to separate the gases, may circumvent this requirement.

Energy inputs were estimated assuming a 90% conversion of methane to hydrogen and carbon and an 80% yield in the pressure swing absorption process, resulting in an estimated 0.32 GJ/kg H_2 of which 0.028 GJ/kg H_2 is required to provide heat for the reaction.

Based on natural gas feedstock costs of \$4/GJ, no value being assigned to the carbon black, and building on a recent analysis[29] for a liquid metal thermal pyrolysis technology, the study calculated the hydrogen production costs at \$1.68/kg H_2 comprising approximately \$1.26/kg for operating costs and \$0.43/kg for capital cost amortization. This is shown in Figure 17.

BC's Ekona Power proposes to use unsteady gas dynamics and multiple reactors to create a continuous output of decarbonized hydrogen at a cost similar to SMR. The startup has attracted funding from Evok Innovations[27] and BC's ICE Fund, has completed modelling of the process and is designing a proof-of-concept reactor to test the process

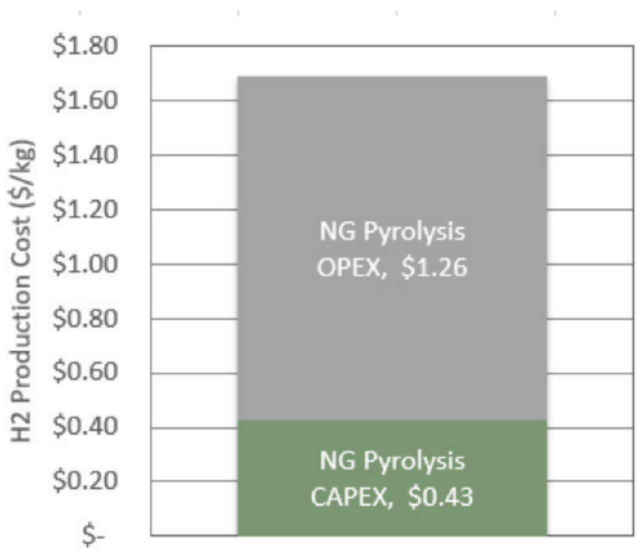

Figure 17. Cost breakdown for hydrogen produced via Liquid Metal Thermal Pyrolysis

The sensitivity of hydrogen costs to natural gas feedstock costs is provided in Figure 18 below:

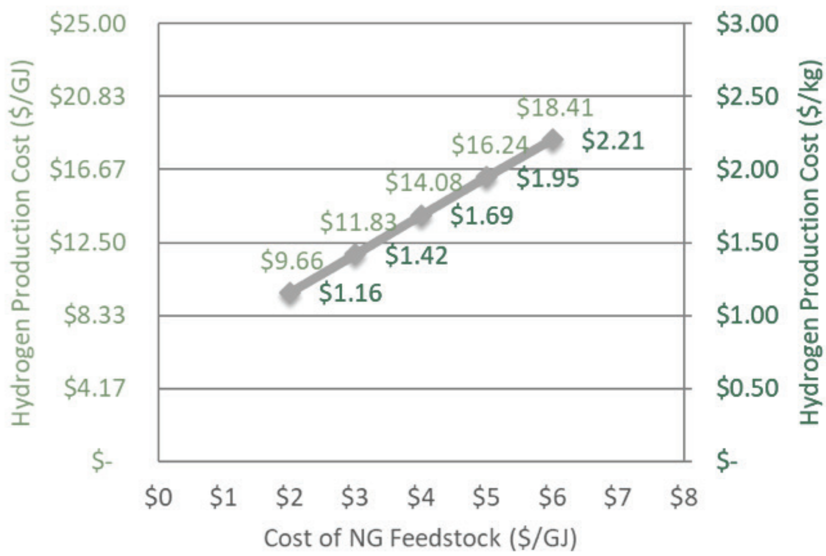

Figure 18. Impact of natural gas feedstock cost on hydrogen cost from liquid metal thermal pyrolysis

The Province estimates emissions associated with natural gas combustion as 57.94 kg CO_2e/GJ.[30] Combined with the above information this provides an emissions intensity of 0.66 kg CO_2e/kg H_2 for the hydrogen produced from thermal pyrolysis, owing to the combustion of natural gas in the process for heat. Factoring in upstream emissions, the GHG emission intensity from thermal methane pyrolysis would be 1.77 kg CO_2e/kg H_2 or 14.7 g CO_2e/MJ.[31]

....

30 *(S&T) Squared Consultants Inc. (2018). GHGenius 5.0d. Calculations conducted by BC Ministry of Energy, Mines and Petroleum Resources Low Carbon Fuels Branch. Retrieved from https://ghgenius.ca/index.php/downloads*

31 *This analysis assumes the 2030 upstream natural gas business as usual emissions in 2030 are equal to 2016/2017 emissions. This is supported by the figure on page 10 of the CleanBC plan. (https://blog.gov.bc.ca/app/uploads/sites/436/2019/02/CleanBC_Full_Report_Updated_Mar2019.pdf) See APPENDIX B: Upstream GHG emissions In BC for full details.*

The cost of carbon capture and storage was calculated (on a \$/tonne CO_2e basis) in section 3.1.4, and an equivalent calculation can be made for pyrolysis processes. Pyrolysis is more expensive than steam methane reforming but produces significantly less GHG emissions, so the cost of the avoided CO_2 emissions can be calculated.

- *The cost of hydrogen from thermal pyrolysis has been calculated as \$1.68/kg H_2, higher than the \$1.32/kg H_2 to produce hydrogen through SMR; a cost premium of \$0.36/kg H_2.*
- *The CO_2e emissions from thermal pyrolysis have been estimated at 1.77 kg CO_2e/kg H_2, significantly less than the 10.7 kg CO_2e/kg H_2 for SMR; a reduction of 8.9 kg CO_2e/kg H_2.*
- *For each kg of H_2 produced, it costs \$0.36 to avoid 8.9 kg CO_2e emissions, for a mitigation cost of \$0.041/kg CO_2e or \$41/tonne CO_2e emissions.*

Put differently, using thermal pyrolysis in place of SMR reduces CO_2e emissions from hydrogen production at an equivalent cost of \$40/tonne CO_2e.

3.1.5.2 : Plasma Pyrolysis

In plasma pyrolysis, electricity is used to generate a plasma arc in a reactor chamber, which decomposes methane into hydrogen and carbon. Process costs relate to the amount of electricity required per kg H_2. Thermal processes use high temperatures to decompose methane, with process costs largely driven by the amount of fuel used to bring reactors to high temperature.

Plasma pyrolysis requires electricity inputs of 10-12 kWh/kg H_2 [32], approximately one-fifth of the amount currently required for PEM electrolysis.[33]

Based on 10 kWh/kg H_2 and \$0.06/kWh industrial electricity costs, electricity inputs for plasma pyrolysis amount to \$0.60/kg H_2. Assuming the cost structure is otherwise similar to that of thermal pyrolysis the total hydrogen production cost for plasma methane pyrolysis is estimated to be \$2.28/kg H_2. This is depicted in Figure 19.

The Cancarb plant in Medicine Hat, AB produces approximately 45,000 tonnes/year of carbon black through thermal pyrolysis; it is currently the only plant in North America producing carbon black from natural gas. Pre-heated natural gas feedstock is decomposed at approximately 1400°C in the absence of air or flame to produce carbon black and hydrogen.

32 Personal communication, Pete Johnson, Monolith Materials

33 Stakeholder input.

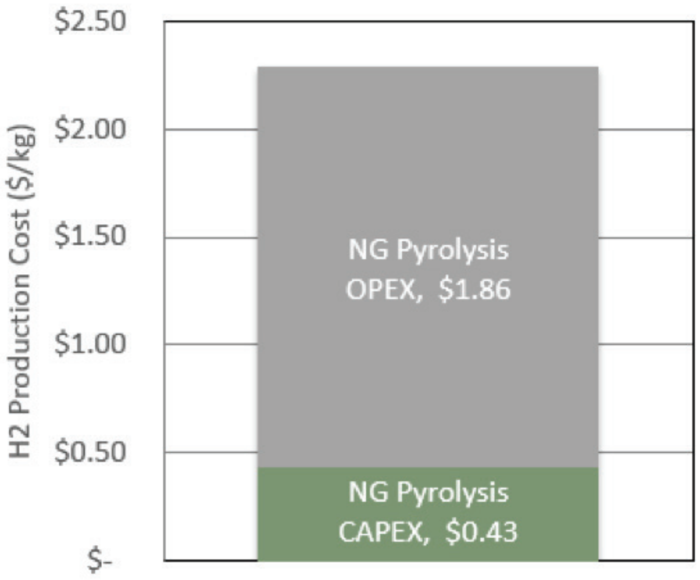

Figure 19. Cost breakdown for hydrogen produced via Plasma Pyrolysis

The sensitivity of plasma pyrolysis to natural gas feedstock costs is shown in Figure 20.

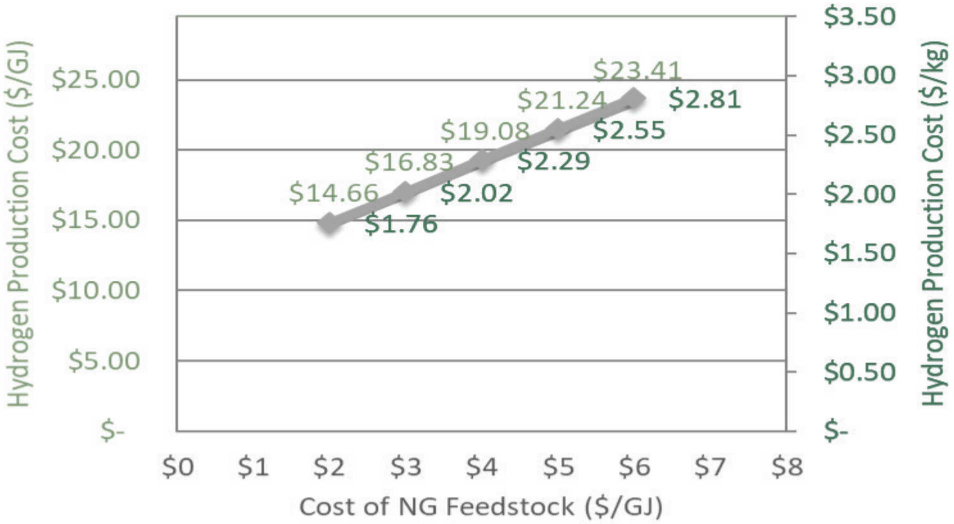

Figure 20. Impact of natural gas feedstock cost on hydrogen cost from plasma pyrolysis

Given the GHG emissions intensity of electricity from BC Hydro (54.72 g CO_2e/kWh)[34] the emissions intensity of hydrogen production from plasma pyrolysis would be on the order of 150 g CO_2e/kg H_2, or 0.150 kg CO_2e/kg H_2.

34 (S&T) Squared Consultants Inc. (2018). GHGenius 5.0d. Calculations conducted by BC Ministry of Energy, Mines and Petroleum Resources Low Carbon Fuels Branch. Retrieved from https://ghgenius.ca/index.php/downloads

Knowing these figures, the equivalent cost of mitigating GHG emissions using plasma pyrolysis in place of SMR can also be calculated.

- *The cost of hydrogen from plasma pyrolysis has been calculated as \$2.28/kg H_2, higher than the \$1.32/kg H_2 to produce hydrogen through SMR; a cost premium of \$0.96/kg H_2.*
- *The CO_2e emissions from thermal pyrolysis have been estimated at 0.150 kg CO_2e/kg H_2, significantly less than the 10.69 kg CO_2e/kg H_2 for SMR; a reduction of 9.18 kg CO_2e/kg H_2.*
- *For each kg of H_2 produced, it costs \$0.96 to avoid 9.18 kg CO_2e emissions, for a mitigation cost of \$0.105/kg CO_2e or \$105/tonne CO_2e emissions.*

Put differently, using plasma pyrolysis in place of SMR reduces CO_2e emissions from hydrogen production at an equivalent cost of \$105/tonne CO_2e.

3.1.6 : CO_2 sequestration

Effective CCS will be necessary for BC to capitalize on its abundant supply of natural gas to produce hydrogen without sacrificing GHG emissions goals. This section describes the state of CCS technology and storage capacity in BC.

3.1.6.1 : Overview

The Intergovernmental Panel on Climate Change (IPCC) defines carbon dioxide capture and storage as:

> "…a process consisting of the separation of CO_2 from industrial and energy-related sources, transport to a storage location and long-term isolation from the atmosphere."[35]

Subterranean geological formations are currently used for CO_2 storage, and are expected to continue being so in the future. The technologies in use are similar to long-established processes in the oil & gas sector. An overview of the storage options is given in Figure 21.

35 *Metz B, et al. (2005). IPCC Special Report on Carbon Dioxide Capture and Storage. IPCC. Retrieved from https://www.ipcc.ch/site/assets/uploads/2018/03/srccs_wholereport-1.pdf*

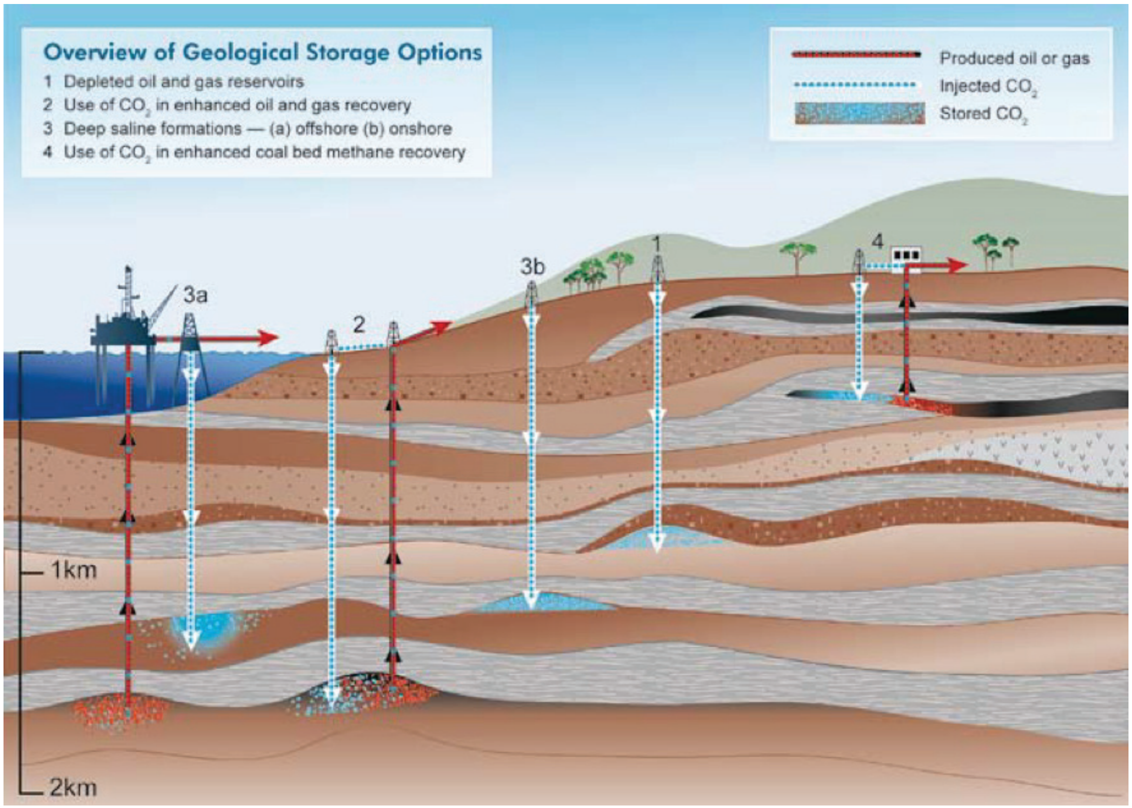

Figure 21. CO_2 Storage Options. Source: IPCC.[35]

A common feature in CO_2 storage options is the presence of a caprock which prevents the CO_2 from migrating back to the surface. Reservoir depths are recommended to be at least 800 m below ground, so the CO_2 can be stored as a supercritical fluid. This is desirable, as CO_2 is about 200x denser as a supercritical fluid than a gas, allowing considerably more CO_2 to be stored in each reservoir.

Shallower coalbeds can also be used for storage, as the CO_2 adsorbs onto the coal.

Over 200 million tonnes of CO_2 have been stored underground to date.[36] The Sleipner Gas Field off the coast of Norway is one the largest CO_2 storage sites; it has been used to sequester approximately 1 million tonnes of CO_2 per year since 1996.[37]

The IPCC conservatively estimates worldwide CO_2 storage capacity in depleted oil and gas reservoirs and saline aquifers to be approximately 3 trillion tonnes[35] representing sufficient capacity to store 80 years' worth of CO_2 from fossil fuel combustion at 2018 consumption rates.[38]

Promising sequestration sites can be found around the globe, including in Canada's Western Canadian Sedimentary Basin (WCSB), which extends from Alberta into BC.[39]

3.1.6.2 : CO_2 storage in BC

CO_2 storage options in BC include depleted gas reservoirs and saline aquifers. Gas reservoirs exist in the Northeast of the Province, in the Western Canadian Sedimentary Basin. Storage potential in these gas reservoirs – shown in Figure 22 – is estimated at approximately 2,000 Mt CO_2 per year.

Carbon dioxide can also be stored in saline aquifers, which exist throughout the province, as shown in Figure 23. The aquifers' potential for CO_2 storage has only been assessed in the Northeast of the province, so there remains considerable uncertainty about the aquifers' storage capacity. Estimates vary from 880 to 3580 Mt CO_2 per year.[40]

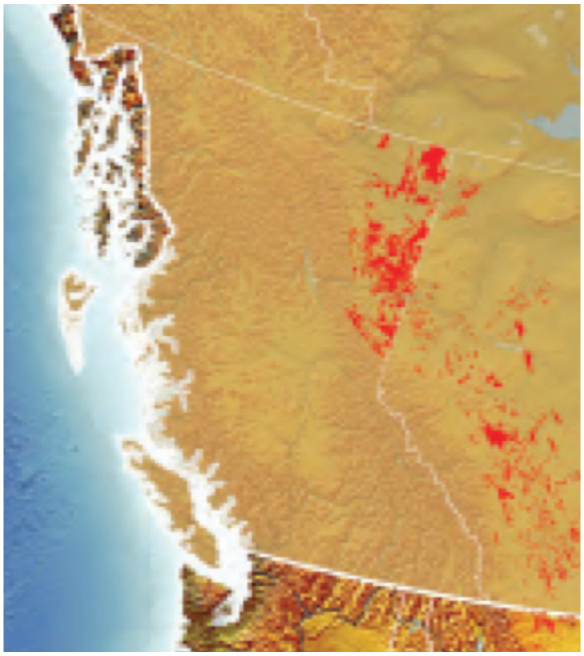

Figure 22. Natural Gas Fields in BC[41]

Figure 23. Location of Saline Aquifers in BC (light blue=non-assessed, dark blue=assessed)[40]

Drawing these together, Table 1 compiles the estimated CO_2 storage capacities for geological formations in the Province.

40 U.S. Department of Energy. (2015). Carbon Storage Atlas, Fifth Edition. National Energy Technology Laboratory. Retrieved from https://edx.netl.doe.gov/dataset/netl-carbon-storage-atlas-fifth-edition

41 Bachu, S. (2006a): The potential for geological storage of carbon dioxide in Northeast British Columbia; Report to the BC Ministry of Energy, Mines and Petroleum Resources, 71 pages.

CO_2 STORAGE OPTION	ESTIMATED CAPACITY (MT CO_2e)
Gas Reservoir	2,000
Saline Aquifer	1,000
Total	3,000

Table 1. CO_2 storage capacity in BC

In our hydrogen supply analysis, the study determined the annual capacity based on the assumption the CO_2 storage capacity would last 160 years. Further assuming that half of the storage capacity would be allocated to hydrogen, the maximum production through SMR+CCS processes would be 1.1 million tonnes hydrogen per year.

3.2 : Cost of Hydrogen Production in Province

The levelized cost of production for each pathway was calculated based on a 100 tonne per day (TPD) hydrogen plant, to evaluate the viability of large-scale centralized hydrogen production in the province. Figure 24 compares the hydrogen production cost of the various pathways relevant to BC's strategic resources. The cost to produce hydrogen via steam methane reformation is shown in the graph as a comparative baseline. It is recommended that the province focus only on low carbon hydrogen pathways, as described in 3.1.

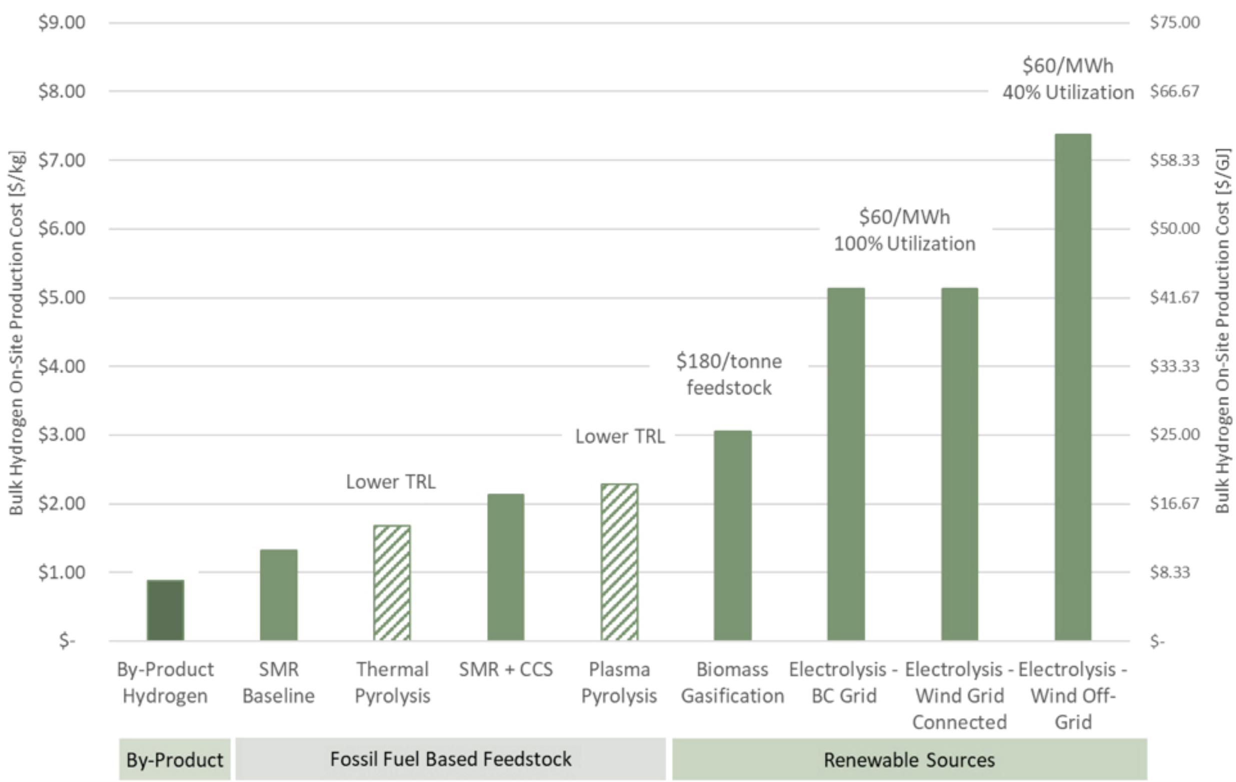

Figure 24. Cost of Bulk On-site Hydrogen Production by Pathway in BC (2030). Production costs are normalized to production scale of 100 TPD

Additional costs will be incurred during transportation, for which three pathways are likely:

1. *Injection into the natural gas grid, leveraging BC's natural gas pipeline infrastructure to store and deliver the hydrogen. In the near-term, hydrogen would be blended at low enough levels into the natural gas that the mixture could be consumed by existing end users without necessitating changes to their equipment. In the longer-term, hydrogen could be blended into natural gas at higher levels and then separated out for hydrogen-specific end users.*
2. *Delivery as a compressed gas, generally done through tube trailer trucks common to the chemical industry.*
3. *Delivery as a cryogenic liquid, also by delivery truck.*

The cost of delivering hydrogen as a compressed gas or a cryogenic liquid are a function of distance; estimated costs are shown in Figure 25.

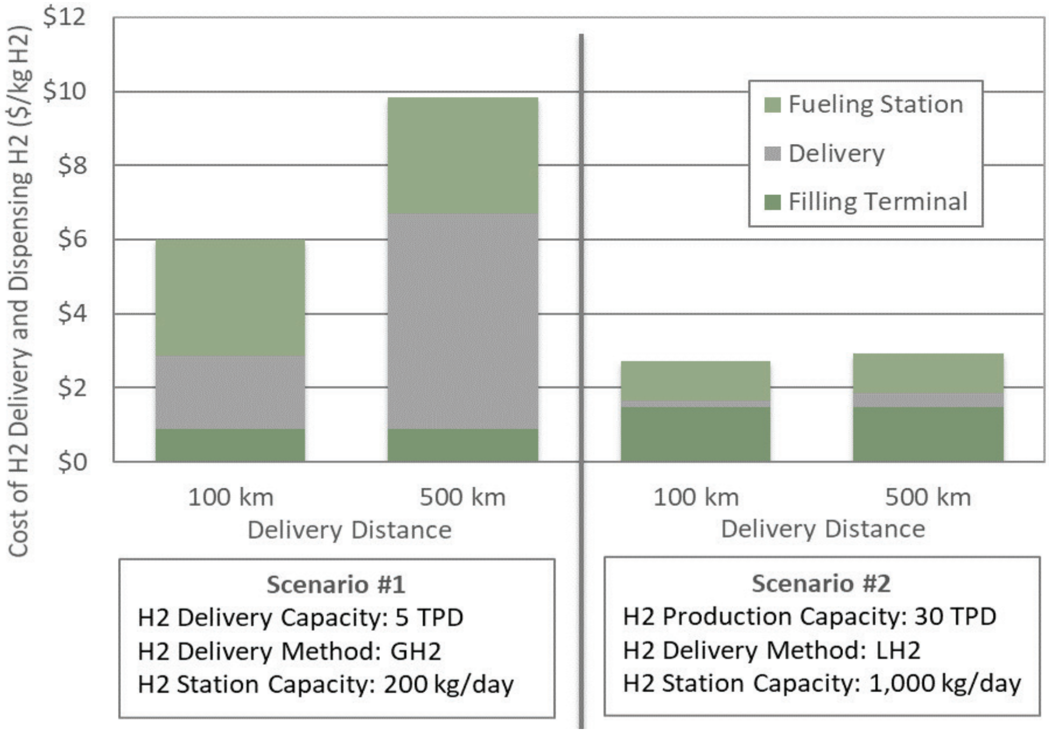

Figure 25. Truck-based delivery cost for hydrogen as a compressed gas and cryogenic liquid

On a per-kg basis, it is more economic to deliver hydrogen as a cryogenic liquid, but not all customers consume enough hydrogen to justify the higher capital expenditures liquid hydrogen deliveries require.

A hydrogen production plant might need to produce at least 10 tonnes H_2 per day to warrant investment in a liquefaction plant by the producer. Most end users are likely to use hydrogen in gas form, so would need to install a cryogenic tank on-site and vaporize it prior to use. Ballard Power Systems has such an installation at their Burnaby facility.

3.3 : Carbon Intensity of Hydrogen Production Pathways in BC

The GHG emissions intensity of the hydrogen pathways considered in this report is given in Figure 26 below. For context, it is noted that 1 kg H_2 contains 120 MegaJoules (MJ) of chemical energy. Thus, SMR baseline emissions of 89.1 g CO_2e/MJ is equivalent to 10.69 kg CO_2e/kg H_2.

All the pathways under consideration provide at least a 69% GHG emissions reduction relative to SMR. It is recommended that the Province set a threshold for hydrogen production carbon intensity of 36.4 g CO_2e/MJ going forward. This is consistent with the European CertiHy threshold.[42]

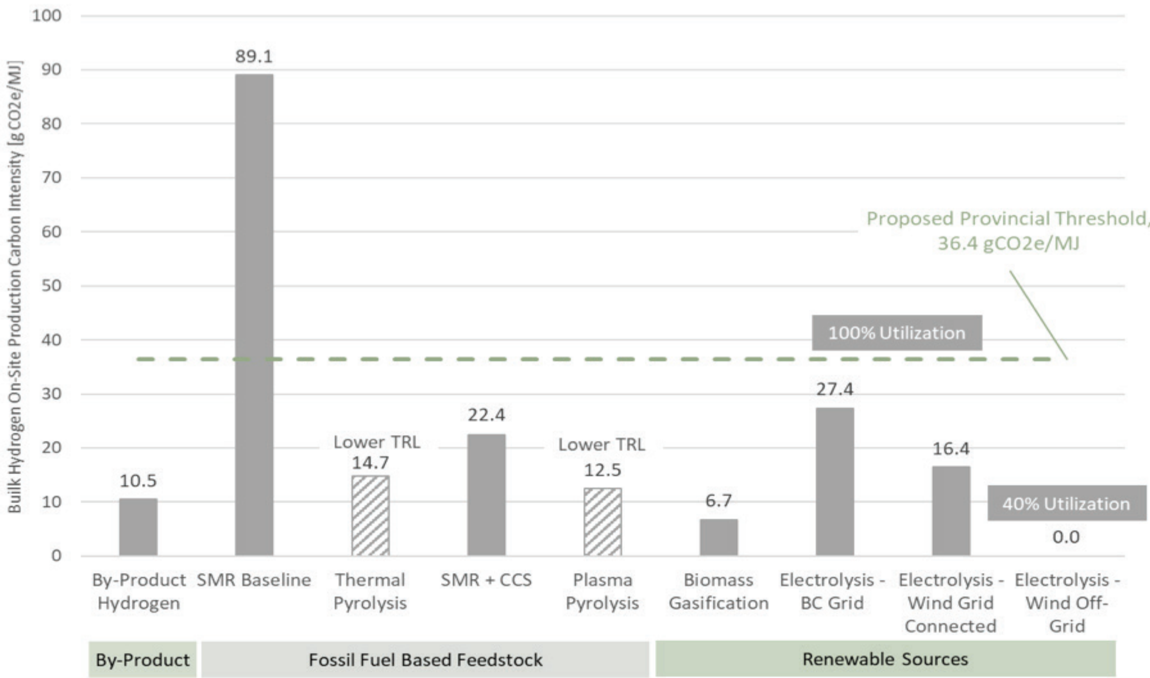

Figure 26. Carbon Intensity of BC's Hydrogen Production Pathways

An important metric for each pathway is the relative cost of carbon mitigation: the hydrogen production cost premium measured in terms of avoided CO_2e emissions. This metric measures the cost effectiveness of each hydrogen production pathway, relative to the emissions reductions it offers over SMR. Figure 27 shows this cost of carbon mitigation for each pathway.

42 *Fuel Cells and Hydrogen 2 Joint Undertaking (2019). Hydrogen Roadmap Europe: A Sustainable Pathway for the European Energy Transition. Retrieved from* *https://www.fch.europa.eu/sites/default/files/Hydrogen%20Roadmap%20Europe_Report.pdf*

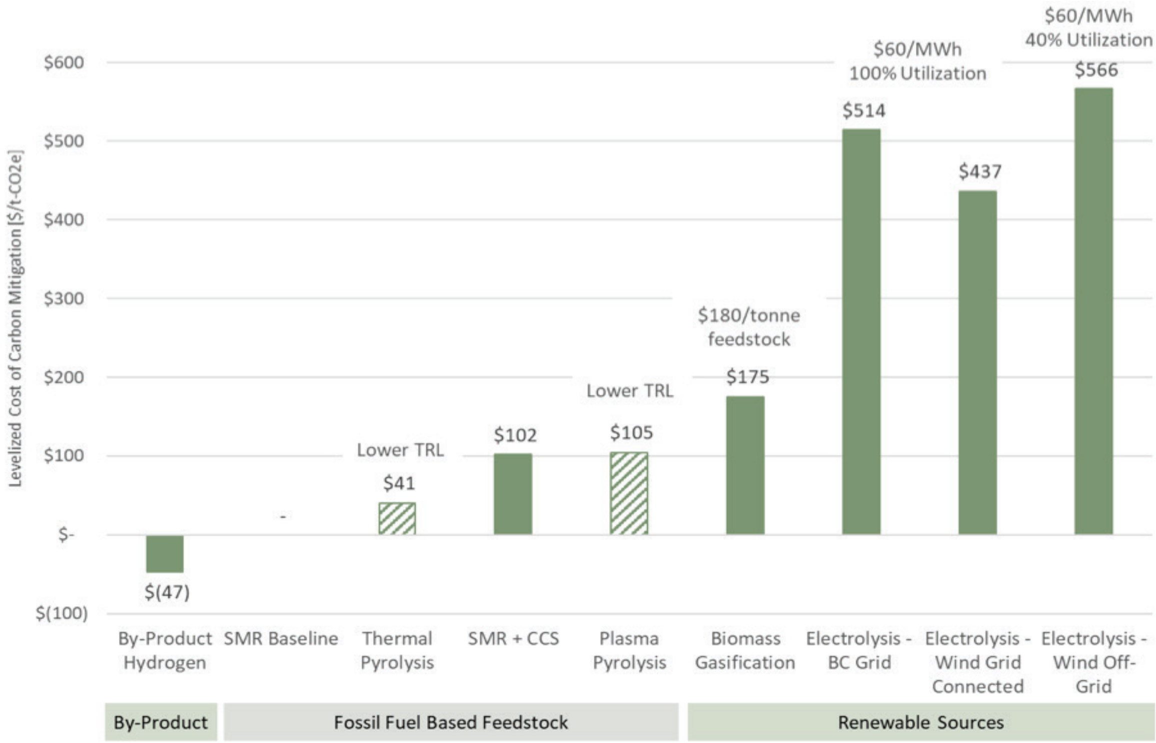

Figure 27. Cost of Carbon Mitigation by Hydrogen Production Pathway in BC (2030)

This chart shows by-product hydrogen to be the most cost-effective means of procuring hydrogen, relative to the avoided GHG emissions. Hydrogen supply from this pathway should be prioritized.

While Figure 24 showed that natural gas-based hydrogen pathways offer the lowest-cost hydrogen supply and Figure 26 showed that renewable hydrogen pathways offered the greatest emissions reductions potential, Figure 27 shows that the natural gas pathways have a lower cost of carbon mitigation.

The inference is that with prevailing price structures, natural gas-based hydrogen production pathways will be critical for cost-effective hydrogen production in the Province. If prevailing natural gas prices rise, perhaps through access to export markets, or if biomass or renewable electricity costs fall, perhaps through public policy measures, preferred rate tariffs or technology development, the cost comparisons would need to be revisited.

3.4 : Hydrogen Availability in BC

Each production pathway can supply different amounts of hydrogen based on the Province's natural resources. Figure 28 and Figure 29 show hydrogen supply curves against production cost; Figure 28 does so for all evaluated sources of hydrogen, while Figure 29 does so only for renewable pathways.

Industrial by-product hydrogen is the lowest-cost source of supply, and it can currently supply approximately 18.5 tonnes per day or 6, 800 tonnes per year.

BC's production capacity is estimated to be in excess of 2.2 million tonnes per year, positioning it to satisfy not just provincial demand but also proving excess capacity that could be exported.

Appendix C outlines the key assumptions underpinning the calculations for both hydrogen cost and availability above.

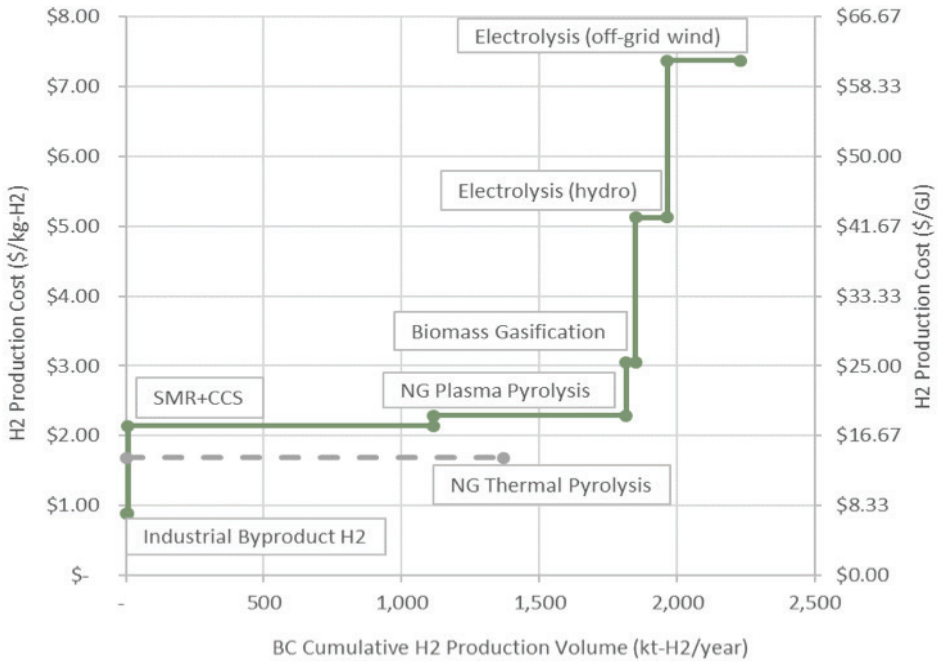

Figure 28. Estimated Hydrogen Production Price and Maximum Annual Volume by Pathway in BC (2030)

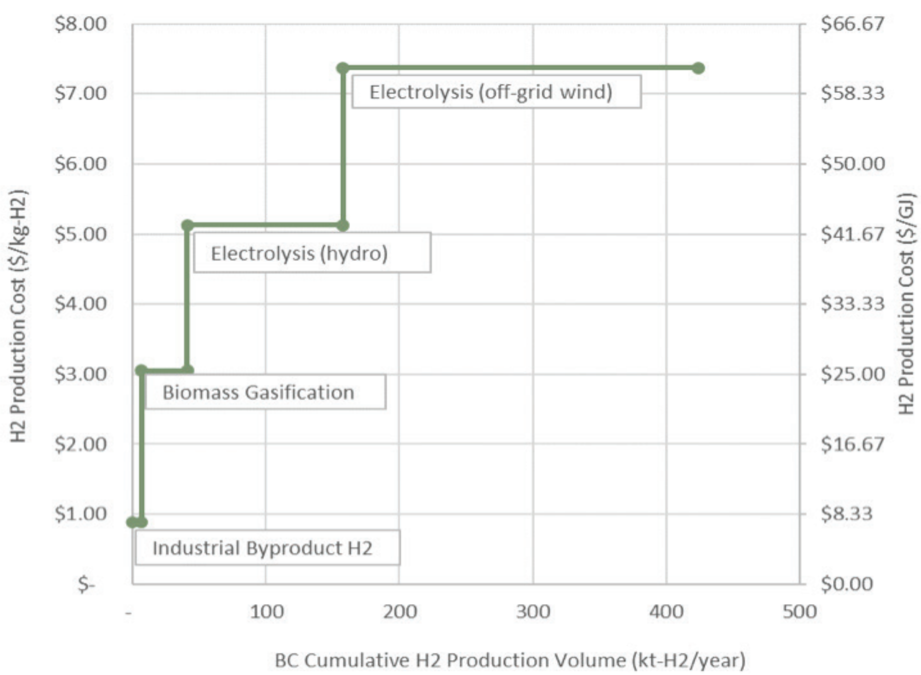

Figure 29. Estimated Hydrogen Production Price and Maximum Annual Volume by non-Fossil Fuel Pathway in BC (2030)

While there are uncertainties in potential production volume for each pathway, uncertainty in hydroelectric capacity warrants elaboration. The Province's CleanBC plan and the more recent City of Vancouver's Climate Change Emergency Response[43] focus on the electrification of transportation and the built environment will tend to increase hydroelectricity consumption; falling electric demand in BC's industrial sector[44] and the deployment of other renewable energy will tend to decrease it.

BC Hydro's peak capacity forecast does not show excess capacity after 2031[45], but the forecast load factor was not provided as input to the study. Both total electricity production and the shape of the load curve are important to accurately model the economics and capacity of electrolyzer development. BC Hydro has indicated that they build capacity to match demand. The values forecasted above for 2030 and 2050 for hydroelectric capacity were deemed to be reasonable by BC Hydro, provided adequate advance forecasting is given.

3.5 : Supply Development Approach

In the near-term, the lowest-cost, low-emissions sources of hydrogen will be necessary to maximize hydrogen's potential for decarbonizing BC's economy, complementing other efforts throughout the Province. Higher-cost hydrogen supplies will have greater challenges displacing GHG emissions in the public and private sector, and winning contracts for hydrogen exports.

In the longer-term it will be necessary for the Province to transition to renewable hydrogen sources rather than risk depleting fossil resources.

To that end, it is recommended that the Province support the development of a provincial industry for the production of clean hydrogen, while mandating that an increasing proportion of hydrogen be sourced from renewable feedstocks. This would allow the Province to capitalize on its natural gas resources in the mid-term while establishing a framework for a transition to renewable hydrogen.

Given the availability of low-cost, low-emissions by-product hydrogen from chemical facilities in Metro Vancouver and Prince George, it is recommended that one or more lighthouse projects be developed in the region to capitalize on the resource. When hydrogen demand exceeds by-product hydrogen supply, if large-scale hydrogen production has not begun, supplemental hydrogen could be generated from modular electrolyzers. These could be placed near end user facilities to minimize transportation costs.

Hydrogen liquefaction facilities will be necessary to move hydrogen economically around the Province. To that end, it is recommended that liquefaction facilities be seen as strategic assets to facilitate the decarbonization of the BC economy through hydrogen. Given the proposed lighthouse projects in Metro Vancouver, a nearby liquefaction facility will be critical to lower the delivered costs of hydrogen in the region.

The Peace Region, with ample natural gas, hydroelectric generation capacity, carbon sequestration and wind resources along with existing gas and electric transmission infrastructure could be suitable for large-scale clean hydrogen production, whether from natural gas or electrolysis or both. Hydrogen could be blended into existing natural gas pipelines in the near-term, as plans develop for larger hydrogen-specific deployments.

3.5.1 : Recommendations

Adopt policy that specifies the GHG intensity of hydrogen, rather than limiting to renewable only

- *Set longer-term objectives for transition to renewable hydrogen supplies through establishing tiered thresholds of required renewable content over time*

Prioritize development of large-scale, low carbon hydrogen supply infrastructure and strategic hydrogen liquefaction and distribution assets in the Province

- *Set a threshold for the GHG intensity of the hydrogen for all provincially funded projects and stipulate that there must be a transition plan for hydrogen to be produced within the province during the project*

Develop flexible, lower cost electricity rate schedule to encourage production of green hydrogen

- *In near term, small, distributed electrolyzers will require lower electric rates*

Lighthouse project: Support a study to look at the potential for centralized hydrogen production and transport from the Peace region, both through the NG pipeline and as liquid through liquefaction plant

BC HYDROGEN PIPELINE

The Peace Region of BC, with extensive gas reserves, CO_2 sequestration potential, hydroelectric generation capacity and wind resources, coupled with an abundant fresh water supply, could become a centralized large-scale producer of clean hydrogen supplying not only BC, but also the US Pacific Northwest and California.

There is potential to use the existing NG grid and inject large amounts of hydrogen and create a blended NG/ H_2 gas stream. Liquefaction coupled with rail or road transport would enable delivery of pure hydrogen. A 'big bold goal' would be to construct a dedicated hydrogen pipeline that runs from the Peace Region right down to California. This would be built with a view to future energy systems, rather than one retrofitted to the hydrocarbon energy systems of the past. There could also be potential to run the pipeline east into Alberta. This carbon-free energy pipeline could provide a means for both provinces to transmit carbon-free energy derived either from renewable resources or fossil resources where the carbon is sequestered directly at the source of extraction, thereby alleviating many of the environmental concerns connected to existing pipeline projects under development.

4.0 : Hydrogen's Role in Decarbonizing BC's Energy System and Economic Sectors

Given the Study goal of identifying roles hydrogen can play in BC's decarbonization efforts, an evaluation of economic sectors in the Province was made, with the following analysis for each sector:

- *Baseline for energy use and emissions;*
- *Opportunities for hydrogen based on technical and commercial factors;*
- *Sector-specific challenges or barriers, and policy recommendations to overcome these;*
- *Adoption scenarios based on factors such as technology maturity, cost, and pertinent and potential policies and regulations.*

4.1 : Natural Gas

4.1.1 : Baseline

As per Figure 30 below, natural gas represents 30% of BC energy consumption and 80% of the Province's energy production.[46] As such, it is an important energy source and a vector for economic development. The upstream oil and gas sector contributes approximately 10,000 jobs and almost $1 billion per year in provincial revenues.[47] Extracting hydrogen from oil and gas, and capturing and sequestering the carbon dioxide produced, could provide a path for BC's oil and gas sector to continue supplying energy in a carbon-constrained future.

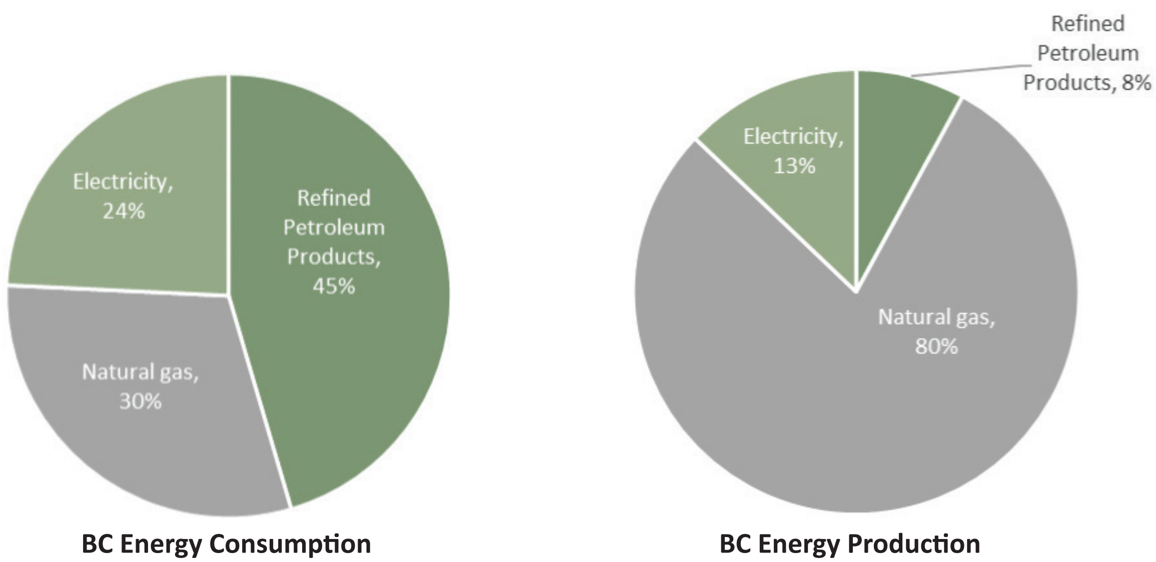

Figure 30. BC Energy Consumption and Production by Energy Type.[46]

46 *Canada's Oil and Natural Gas Producers. (2018). British Columbia's Oil and Natural Gas Industry. Retrieved from* https://www.capp.ca/publications-and-statistics/publications/335337

47 *Ibid 46*

The Province has extensive low-cost natural gas resources which technology innovations have made feasible for extraction. BC's natural gas fields are located in the Northeast of the Province, which overlaps the Western Canadian Sedimentary Basin; the largest are the Montney Formation, the Horn River Basin, the Cordova Embayment and the Liard Basin.

BC's natural gas reserves are estimated at more than 525 trillion cubic feet (tcf), sufficient to meet more than 100 years of natural gas demand at current levels. The Province's approximately 10,000 producing wells produce about 1.5 tcf of natural gas per year, representing about 28% of Canadian natural gas production, only 10% of which is consumed in-province.[48]

Natural gas is distributed around the Province and to neighbouring jurisdictions through networks of pipelines, shown in Figure 31 below. Pipeline operators include Enbridge, FortisBC and Pacific Northern Gas (PNG). BC's extensive natural gas pipeline network represents a significant capital investment and infrastructure for energy supply that presently serves all major population centres in the province.

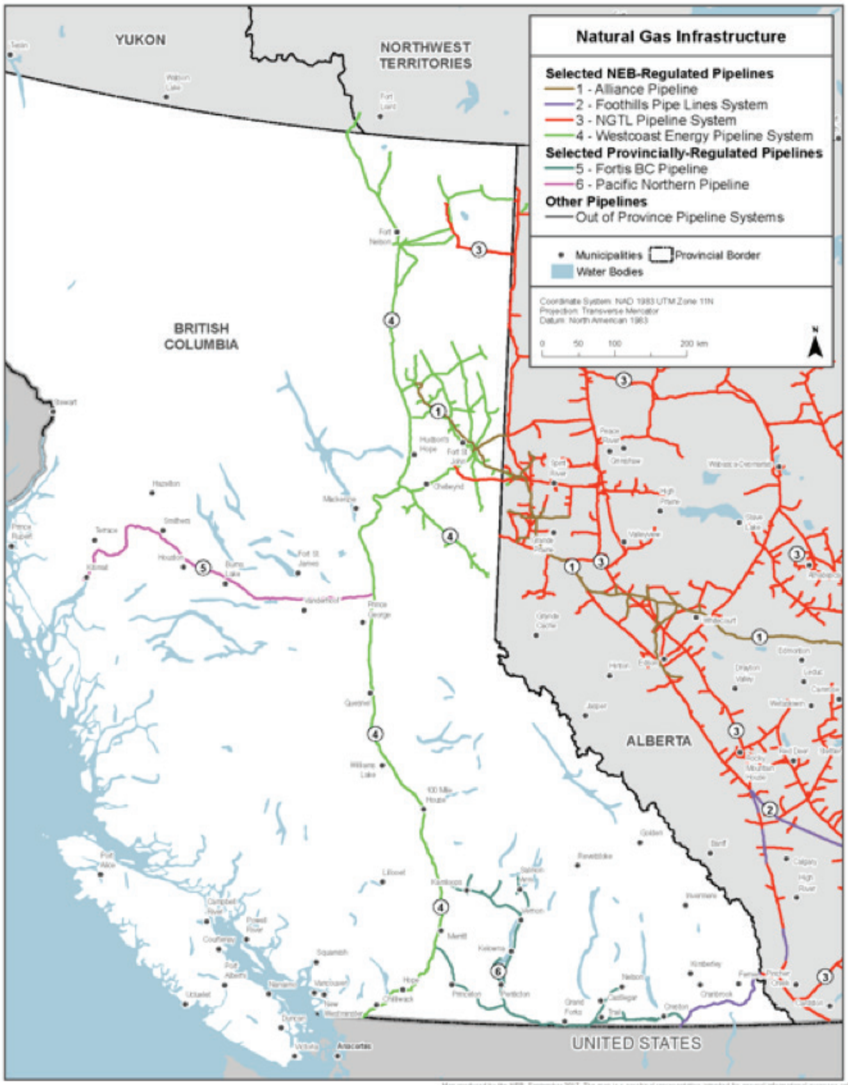

Figure 31. Map of BC Natural Gas Infrastructure [49]

48 *Ibid 46.*

49 *National Energy Board. (2017). Electricity Capacity and Primary Fuel Sources. Retrieved from* [*https://www.neb-one.gc.ca/nrg/ntgrtd/mrkt/nrgsstmprfls/mg/bc-fg03-lg-eng.png*](https://www.neb-one.gc.ca/nrg/ntgrtd/mrkt/nrgsstmprfls/mg/bc-fg03-lg-eng.png)

The Westcoast Energy Pipeline, operated by Enbridge and sometimes called the Westcoast Transmission System or the BC Pipeline, was built in 1957. It is shown in green in the Figure above. The Enbridge-owned and operated pipeline delivers natural gas from the Western Canadian Sedimentary Basin to Metro Vancouver. It transports about 60% of the natural gas produced in BC and supplies about 50% of natural gas demand in Washington, Oregon and Idaho. The pipeline consists of two systems, Transmission North and Transmission South, both of which are being upgraded to increase capacity beyond the current 2.9 billion cubic feet (Bcf) per day. (This figure is equivalent to approximately 1.0 tcf/year of transmission capacity, as compared to the province's current 1.5 tcf/year of production.)

BC's eastbound natural gas flows through TransCanada's Nova Gas Transmission Limited (NGTL) system, which is also expanding to accommodate new supply from the Montney Formation. The Province's natural gas is also exported to the U.S. Pacific Northwest at the Huntingdon export point, via the Westcoast Pipeline (Enbridge), or exported to the U.S. Midwest via the Alliance Pipeline (Enbridge) and through the Alameda, Saskatchewan export point.

The BC Oil and Gas Commission (OGC) provides oversight for industrial activities, licensing, regulations, growth and associated economic development. Natural gas prices are regulated in the Province through the BC Utilities Commission. Rates vary between customer type – residential, commercial or industrial – and from region to region. Medium-sized commercial operations in BC pay a rate structure for NG supply broadly in line with that outlined in Table 2.

COST ELEMENT	COST ($/GJ)
Cost of Natural Gas	$1.50
Delivery Charge	$3.00
Storage and Transport Charge	$1.20
Total	$5.70

Table 2. Typical Natural Gas Rate Structure, Medium-Sized Commercial Operation[50]

50 Fortis BC. (2019). Business Natural Gas Rates. Retrieved from https://www.fortisbc.com/accounts-billing/billing-rates/natural-gas-rates/business-rates

4.1.1.1 : BC Energy Demand and GHG Emissions

In 2016 BC end use energy demand was 1,165 petajoules (PJ) of which natural gas accounted for 346 PJ, supplying approximately 30% of total energy demand for the province.

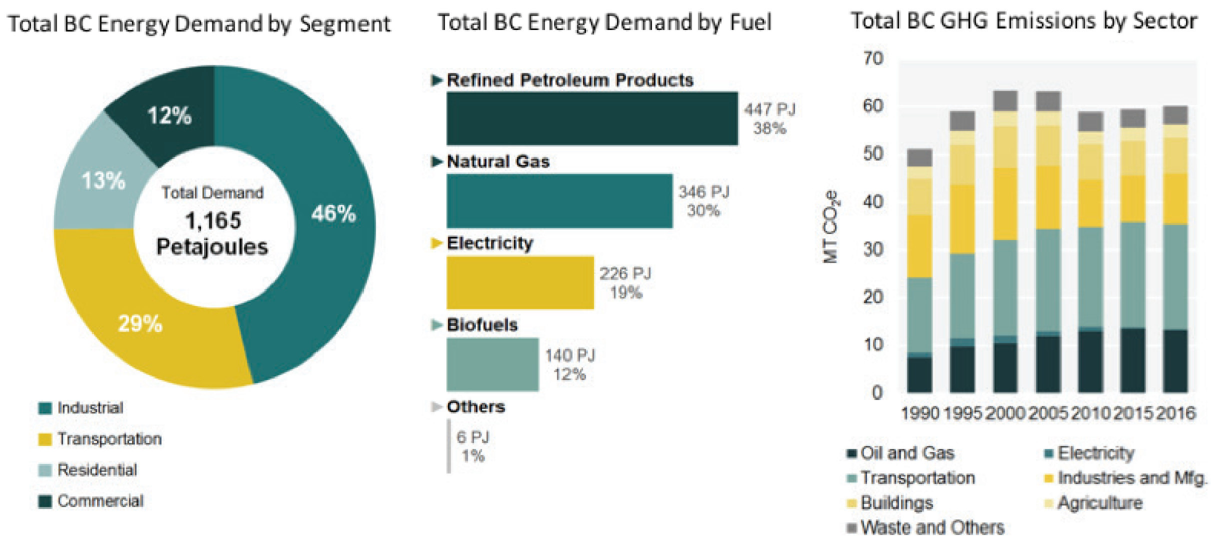

Figure 32. Energy Demand and GHG Emissions in BC[51]

BC's GHG emissions in 2016 were 62.3 Mt of CO_2e.[52] Natural gas plays a role in the largest emitting sectors of the Province's economy: transportation, oil and gas, and the built environment.

4.1.1.2 : Renewable Natural Gas

Biogas is a renewable form of methane gas, generally produced from biomass feedstocks. Renewable Natural Gas, or RNG, is biogas that is cleaned to pipeline-quality standards. It is typically blended with fossil natural gas. Sometimes called bio-methane, it is carbon-neutral and chemically similar to fossil natural gas.

RNG is produced from a variety of resources, including landfill gas (from anaerobic decomposition of organic matter), sewage, farm waste and food waste. Forestry residues and dedicated energy crops can also be cultivated for RNG production, although these have more often been considered for liquid fuels production. The major benefit of RNG production is that the methane that is already naturally produced from waste is captured and utilized before it can escape to the atmosphere.

Given its feedstocks, RNG is a carbon-neutral fuel that can displace fossil natural gas and the upstream GHG emissions associated with its production and supply. Recent studies have suggested that anywhere from 5% to 20% of current natural gas demand could be met with RNG.[53] That said, at present only 0.3% of natural gas consumption in the Province consists of RNG.[54]

51 *National Energy Board. (2019). Provincial and Territorial Energy Profiles – British Columbia. Retrieved from https://www.neb-one.gc.ca/nrg/ntgrtd/mrkt/nrgsstmprfls/bc-eng.html*

52 *British Columbia Provincial Government. (2018). Provincial Greenhouse Gas Emissions Inventory: 2016 Provincial Inventory. Retrieved from https://www2.gov.bc.ca/gov/content/environment/climate-change/data/provincial-inventory*

53 *Alberta Research Council - Potential Production of Methane from Canadian Wastes*

54 *Provided by FortisBC during Stakeholder workshop #1.*

One barrier for RNG is its cost of production, which ranges from $6 to $45/GJ depending on plant size, feedstock, and location, and in most cases is significantly higher than fossil-derived natural gas. Other barriers to RNG adoption include lack of standards, dispersed feedstock supply and geographical constraints for pipeline delivery. Nevertheless, the most attractive sources of renewable biogas, such as landfill gas, can yield energy supply in the form of RNG at half the cost of electricity in British Columbia, and these sources of renewable and carbon-neutral energy are being rightly exploited in BC and elsewhere.

4.1.2 : Opportunities for Hydrogen

4.1.2.1 : Hydrogen's Role in Decarbonizing the Natural Gas Grid

Hydrogen can be blended into the natural gas grid; if cleanly generated it can reduce the GHG emissions intensity of the delivered blend. Large-scale demonstration and lighthouse projects have been undertaken in the past decade. At relatively low concentrations of 5-15% hydrogen by volume, this approach does not appear to increase risks associated with utilization of the gas blend in end use devices such as household appliances, for overall public safety, or the durability and integrity of the existing natural gas pipeline network.[55]

The blending of hydrogen into natural gas pipelines has also been proposed as a means of delivering pure hydrogen to markets; separation and purification technologies could separate hydrogen downstream of the injection points and closer to end users. Blending can delay costs associated with building dedicated hydrogen pipelines or other costly infrastructure during early market development.

4.1.2.2 : Hydrogen's Role in the CleanBC 15% Renewable Gas Target

The CleanBC plan establishes a target of 15% renewable content for natural gas consumption in industrial, commercial and residential sectors in BC by 2030. The Province, FortisBC and PNG are evaluating the expanded use of RNG from wastewater treatment plants, landfills and the anaerobic digestion of agricultural waste. While these sources of renewable biogas supply are an excellent resource for scaling RNG production in the province, challenges remain in terms of meeting the 15% RNG target by 2030 at a cost structure that competes with incumbent fossil-based natural gas. This report recommends adopting low-cost, low carbon hydrogen production for natural gas grid injection as a means to complement more traditional RNG supply methods and meet the Province's renewable gas targets.

It is recommended that all sources of low carbon hydrogen qualify towards the CleanBC target given the primary objective of decarbonization. Defining the CleanBC target as "Renewable Gas" could restrict the Province's ability to cost-effectively decarbonize natural gas energy services.

55 *Melaina MW., et al. (2013). Blending Hydrogen into Natural Gas Pipeline Networks: A Review of Key Issues. National Renewable Energy Labs Technical Report 5600-51995. Retrieved from https://www.nrel.gov/docs/fy13osti/51995.pdf*

THE ORKNEY ISLANDS HYDROGEN COMMUNITY

Orkney is a group of islands off the north coast of Scotland with abundant wind, tidal, and wave energy resources. Orkney aims to establish a sustainable hydrogen supply chain to replace fossil fuels with clean, locally-sourced energy. To minimize curtailment, excess electricity powers a 500 kW electrolyzer on Eday Island and a 1 MW electroyzer on Shapinsay Island to produce hydrogen. The compressed hydrogen is transported on a storage trailer via truck and ship to Kirkwall where it is either run through a 75 kW fuel cell to power the local electricity grid when there is not enough renewable electricity being generated or fuels FCEVs. Waste heat produced from the fuel cell is piped into nearby buildings. Eventually, the hydrogen will also be used to power passenger and vehicle ferries between the islands and the mainland.

Hydrogen can contribute to meeting the 15% Renewable Gas target through two principal pathways: (1) direct injection, or (2) methanation/biomethanation through the Sabatier reaction. Methanation combines CO_2 with hydrogen to produce synthetic methane and steam, according to the reaction below:

$$CO_2 + 4\ H_2 \rightarrow CH_4 + 2\ H_2O + \text{energy}$$

Synthetic methane production has the advantage of providing a gas supply that is chemically similar to fossil-based natural gas and can be added to the pipeline network with virtually no restriction. However, the methanation process adds cost, which makes it less favoured to direct grid injection of low carbon hydrogen.

- *Prevailing natural gas costs are on the order of $4/GJ.*
- *Low carbon hydrogen pathways range from $2 to $5/kg H_2, equivalent to $17 to $42/GJ.*
- *Approximately 10 kg of H_2 are required to produce 1 GJ of synthetic methane, in addition to capital and operating expenditures for the Sabatier process, meaning synthetic methane would be the most expensive option.*

Therefore, strategies for injecting low carbon and/or renewable gas into the natural gas pipeline network will always favour direct hydrogen injection over synthetic methane production, provided hydrogen injection levels are acceptable to prevailing pipeline networks and end use technologies. As such, synthetic natural gas production is expected to play only a minor role in meeting the CleanBC 15% Renewable Gas target.

As hydrogen has a lower heating value than natural gas, its injection into natural gas networks will result in a mixture with a lower heating value on a volume basis. Delivering the same amounts of energy to end users would therefore necessitate increased volumetric flows. For example, injecting 10% H_2 by volume will require the total volumetric flow rate in the pipeline to increase by ~ 8% compared to pure natural gas. At 40% hydrogen, the total volumetric flow rate must increase by 40% indicating a slightly non-linear trend.

To accommodate higher flows, pipelines and distribution networks will need to increase system pressure and increase the density of the gas mixture flowing through the pipeline. Pipelines' pressure ratings may therefore constrain the amount of hydrogen injection into natural gas infrastructure, along with the compatibility of end users' appliances as hydrogen concentrations increase.

Hydrogen injection limit concerns could be circumvented by localizing portions of the natural gas infrastructure or end customers who can tolerate higher hydrogen concentrations. The 15% Renewable Gas target is a provincial annual average, and so could be met if selected pipelines and end users converted to renewable or low carbon hydrogen, even if the rest of the province remained on fossil-based natural gas. For example, if the PNG pipeline system terminating at Kitimat was converted to 100% hydrogen, it would fulfill 2.3% of the 15% Renewable Gas requirement.

DECARBONIZING THE LNG SECTOR

In October 2018, the Government of British Columbia approved the construction of LNG Canada's export terminal in Kitimat; an export license has been awarded for 40 years. The capacity of the project is 26 Mt per year of LNG exports, expected to be deployed in two stages, the first of which will build two LNG trains with a total capacity of 13 Mt/year.

At full capacity, total emissions for the LNG Canada project are expected to be 6.9 Mt CO_2e/year. Of these emissions, about one half are due to upstream and pipeline emissions – mostly caused by leaks, or "fugitive" methane -- and the balance relates to LNG Canada's liquefaction plant. Currently, power for the facility is expected to come from natural gas.

The cost of natural gas for the Kitimat terminal is estimated to be about $3/GJ. This is equivalent to an electricity cost of $11/MWh, much lower than BC Hydro's $60/MWh industrial rate. If the terminal's power consumption were fully electrified with hydroelectricity, there would be a decrease of approximately 3.0 Mt CO_2e/year, representing about 42% of the project's overall emissions.

Clean hydrogen could be used in place of natural gas to power the LNG terminal and reduce its environmental footprint. The hydrogen could be run through the turbine to generate clean power and significantly reduce the emissions associated with producing LNG in the Province.

If electrolysis was used to generate renewable hydrogen for the 15% Renewable Gas requirement, it would represent a significant new electrical load for the Province. Meeting just a third of the CleanBC target in this manner would require approximately 100,000 tonnes per year of hydrogen, representing an average load of approximately 700 MW. As this exceeds BC Hydro's surplus capacity, and the Province has committed to self-sufficiency in electricity, it would be necessary for some renewable hydrogen to be derived from biomass or for new renewable electricity projects to come online.

4.1.3 : Challenges and Barriers

Blending hydrogen into natural gas networks can significantly reduce GHG emissions if low-emission hydrogen is used. Implementing hydrogen blends into the natural gas pipeline network however introduces considerations of composition, pressure, material compatibility and appliance operation, and in some cases hydrogen extraction, to ensure a robust gas delivery system is achieved.

Embrittlement

Some metal pipes can degrade when exposed to hydrogen over long periods, particularly for the higher hydrogen concentrations and pressures that may occur when it is injected into high-pressure natural gas transmission systems. Embrittlement effects depend on the type of steel and on operating conditions and must be assessed on a case-by-case basis.

Natural gas transmission pipelines are typically made of high-strength steels, with diameters of 4–48 inches, operate at high pressures of 600–2,000 psi_g (42–139 bar) and are usually wrapped/coated and cathodically protected against corrosion. Because of the high strength steels employed and the high pressure of operation, transmission pipelines can be susceptible to hydrogen embrittlement. Therefore hydrogen concentrations are more limited in transmission networks. Nevertheless, the high pressure and large throughput of gas in transmission networks can translate into significant hydrogen volumes, even if conservative grid injection levels of 5-10% by volume are employed.

Steel and polyethylene (PE) are the dominant materials for natural gas distribution systems. The metallic pipes used in the lower-pressure natural gas distribution systems are usually made of low-strength steels, and these materials are not generally susceptible to hydrogen-induced embrittlement under normal operation. Other metallic pipes including iron (ductile, cast and wrought) and copper that are sometimes used in natural gas distribution are also free from embrittlement concerns. Town gas, containing approximately 50% H_2, was in common use in Europe prior to the switch to natural gas, and continues to be used in some jurisdictions, including Hong Kong.[56]

There are no major concerns about hydrogen aging the polyethylene (PE), polyvinylchloride (PVC) or elastomeric materials more common in recent natural gas distribution networks.

While the allowable concentrations of hydrogen in natural gas pipeline networks remains an area of active research and evaluation, recent studies have concluded that transmission pipelines can accept hydrogen concentrations of 5% (by volume) with minimal risk.[57] Distribution networks have been judged able to accept hydrogen concentrations of up to 25% with minimal risk and as high as 50% with additional validation. The majority of stakeholders consulted in this study concluded that a hydrogen concentration target of 10% represents a conservative near-term target for hydrogen grid injection into the natural gas network.

Pipeline Standards and Policy

The amount of hydrogen presently allowed in natural gas infrastructure is limited by country-specific standards and regulations. In certain countries, hydrogen injection limits have been established, ranging from less than 1% to as high as 12% H_2 by volume (see sidebar).

Hydrogen injection standards have yet to be established in British Columbia and elsewhere in North America. The Canadian Gas Association was interviewed for this study and anticipates the release of a report advising that hydrogen blending of up to 5% by volume is acceptable in the near-term.

Technical specifications and interface requirements for hydrogen blending will need to be established and standardized across affected regions. These steps should be considered for near-term policy development.

The amount of H_2 presently allowed in the NG grid is limited by country-specific standards and regulations

Reference: Review of hydrogen tolerance of key Power-to-Gas (P2G) components and systems in Canada, NRC, July 2017

Pipeline Capacity

For hydrogen blending to occur, hydrogen production capacity must be matched to existing natural gas pipeline capacity. A detailed study of pipeline capacity and injection location must be conducted to optimize hydrogen injection efforts.

Appliances

Natural gas-consuming appliances must be able to operate without impediment on hydrogen-blended natural gas. While most appliances are compatible with hydrogen concentrations of up to 10% H_2 by volume and lower, this is unlikely to be the case for combustion turbines, compressors (which may contain natural gas but leak hydrogen) and CNG tanks.

For higher hydrogen concentrations – in the range of 30% and higher – performance issues may arise with engines, burners, boilers and stoves. Appliance testing and validation for all product models and makes would be necessary to move to these higher hydrogen levels.

Hydrogen Separation

A low-cost method for separating hydrogen from a natural gas stream would be an enabling technology for hydrogen blending, and reduce concerns relating to downstream appliance compatibility. Pressure swing absorption (PSA) technology is mature and could be used to remove hydrogen from a natural gas pipeline. Leveraging the pressure difference between (high-pressure) transmission and (low-pressure) distribution networks could facilitate a low-cost PSA solution for hydrogen separation, and it is recommended that research to this end be supported.

Hydrogen separation technology would be particularly important where downstream natural gas might be used by CNG vehicles, as some Type 3 CNG tanks can only tolerate hydrogen concentrations of less than 2%. An alternative would be to require the replacement of the affected tanks.

Gas Metering

Hydrogen blends can influence the accuracy of existing gas meters. Studies have shown that gas meters would not need to be tuned for low hydrogen blend levels (less than 50% volume).[58]

57 *Yoo Y., et al., (2017). Review of Hydrogen Tolerance of Key Power-to-Gas (P2G) Components and Systems in Canada. NRC-EME-55882. Retrieved from* https://nrc-publications.canada.ca/eng/view/fulltext/?id=94a036f4-0e60-4433-add5-9479350f74de

Contaminants

The potential impact of contaminants associated with hydrogen injection into the natural gas network deserves examination, though this would be less urgent for hydrogen production methods producing relatively pure hydrogen, such as electrolysis methods.

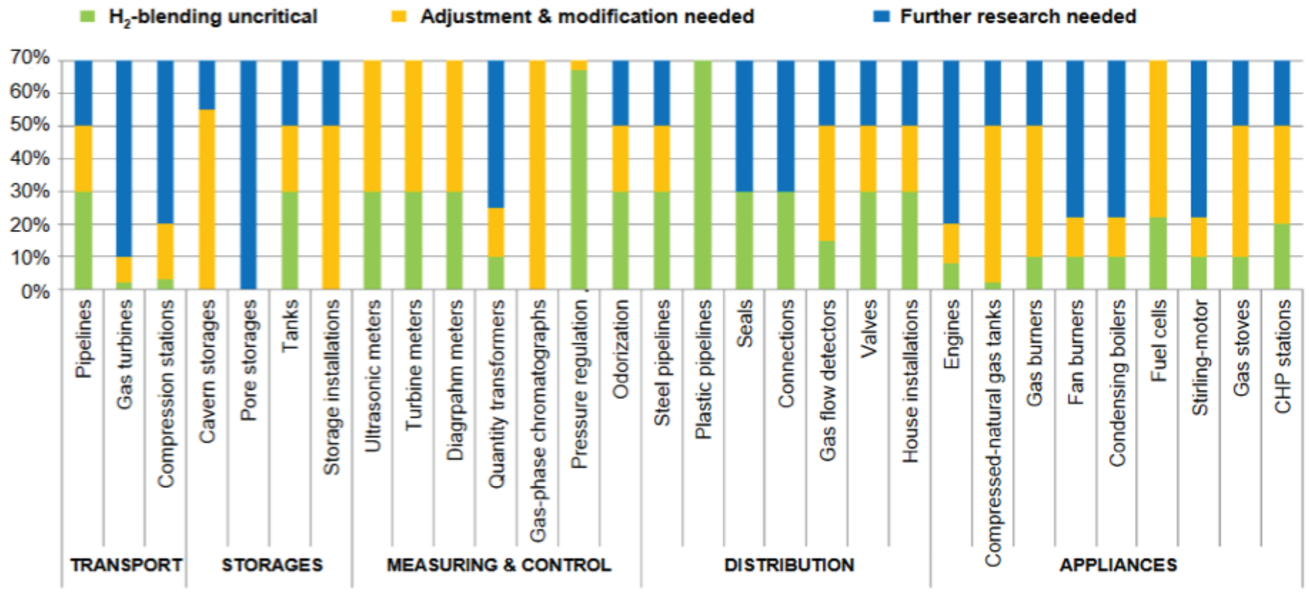

Figure 33. Limit of Hydrogen Blending along the Natural Gas Infrastructure[59]

4.1.4 : Adoption Scenarios

Adoption scenarios that project hydrogen demand through 2050 have been developed on conservative and aggressive cases. The amount of hydrogen introduced into the grid has been defined as a percentage of natural gas volume consumed by the Province's industrial, commercial and residential sectors. Natural gas demand in

58 *Melaina MW, Antonia O, Penev M. (2013). Blending Hydrogen into Natural Gas Pipeline Networks: A Review of Key Issues. NREL Technical Report 5600-51995. Retrieved from https://www.nrel.gov/docs/fy13osti/51995.pdf*

59 *SBC Energy Institute. (2014). Hydrogen-Based Energy Conversion. Retrieved from http://www.4is-cnmi.com/feasability/doc-added-4-2014/SBC-Energy-Institute_Hydrogen-based-energy-conversion_Presentation.pdf*

BC was forecasted based on FortisBC's long-term planning report [60] and assuming FortisBC continues to provide 95% of natural gas delivered in the Province.[61] Beyond 2036, which is the last year forecasted in FortisBC's long term planning report, natural gas demand was assumed to remain constant through 2050.

YEAR	BC FORECASTED NATURAL GAS DEMAND (PJ)		
	Non-Transportation	Transportation	Total
2015	202	1	204
2020	203	8	211
2025	205	40	245
2030	208	58	266
2035	212	75	287
2040	212	78	291
2045	212	78	291
2050	212	78	291

Table 3. BC Natural Gas Demand Forecast 2020-2050

The conservative scenario assumes that hydrogen content reaches 10% by volume by 2030 and increases to 20% by volume 2050. The aggressive scenario assumes hydrogen represents 15% by volume by 2030 and increases to 45% by volume by 2050. The scenarios represent plausible pathways to help meet CleanBC renewable gas targets.

The resulting hydrogen demand curves for natural gas grid injection are given in Figure 34 below.

BC HYDROGEN COMMUNITY

Some regions are exploring the conversion of entire communities and regions to run on 100% hydrogen to decarbonize their energy system. The City of Leeds is one such example and the United Kingdom has developed long-term plans to convert Northern England to hydrogen. The H21 North of England is a detailed engineering solution for converting 3.7 million UK homes and businesses from natural gas to hydrogen, in order to reduce carbon emissions. H21 North of England finds that converting the UK gas grid to hydrogen has the ability to provide "deep decarbonisation" of heat, as well as transport and power generation, with minimal disruption to customers.

In that spirit, BC could adopt a "Big Bold Goal" to convert one of its communities to hydrogen. This could include local hydrogen production, distribution through a pipeline, zero carbon energy delivery to houses running fuel cell cogeneration systems, and a fully zero emission transportation system consisting of light duty FCEVs and transit buses. A smaller community such as Revelstoke, which has an isolated LPG grid, is one such option. A bolder option would be to convert Vancouver Island -- which is at the end of the BC's natural gas pipelines – to 100% hydrogen by 2050.

61 BC Provincial Government. (2018). Production and Distribution of Natural Gas in BC. Retrieved from https://www2.gov.bc.ca/gov/content/industry/natural-gas-oil/statistics

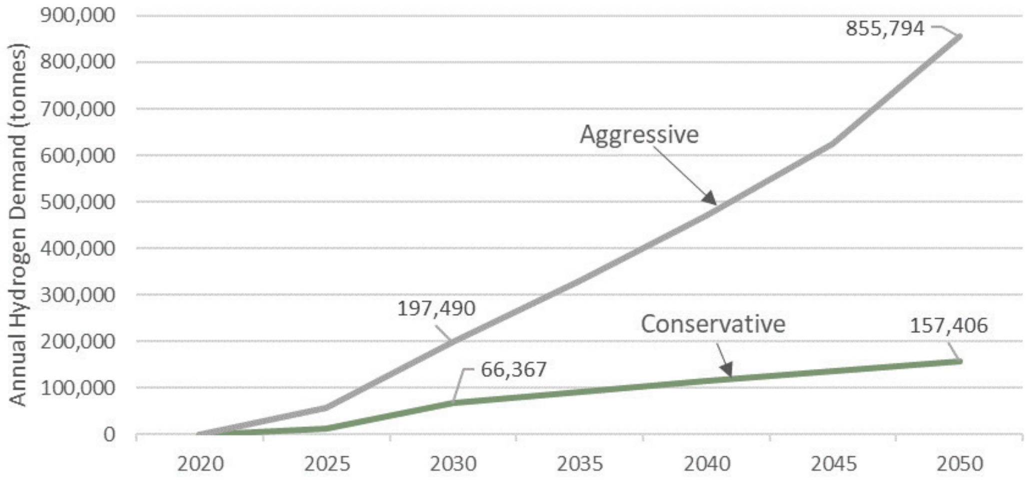

Figure 34. Hydrogen Demand for Natural Gas Grid Injection in BC

These adoption rates of hydrogen into the natural gas grid will result in significant GHG emissions reductions. In 2030, the projected emissions reduction ranges from 0.3 to 0.5 Mt CO_2e/year while in 2050 the projected emissions reductions would range from 0.8 to 2.3 Mt CO_2e/year. The GHG emissions were calculated assuming the hydrogen displaces natural gas based on lower heating values of natural gas of 38.9 MJ/m^3 and hydrogen of 10.8 MJ/m^3. The natural gas carbon intensity was assumed to be 57.9 g CO_2e/MJ[62] and the hydrogen carbon intensity was estimated to be 15.9 g CO_2e/MJ (1.91 kg CO_2e/kg H_2) based on the weighted average of carbon intensity for the different low carbon pathways studied in this report based on capacity in BC. It was assumed that all the hydrogen injected into the grid is burned. If the hydrogen was separated from the natural gas before consumption and run through a fuel cell to generate electricity and heat, the improved efficiency would increase the abated emissions by a factor of at least 2 depending on the energy efficiency ratio (EER) of the equipment.

4.1.5 : Recommendations

Allow all sources of clean hydrogen to qualify as "Renewable Gas"

- *Specify fraction of green hydrogen content to support transition to renewable pathway*

Develop provincial codes and standards for hydrogen blending into the natural gas grid

Change provincial codes to mandate all new gaseous pipelines are compatible with 100% hydrogen

Investigate integration of electricity grid and natural gas grid through low cost hydrogen production

Lighthouse Project: Hydrogen Community Feasibility Study

4.2 : Transportation

4.2.1 : Baseline

Transportation makes up approximately 37% of total GHG emissions in BC.[63] This sector can be divided into the several broad categories shown in Table 4.

CATEGORY	DESCRIPTION
Light-Duty Vehicles	Light-duty vehicles registered in BC and licensed to operate on roads
Heavy-Duty Vehicles	Heavy-duty vehicles registered in BC and licensed to operate on roads
Off-Road Vehicles	Vehicles not licensed to operate on roads excluding oil & gas, heavy industry, agricultural, manufacturing, construction, and forest resource services.
Domestic Railway and Marine	Locomotives operating in BC and marine vessels registered and fueled in BC
Pipeline Transport	Transportation and distribution of crude oil, natural gas and other products
Domestic Aviation	Canadian registered aircrafts flying domestically within Canada and originating in BC, including commercial, private, and agricultural flights

Table 4. Definition of Transportation GHG Emissions Categories[63]

Figure 35 shows the GHG emissions of each category in BC from 1990 to 2016.

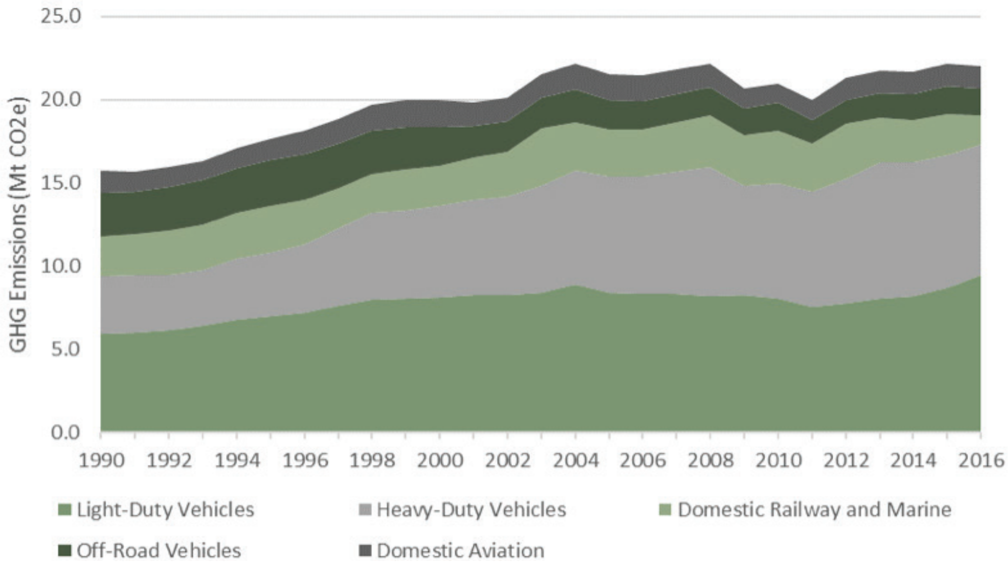

Figure 35. BC Transportation GHG Emissions by Category (1990-2016)[63]

63 *Environment and Climate Change Canada. (2018). National Inventory Report 1990-2016: Greenhouse Gas Sources and Sinks in Canada, Annex 10. Retrieved from https://open.canada.ca/data/en/dataset/779c7bcf-4982-47eb-af1b-a33618a05e5b*

Total transportation GHG emissions peaked in 2004, but following a dip to 2011, have trended upward through 2016. Figure 36 shows the percent of total transportation GHG emissions attributable to each category in 2016.

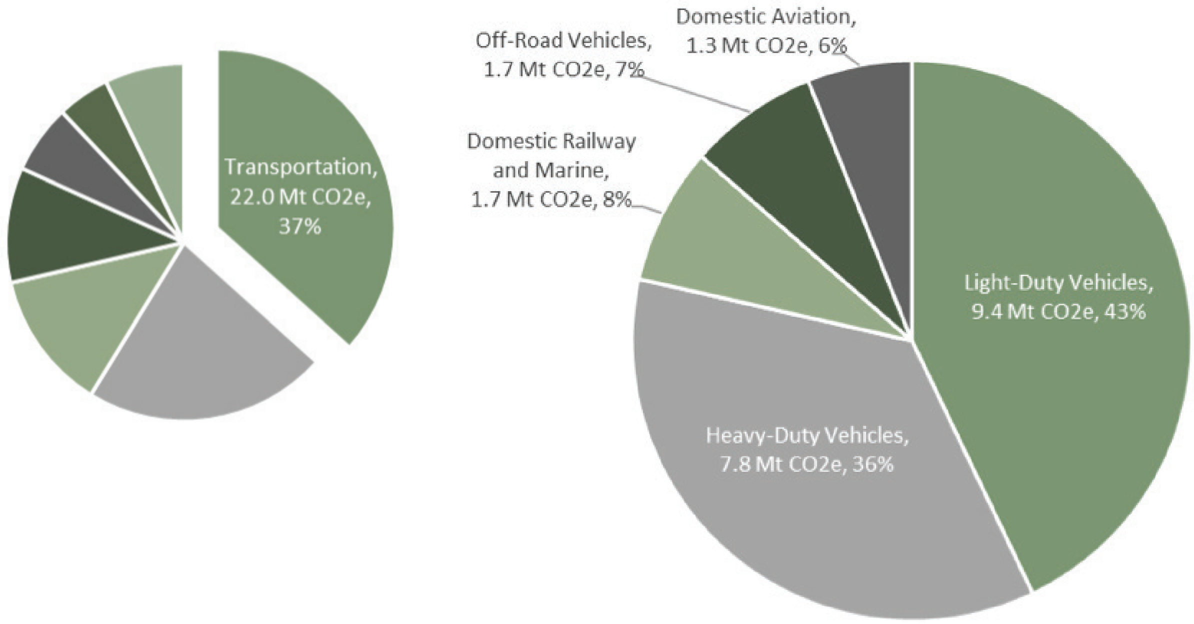

Figure 36. BC Transportation GHG Emissions by Category (2016)[63]

Combined, light and heavy-duty vehicles make up almost four-fifths of BC's total transportation GHG emissions (79%). Domestic railway, marine and aviation comprise 14% of GHG emissions and off-road vehicles make up the remaining 7%.

4.2.1.1 : Light- and Heavy-Duty Vehicle Baseline

Since light-duty vehicles (LDVs) and heavy-duty vehicles (HDVs) are the primary sources of BC's GHG emissions, they are the predominant categories of interest in this study within the Transportation sector.

VEHICLE TYPE	NEW VEHICLE REGISTRATIONS (2018)[64]	REGISTERED VEHICLES (2017)[65]	PER-VEHICLE GHG/YEAR (2016) (TONNES CO_2E)[63, 65]	EST GHG/ YEAR (2016) (MT CO_2E)[63]
Light-Duty Vehicles	219,387	3,082,813	3.2	9.4
Heavy-Duty Vehicles (excluding buses)	5,788	165,675	47.4	7.8
Buses	364	10,211		

Table 5. BC New Vehicle Registrations, Registered Vehicles, and Related GHG Emissions

Light-duty vehicles far outnumber heavy-duty vehicles, but because of the latter's greater size and annual driving distances, each heavy-duty vehicle generates almost fifteen times as many GHG emissions per year: an average of 47.4 tonnes CO_2e per HDVs compared to 3.2 tonnes per LDV.[63, 65]

Public transit accounts for approximately 30% of buses in BC.[65] Public transit fleets are operated by two large agencies: TransLink in Metro Vancouver, and BC Transit in the rest of the province. Table 6 shows the makeup of both agencies' fleets.

TRANSIT VEHICLE TYPE	TRANSLINK[66]	BC TRANSIT[67]
Electric Trolley Bus	262	0
Compressed Natural Gas (CNG) Bus	116	120
Diesel-Electric Hybrid Bus	226	6
Non-Hybrid Diesel Bus	697	683
Gasoline Community Shuttle Bus	147	0
Diesel Community Shuttle Bus	47	0
Marine Vessels	3	0
Conventional Diesel or Hybrid Bus (Unspecified)	48	0
HandyDART (Accessible Transit) Vehicle	307	347
TOTAL	**1,853**	**1,156**

Table 6. Transit Vehicle Fleet Inventory in BC

64 *Statistics Canada. Table 20-10-0002-01 New motor vehicle sales, by type of vehicle. Retrieved from https://www150.statcan.gc.ca/t1/tbl1/en/tv.action?pid=2010000201*

65 *Statistics Canada. Table 23-10-0067-01 Road motor vehicle registrations, by type of vehicle. Retrieved from https://www150.statcan.gc.ca/t1/tbl1/en/tv.action?pid=2310006701*

66 *TransLink. (2016). Fleet and Technologies. Retrieved from https://www.translink.ca/About-Us/Corporate-Overview/Operating-Companies/CMBC/Fleet-and-Technologies.aspx*

67 *BC Transit. Our Fleet. Retrieved from https://www.bctransit.com/about/fleet*

Translink has been incorporating CNG vehicles into their fleet as a way to reduce emissions. Hydrogen can play a role in CNG vehicles by enabling a greater availability of renewable gas (RG) in the network for operators, like Translink, willing to pay a premium to further reduce emissions. Both Translink and FortisBC are working together to increase the use of RG in BC's transit system.

Although buses are a small percentage of vehicles on the road, they provide an early opportunity for hydrogen adoption as a direct transportation fuel with higher efficiencies because of the high commercial readiness of FCEBs. There are currently 30 FCEBs on roads in California and 22 more in development.[68] The 22 buses to be deployed in the near-term are all manufactured by Canada's New Flyer Industries and incorporate heavy-duty fuel cell modules designed and manufactured by BC's Ballard Power Systems.

Europe is projected to deploy 300 FCEBs by the early 2020's and Japan plans to operate 100 FCEBs for the 2020 Tokyo Olympics.[69]

Jurisdictions around the world are setting aggressive targets to reduce emissions from public transit vehicles, and in some cases are mandating a transition to zero emission fleets. For example, California's Innovative Clean Transit (ICT) ruling in December 2018 legislated that all public transit vehicles in California must be zero emission vehicles by 2040. This has driven transit agencies to consider the challenges of scale deployments of Battery Electric Buses and FCEBs. Several agencies including SunLine Transit, Orange County Transit and Alameda-Contra Costa Transit District are scaling their fleets of FCEBs. They cite FCEBs' longer range, flexibility for route deployment, faster fueling times and improved refueling logistics as advantages over Battery Electric Buses.

4.2.1.2 : Deployments to Date

EV-Volumes.com estimates that 550,000 plug-in electric heavy-duty vehicles (encompassing trucks and buses, plug-in hybrid and battery electric vehicles) had been deployed around the world through 2018. Virtually all these deployments came in China due to strong policy support. EV-Volumes.com tracked 5,800 plug-in electric heavy-duty vehicle deployments in the rest of the world, or one percent of the Chinese total.[70]

Significantly, China's industrial policy has shifted to favour fuel cell vehicles, with a focus on taxis, long- distance buses, urban logistics and long-haul trucks, the latter three being heavy-duty applications.[71] Chinese automotive conglomerate Weichai recently reaffirmed its plans to deploy a minimum of 2,000 commercial fuel cell vehicles containing stacks from BC's Ballard Power Systems.[72]

4.2.1.3 : Other Transportation Baseline

Rail

Railway operations in BC are dominated by two large freight operators: Canadian National Railway and Canadian Pacific Railway. Several other rail companies operate short line routes in BC, including BNSF Railway, which travels from the U.S. border to Vancouver, and the Southern Railway of British Columbia, which travels from Vancouver to Chilliwack.

Several passenger railway companies also operate in BC, including VIA Rail, Rocky Mountaineer, Amtrak *Cascades*. TransLink also provides a commuter rail service called the West Coast Express between Metro Vancouver and the Fraser Valley Regional District.

Transport Canada has a Memorandum of Understanding with the Railway Association of Canada to reduce GHG emissions from the rail industry. In 2017, Locomotive Emissions Regulations came into effect, which enforces mandatory emissions standards and reduced idling.

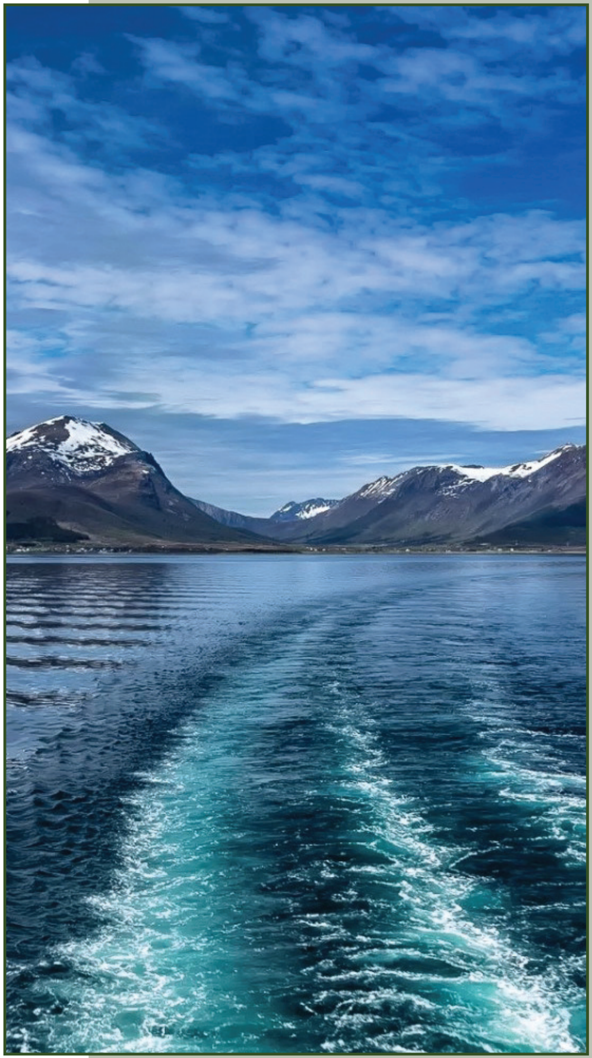
Marine

BC Ferries is one of the world's largest ferry operators, providing vehicle and passenger service on 25 routes between 47 terminals. Their fleet comprises 35 vessels powered by a mix of diesel and liquid natural gas (LNG). In fiscal 2018, the company consumed 118.2 million litres of diesel and 2.0 million diesel litres-equivalent at a cost of $102.5 million, representing its second-largest operating expense.[74]

BC Ferries is a leader in transitioning to lower carbon and more efficient fuel sources. They were the first passenger ferry system in North America to adopt LNG, and by 2020 project LNG will make up 22% of their fuel consumption.Their diesel vessels currently consume an average of 5% biodiesel, making them one of the largest biodiesel consumers in the Province. They have also been using ultra-low sulfur diesel in all diesel applications since 2007.[74]

HYDROGEN FERRIES

Norway plans to deploy the world's first hydrogen-electric ferry in 2021. Norled is leading the development of the ferry, which will carry 299 passengers and 80 vehicles. According to the development contract, at least 50% of the energy requirement must come from hydrogen.[73] Norway is aggressively focused on marine vessel emissions, as the marine fleet accounts for approximately 30% of the country's total NOx emissions.



73 *World Maritime News. (2019). Norled to Build World's 1st Hydrogen-Electric Ferry. Retrieved from https://worldmaritimenews.com/archives/268356/norled-to-build-worlds-1st-hydrogen-electric-ferry/*

74 *British Columbia Ferry Services Inc. (2018). Fuel Management Plan Outcomes in Performance Term Four. Retrieved from https://www.bcferries.com/files/AboutBCF/2018_09_28_PT4_fuel_management_outcomes_report.pdf*

Aviation

There are 5,198 aircraft registered in BC. The majority are airplanes (82%) and helicopters (16%); a small number of gliders, gyroplanes, and balloons are also registered. Nearly three quarters of aircraft are privately owned (74%) and almost the entire balance (26%) is used for commercial purposes. The exceptions are a small number of airplanes (5) and helicopters (11) owned by the Provincial government.[75]

In 2012, the Federal Government published Canada's Action Plan to Reduce GHG Emissions from Aviation, which sets target to improve fuel efficiency by 1.5%, measured in litres of fuel per 100 revenue tonne-kilometers, by 2020 compared to a 2008 baseline.[76] In 2019, BC airline Harbour Air announced plans to electrify its fleet of airplanes. While an excellent solution for the airline's typical flights, batteries are not expected to be practical for larger flights.

4.2.1.4 : Transportation Hydrogen Baseline

From 2009 to 2014, BC Transit deployed 20 fuel cell electric buses in Whistler. These comprised almost the entire Whistler bus fleet, which totaled 23 buses (26 during peak season). During this period, it was the largest single deployment of fuel cell electric buses in the world. The buses drove over 4 million kilometers and avoided more than 5,835 tonnes of CO_2e emissions.[77]

While this was an important flagship deployment for the Province timed with the 2010 Winter Olympics, the buses suffered reliability and operating cost challenges. Not being able to secure a local supply of hydrogen in BC, liquid hydrogen was trucked in from Quebec, adding to operating costs, and leading to negative public perception. As a result, BC Transit decided to retire the fleet in 2014.

In 2015, Hyundai selected BC as its first market for FCEVs in Canada, leasing up to 10 Tucson FCEVs.

At time of writing there are nine light-duty FCEVs on-the-road in BC: three Hyundai Tucsons, five Hyundai Nexo, and one Toyota Mirai. Since 2016, BC-based Hydra has run a pilot project demonstrating a heavy-duty hydrogen/diesel co-combustion engine on a semi-trailer, logging approximately 250,000 km of operation.

Hydrogen has yet to be deployed to power marine vessels, railway locomotives, off-road vehicles or aircraft in BC.

4.2.2 : Opportunities and Challenges

Hydrogen technologies can significantly reduce GHG emissions from the transportation sector.

Battery electric vehicles (BEVs) and FCEVs are complementary types of Zero Emission Vehicle; both will play roles in decarbonizing transportation in the Province.

Batteries provide greater "well-to-wheel" efficiency for transportation than fuel cells but offer lower energy storage density than compressed or liquid hydrogen tanks. That said, batteries remain very well-suited for many light-duty vehicle applications, and for heavy-duty vehicles with shorter routes.

Though battery fast charging speeds have increased with ever-more powerful DC Fast Chargers (DCFCs) hydrogen refueling remains faster, and the infrastructure has potential to be more scalable and economic at mass scale. This is because fuel cell vehicles can be expected to refuel at regular intervals. Because BEVs can be charged more slowly but more cheaply at home, at work, or at publicly available "Level 2" stations, drivers can be expected to use DCFCs sparingly – except on weekends and long weekends, when overcrowding is likely to occur. In short, regular fueling from FCEV owners provides a path to return-on-investment for owners of hydrogen stations.

76 *Federal Government of Canada. (2018). Summary: 2017 Annual Report – Canada's Action Plan to Reduce Greenhouse Gas Emissions from Aviation. Retrieved from http://www.tc.gc.ca/eng/policy/2017-greenhouse-gas-emmissions-aviation-annual-report-summary.html*

77 *Eudy L., Post M. (2014). BC Transit Fuel Cell Bus Project Evaluation Results: Second Report. National Renewable Energy Laboratory. Retrieved from https://www.nrel.gov/docs/fy14osti/62317.pdf*

For these reasons and others, a variety of studies have concluded that hydrogen infrastructure can be less expensive, on balance, as vehicle penetration increases.[81]

Fuel-related GHG emissions per km were calculated using provincially-established carbon intensities for gasoline and electricity as a transportation fuel, as well as efficiency equivalent ratios. The carbon intensity used for gasoline was 3.2 kg CO_2e/L[82] with an efficiency of 10 L/100km. The carbon intensity for electricity used was 0.05 kg CO_2e/kWh[83] with an efficiency equivalent ratio (EER) of 3.4.[84] The carbon intensity for hydrogen was established to be 15.9 g CO_2e/MJ (1.91 kg $CO_2e/kg\ H_2$) based on the weighted average of carbon intensity for the different low carbon pathways studied in this report based on capacity in BC.

Figure 37 shows the calculated per kilometer GHG emissions from a gasoline, fuel cell electric, and battery electric vehicles.

IS ELECTRIFICATION THE ANSWER?

While the Province should do everything it can to leverage its renewable electricity infrastructure to reduce GHG emissions, electrification has limitations.

Consider the light-duty vehicle transportation sector. In 2017, there were 3 million light-duty vehicles registered in BC [78]. Assuming an average annual distance traveled of 15,000 km, fuel efficiency of 10 L/100-km, and an energy effectiveness ratio of 3.4, the resulting electricity demand would be 46 PJ per year if all of these vehicles were electric.

This would require an increase in annual electricity generation of 21% [79], equivalent to 2.5 Site C projects.[80] Electrification of the medium- and heavy-duty transportation sectors would roughly double this effect. Hydrogen powered vehicles will allow BC to leverage its abundant natural gas supplies while reducing emissions if the hydrogen is produced via SMR or Pyrolysis with carbon capture and sequestration.

4.2.2.1 : Light-Duty Vehicles

The future light-duty vehicle market will comprise a mix of BEVs and FCEVs. Compared to BEVs, FCEVs offer greater range and faster refueling, which allows for a driver experience closer to a conventional internal combustion engine (ICE) vehicle. However, BEVs are expected to dominate the light-duty vehicle market, having already achieved widespread commercialization and benefiting from electricity's relative ubiquity. FCEV commercialization is lagging by approximately one decade, and hydrogen fueling infrastructure remains limited.

Fuel cell vehicles are likely to be more attractive for drivers in multi-unit residential buildings (condominiums, apartments, townhouses with shared garages, etc.) where cost and strata law barriers can make retrofits of home charging stations expensive and difficult: a comprehensive literature review from UC Davis found that the availability of a home charging station was the most important piece of infrastructure in convincing consumers to purchase a BEV, followed by workplace charging, and lastly public charging stations.[86]

This is particularly pertinent for the Province, where 33% percent of households live in multi-unit residential buildings.[87] Households who cannot recharge their vehicles from their parking stalls may opt for fuel cell electric vehicles – providing they feel well-served by hydrogen fueling infrastructure.

Three-shift (24/7) fleet vehicles such as taxis will find fast refueling times attractive, again providing hydrogen fueling infrastructure is adequate. The cost premium for hydrogen over electricity will have to be modest enough that fleet operators value increased uptime higher than the potential cost savings from battery electric vehicle options.

Although FCEVs are currently available on the market, they are still produced at a relatively small scale. The greatest impediment to deployment of light-duty fuel cell vehicles in the Province in the near-term is supply. The Province could incentivize auto manufacturers (generally referred to as original equipment manufacturers, or OEMs) to bring their vehicles to BC by recognizing the benefits of long range and fast fueling in the credit system adopted by the ZEV mandate.

Since FCEVs are currently produced in small volumes, they remain more expensive than comparable ICE or BEVs. Until production scale reduces costs, the Province is advised to incentivize the purchase of light-duty fuel cell vehicles. The $6,000 Provincial incentive available as of the initial issue of this study in June 2019[88] (comprising the $5,000 CEV for BC purchase rebate and $1,000 in fuel) can be applied to fuel cell vehicles, however the base model price cap of $45,000 on the $5,000 federal incentive excludes FCEVs at this time. The Province could also set up a support mechanism to incentivize the purchase of used fuel cell and battery electric vehicles. This would increase the overall demand for ZEVs and reduce the number of older, higher-polluting fossil fuel vehicles on the road. The availability of used ZEV purchase incentives could also make it easier for lower income households to purchase zero emission vehicles.

Other jurisdictions have had success driving adoption of ZEVs using non-financial incentives. In addition to incentives on the initial purchase price, Norway, offers discounted or free ferry travel, toll road access, and municipal parking to ZEV drivers as well as access to bus lanes. California has increased demand for ZEVs by allowing them access to HOV lanes with only a single occupant. China has expedited the vehicle registration process for ZEVs, reducing the wait time from as long as two years to as short as a single day. BC already allows ZEV drivers to register their vehicles for High-Occupancy Vehicle (HOV) lane access. It is recommended that the Province consider additional cost-effective measures to drive their adoption. Local governments can also play a role, through incentivizing in areas they control such as preferred parking.

88 *On June 22, 2019 the Province's CEV incentive was reduced to $3,000 for battery, fuel-cell, and longer-range plug-in hybrid electric vehicles and to $1,500 for shorter-range plug-in hybrid electric vehicles.*

4.2.2.2 : Hydrogen Infrastructure

Lack of hydrogen fueling infrastructure in BC is a key barrier to the near-term adoption of FCEVs. California has had success stimulating fuel cell vehicle adoption by carefully and consistently expanding their network of stations and have determined that infrastructure expansion precedes vehicle adoption. In that state the process is overseen by the California Fuel Cell Partnership, who aggregate data from OEMs to determine how many vehicles will be on the road and plan the optimal location for new fueling stations. A similar body could help encourage growth in BC; significant infrastructure investment will be required to ensure FCEVs can be deployed as successfully in the Province as in California. Section 4.2.4 provides more detail related to infrastructure.

4.2.2.3 : Medium- and Heavy-Duty Vehicles

In most instances, medium- and heavy-duty trucks are better suited to hydrogen technology than batteries. There will be opportunities for battery powered trucks for applications with a limited daily range, like parcel distribution, but the heavy loads and long distances required of most applications are better suited to hydrogen fuel cells. A fuel cell truck would end up roughly the same weight as a conventional diesel truck, whereas a battery for a 40-ton truck would add about 3 tonnes of payload.[89] Fuel cell vehicles also require less raw materials, are cobalt free, and research targets are to use less platinum than a comparable diesel vehicle.[90]

Medium- and heavy-duty vehicle hydrogen fuel cell trucks have been demonstrated around the world but have not yet been widely deployed. It is recommended that the Province encourage near-term zero emission medium- and heavy-duty vehicle adoption in applications that have central fueling locations as an early means of deploying hydrogen in these segments.

DIESEL/HYDROGEN CO-COMBUSTION

Diesel/hydrogen co-combustion is a near-term path by which hydrogen could reduce emissions from medium and heavy-duty vehicles. BC-based Hydra Energy retrofits heavy-duty trucks with a co-combustion system that reduces diesel fuel consumption by 30%, and aims to scale up to 120 trucks by 2022.

Hydra plans to build out 350 bar hydrogen fuelling infrastructure that will be compatible with FCEVs in the long-term.

BC could seek to leverage work in other jurisdictions. China has experienced a rapid increase in the deployment of medium-duty hydrogen fuel cell trucks. Homologation efforts could speed technical readiness for deployment in the Province.

90 *Ibid.*

4.2.2.4 : Public Transit

Public transit agencies around the world are shifting towards low and zero emission vehicles. Low emission technology includes CNG and RNG as a transit fuel. Zero emission transit options include BEBs and FCEBs. As is the case with light-duty vehicles, battery electric buses are most cost effective on relatively short routes. Fuel cell electric buses are advantageous on long routes with higher power requirements. Provincial support for a fuel cell electric coach bus program would provide an opportunity for BC's hydrogen and fuel cell cluster to lead that market segment in the near- to mid-term.

Hydrogen powered buses are more easily scaled than battery electric buses. Fuel cell buses can be refueled at comparable speeds and in a similar way as conventional diesel buses, whereas battery electric buses require much longer charging times. Battery electric buses are either charged over several hours, typically overnight in a depot, or through opportunity charging en-route. Opportunity charging typically requires a bus to be recharged over a shorter period several times a day. It allows for less onboard battery power, and therefore less weight, but increases the operational complexity and constraints. Feedback from transit authorities has been that while longer bus charging times are not an issue at demonstration scale, challenges of cost and complexity increase significantly at fleetwide scale.

California has adopted the ICT rule, which requires 25% of new bus purchases by large transit agencies to be zero emission by 2023, 50% by 2026, and 100% by 2029. By 2040 it requires all buses in operation to be zero emission. It is recommended that BC develop a similar policy. A support mechanism such as the province's Specialty-Use Vehicle Incentive Program[91] or a voucher system could mitigate the higher purchase prices for zero emissions buses. As in the ICT, policies should require transit agencies to develop plans for reaching 100% zero emission vehicle fleets. This will ensure fleet infrastructure needs, whether for electricity or hydrogen, are considered in a holistic, fleetwide manner, and ensure the most cost-effective technology mix is deployed.

91 BC's Special Use Vehicle Incentives are described at: https://www2.gov.bc.ca/gov/content/industry/electricity-alternative-energy/transportation-energies/clean-transportation-policies-programs/clean-energy-vehicle-program/suvi

RENEWABLE NATURAL GAS FOR TRANSPORTATION

In April 2019, TransLink and FortisBC announced a partnership whereby FortisBC will supply Renewable Natural Gas (RNG) for TransLink's natural gas powered buses, which make up roughly a fifth of TransLink's bus fleet. The parties have signed an RNG-supply contract for up to 500,000 GJs annually within five years. This is expected to provide enough to fuel the existing natural gas bus fleet with 100 per cent RNG. Over the five-year period, the transition to RNG will reduce TransLink's greenhouse gas (GHG) emissions by 50,000 tonnes.

How does hydrogen fit?

By updating the B.C. Greenhouse Gas Reduction Regulation definition of RNG to include hydrogen, the Province can accelerate the decarbonization of the transportation sector for near-term opportunities such as Translink. While TransLink will purchase 100% RG, any hydrogen blended into the natural gas would be separated before filling the vehicles. There can be technical challenges in using a H_2/CNG blend in the vehicles related to tank embrittlement and NOx emissions. Separation of hydrogen at the point of use could lead to fueling stations with dual fuel sources – CNG and hydrogen. Pure hydrogen can be used in fuel cell vehicles or other applications that required pure hydrogen, and the buses will run on CNG. This is in essence a credit trading mechanism that will lead to real benefits in overall decarbonization of the transportation network.

4.2.2.5 : Long Haul Trucking

The past few years have seen heightened interest in fuel cells for class 8 long haul trucks, known colloquially as freight trucks, semi-trucks or tractor-trailers. Nikola Motor, Toyota and Hyundai are all developing fuel cell powertrains for this market segment. Cummins Inc. recently announced that it has entered into a definitive agreement to acquire Hydrogenics Corporation, which is a major move into the fuel cell space for this major diesel and natural gas engine OEM. A number of demonstration projects have been piloted, including the Alberta Zero-Emissions Truck Electrification Collaboration (AZETEC) project, which will trial class 8 fuel cell trucks on the corridor between Edmonton and Calgary.[93]

It is recommended that BC develop similar projects for this market, and it is noted that the CleanBC plan references a pilot project to switch 1,700 freight trucks to cleaner or zero-emission fuel. The larger quantities of hydrogen fuel consumed by these heavy-duty vehicles would have the additional benefit of increasing hydrogen demand within the Province; the increased hydrogen consumption should also help bring down retail hydrogen prices.

AZETEC PROJECT

The Alberta Zero-Emissions Truck Electrification Collaboration (AZETEC) project will include the design, manufacture, and deployment of two heavy-duty extended range hydrogen fuel cell electric trucks that will move freight between Edmonton and Calgary year round. The $15 million project is led by the Alberta Motor Transport Association and will receive more than $7.3 million from Emissions Reduction Alberta. Over the three-year lifespan of the project, the trucks will have travelled more than 500,000 km and carried about 20 million tonne-km of freight.[92]

93 *Ibid 92*

4.2.2.6 : Rail and Marine

Given the range and power required, hydrogen fuel cells may have the potential to displace fossil fuels as a major energy source in rail and marine applications. Pilot projects are currently underway in Europe and Asia, but the technology and the infrastructure required to enable it is still at an early stage. In this report, only BC Ferries were considered as a possible use for hydrogen technology. It was assumed that other marine or rail projects will be undertaken in the Province before 2050. However, given the activity in other jurisdictions, the Province should support development through feasibility studies and pilot projects if suitable opportunities become available. The aforementioned South Fraser Community Rail proposal to revive commuter rail in the Fraser Valley through hydrogen rail could be a suitable lighthouse project.

HYDROGEN RAIL (HYDRAIL)

In 2018, the world's first commercial hydrogen powered trains entered service in Germany. There are currently two trains in operation and plans in place to deliver another 14 trains by 2021. The trains are capable of travelling 1,000 km without refueling, which is comparable to a diesel alternative.[94] The trains are being built by French train manufacturer Alstom and the fuel cells are being provided by Ontario-based Hydrogenics.[95]

While no hydrogen powered rail deployments currently exist in BC, an organization called South Fraser Community Rail is actively campaigning for a hydrogen powered commuter train project to connect Surrey to Chilliwack along the Fraser Valley corridor.[96]

4.2.3 : Adoption Scenarios

Projecting hydrogen technology adoption in the transportation sector is dependent on a wide range of economic, social, and technical factors, and inherently contains a high degree of uncertainty. As such, the approach used in this study sought to provide a realistic range of adoption that is bound by conservative and aggressive scenarios of technology development and policy implementation. Within the transportation sector, adoption was estimated for light-duty passenger vehicles, medium- and heavy-duty trucks, public transit and private coach buses, and ferries. Although hydrogen could also be used in rail and aviation applications, this analysis assumed hydrogen does not play a role in either category by 2050.

Hydrogen demand was modelled for each segment of the transportation sector based on the projected number of vehicles in operation, assumed kilometers driven per year, fuel economy of the gasoline/diesel baseline and hydrogen alternative. Figure 39, Figure 40, and Figure 41 show the modelled hydrogen demand in the conservative and aggressive scenarios for transportation from 2020 to 2050.

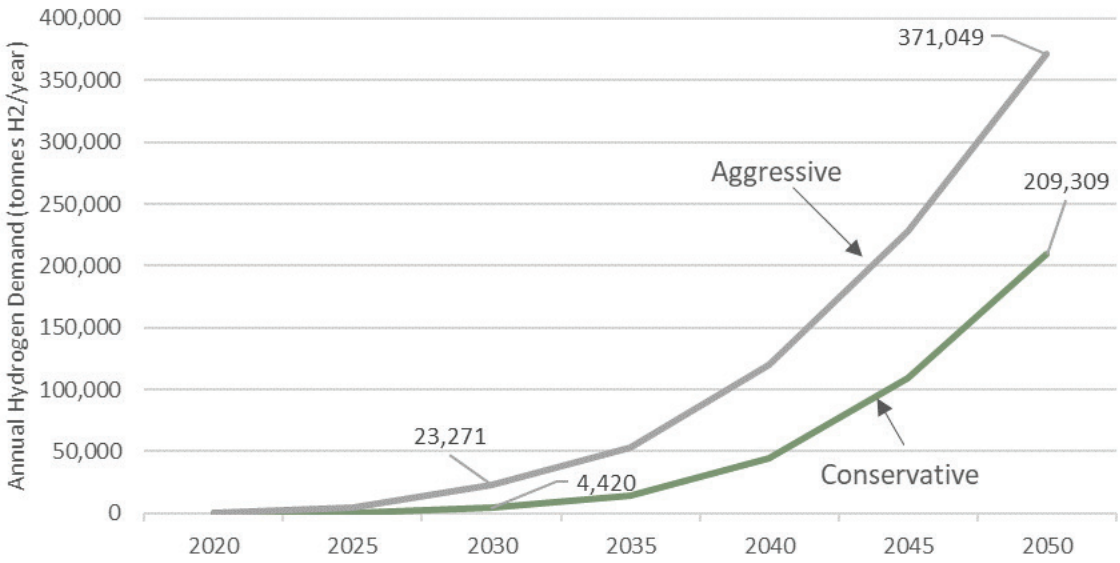

Figure 39. Transportation Conservative and Aggressive Hydrogen Demand (2020-2050)

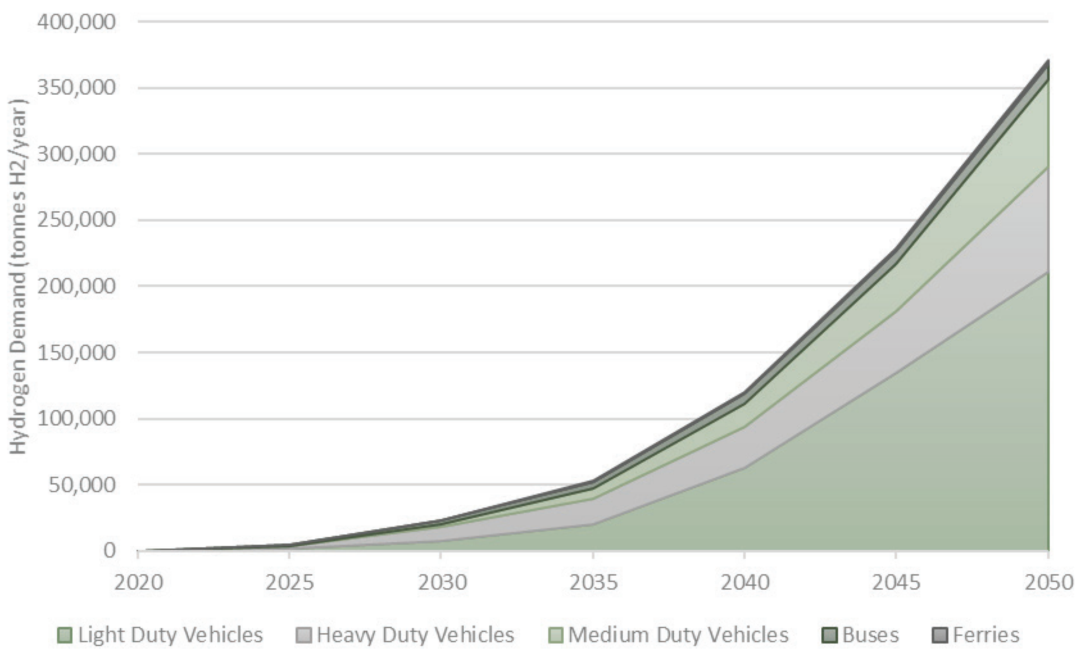

Figure 41. Transportation Aggressive Hydrogen Demand by Vehicle Type (2020-2050)

Figure 42 shows the modelled share of hydrogen demand for each vehicle type in 2030 and 2050 in the conservative and aggressive scenarios.

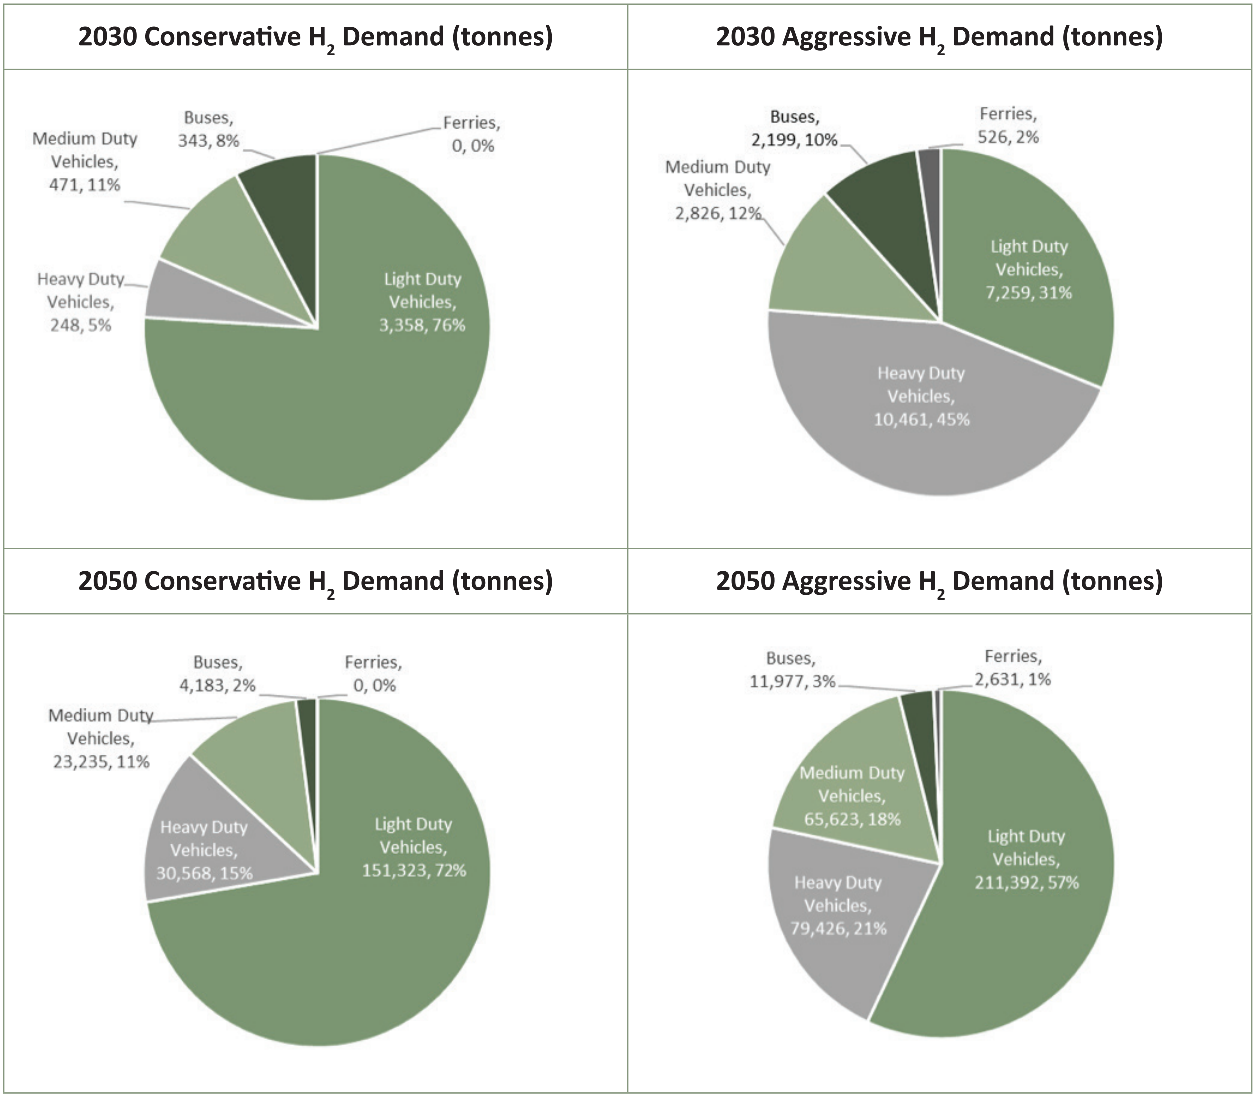

Figure 42. Conservative and Aggressive Transportation Hydrogen Demand in tonnes by Vehicle Type (2030 & 2050)

4.2.3.1 : Light-duty Vehicles

The upcoming ZEV mandate will drive the adoption of fuel cell light-duty vehicles in BC. The analysis considered both how the ZEV standard will impact the sales of vehicles across the industry and how it could impact OEMs individually based on their current offerings assuming a credit scheme similar to Quebec's ZEV standard is put in place.

From 2020 to 2030, FCEV sales are highly dependent on how the ZEV mandate is legislated. The aggressive scenario assumes that credits will be allocated per vehicle using the formulas currently in place in Quebec[97] and that each OEM will have to meet the sales targets outlined in the Zero-emission Vehicles Act (10% by 2025, 30% by 2030, 100% by 2040).[98] Under this scenario, FCEV adoption will be driven largely by each OEM's need to meet their credit requirement. The analysis considered annual new vehicle sales across the province,[99, 100] the approximate market share of OEMs offering FCEVs,[101] how many credits each FCEV would receive, and how many FCEVs would need to be sold to satisfy the ZEV mandate taking into account sales of BEVs and PHEVs. Toyota is expected to drive sales more than other OEMs because, unlike other major car brands that offer a BEV, they currently only offer the Mirai (FCEV, 3.6 credits) and the Prius plug-in hybrid (0.6 credits). The conservative scenario assumes the OEMs will not be required to meet targets through their own direct sales, but the ZEV legislation will drive adoption across the entire industry. This could occur if it is easy for OEMs to purchase credits from others that achieve greater ZEV sales than the target. In this conservative scenario, it is assumed that the Province falls short of its ZEV targets, reaching 8% of sales in 2025 and 20% in 2030. It was assumed that FCEV sales make up 8% of ZEV sales by 2030, which is 20% less than a model developed for ZEV deployment in Europe.[102, 103]

From 2030 to 2050, the estimates are not based on how a credit system could impact specific OEMs, since many of the OEMs will likely be offering different vehicle models by that time. The aggressive scenario assumes that the Province meets its ZEV targets of 100% sales by 2040, and that FCEVs make up 19% of ZEV sales in 2040 and 26% in 2050, which matches the model developed for Europe.[102] The conservative scenario assumes the Province falls short of its ZEV targets, reaching 80% of sales in 2040 and 100% in 2050, and that FCEV sales as a percent of ZEV sales are 80% lower than the penetration in the aggressive scenario (15% in 2040 and 21% in 2050).

In all scenarios it was assumed that total new vehicle registrations increase linearly based on the past five years of data at 7,711 new vehicles per year[104] and that vehicles remain on the road for an average of 13 years. There is considerable uncertainty in projecting vehicle sales growth through 2050 based on historical sales trends, given potentially disruptive changes to car ownership such as car-sharing, ride-hailing and autonomous vehicle technology. These could each result in a decrease in the number of registered vehicles on provincial roads in the future, though total vehicle km travelled might remain largely unaffected.

102 *Cambridge Econometrics. (2018). Fueling Europe's Future: How the Transition from Oil Strengthens the Economy. Retrieved from https://europeanclimate.org/wp-content/uploads/2018/02/FEF_transition.pdf*

103 *The analysis in this report is based on historical data through 2018. In 2019, ZEV sales have accelerated in BC, largely driven by the newly available federal incentive and record high gas prices. The analysis was not revised to account for this increase in sales. At this time, FCEV sales are limited by supply and it is unclear if the uptick in sales will translate to FCEVs as they are not currently eligible for the federal incentive because of the cap on vehicle retail price.*

104 *Statistics Canada. Table 23-10-0067-01 Road motor vehicle registrations, by type of vehicle. Retrieved from https://www150.statcan.gc.ca/t1/tbl1/en/tv.action?pid=2310006701*

The adoption scenarios were compared to past and projected adoption in California, the world leader in light-duty fuel cell passenger vehicle adoption. Since the passenger vehicle market in California is significantly greater than BC, the data was scaled to be proportional to the BC passenger vehicle market. Additionally, the California reference data was shifted by four years because the number of light-duty fuel cell vehicles on the road in California has been growing since 2015. Thus, the California reference value for 2019 is the number of light-duty fuel cell vehicles on the road in California in 2015 scaled by the passenger vehicle market, the value in 2020 is related to California in 2016, etc. From 2019 to 2022, the California reference values are based on the number of fuel cell vehicles on the road from 2015 to 2018.[105] From 2022 to 2028, the California reference values are based on California Air Resource Board projections of vehicles on the road in California from 2019 to 2024.[106] From 2028 to 2034, the California reference values are based on achieving the aspirational goal of 1,000,000 fuel cell vehicles on the road in California by 2030. The California reference case was not extended beyond 2034 (i.e., beyond the 1,000,000 vehicles in 2030 target).

Figure 43 shows the range of annual light-duty fuel cell vehicle new sales per year and Figure 44 shows total projected fuel cell vehicles on the road as well as hydrogen demand from 2019 to 2050. Hydrogen demand was estimated as 0.5 kg/vehicle/day, which is corresponds to a driving range of approximately 15,000 km/year.

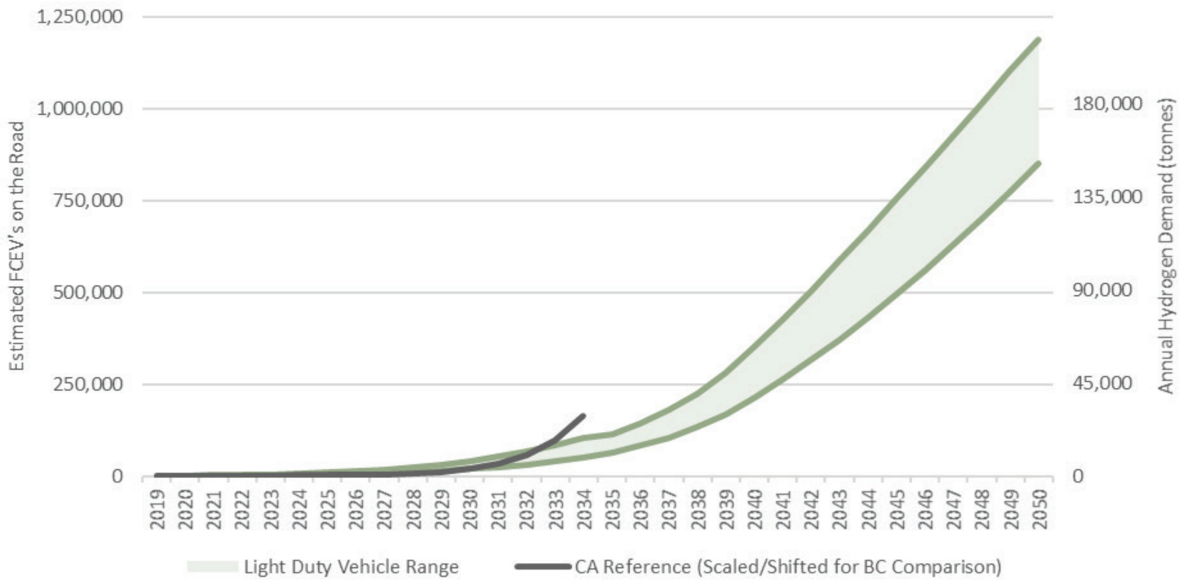

Figure 44. Light-duty Fuel Cell Passenger Vehicles on the Road per Year (2019-2050)

The number of fuel cell vehicles sold is expected to increase exponentially from 2019 to 2040. After 2040, the ZEV mandate will require all new vehicles sold to be ZEVs, so the growth continues linearly assuming the total number of vehicles sold continues to grow.

The sales targets of the BC ZEV mandate are more aggressive than the mandate currently in place in California, which is only defined through 2025. As a result, the projected fuel cell vehicles in BC exceed the California reference case in the near-term. However, for California to meet its 2030 target of 1,000,000 vehicles, sales will need to ramp up rapidly, which causes the California reference case to exceed the projected range for BC adoption.

Table 7 shows the estimated number of new vehicle registrations, FCEV new registrations, and FCEVs on the road per year from 2019 to 2050.

YEAR	VEHICLE REGISTRATIONS	FCEV NEW REGISTRATIONS		FCEV % OF NEW VEHICLE REGISTRATIONS		FCEV'S ON ROAD	
		Low	High	Low	High	Low	High
2019	237,251	30	50	0.0%	0.0%	33	53
2020	244,962	60	816	0.0%	0.3%	93	869

Table 7. LDV FCEV Registrations and Vehicles on the Road (2019-2050)

4.2.3.2 : Medium- and Heavy-Duty Trucks

Due to the required range and power, medium-duty vehicles (MDVs) and HDVs present one of the best opportunities for hydrogen technology. Outside of China, which is rapidly deploying MDV fuel cell vehicles, few hydrogen-powered MDVs and HDVs are currently in operation. Given the Province's technical expertise and commitment to reducing emissions, BC is well positioned to become a world leader in the deployment of hydrogen-powered MDV and HDV trucks. Crucially, leadership in this market segment would allow the Province's hydrogen and fuel cell cluster to gain insights from early local deployments. BC companies would then enjoy a competitive advantage over competitors from other jurisdictions, when slower-moving jurisdictions prepare their own deployments of zero emission medium- and heavy-duty trucks.

The aggressive scenario for medium- and heavy-duty hydrogen powered trucks assumes the Province supports multiple lighthouse projects to demonstrate the effectiveness of the technology by 2030 and wide scale adoption by 2050. In the near- to mid-term, it was assumed that diesel-hydrogen co-combustion proves effective for heavy-duty vehicle retrofits, leading to up to 1,700 retrofit heavy-duty hydrogen diesel co-combustion vehicles on the road. Under this scenario, we expect the deployments of hydrogen co-combustion vehicles will peak in 2040, after which fuel cell vehicles will dominate. The conservative scenario assumes small demonstration projects with medium- and heavy-duty fuel cell vehicles through 2030 leading to moderate adoption through 2050 and no diesel co-combustion vehicles.

HYUNDAI AND H_2E: 1600 TRUCK PROJECT – SWITZERLAND

Hyundai and H_2 Energy (H_2E) have established the Hyundai Hydrogen Mobility joint venture (JV) in Europe, focused on heavy-duty commercial hydrogen fuel cell vehicles. The goal of the JV is to deliver 1600 fuel cell heavy-duty trucks and supporting fueling stations in Switzerland between 2019 -2025.[107]

Hyundai Motor will deliver the trucks, and H_2E will be responsible for marketing the fleet as well as developing the infrastructure. A stringent road tax on diesel trucks imposed by Switzerland is incentivizing fleet operators to switch to zero emission vehicles. The road tax on commercial vehicles is meant to prevent diesel trucks from crossing through Switzerland as they traverse Europe, and depending on weight and distance the annual road tax can cost up to $50,000 per vehicle.[108]

After scaling up to meet the demand in Europe, Hyundai then plans to launch its fuel cell commercial vehicle businesses in other regions around the world, including the U.S. and domestic market in Korea.

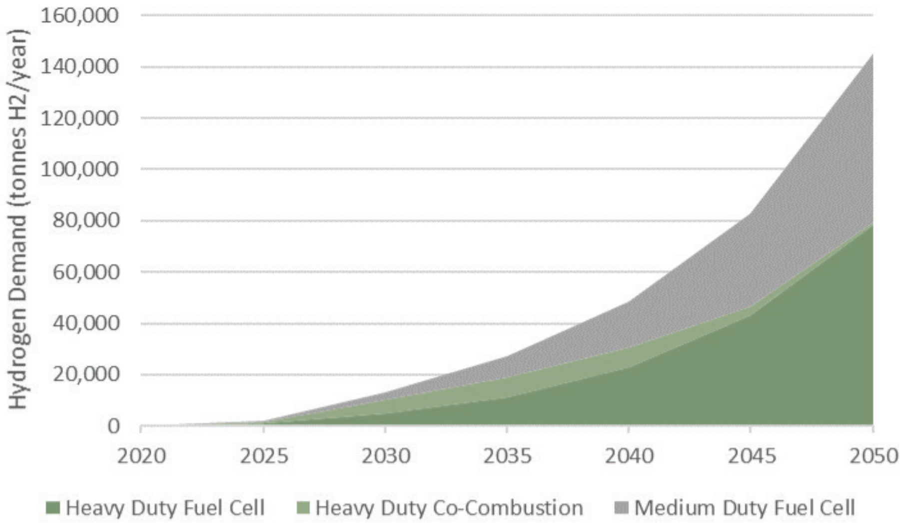

Figure 46. Aggressive Projected Medium- and heavy-duty Truck Hydrogen Demand (2020-2050)

4.2.3.3 : Buses

Transit agencies around the world are looking at reducing emissions through deployment of hydrogen fuel cell and battery electric buses. Though more expensive than conventional diesel buses, hydrogen fuel cell public transit buses are currently available on the market from several suppliers. The modelled scenarios are based on feedback from TransLink and BC Transit. The aggressive scenario assumes the Province institutes a zero-emission bus mandate similar to the Innovative Clean Transit regulation in California, leading to 25% of the Province's public transit fleet comprising fuel cell electric buses by 2035. The conservative scenario assumes slow adoption of fuel cell public transit buses, peaking at 12% of the fleet in 2050.

Hydrogen powered inter-city buses (also called "coaches" or "coach buses") are at an earlier stage of development than public transit buses, primarily due to technical challenges with current vehicle configurations that constrict hydrogen storage on the rooftops due to centre of gravity restrictions. This fuel storage technical challenge can be overcome with emerging technologies, and as with medium- and heavy-duty trucks, coach buses are well suited to hydrogen fuel cell technology because of the long ranges and short refueling times required for existing duty cycles.

It is assumed that there will be zero and low emissions regulations applied to these buses in the post-2025 period building on the regulation of transit buses. The aggressive scenario assumes a successful technology development program in BC leading to adoption of 15% of new sales by 2035 and 75% of new sales in 2050. The conservative scenario assumes moderate adoption of fuel cell coach buses beginning in 2030 and peaking at 25% of new sales in 2050.

Table 9 shows the estimated adoption schedule for public transit and coach buses from 2020 to 2050.

YEAR	NUMBER OF HYDROGEN POWERED VEHICLES ON THE ROAD			
	PUBLIC TRANSIT BUSES		COACH BUSES	
	Conservative	Aggressive	Conservative	Aggressive
2020	0	0	0	0
2025	0	20	0	65
2030	20	209	64	257
2035	62	522	192	577
2040	125	522	384	1,153
2045	188	522	576	1,923
2050	250	522	768	2,565

Table 9. Public Transit and Coach Bus Adoption Projections (2020-2050)

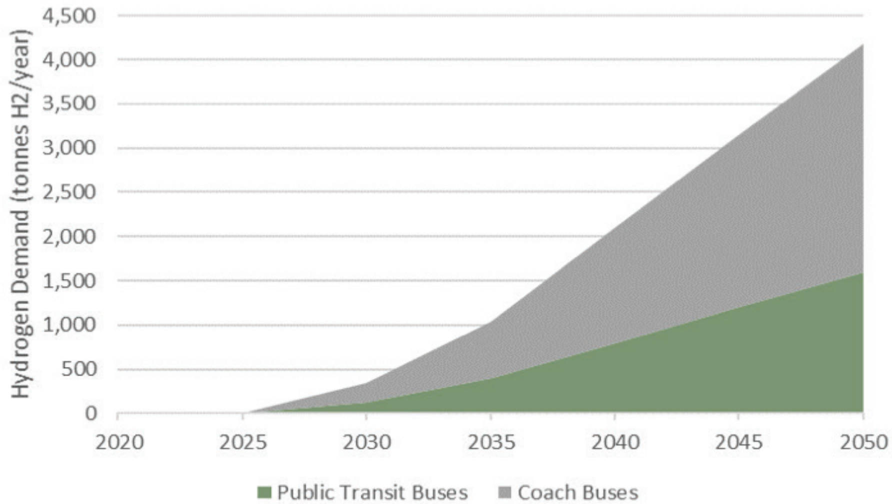

Figure 47. Conservative Projected Public Transit and Coach Bus Hydrogen Demand (2020-2050)

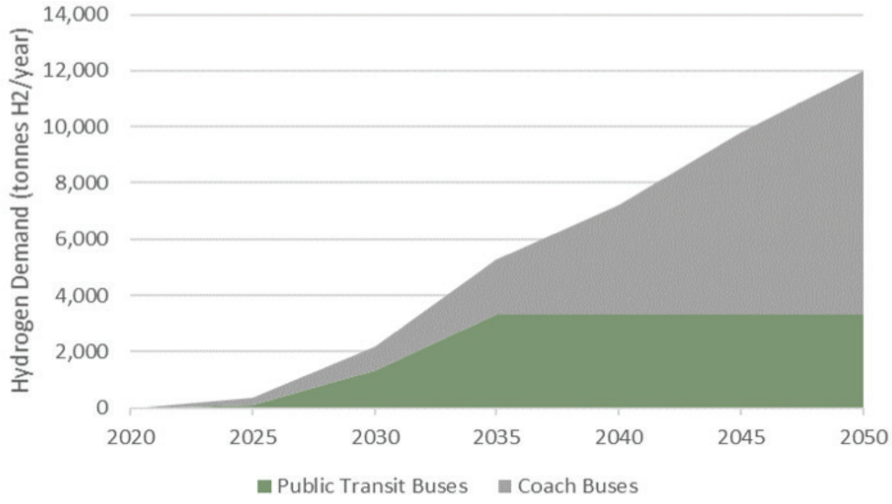

Figure 48. Aggressive Projected Public Transit and Coach Bus Hydrogen Demand (2020-2050)

4.2.3.4 : Ferries

BC Ferries is committed to reducing emissions and, though is at an early stage relative to road transportation applications, hydrogen fuel cell technology shows promise in marine applications. The aggressive scenario assumes a successful pilot project of a single ferry in 2030 leading to 3 vessels in the fleet by 2040 and 5 by 2050. The conservative scenario assumes no hydrogen powered ferries by 2050.

Table 10 shows the estimated adoption schedule for ferries from 2020 to 2050.

YEAR	NUMBER OF HYDROGEN POWERED VESSELS IN FLEET	
	Conservative	Aggressive
2020	0	0
2025	0	0
2030	0	1
2035	0	1
2040	0	3
2045	0	3
2050	0	5

Table 10. Ferry Adoption Projections (2020-2050)

Figure 49 shows the projected hydrogen demand from ferries from 2020 to 2050 in the aggressive scenario (the conservative scenario is not shown because there are no hydrogen powered vessels in the fleet).

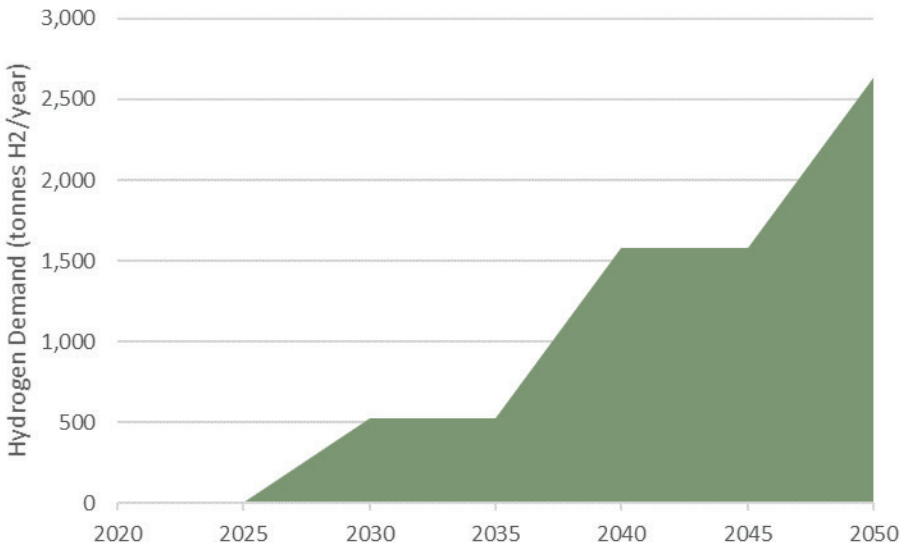

Figure 49. Aggressive Projected Ferry Hydrogen Demand (2020-2050)

Although there is potential for marine applications of hydrogen technology in BC other than ferries, the technology is still at a relatively early stage of development. For the purposes of this report, it was assumed that there will not be significant adoption of hydrogen for non-ferry marine applications before 2050

.

4.2.3.5 : GHG Emissions

The GHG emissions reduction for each vehicle type based on the average annual distance travelled, fuel economy, and diesel and gasoline emissions factors were modeled.[109] The assumed carbon intensities was 3.59 kg CO_2e/L for diesel in medium- and heavy-duty vehicles, 3.20 kg CO_2e/L for gasoline light-duty vehicles, 3.49 kgCO_2e/L for diesel in marine vessels.[110] Hydrogen as a transportation fuel was estimated to have an emissions factor of 15.9 g CO_2e/MJ (equivalent to 1.91 kg CO_2e/kg H_2) based on the weighted average carbon intensity of the pathways studied in this report based on their capacity in BC.

Fuel cell vehicles were assumed to have an energy effectiveness ratio (EER) of 1.9 compared to diesel engines and 2.5 compared to gasoline engines.[111]

Figure 50, Figure 51, and Figure 52 show the estimated GHG abated in the conservative and aggressive scenarios for transportation from 2020 to 2050.

Figure 53 shows the estimated share of GHG abated for each vehicle type in 2030 and 2050 in the conservative and aggressive scenarios.

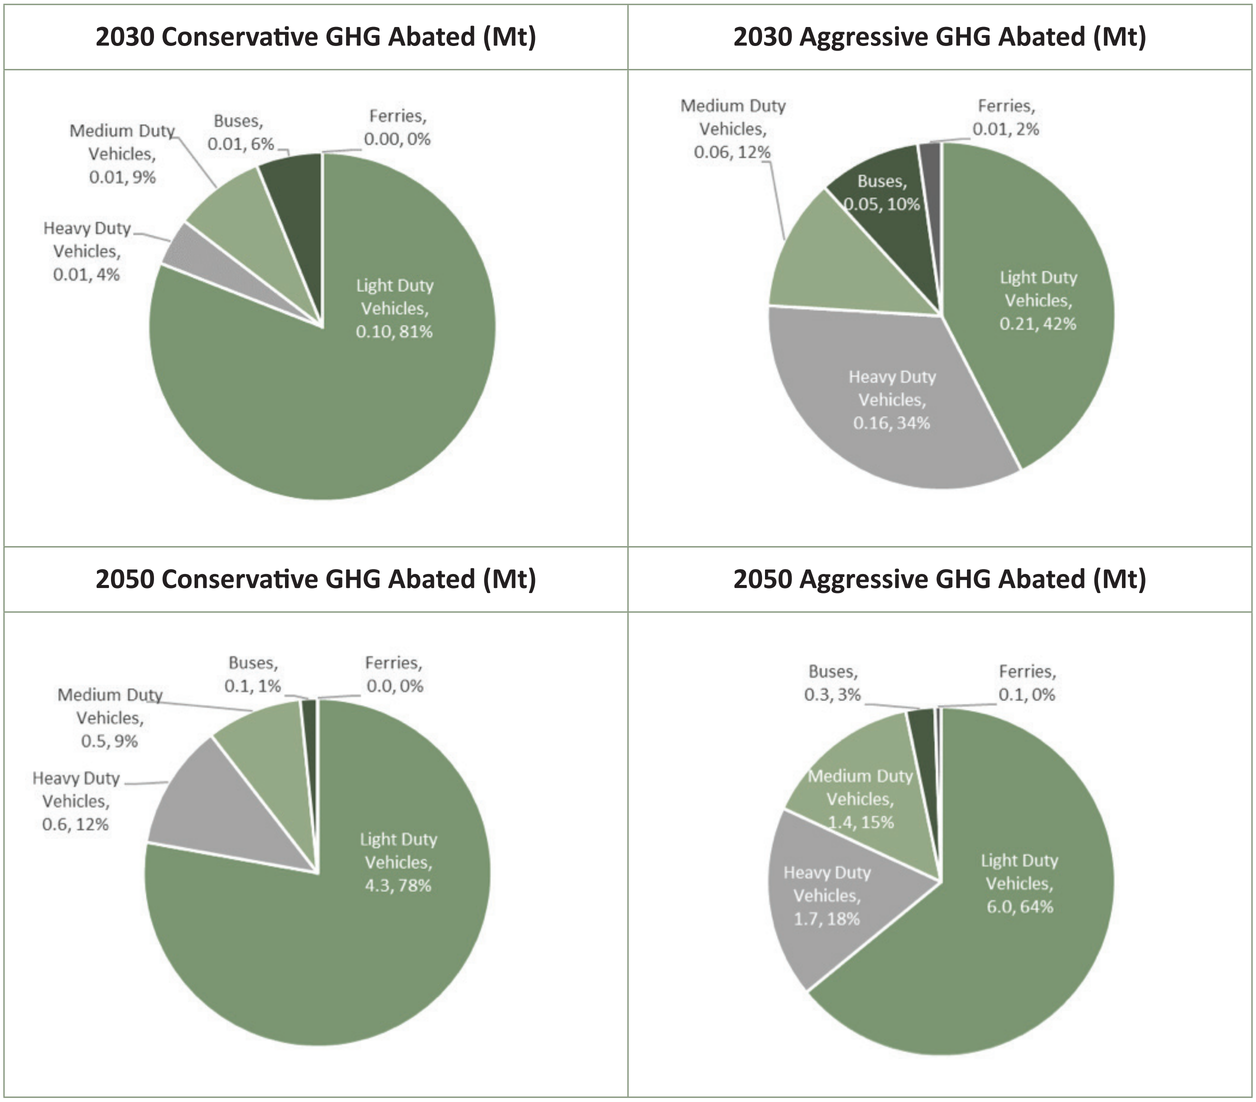

Figure 53. Conservative and Aggressive Transportation GHG Abated in Mt CO_2e by Vehicle Type (2030 & 2050)

In all cases, the deployment of light-duty FCEVs will have the greatest emissions reduction impact, driven primarily by the far larger vehicle populations under consideration. It is therefore recommended that in the near-term a strong credit system favouring FCEVs (to incentivize OEMs to preferentially supply FCEVs to the province) be implemented, and that the continued roll-out of light-duty vehicle hydrogen fuel infrastructure be strongly supported.

4.2.4 : Infrastructure to Support Adoption

4.2.4.1 : 2019 Current Status

BC has been a leader in developing and deploying hydrogen fuel cell technologies. In 2002, Powertech Labs installed the world's first 700 bar hydrogen refueling station in Surrey and in 2018, Hydrogen Technology & Energy Corporation (HTEC) opened Canada's first retail hydrogen fueling station at a Shell site in Vancouver. This is the first of 5 stations that HTEC intends to deploy over the next 18 months to support anticipated fuel cell electric vehicle operations in the Province. An additional station is being developed by the University of British Columbia, scheduled to open in the second half of 2020.

Figure 54. Hydrogen Infrastructure Map of Active and Planned Stations

Turning to heavy-duty vehicle infrastructure, since the Whistler Transit fueling station was decommissioned in 2014, the only operational fueling equipment for heavy-duty transportation equipment in the Province is a 250-bar Praxair dispenser used by Ballard Power Systems for testing buses and trucks out of their Burnaby facility.

4.2.4.2 : 2020 -2025 Lighthouse Project Adoption, Light-Duty Vehicle Growth

To support the vehicle adoption numbers outlined in section 4.2.3 under both the conservative and aggressive scenarios, the Province will need substantial infrastructure investment.

For light-duty vehicles, it is estimated that the currently planned and funded network will support approximately 1,000 vehicles based on 6 stations supporting an average of 150-200 vehicles per dispenser by mid-2020.

Based on the vehicle adoption modeling, the Province will need to begin adding retail fueling station capacity between 2021 and 2024, growing to 19 - 47 dispensers by 2025. During this period, stations with higher throughput capacity (larger storage tanks and compression sub-systems, and multiple dispensers) will be necessary. It is anticipated that geographic coverage will extend outside of Metro Vancouver and the Capital Region District to include clusters in other parts of the Province such as Kelowna and Whistler.

It must be noted that the current development cycle for deploying fueling station equipment in BC and elsewhere is approximately 18 -24 months from issuing the RFP, to the first vehicle fueling event. Solicitations would therefore need to be released in Q4 2019 to support the infrastructure requirements for the aggressive adoption scenario.

For medium- and heavy-duty vehicles, multiple lighthouse projects are recommended during this period, requiring both 350 and 700-bar infrastructure:

- *1x Port of Vancouver heavy-duty fueling station capable of supporting up to 50 vehicles including drayage and terminal tractors.*
- *2x heavy-duty fueling station (with multiple dispensers) capable of supporting up to 75 class 8 long-haul trucks within the Metro Vancouver Regional District (MVRD).*
- *1x heavy-duty fueling station (with multiple dispensers) capable of supporting up to 125 co-combustion, class 8 long-haul trucks in the Prince George region, to leverage the availability of by-product hydrogen from the Chemtrade plant.*
- *2x medium-duty fueling stations capable of supporting up to 100 class 6 delivery trucks within the GVRD.*
- *2x heavy-duty fueling stations to support 65 fuel cell electric coaches, one to be located in Metro Vancouver and the other to be located in a community outside of Metro Vancouver.*

BEV CHARGING FACILITIES

BEV charging facilities take far less time to plan and install than FCEV hydrogen fueling stations. The situation has an unexpected parallel in the renewable energy sector. There, utility-scale solar arrays can be planned and installed over a matter of months.

In contrast, wind farms of any scale frequently require two or more years, including a minimum of one year of data collection, owing to the unique complexities of each wind farm site.

Figure 55 below outlines an example of the network in BC that would be required to support the roll-out of fuel cell electric vehicles (conservative to aggressive range) and lighthouse projects (aggressive) for medium- and heavy-duty applications in the 2020-2025 timeframe.

Figure 55. Potential Hydrogen Infrastructure Map (2025)

4.2.4.3 : 2025 -2030 Light-Duty Vehicle Adoption, Medium- and Heavy-Duty Growth in Niche Applications

This five-year period will be characterized by an acceleration in the adoption rate of light-duty vehicles and an evolution in the market for medium- and heavy-duty vehicles from lighthouse projects to early market growth in specialized applications where fuel cell technology offers a positive value proposition relative to competing technologies.

For light-duty vehicles, it is assumed that dispenser capacity per station will dramatically increase to 2-3 dispensers per station to satisfy fuel demand. Based on the light-duty vehicle projections, 96 to 206 dispensers will be required by 2030, expanding into rural communities beyond the targeted clusters that will be the focus of the previous phase, and strategically intersecting major highways to facilitate travel.

It is anticipated that a number of these fueling stations will be containerized or "connector" stations that will be replaced and re-deployed as the demand for full-scale retail fueling stations is realized in different regions. Also, as car sharing businesses begin to incorporate fuel cell electric vehicles into their fleets, mobile fueling systems will be deployed to fuel vehicles in-situ as is currently happening with gasoline refueling. Based on BC Hydro capacity projections, this phase of deployment is where electrical generation and transmission will be significantly constrained in supporting battery electrical vehicle infrastructure, driving a higher percentage (6.4% - 8.0%) of new fuel cell vehicles relative to all new zero-emission vehicles deployed. As presented in 4.2.2.1, this range of dispensers is heavily influenced by the relative strength of the BC ZEV mandate, and the OEM's ability to deploy vehicles.

Medium- and heavy-duty vehicles, during this period, will transition from the testing and demonstration phase into early commercial adoption. Deployment will be focused on applications where the duty cycle for the vehicles offer a comparative advantage compared to other zero-emission technologies. Examples include Class 8 trucks with heavy payloads, inter-city buses for both transit and commercial operations, and goods movement equipment requiring short fueling times. Based on the medium- and heavy-duty projections, assuming 50 fleet vehicles per dispenser, it is expected that up to 48 medium- and heavy-duty dispensers will be required by 2030, each capable of supplying a minimum of 25 kg per fill.

QUEBEC CONTAINERIZED STATION

In 2019, the first 700 bar retail hydrogen station opened in Quebec. The station is fully enclosed in a 28-foot containerized package. It is capable of fueling four vehicles consecutively and is sized to fill 20 vehicles per day. The station was constructed by Powertech, a subsidiary of BC Hydro, and installed by North Vancouver based HTEC. Powertech has designed and constructed 16 other turnkey compressed hydrogen fueling stations across North America.

4.2.4.4 : 2030 -2050 Light-Duty, Medium- and Heavy-Duty Commercial Operation

It is easier to predict the energy demand for hydrogen during this time period than to predict the corresponding fueling model for energy delivery, as car sharing, ride hailing, and autonomous operation of private and commercial vehicles proliferate. In addition to these changes to vehicle operation, it is anticipated that fueling technology will change as well, moving to more energy dense fuel storage mediums such as liquid or cryo-compressed hydrogen.

Based on the light-duty vehicle projections, it is estimated that between 3,330 to 4,260 dispensing points will be required by 2050, distributed across every community across the Province. The network of fueling stations will need to become ubiquitous enough to allow convenient travel anywhere/anytime in the Province for commercial and private drivers.

Medium- and heavy-duty vehicle infrastructure will continue to grow in commercial volumes. Based on the projections, up to 278 medium- and heavy-duty dispensers will be required to support the trucks, goods movement equipment, transit and inter-city buses, passenger ferries and rail applications by 2050. Note that many of these dispensers will be co-located at fleet fueling facilities as the scale of deployment expands.

4.2.4.5 : Low Carbon Fuel Regulation

BC's Low Carbon Fuel Regulation has provided a funding mechanism for developers, such as North Vancouver's HTEC, to deploy the hydrogen infrastructure planned in the Province to date. Under the LCFR, credits can be approved by the Province based on the projected station capacity and displacement of fossil fuel emissions by hydrogen, then sold to fuel suppliers bound by the LCFR.

While credit sales have assisted, other sources of funding have been required; examples include the Province's CEV program and federal funding through Natural Resources Canada (NRCan) funding. OEMs have also invested in infrastructure in limited cases.

At present, this approach is that project development takes significant time and effort, and lacks a cohesive strategic direction supported by government. It is recommended that the Province take a more active role in guiding infrastructure development, including through the release of special prescriptive call for hydrogen LCFR Part 3 agreements, likely required every 2-3 years, until hydrogen infrastructure in the province is well established.

4.2.5 Recommendations

Structure the light-duty ZEV mandate to encourage OEMs to make FCEVs available in BC

- *Make British Columbia the world leader in credit value for FCEVs.*

Implement a Zero Emission Bus Mandate for public transit vehicles and a Voucher Program to offset incremental costs.

Strengthen funding to support rollout of hydrogen infrastructure in the Province

Support feasibility study for the use of hydrogen in Marine, Rail and off-road applications in BC.

Support lighthouse projects to deploy medium- and heavy-duty fuel cell vehicles in the Province.

- *Support a fuel cell electric coach pilot program.*
- *Create a large-scale, zero-emission heavy-duty vehicle program focused on Vancouver ports*

4.3 : Industry

4.3.1 : Baseline

BC industries that currently use hydrogen include the production of liquid transportation fuels and sodium chlorate and chlor-alkali plants. The two remaining refineries in BC, located in Burnaby and Prince George, use hydrogen as part of the refining process. Sodium chlorate plants are located in North Vancouver and Prince George while the only chlor-alkali plant is in North Vancouver.

The Parkland refinery in Burnaby, has a production capacity of 55,000 barrels per day (bbl/d) of light crude into a range of products including gasoline, diesel, aviation fuel, LPG and industrial fuel supplying ~ 25% of the Province's transport fuel needs. Hydrogen is produced from naphtha as an internal part of the refining process at a rate of ~ 26 tonnes/day or 10,000 tonnes/year.[112]

The Husky refinery in Prince George has a production capacity of 12,000 bbl/day of light crude into a range of products including gasoline, diesel, LPG/butane and industrial fuel supplying ~ 5% of the Province's transport fuel needs. The facility produces hydrogen from a steam methane reformer at a rate of 3.3 tonnes/day or 1,200 tonnes/year.[113]

Chemtrade operates both the chlor-alkali plant in North Vancouver and the sodium chlorate plant in Prince George. The North Vancouver plant produces hydrogen as a by-product but uses this during the production of HCl. To supplement this hydrogen demand, Chemtrade buys by-product hydrogen from the neighbouring ERCO sodium Chlorate plant. ERCO dechlorinates, compresses and sends the hydrogen via a dedicated hydrogen pipeline to the Chemtrade plant. The total ERCO by-product hydrogen production is approximately 15 tonnes/day or 5,500 tonnes/year of which ~50% is sold to Chemtrade and 50% or 7.5 tonnes/day is vented to atmosphere. This is sufficient to meet the needs of approximately 7,500 light-duty FCEVs.

The Chemtrade sodium chlorate plant in Prince George produces approximately 11 tonnes/day or 4,000 tonnes/year of by-product hydrogen,[113] enough to provide fuel for about 22,000 light-duty FCEVs. This hydrogen is currently vented however a portion of this capacity may be contracted to a potential customer in the near future.

Combined, the Parkland, Husky, and Chemtrade facilities produce 20,700 tonnes of hydrogen annually. This is equivalent to approximately 2.5 million GJ of energy.

The industrial sector in BC accounted for approximately 38% of natural gas consumption in the province as of 2017.[114] Natural gas is primarily used in industry for high-grade process heat, for space and hot water heating in industrial complexes, and as a chemical feedstock. The natural gas use accounts for GHG emissions of approximately 4.2 Mt CO_2e/year.

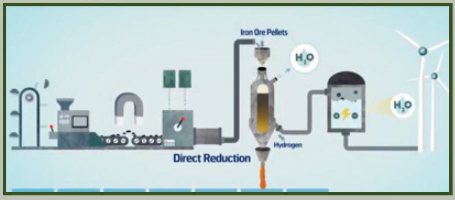
ATTRACTION OF NEW INDUSTRY TO BC

Hydrogen is used as a feedstock in several major industrial processes. Establishment of large scale, low carbon intensity, and cost competitive hydrogen supply in the Province has the potential to attract new industry and drive economic growth in the Province. By-products in the hydrogen production process, such as oxygen in the case of electrolysis, and waste heat can also attract new industry.

Hydrogen is used in the following industrial processes:

- *Ammonia production (NH3), through the Haber-Bosch process which combines hydrogen and nitrogen together. Approximately 90% of Ammonia produced goes into fertilizer production.*
- *Processing crude oil into refined fuels, such as gasoline and diesel, and also removing contaminants like sulfur form these fuels.*
- *Steel-making – SSAB, LKAB and Vattenfall joined forces to create HYBRIT – an initiative that endeavours to revolutionize steel-making. HYBRIT aims to replace coking coal, traditionally needed for ore-based steel making, with hydrogen.*



- *In the electronics industry, it is widely employed as a reducing agent and as a carrier gas.*
- *In margarine production, for the hydrogenation of fats. It consists of adding hydrogen to compounds that contain multiple bonds.*
- *In methanol production or methyl alcohol production.*
- *In synthetic liquid fuel production.*

The greatest opportunity for hydrogen is in the production of low carbon or renewable liquid fuels. BC's renewable and low carbon fuel standard (LCFS) is a performance-based standard which specifies the GHG intensity and renewable content of fuels used for transportation. Part 3 of the LCFS calls for a 10% reduction in GHG intensity for transportation fuels sold in the province by 2020 relative to 2010. Part 2 of the Standard calls for a minimum of 5% renewable content for gasoline and 4% for diesel. Currently the renewable fractions are higher than the minimum which indicates that GHG intensity part of the standard is more stringent to meet.

The CleanBC plan further decreases the GHG intensity by another 10% by 2030 or a 20% reduction compared to 2010. This is projected to increase the production of renewable gasoline and diesel to 650 million litres per year by 2030 representing 8% of the total fuel demand.[115]

There are a number of ways to meet this projected fuel demand. Biomass based fuels such as corn ethanol, methanol and biodiesel can be produced. Ethanol and methanol can be mixed with gasoline and biodiesel can be mixed with or replace fossil produced diesel.

The pathways for biomass to produce renewable diesel are shown in Figure 56.

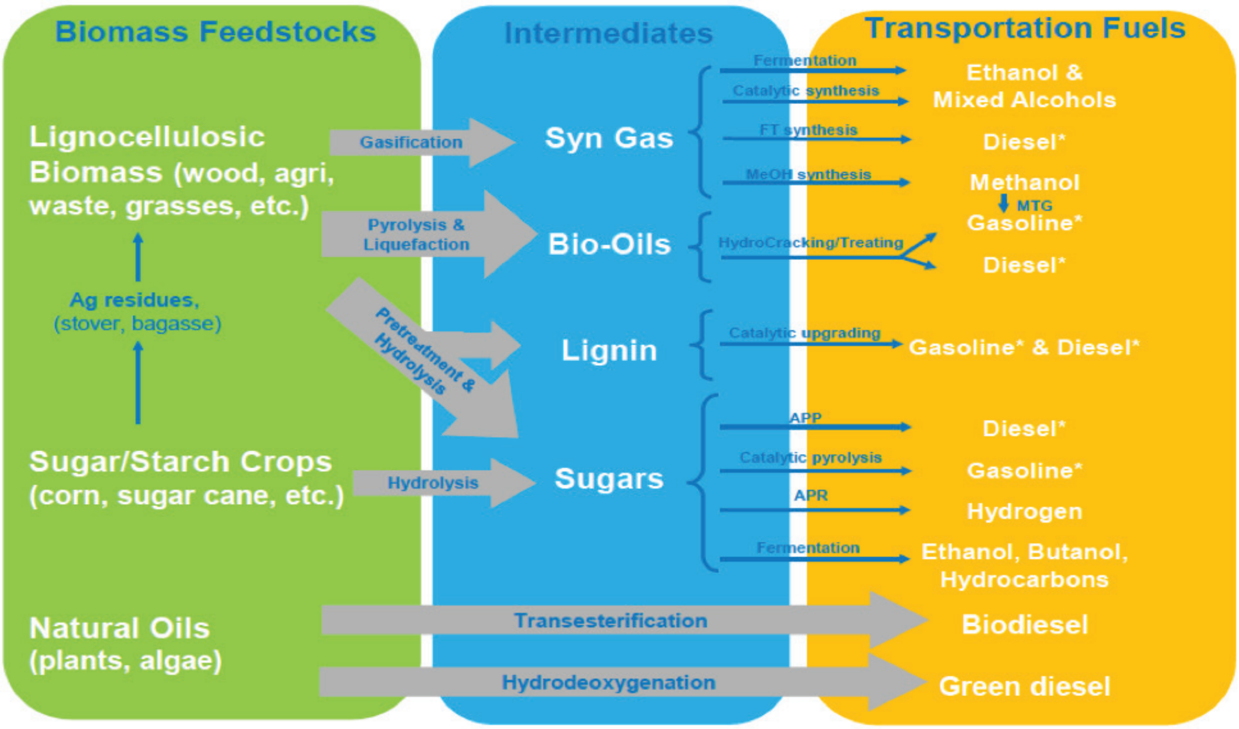


Figure 56. Biomass to Liquid Fuel Pathways

Current biomass feedstocks being investigated at the Parkland refinery include canola and tallow oil which are co-processed with fossil crude in the refinery. However, the available bio feedstocks will be insufficient to meet the projected demand.

115 *BC Provincial Government. (2018). CleanBC: Our Nature. Our Power. Our Future. Retrieved from https://www2.gov.bc.ca/assets/gov/environment/climate-change/action/cleanbc/cleanbc_2018-bc-climate-strategy.pdf*

Forest residues are being considered as a biomass feedstock to meet the 2030 demand. This source of biomass contains a high proportion of oxygen and will require additional hydrogen during production. Parkland is currently investigating this pathway in their refinery but were unable to provide estimates of how much hydrogen would be required.

Another pathway to meet the LCFS proposed in BC is via the production of synthetic crude or fuels using low carbon or renewable hydrogen and CO_2 captured from the air. This pathway is shown in Figure 57.

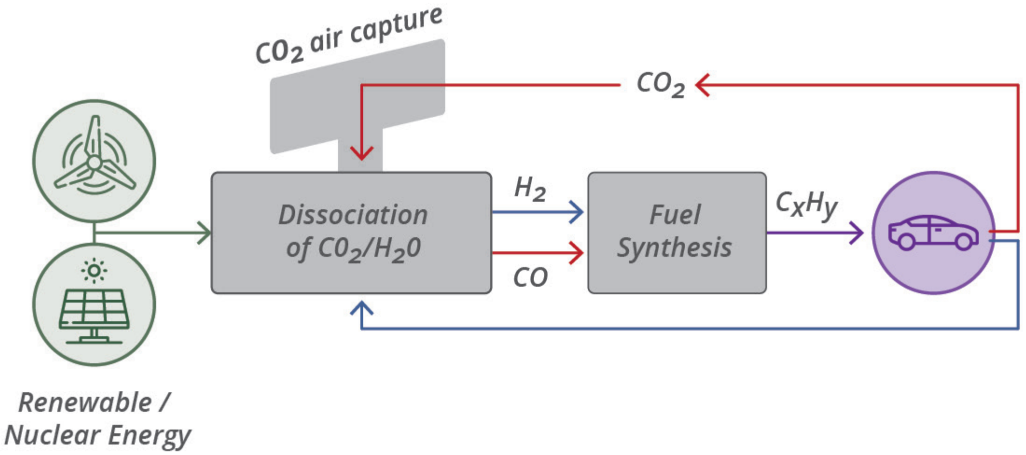

Figure 57. Synthetic Fuel Production Process

Carbon Engineering, based in Squamish, is developing an AIR to FUELS™ process whereby CO_2 from air and hydrogen are converted in conventional chemical processes to produce synthetic crude which can be processed in conventional refineries without any modifications. A commercial scale plant producing 100 million litres/year of synthetic crude would require 100 tonnes/day of clean hydrogen and 550 tonnes per day of CO_2 captured from the air. Depending on the GHG intensity of the hydrogen and the energy required in the direct air capture (DAC) process, the GHG intensity of the liquid fuels will be reduced by 70 – 90%.[116] If this hydrogen is produced by electrolysis, electrical input power would comprise approximately 250 MW[117] per plant for hydrogen production with another 8 MW for the DAC plant.[118] This is a significant electrical load, representing 23% of total Site C dam nameplate capacity.

By-product hydrogen produced by ERCO and Chemtrade provides a relatively small but low-cost hydrogen pathway of up to 18.5 tonnes per day. Due to their locations, the hydrogen must be either used on-site or transported to another location. Given the very high demand for low-cost hydrogen in the synthetic fuels production pathway, other sources of bulk, clean hydrogen and production will likely have to be constructed. Technology hurdles remain that will need to be overcome for synthetic fuel production to happen at scale in BC. In addition, as fuel cell electric vehicle adoption increases, the hydrogen market is likely to tip towards the more efficient pathway of directly using hydrogen for transportation, rather than using it to produce a synthetic fuel. That said, the synfuels pathway can immediately reduce the emissions of the existing vehicle fleet. Synfuels may also play a key role in helping to decarbonize emissions relating to marine and aviation transport.

An additional opportunity for hydrogen in the industrial sector is through the displacement of natural gas related to heating. This opportunity is discussed in Section 4.1 so is not treated further here.

4.3.3 : Challenges and Barriers

Due to the quantity of low carbon fuels required by 2030, hydrogen production at large scale in the province will likely be required regardless of the method used to produce the low carbon fuel. These hydrogen plants may be located near existing refineries to support production of biofuels using lignocellulosic feedstocks such as forestry residue or located in other regions where hydrogen production is co-located with DAC plants to produce synthetic crude which is transported to the refineries by rail, truck or pipeline. The main challenges for installing these large-scale plants include long upfront delays to obtain the necessary permits required to build the plant, as well as the potential for protests if the hydrogen is produced from natural gas.

If the plants are located at the existing refineries, hydrogen production via SMR+CCS is not possible due to the lack of CO_2 storage at the refinery sites. Unless there is a local use for solid carbon, hydrogen production via pyrolysis may also not be feasible at refineries. Lastly, due to the large electrical demand for large-scale electrolysis, onsite multi-MW supply at these locations may not be available due to local electrical transmission constraints.

In either case, intermittent hydrogen production from wind – electrolysis is also not viable due to the likely requirement of continuous hydrogen supply. Therefore, it appears likely that large-scale hydrogen production to support low carbon fuels demand will be located remotely from the refinery.

Finally, in order for the cost of low carbon fuels to remain low, hydrogen must be supplied at a low cost. Hydrogen produced for a cost of $5/kg will likely be too expensive as the cost of hydrogen alone equates to almost $2/litre of fuel.

Policies that could help drive hydrogen demand in the province includes maintaining the performance basis of the LCFS. By creating lower GHG intensity fuels and not allowing producers to exceed the intensity by paying a fee, clean hydrogen demand will be increased significantly and result in GHG emissions reductions in the province. Also, Part 2 of the LCFS should be modified to increase the proportion of renewable content in the LCFS over the longer-term as costs for renewable feedstocks decrease. The province could also consider further decreases in the GHG intensity for transportation fuels beyond 2030.

The province should consider supporting an initial large-scale project to kickstart hydrogen production for LCFS production. This could be either an AIR to FUELS™ plant to produce synthetic crude or a forestry biomass fed plant to produce renewable diesel and/or gasoline.

4.3.4 : Adoption Scenarios

Adoption scenarios that project hydrogen demand to 2050 have been based on conservative and aggressive policies. Due to the unknown hydrogen requirements to produce liquid fuels from biomass feedstocks, hydrogen demand was estimated using Carbon Engineering's AIR to FUELS™ pathway for a 100 ML/year of synthetic crude oil facility. The GHG reduction potential for this pathway is assumed to be 90%.[119] Finally, the overall transport fuel demand in BC is assumed to stay constant based on actual 2017 demand.[120]

The conservative scenario assumes the CleanBC target of 20% reduction in GHG intensity for transportation fuels continues until 2050. In this scenario, synthetic fuels will only meet 5% of the low carbon fuel requirement by 2030 and produce approximately 76 million litres/year. By 2050, growth to 25% of the low carbon fuel requirement is projected, with production of 380 million litres/year.

In the aggressive scenario, the GHG intensity reduction continues past 2030 and reaches 30% below 2010 levels by 2050. In this case, it is projected that synthetic fuels meet 25% of the total low carbon fuel demand by 2030, the equivalent of 380 million litres/year. By 2050, synthetic fuels plants meet 75% of the total low carbon fuel demand with production of 1,710 million litres/year.

119 Personal Correspondence – Carbon Engineering April 3, 2019

120 The Ministry of Energy, Mines and Petroleum Resources has provided a forecast that liquid fuel demand (gasoline, diesel) in BC will remain flat.

The demand curves for Industry for these scenarios are given in the figure below.

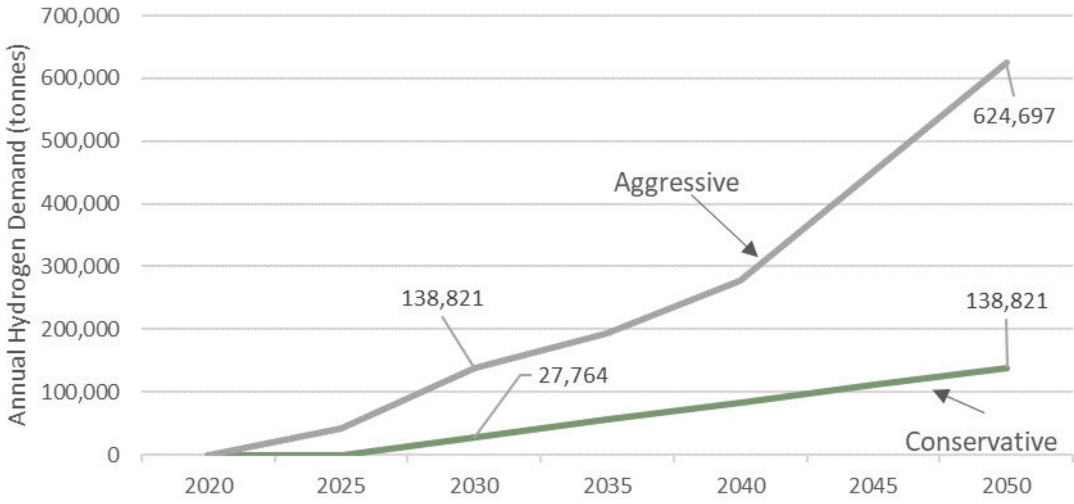

Figure 58. Hydrogen demand for Industry in BC

4.3.5 : Recommendations

Maintain the current performance base, GHG intensity reduction mandate of the LCFS

- *Include increasing proportion of renewable content over time*

Extend and Increase the proportion of low carbon fuels beyond 2030

- *Provides assurances to developers on a long-term market to justify large capital expenses*

Support a large-scale demonstration project in BC which uses clean hydrogen for the production of synthetic liquid fuels.

4.4 : Built Environment

4.4.1 : Baseline

The built environment makes up approximately 13% of total GHG emissions in BC. This sector can be divided into two broad categories as shown in Table 11.[121]

CATEGORY	DESCRIPTION
Residential	Personal residences (homes, apartment hotels, condominiums and farmhouses).
Commercial	Service industries related to mining, communication, wholesale and retail trade, finance and insurance, real estate, education, etc.; offices, health, arts, accommodation, food, information & cultural; Federal, provincial and municipal establishments; National Defense and Canadian Coast Guard; Train stations, airports and warehouses.

Table 11. Definition of Built Environment GHG Emissions Categories[121]

Figure 59 shows the GHG emissions from both built environment categories in BC from 1990 to 2016.

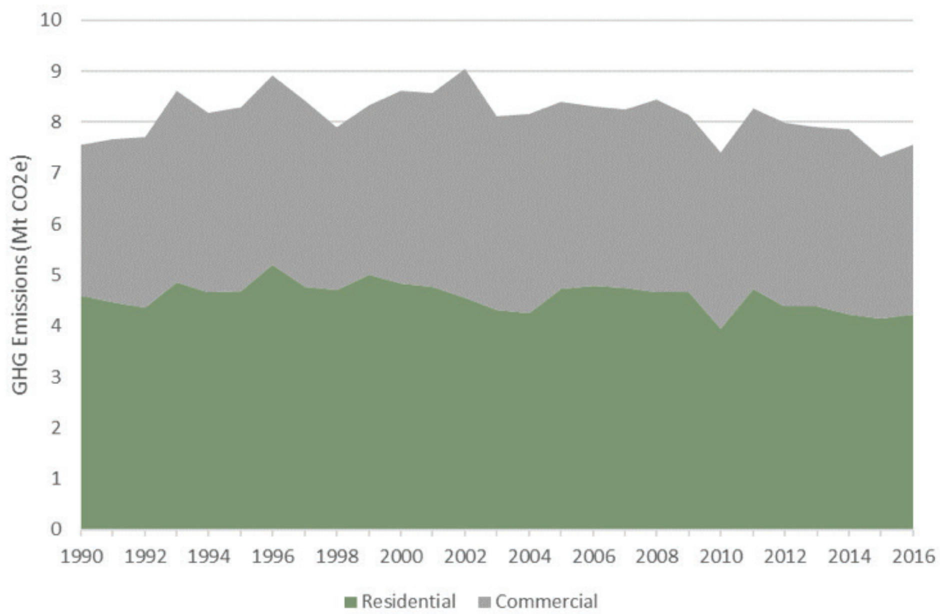

Figure 59. BC Built Environment GHG Emissions by Category (1990-2016)[121]

121 *Environment and Climate Change Canada. (2018). National Inventory Report 1990-2016: Greenhouse Gas Sources and Sinks in Canada, Annex 10. Retrieved from* https://open.canada.ca/data/en/dataset/779c7bcf-4982-47eb-af1b-a33618a05e5b

Total built environment GHG emissions trended slightly upward from 1990 to 2004 and have trended slightly downward since then. The split between residential and commercial/industrial has remained relatively consistent ranging from 61%/39% to 50%/50%. Figure 60 shows the percent of total built environment GHG emissions attributable to both categories in 2016.

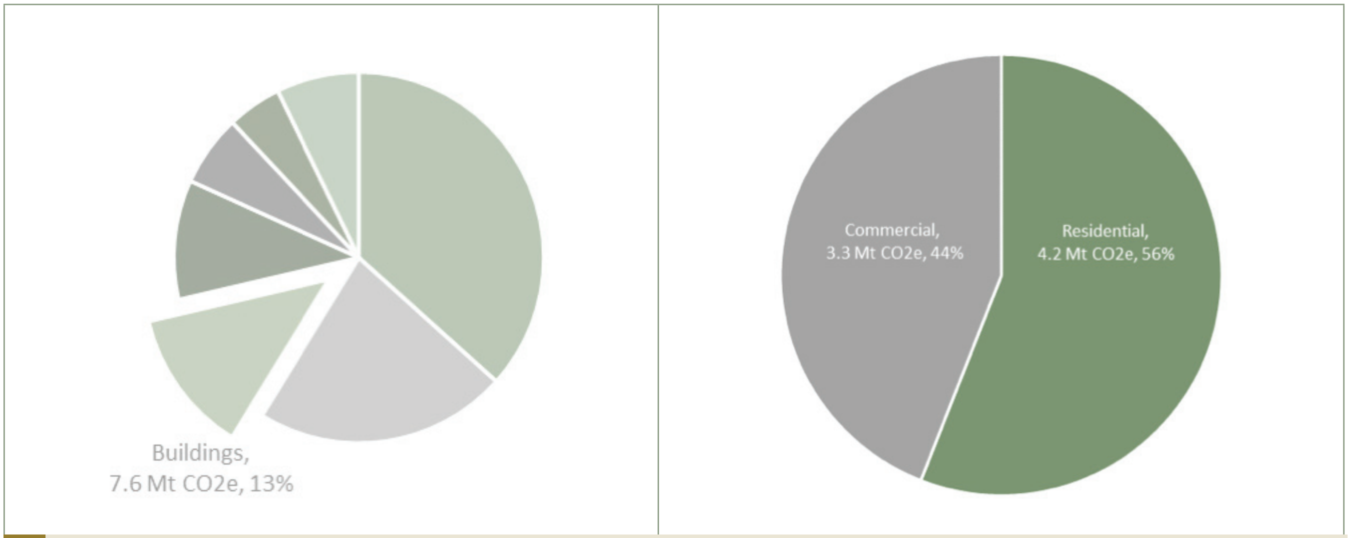

Figure 60. BC Built Environment GHG Emissions by Category (2016)[121]

4.4.1.1 : Residential Built Environment Baseline

Figure 61 shows residential building GHG emissions by source and end use (neglecting electricity).

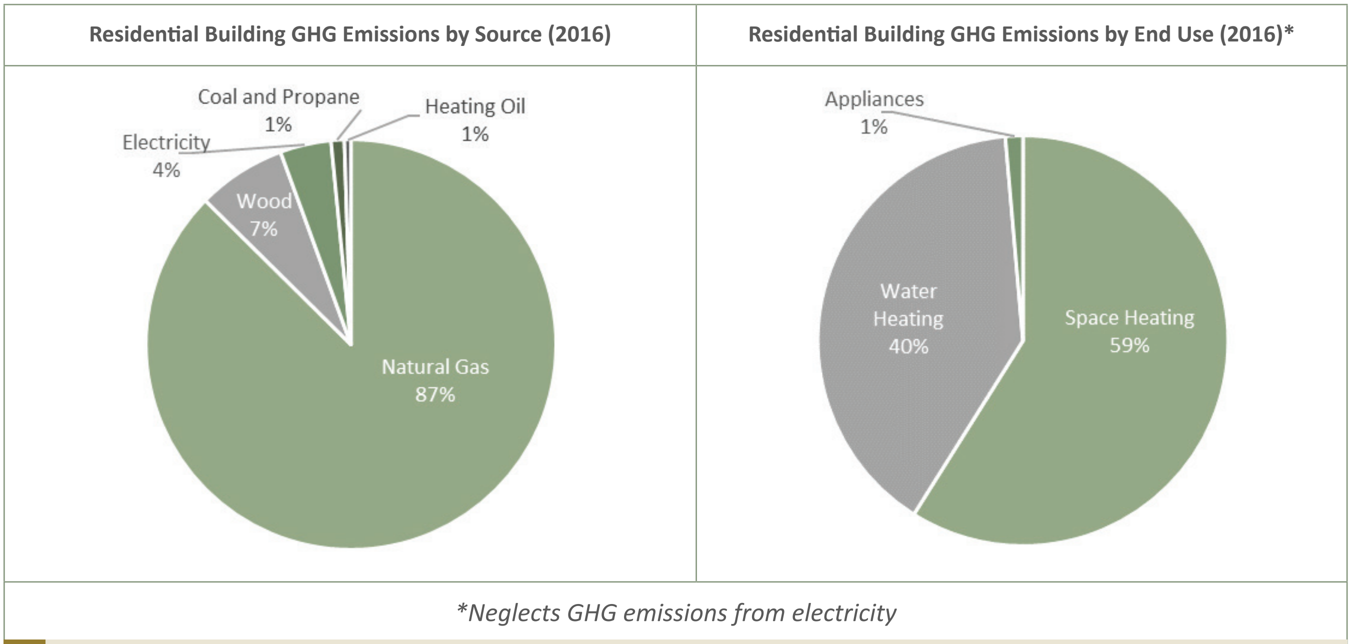

Figure 61. BC Residential Building GHG Emissions by Source and End Use (2016)[122]

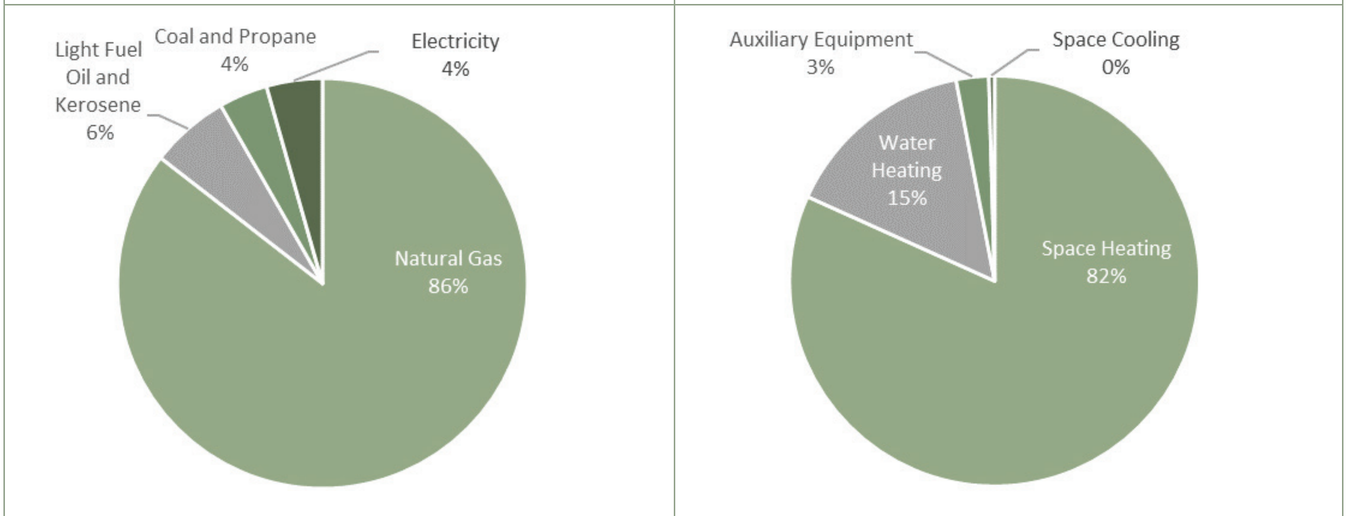
122 Natural Resources Canada. Comprehensive Energy Use Database: Residential Sector – British Columbia. Retrieved from http://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/menus/trends/comprehensive/trends_res_bc.cfm

The majority of residential GHG emissions results from natural gas consumed for space and water heating. The prevalence of heating oil has decreased significantly in BC, from 16.1% of GHG emissions in 1990 to less than 1% in 2016. Over the same period, emissions from water heating have increased while emissions from space heating decreased.[122]

4.4.1.2 : Commercial Built Environment Baseline

The majority of GHG emissions from the commercial and industrial built environment results from the burning of natural gas for space heating (Figure 62). The proportions shown have stayed relatively constant over time.

Commercial Building GHG Emissions by Source (2016)	Commercial Building GHG Emissions by End Use (2016)*



*Neglects GHG emissions from electricity

Figure 62. BC Commercial Building GHG Emissions by Source (2016)[122]

4.4.1.3 : Built Environment Hydrogen Baseline

Hydrogen is not currently in use to provide heating, cooling, or on-site electricity generation for the built environment in BC. The CleanBC plan primarily focuses on reducing emissions in the built environment by increasing the percent of natural gas that comes from renewable sources, improving the building code, investing in demand side management, and encouraging the installation of heat pumps.

4.4.2 : Opportunities and Challenges

The best opportunity for hydrogen to reduce GHG emissions in the built environment is through the displacement of natural gas in the grid. The built environment makes up approximately three quarters of the demand for natural gas across the Province. Achieving the CleanBC goal of 15% renewable gas by 2030 will result in significant emissions reductions, and hydrogen can play a pivotal role, as described in Section 4.1.

Off-setting natural gas consumption through the addition of hydrogen to the grid is particularly attractive for the built environment because at low concentrations it requires no action on behalf of the building occupants. Research suggests the natural gas stream feeding most domestic appliances could contain up to 20-30% hydrogen by volume without the need to separate the gases at their end use or making major changes to the grid or appliances.[123, 124, 125] Retrofitting buildings with improved insulation and weatherization, or installing energy efficient equipment like heat pumps or tankless water heaters requires effort and capital expenditure on the part of building owners. Adding hydrogen to the gas grid requires no action from the population at large, though it is likely to impact the rates paid.

Beyond the 20-30% range, the hydrogen/natural gas blend may become incompatible with domestic appliances like furnaces and stoves because of hydrogen's relatively low energy content, low density, and high burning velocity. To increase the hydrogen content beyond this level would require modifications to the pipe network as well as the appliances themselves. Though challenging, a major overhaul of this sort is not unprecedented. In 2009, Whistler underwent a transition from propane to natural gas, which involved similar retrofits of about 14,000 domestic appliances.[126]

Another opportunity for hydrogen in the built environment is stationary fuel cell systems that provide combined heat and power (CHP), sometimes called cogeneration, or cogen. These systems, which can run on natural gas, pure hydrogen, or a blend, have been successfully deployed at scale in Japan. However, they are not well suited to most regions in BC because of their relatively high capital cost and the availability of inexpensive renewable electricity in BC. Residential cogeneration systems might make sense if an entire community converted to 100% hydrogen, as described in Section 4.1 and Section 4.5.

4.4.3 : Adoption Scenarios

Hydrogen adoption in the built environment was not modeled independent of the natural gas pipeline (Section 4.1) and remote communities (Section 4.5). The hydrogen demand in both of those sectors will be largely consumed in the built environment. Figure 63 shows the natural gas demand by segment in 2017.

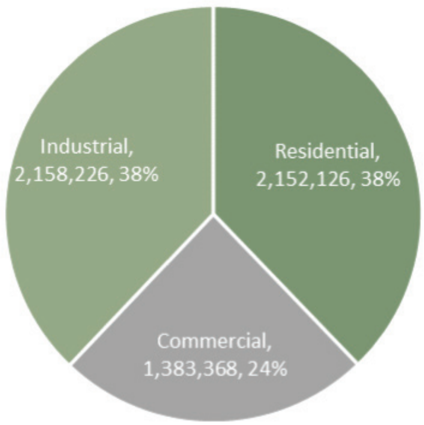

Figure 63. Natural Gas Demand in m^3 in BC by Segment (2017)[127]

The modeling assumed the percent share of each segment remained constant through 2050, so the built environment represents approximately three quarters of the hydrogen demand projected in Section 4.1. Effectively all the hydrogen demand modeled for remote communities are attributable to the built environment.

4.5 : Remote / Off-Grid Communities

4.5.1 : Baseline

4.5.1.1 : Overview

A remote community is defined as a permanent community not connected to North America's integrated electrical or natural gas grids. It must have been settled for longer than 5 years, with 10 or more dwellings. The NRCan Remote Communities Energy Database[128] (based on 2017 or most recently available data) identifies 75 remote communities in BC, illustrated in Figure 64.

Fourteen remote communities rely on hydro with backup diesel generation for their electricity. Fifty-two communities rely on diesel as their primary power source. Six communities have unknown power sources.

127 *BC Provincial Government. (2018). Production and Distribution of Natural Gas in BC. Retrieved from https://www2.gov.bc.ca/gov/content/industry/natural-gas-oil/statistics*

Figure 64. BC Remote Communities with Power Source

4.5.1.2 : Microgrids

A microgrid is a complete system (diesel generators or small-scale hydro, distribution wires/equipment, control systems) that provides electricity to a community; in some cases, they may provide power to surrounding communities as well. Fourteen of BC's remote communities are connected to one of four local microgrids owned by BC Hydro: Bella Bella, Bella Coola (Ah-Sin-Heek power plant) and Sandspit provide hydroelectric power with diesel as back-up, while Masset is 100% diesel generation.

NAME	#*	PRIMARY POWER	SECONDARY POWER	FOSSIL FUEL GENERATION (MWH/Y)	FOSSIL GENERATING CAPACITY (MW)	PEAK LOAD (MW) (2016)	NOTES ON POWER SOURCE
Bella Bella	4	Hydro	Diesel	983	4.90	4.30	93% hydro, diesel as backup
Bella Coola	3	Hydro	Diesel	7939	9.25	4.85	70% hydro, Clayton Falls Hydroelectric
Sandspit	4	Hydro	Diesel	5507	10.15	6.96	70-90% hydro, Moresby Lake Hydro Station
Masset	3	Diesel	n/a	26433	13.10	6.22	5 Generators, 10.455 MW capacity
**Number of communities supported*							

Table 12. BC Hydro Local Microgrids

Diesel generators and small-scale hydro can provide consistent 24/7 electricity, facilitating the balancing of supply and demand. Variable renewable electricity, or VRE, composed of intermittent wind and variable solar, can provide intermittent power which can help reduce costs and emissions, but which increase the complexity of a microgrid system. Hybrid systems of hydroelectricity with diesel back-up can supply the majority of a community's power needs, providing lower-cost, cleaner electrical supply most of the time, while using diesel generators as back-up to ensure uninterrupted electricity supply.

For a microgrid without storage (generally lithium-ion battery, though in some cases flow battery), intermittent renewables penetration is estimated at 20-30%. As integration of renewable sources increases (bringing down the overall cost of generating the electricity), combined with falling battery prices, investing in storage options could become an economically viable option.

4.5.1.3 : Single Off-Grid Communities

Sixty-one (61) off-grid communities in BC are powered primarily by diesel, but also by small hydroelectric projects as well as demonstration projects for LNG, Biomass and solar.

Fifty-two (52) communities rely on diesel generation as their primary source for electricity, three communities get electricity from small local hydroelectric projects (run of river with no storage) and three additional communities use hybrid systems of Diesel with LNG, biomass or solar. Service is provided by BC Hydro (diesel generation from 10 stations and two small hydroelectric projects), Independent Power Producers (IPP) provide diesel electricity to 31 communities and ATCO Electric Yukon to a single community.

SERVICE PROVIDER	COMMUNITIES	PRIMARY POWER	SECONDARY POWER	FF* DEMAND (MWH/Y)	FF GEN** CAPACITY (KW)	NOTES ON POWER SOURCE
BC Hydro-2 IPP-1	3	Hydro	Diesel	348		Minimal diesel as backup
BC Hydro-8 IPP-30 Unknown-10 ATCO Electric YT-1	49	Diesel		92,513	58,514	100% diesel
BC Hydro	1	Diesel	LNG	6,649	3,550	50% diesel, 50% LNG
BC Hydro	1	Diesel	Biomass	2,963	1,800	20-25% biomass
IPP	1	Diesel	Solar	1,400	78	250 kW solar + 1 MWh storage; target 80% solar
Unknown	6	Unknown		Unknown		Small amounts of diesel, Propane, Gasoline, Small solar
** Fossil Fuel* ***Fossil Fuel Generation*						

Table 13. Power Source(s) for 61 Single Off-grid Communities

4.5.1.4 : Diesel GHG Baseline

Remote communities in BC and across Canada rely primarily on diesel for electricity, and efforts continue to reduce this reliance. Data on diesel use and the resulting GHG emissions remains limited. The Pembina Institute estimated that more than 90 million litres of diesel[129] are consumed in Canada's remote communities with BC communities estimated to use 3 million litres per year.

To establish a GHG baseline for BC's remote communities, information was gathered on annual diesel demand at the community level. Data was unavailable for some of the smallest communities, but these likely use 3 (or fewer) installed gensets with capacity well below 1MW. Data was gathered from the NRCan Remote Community database and an earlier report (2011) on the Status of Remote/Off-Grid Communities in Canada[130] prepared by NRCan and Aboriginal Affairs and Northern Development Canada (AANDC).

CO_2e emissions from FF generation in BC Remote Communities	**33.47 kt CO_2e/year**

Table 14. Annual Fossil Fuel Power Generation and Generating Capacity

4.5.1.5 : Diesel Issues – Economic, Environmental, Social

In Canada, the average cost of electricity is between $0.07-$0.17/kWh, while the unsubsidized cost of electricity from diesel generation is approximately $1.30/kWh[133]. BC has some of the lowest electricity costs in the country and under their Non-Integrated Area rate plan BC Hydro provides diesel energy to remote communities in BC at the following subsidized rates:[134]

- *$0.1028/kWh for the first 1,500 kWh per month,*
- *$0.1767/ kWh for remaining kWh per month;*

The initial rate is equivalent to the rate paid by grid-connected customers, while the second rate is higher, although much lower than remote communities pay in other parts of the country.

134 Kennedy M. (2017). Energy Shift: Reducing Diesel Reliance in Remote Communities in BC. Simon Fraser University. Retrieved from http://summit.sfu.ca/item/17979

In general, the high cost of diesel is driven by the cost of transportation over long distances and often very challenging terrain. Without the highly subsidized rates from BC Hydro, the high cost of diesel would make it very difficult for any industry consuming even small amounts of electricity to operate economically in these remote communities. As well, residents of remote communities often live at a subsistence level with the high cost of electricity contributing heavily to this. Poor building energy efficiency and cold northern climate also increase overall electricity use in these communities.

In addition to the substantial GHG emissions from the diesel generation, transportation by truck, ship or plane creates additional GHG emissions, and long transport over rough terrain increases the risk of spills. Diesel generators are also noisy, disruptive, have unpleasant fumes and the emissions can contribute to health problems (asthma, bronchitis, allergies, lung function, heart problems)[135]. Finally, the unreliability of aging generators running at capacity increases the risk of power outages which negatively impacts services and businesses and can be dangerous in cold, remote locations.

4.5.1.6 : Other Power Sources

Micro Hydroelectric Projects

Run-of-river hydroelectric projects use the natural elevation, channeling water through a penstock to a downstream turbine. Water is diverted from the stream/river for a short distance and returned to the stream after the turbine. These projects have far less environmental footprint than a traditional dam, and there are many rivers and streams in BC, however these projects require over 50 permits, licenses, approvals and reviews by many Government agencies and consultation with First Nations and public groups. BC Hydro and one Independent Power Provider (IPP) operate 6 small hydro projects in the Province: 3 hydroelectric microgrids supporting 11 communities (See Table 12 above) and 3 single community micro hydro projects.

PROVIDER	ANNUAL GENERATION (MWH/Y)	CAPACITY (MW)
BC Hydro - Atlin	5,000	2.1
BC Hydro - Dease Lake	5,000	3.0
IPP - Klemtu/Kitsoo*	At capacity	1.7
** Klemtu/Kitsoo is installing small solar (23kW) to avoid using diesel as backup*		

Table 15. Single Community Micro Hydro Projects

LNG

BC Hydro is the power provider for the community of Anahim Lake and in the fall of 2016, began a 3-year pilot project, converting the largest of 5 diesel generators to operate with LNG, with the goal of reducing both GHG emissions and fuel costs. Cryopeak trucks LNG from FortisBC's Tilbury Island facility in Delta, stores it and regasifies it in Anahim Lake. Long-term expectations are that 60% of Anahim Lake's power could come from LNG. The NRCan remote community database estimates that 50% of the electricity is currently being generated by LNG.

135 *Huter, H.-P., Kundi, M., Moshammer, H., Shelton, J., Kruger, B., Schicker, I., & Wallner, P. (2015). Replacing Fossil Diesel by Biofuel: Expected Impact on Health. Environmental & Occupational Health, 4-9.Retrieved from* https://www.ncbi.nlm.nih.gov/pubmed/24965323

Biomass

The community of Kwadacha First Nation (Tsek'ene) is using biomass gasification-to-electricity to reduce reliance on diesel. In April of 2017, the biomass system, consisting of three CHP biomass generators and a dryer, began operation, producing electricity for the majority of the community and heat for the local school and greenhouses. Each generator produces 45kW of electricity and 108KW of heat in the form of hot water.[136] The project is projected to reduce reliance on diesel by 20-25% (reducing GHG emissions by ~400 tonnes/year[137]) as well as reduce the use of propane for heat. BC Hydro provides the diesel generation and under a 20-year electricity purchase agreement, purchases power resulting from the biomass project and reduces diesel generation by an equivalent amount.

Solar

Xeni Gwet'in First Nation, located in south-central BC, is reducing their reliance on diesel through a solar installation project. The system includes 250 kW PV with 1,000 kWh storage that provides a full day of backup under cloudy skies and is expected to reduce diesel consumption by an estimated 143,000 litres/year, reducing GHG emissions by 382 tonnes/year.[138] While the system clearly reduces electricity cost and GHG emissions, replacement of the lithium battery storage in 15-20 years will be a significant cost.

Previous Hydrogen Related Projects

Hydrogen Assisted Renewable Power (HARP) Project in Bella Coola[139, 140]

The HARP project was a small demonstration project that ran from 2009-2013 and combined hydrogen production via electrolysis, hydrogen storage, and Fuel Cells. Renewable energy from the Clayton Falls hydro station was used to power an electrolyzer to create hydrogen which was then compressed and stored at 200 bar (20 MPa). PEM fuel cells converted the hydrogen into 100 kW of electricity during peak demand periods, offsetting diesel generation. The demonstration project used a microgrid control system to balance the electrical load between the renewable energy source, diesel generation, and the power provided by the fuel cells.

The project reduced diesel consumption by an estimated 10%, however, it came with very high costs and reliability issues. Not only was the fuel cell and electrolyzer equipment very costly, the 3-step process for generating electricity, (hydroelectricity generation, electrolysis, fuel cell) was very expensive with a system efficiency of only ~35%.

As well, at the time, a 100 kW fuel cell was unavailable, so 100x 1 kW fuel cells were connected in series creating a system with 100 discrete modules each with its own compressor, controls, etc. With so many components in the overall system, the number of failure points increased, and reliability became a significant issue.

The project demonstrated that the system was not ready for full deployment in real-world situations where equipment reliability is critical.

4.5.2 : Opportunities for Hydrogen

As part of the CleanBC plan, the Province has set a target of reducing diesel electricity generation in remote communities by 80% by 2030. This is an ambitious target and will require many solutions. Every remote community in BC differs in size, weather, geography, skill base and power requirements and solutions for reducing diesel dependence will be community and site specific.

Most of the remote communities in BC rely solely on trucked or barged in diesel fuel for their electricity supply and there is an opportunity to replace the diesel fuel imports with hydrogen imports. The hydrogen could supply a microgrid system, either centralized, or distributed with co-generation of heat and power. Renewable energy sources can also be incorporated to produce hydrogen using electrolysis, reducing reliance on imported fuel.

A hydrogen supplied microgrid offers significant advantages over diesel generation:

- *Eliminates GHG emissions*
- *Eliminates spill pollution risk*
- *Lower transport weight (in the case of LH_2 supply) reducing transport cost*

If hydrogen is produced for export and shipped through Kitimat, it may be possible to divert some of the hydrogen for delivery to remote communities in the northern part of the Province. This could provide a reliable and reasonably priced hydrogen source.

Compressed natural gas (CNG) also offers the opportunity to transition away from diesel to a cleaner burning fossil fuel. Hydrogen can play a role here as well, as it can be injected into the natural gas prior to compression, reducing the gas's carbon intensity and its associated emissions.

Each of these opportunities is discussed in more detail below.

Hydrogen Microgrid with Distributed Heat and Power Generation

In a distributed hydrogen micro-grid system, imported hydrogen is stored centrally and distributed via pipeline to local houses and buildings which are each outfitted with a local combined heat and power (CHP) generation system. The ENE-FARM system, shown in Figure 65, is an example of a CHP system being used in Japan, where over 300,000 units have been installed.[141]

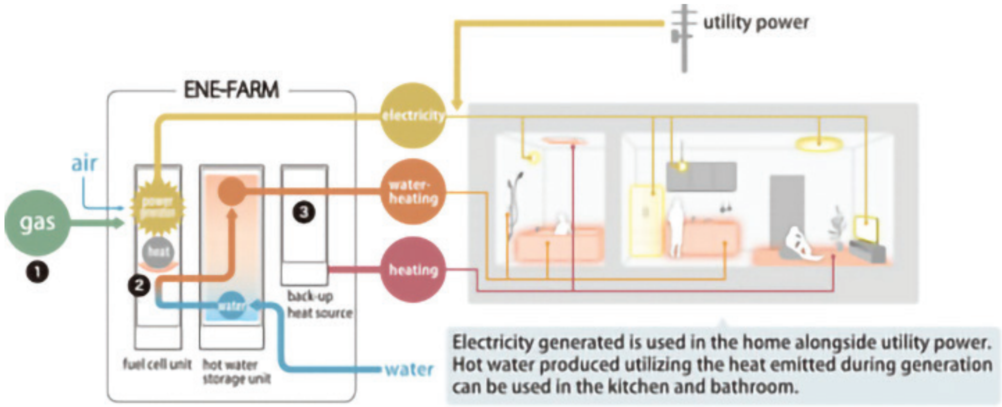

Figure 65. ENE-FARM System

141 FuelCellsWorks. (2019). FCW Exclusive: Tokyo Fuel Cell Expo 2019 – 300,000 Ene-Farms. Retrieved from https://fuelcellsworks.com/news/fcw-exclusive-tokyo-fuel-cell-expo-2019-300000-ene-farms/

The CHP system converts hydrogen into electricity as needed via a PEM fuel cell and heat produced during the process is captured and used to heat hot water for the building. By re-using the waste heat, CHP systems can be up to 95% efficient and significantly reduce overall electricity requirements. The up-front capital cost for a distributed micro-grid system is fairly high, but the higher efficiency would reduce overall hydrogen imports, lowering operating costs.

Hydrogen Microgrid with Centralized Power Production

Fuel cell generators running on pure hydrogen are becoming available and could offer a direct replacement for diesel gensets. In this scenario, hydrogen is imported and stored centrally, with hydrogen fuel cell generators creating power as needed and distributing it to homes and buildings. Hydrogen fuel cell generators are relatively new and higher cost than their diesel counterparts, but connection into the existing distribution lines, previously used by the diesel generators, would minimize the up-front capital costs of the system.

Electricity requirements, and hence hydrogen import requirements, are higher in this centralized microgrid scenario vs. a distributed system, as electricity must be generated for heat and hot water (via baseboard heaters and electric water heaters) as well as power. Efficiency of fuel cell generator systems is ~40% as heat generated by the fuel cells is not re-used.

Hydrogen Microgrid with Renewable Sources

A hydrogen microgrid, either centralized or distributed, can be combined with renewable energy sources, reducing both the amount of hydrogen imported and the GHG emissions due to transport.

Most remote communities are completely reliant on imported diesel for their power generation and transportation needs, and the transport costs make energy supply to these regions very expensive. As such, remote communities provide an attractive cost basis for new competing renewable electricity and hydrogen technologies that can offset imported fuel requirements.

Remote communities can take advantage of renewable energy sources such as wind, solar, and run-of-river hydro. The renewable energy source is connected to a microgrid controller to balance the supply and demand of electricity. In times of excess supply, hydrogen can act as an energy storage medium with surplus electricity fed into an electrolyzer to create hydrogen on-site, thereby reducing hydrogen import requirements.

The Raglan Nickel Mine in Northern Quebec is a successful example of wind energy and hydrogen storage reducing diesel consumption.

WIND POWER AND HYDROGEN STORAGE AT RAGLAN NICKEL MINE IN NORTHERN QUEBEC

At the Raglan Nickel Mine in Nunavik, hydrogen is used as an energy storage solution to reduce diesel consumption.

A 3MW wind turbine was installed and combined with a 3 tiered energy storage system. A flywheel and battery combination filters out large wind variations and transitions the system to diesel generator or 200kW fuel cell for back up power when needed.

A 315kW electrolyzer converts excess renewable supply into hydrogen for storage. A micro-grid controller manages the supply and demand, producing a smooth power output that has allowed wind to generate 50% of the mine's power requirements. The system has reduced diesel consumption at the mine by 2.4 million litres annually and the project can act as a flagship site for future wind development projects.

CNG with Injected Hydrogen as a Transition Step

CNG is the cleanest burning fossil fuel and can support communities as they transition away from diesel. It provides a cleaner, lower cost alternative and poses much less risk to the environment as it vaporizes, eliminating any contamination or cleanup, in the event of a spill.

CNG generators or Jenbacher engines running on CNG could be used as direct replacements for diesel gensets. They could tie into existing distribution lines in a community and be coupled with renewable energy sources to reduce overall fuel import requirements.

Hydrogen can also play a role with CNG as low carbon hydrogen can be injected into the natural gas grid, reducing the carbon intensity of the CNG produced and shipped to remote communities.

4.5.3 : Challenges and Barriers

Transitioning to clean energy in remote communities can be difficult due to logistical, technical, financial and human capacity challenges that larger communities take for granted.

Geography and Remoteness

Logistically, transporting equipment long distances over difficult terrain can be challenging and expensive. Delays are common, pushing out project schedules and further driving up costs. Construction can be more challenging as infrastructure and equipment taken for granted in larger centres is limited or unavailable. And once a project is up and running, the remote location can limit quick access to technical service people and spare parts which can leave a system down for weeks.

Human capacity is also a huge concern for these projects. Communities often do not have the local technical expertise to plan, develop and support clean energy projects. If outside expertise is brought in to implement the project, the community runs the risk of being left without critical technical knowledge should that person ultimately leave the community.

These factors increase the costs and risks of projects making it difficult to get project financing.

System Complexity and Economies of Scale

Renewable energy sources present an opportunity for remote communities, but also come with challenges. The imbalance between electricity supply and demand must be managed. This means enhanced control systems to manage the intermittent supply sources, adding cost and technical complexity to a new clean energy system. The added complexity increases the risk of downtime and delays in accessing necessary spare parts and expertise to fix the system.

Maturity of technology is of critical concern to remote communities in order to avoid the risk of interruptions and downtime typical of new technology deployments. As such, technology being considered for implementation in a remote community must have been tested for 3 years in 3 separate locations to ensure the reliability of the technology. This requirement will make it challenging to deploy new technologies in the near-term.

Renewable energy projects are becoming more common and can have reasonable project economics when sized at 200-300 MW for wind, 50-100MW for solar and 10MW for small-scale hydro.[142] For remote communities, the system requirements are often an order of magnitude smaller, but still require all the typical project costs, such as engineering, project management and permitting, and thus have higher relative costs. The high costs and small project size make it difficult to get funding or attract private financing.

142 *Pembia Institute. (2018). Renewables in Remote Communities: 2017 Conference Proceedings. Retrieved from https://www.pembina.org/pub/renewables-remote-communities*

4.5.4 : Adoption Scenarios

The opportunity for hydrogen use in remote communities is very small in comparison to other sectors, but can provide significant and meaningful improvement to local air quality. For adoption, these communities require technologies to be more mature (three years of proven deployment) to make the costs and risks more realistic for small-scale deployments. In the near-term, remote communities will focus on energy efficiency improvements in local homes and buildings to reduce overall energy demands and therefore it is assumed that there will be no increase in diesel consumption beyond current levels. Communities will be encouraged to investigate clean energy opportunities such that by 2025 some technologies supporting hydrogen use start to be deployed.

In developing scenarios for hydrogen use in remote communities, it is assumed that hydrogen microgrids will be adopted with centralized diesel gensets replaced by either centralized hydrogen fuel cell generation systems, or distributed small-scale (~ 1-3 kW) cogeneration systems fed through a hydrogen pipeline, similar to the long-term vision for the Japan ENE-FARM project.

Because the CleanBC plan is focused on the 22 largest diesel operations (12 BC Hydro operations and 10 Indigenous Services Canada stations which combined provide ~75% of all diesel generation for BC remote communities), diesel use for these operations was considered separately from the remaining communities. Conservative and aggressive scenarios were developed by estimating the diesel reduction percentage, and the percentage of this reduction that will be attributed to hydrogen.

Conservative Scenario

In the top 22 communities, diesel reduction is assumed to increase gradually from 20% in 2025 to 80% in 2050, with hydrogen responsible for 25% of the reduction. In the remaining communities, diesel reduction increases from 5% in 2025 to 30% in 2050 with no use of hydrogen technologies.

Table 16 summarizes the demand reduction and hydrogen use assumptions for the Conservative Scenario, and the resulting hydrogen demand and GHG reduction.

CONSERVATIVE SCENARIO						
	Top 22 Communities		Remaining Communities		Total	
Year	Diesel Demand Reduction	Energy Use Reduction from H_2	Total Diesel Demand Reduction	Energy Use Reduction from H_2	Total H_2 Demand (t)	GHG Abated (t CO_2e)
2020	0%	0%	0%	0%	0	0
2025	20%	25%	5%	0%	55	1,251
2030	40%	25%	10%	0%	110	2,502
2035	50%	25%	15%	0%	137	3,128
2040	60%	25%	20%	0%	165	3,753
2045	70%	25%	25%	0%	192	4,379
2050	80%	25%	30%	0%	220	5,004

Table 16. Conservative Scenario - Remote Community Hydrogen Demand (2020-2050)

Aggressive Scenario

In the top 22 communities, diesel reduction increases aggressively to 80% by 2030 to achieve the target reduction laid out in the CleanBC plan and then a much more gradual increase to 95% occurs between 2030 and 2050. Hydrogen is assumed to be responsible for 50% of the reduction. In the remaining communities, diesel reduction increases from 10% in 2025 to 60% in 2050 with 10% reduction attributed to hydrogen technologies.

Table 17 summarizes the demand reduction and hydrogen use assumptions for the Aggressive Scenario, and the resulting hydrogen demand and GHG reduction.

AGGRESSIVE SCENARIO						
	Top 22 Communities		Remaining Communities		Total	
Year	Total Diesel Demand Reduction	Energy Use Reduction from H_2	Total Diesel Demand Reduction	Energy Use Reduction from H_2	Total H_2 Demand (tonnes)	GHG Abated (tonnes CO_2e)
2020	0%	0%	0%	0%	0	0
2025	40%	50%	10%	10%	223	5,087
2030	80%	50%	20%	10%	446	10,174
2035	85%	50%	30%	10%	477	10,882
2040	90%	50%	40%	10%	508	11,590
2045	95%	50%	50%	10%	539	12,299
2050	95%	50%	60%	10%	543	12,381

Table 17. Aggressive Scenario - Remote Community Hydrogen Demand (2020-2050)

The results from both the Conservative and Aggressive Scenarios are shown in Figure 66. The potential for hydrogen demand in remote communities in 2050 is estimated to range from 220 to 540 tonnes annually, with GHG reductions in the range of by 5,000-12,400 tonnes CO_2e/year.

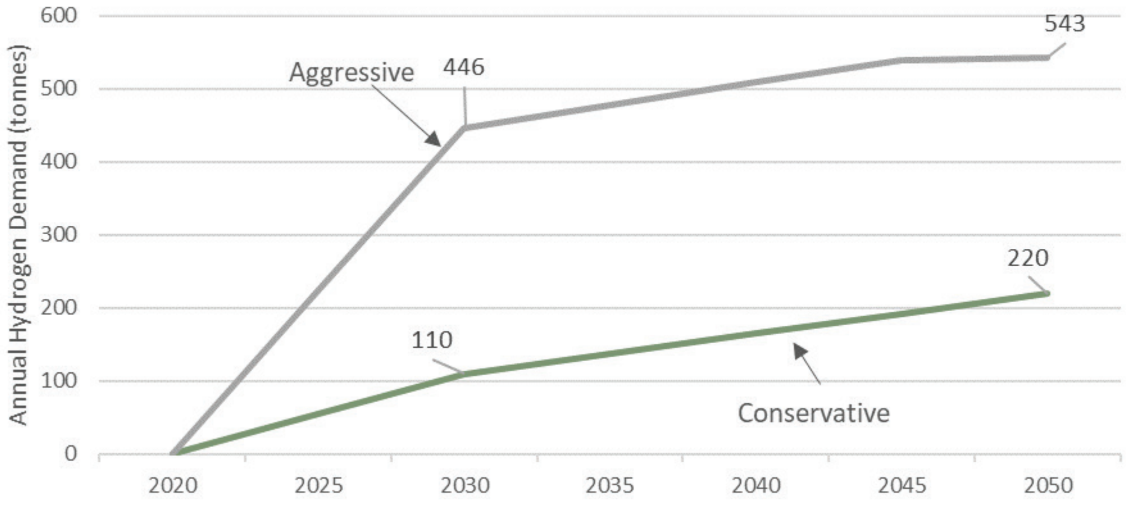

Figure 66. Remote Community Conservative and Aggressive Hydrogen Demand (2020-2050)

4.5.5 : Recommendations

Encourage development of hydrogen microgrids

- *For communities that rely entirely on trucked or barged in energy supply, encourage development of microgrids that utilize a 100% hydrogen distribution grid with local combined heat and power (CHP) generation such as the ENE-FARM program in Japan*

Work with remote communities to develop plans to implement hydrogen related projects and make it easier for communities to own and operate their own facilities

- *Provide a 'hydrogen toolkit' including: support to navigate funding opportunities; technical expertise for planning, implementation and operations; and database with technical and cost details of successful hydrogen projects*

Create access to financing for cleaner fossil fuel-based systems that utilize a CNG / hydrogen blend

5.0 Power to Gas and Energy Storage

5.1 : Power to Gas

Power to Gas (P2G) is the process of converting surplus renewable electricity into hydrogen gas through electrolysis. It is a use case for electrolysis technology discussed in section 3.1.2.

The hydrogen can then be injected into natural gas pipeline networks or for other applications such as a transportation fuel. As shown in Figure 67, hydrogen is versatile once generated, and can be converted into methane or even liquid fuels. (As noted in section 4.1.2, the economics for such transformations may be challenging.)

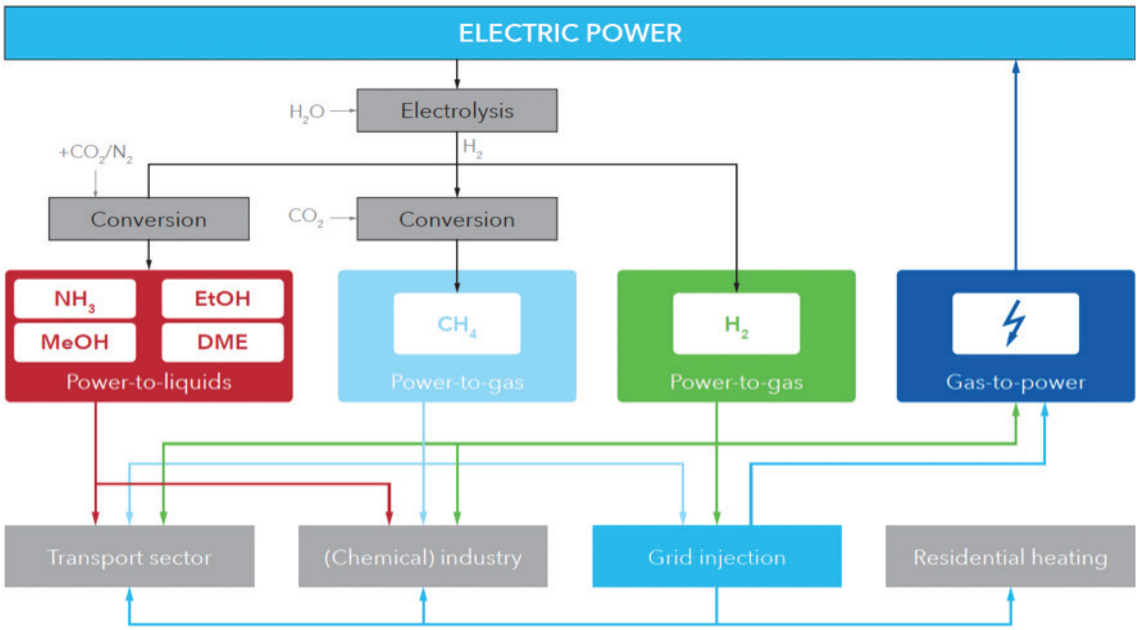

Figure 67. Options for Hydrogen Generated via Power to Gas. Source DNV GL.

Given that hydrogen can be injected into natural gas networks, P2G is sometimes described as a means of connecting the electric and natural gas energy systems; it can also be a key enabler of the transition from a fossil natural gas grid to a decarbonized one.

Rising P2G interest in Europe has been driven by aggressive GHG reduction targets and an increasing supply of variable renewable electricity (wind and solar). Figure 68 shows a DNV GL projection for power generation capacity in Europe. It should be noted that while capacity factors for solar and wind are known to be low, their proliferation has displaced thermal power generation ("combustibles" in the Figure) such that thermal power plants' own capacity factors have begun to decrease over time.

REGENSBURG UNIVERSITY

In 2008 the Regensburg University of Applied Sciences and the Centre for Solar Energy and Hydrogen Research in Ulm jointly developed the concept of power to gas for energy storage. The German government energy agency established a P2G strategy in 2011. There are currently more than 45 P2G projects in Europe.

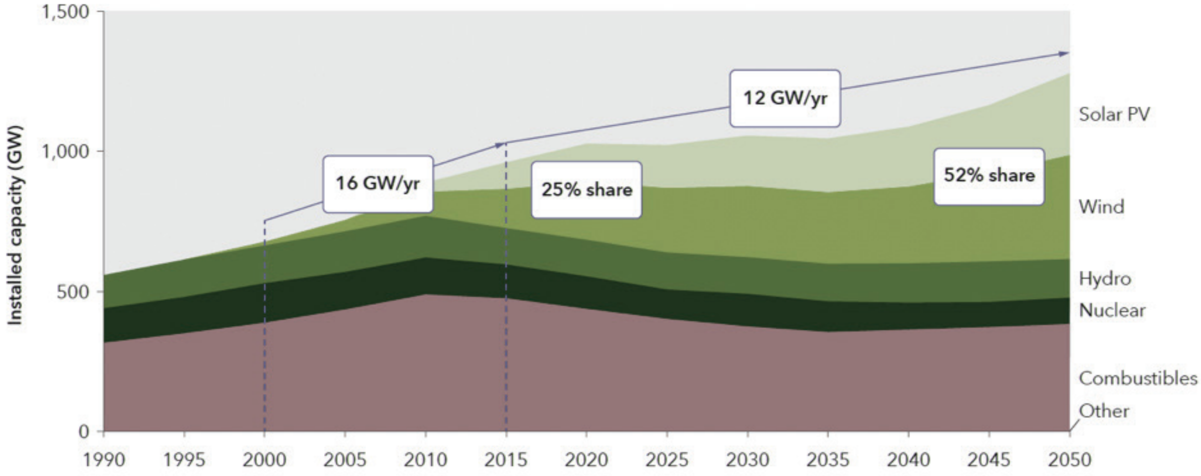

Figure 68. Historic & Future Installed Power Generation Capacity Projections for Europe. Source: DNV GL.

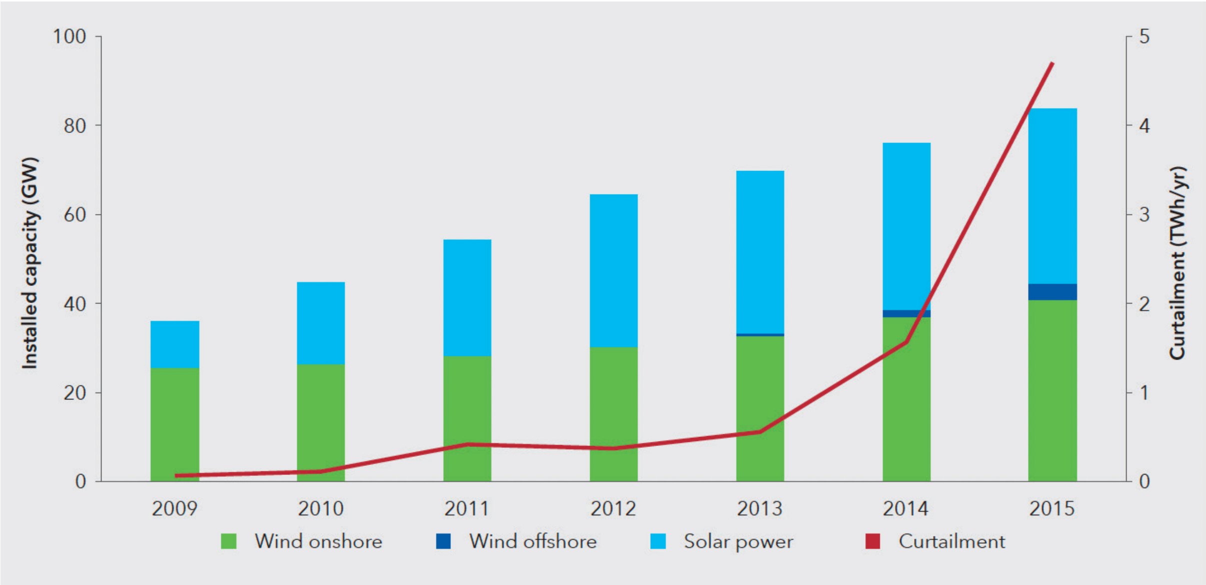
Figure 69 shows the case of Germany, where in 2015 a total of 4.7 TWh of electricity was curtailed, the overwhelming majority from renewables, impairing economic returns for the sector. (4.7 TWh is the amount of electricity that would be generated by a 540 MWh generator operating 24/7/365.)



Germany had an installed capacity of 44.5 GW of wind turbines and 39.3GW of solar power at the end of 2015. The average load profile in Germany fluctuates between 50 and 80GW on a work day and 40 and 60GW during weekends. When both renewable sources produce electricity at full capacity in periods of a lower load profile, there is surplus electricity generation. This situation occurred various times in 2015 resulting in 4.7 terawatthours (TWh) of electricity being curtailed (93% wind and solar power). The network operators had to pay compensations in total of €315 million (m). This amount is expected to increase in the coming years as grid extensions do not have the necessary velocity.

Figure 69. Wind and Solar Deployment and Annual Electricity Curtailment in Germany. Source: Bundesnetzagentur

.

5.1.1 : Advantages of P2G Deployment

Advantages of P2G deployment include a reduced need to expand or upgrade electricity transmission networks, and the facilitation of electric grid balancing through demand response and ancillary services. P2G can also help reduce the carbon intensity of natural gas supply, as discussed in section 4.1, and can leverage natural gas infrastructure and storage facilities.

Finally, P2G – as an application of electrolysis – can also facilitate the production of low carbon hydrogen as a zero-emission transportation fuel. In this application hydrogen has a much higher value than when used in natural gas networks, where it is valued purely on heat content.

5.1.2 : Barriers to P2G Deployment

A variety of barriers to P2G have impeded their greater deployment. Barriers have included:

Technology: the PEM electrolyzers best suited to P2G applications remain an early-stage technology.

Economics: though capital costs are expected to fall significantly, they remain high, limiting business cases for deployment.

Carbon pricing: carbon tariffs generally remain too low to incentivize commercial P2G efforts.

Lack of collaboration: a lack of collaboration between the electricity and natural gas grids has impeded P2G's use as a bridge linking the two energy infrastructures.

5.1.3 : P2G in Europe

Figure 70 shows the locations of 45 P2G demonstration projects underway in Europe as of October 2018. Germany is home to more than 30 of the demonstration P2G projects, comprising an electrolysis load capacity of approximately 25 MW.

The main challenges have related not to the technology, but to achieving commercial cost targets. Equipment cost reductions, efficiency improvements and policies such as renewable energy tariff structures are believed necessary for P2G to be viable beyond demonstration projects. (The CleanBC target for 15% Renewable Gas is an example of such a policy.)

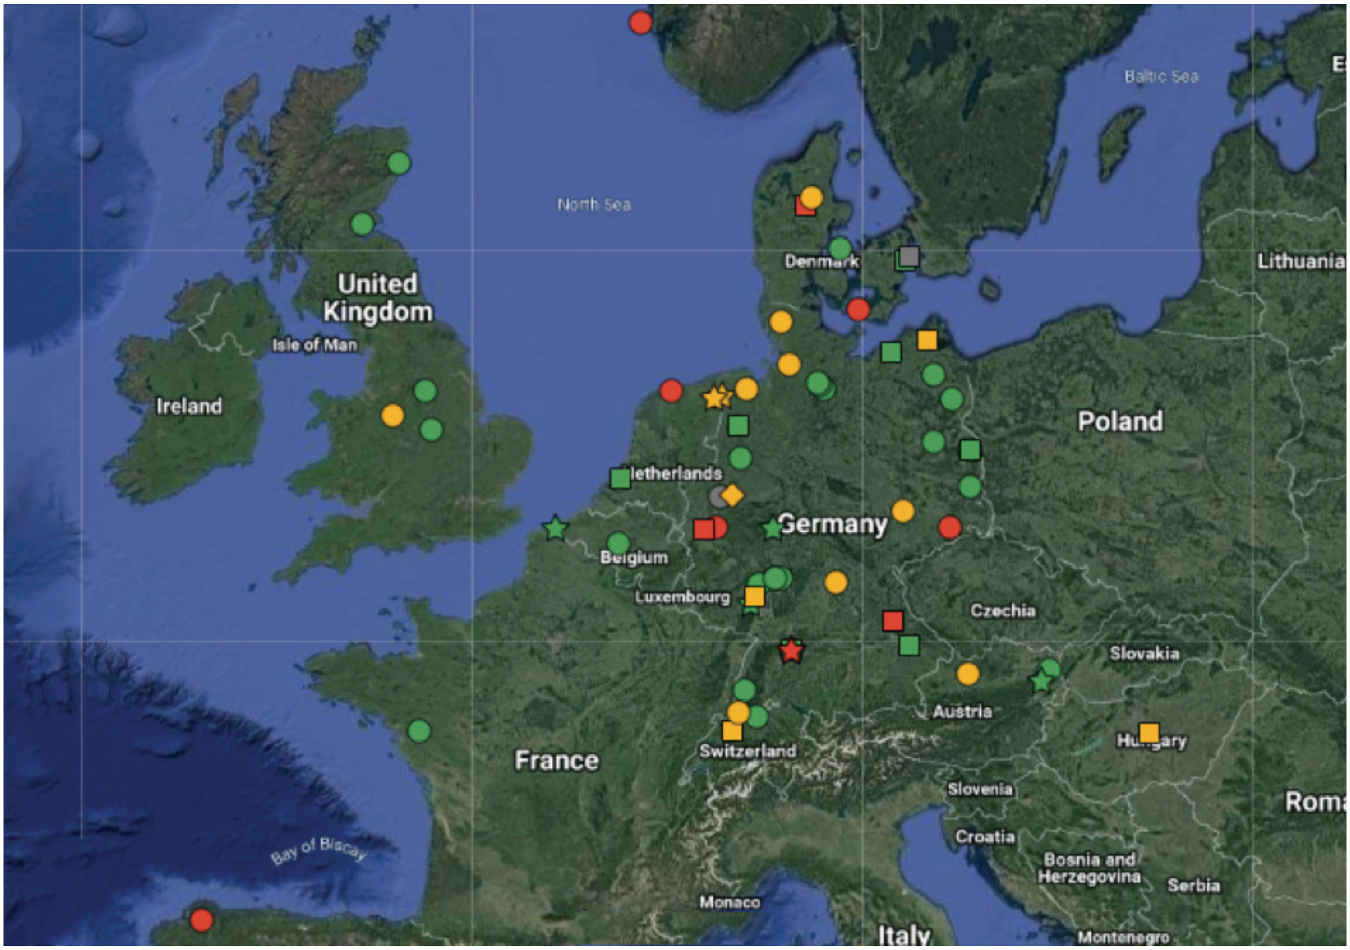


Figure 70. P2G Projects in Europe. Source: Europeanpowertogas.com

5.1.4 : P2G in North America

North America's first P2G facility began operations in Ontario in July 2018 when a 2.5 MW PEM electrolyzer from Hydrogenics was installed under contract to the Ontario Independent Electricity System Operator (IESO). The electrolyzer will provide grid energy demand response functions to the IESO and the hydrogen produced will be injected into the Enbridge gas distribution network.

In the United States, California utility SoCalGas has teamed with other organizations to run an electrolyzer powered by solar photovoltaics and inject renewable hydrogen into the campus power plant at UC Irvine. The utility has also established a partnership with the U.S. Department of Energy's National Renewable Energy Laboratory to install the United States' first biomethanation plant, located at the Energy Systems Integration Facility in Golden, Colorado.

5.2 : P2G Opportunities in BC

BC's geography provides an abundant supply of clean, renewable hydroelectricity, which with other renewables provides more than 90% of BC Hydro's annual production. Equally importantly, hydroelectric dams serve as a reservoir for storing and discharging energy. As variable renewables are added to the grid, hydroelectric dams alleviate the need for energy storage in the near-term.

There remain advantages to producing hydrogen via electrolysis in BC for use as a bridge linking the electric and natural gas energy systems. As an example, hydrogen produced via electrolysis could be used directly by utilities such as BC Hydro and FortisBC to optimize the use of their utility infrastructure.

5.3 : Recent P2G Developments

Hydroelectric utilities in the U.S. Pacific Northwest are developing plans to produce hydrogen to complement their energy offerings. The states of Washington and Oregon have conducted studies to determine opportunities for decarbonizing their energy systems, and the production of clean hydrogen from hydroelectricity for transportation fuels was found to be a strategic opportunity.

In April 2019, Substitute Senate Bill 5588 was signed in Washington State authorizing Public Utility Districts (PUDs) to produce, distribute and sell renewable hydrogen.[143] Douglas County PUD announced plans to be the first utility to do so; during periods of high river flows, solar and wind generation, it had resorted to spilling excess water. Hydrogen production would be a means of creating value.

It is anticipated that similar benefits could be realized by BC's utilities, so it is recommended that energy storage/ hydrogen production opportunities be evaluated further through pilot demonstration projects. Expanding the mandate of utilities to include the production, distribution and sale of hydrogen could also be a key enabler for increasing hydrogen supply in the Province.

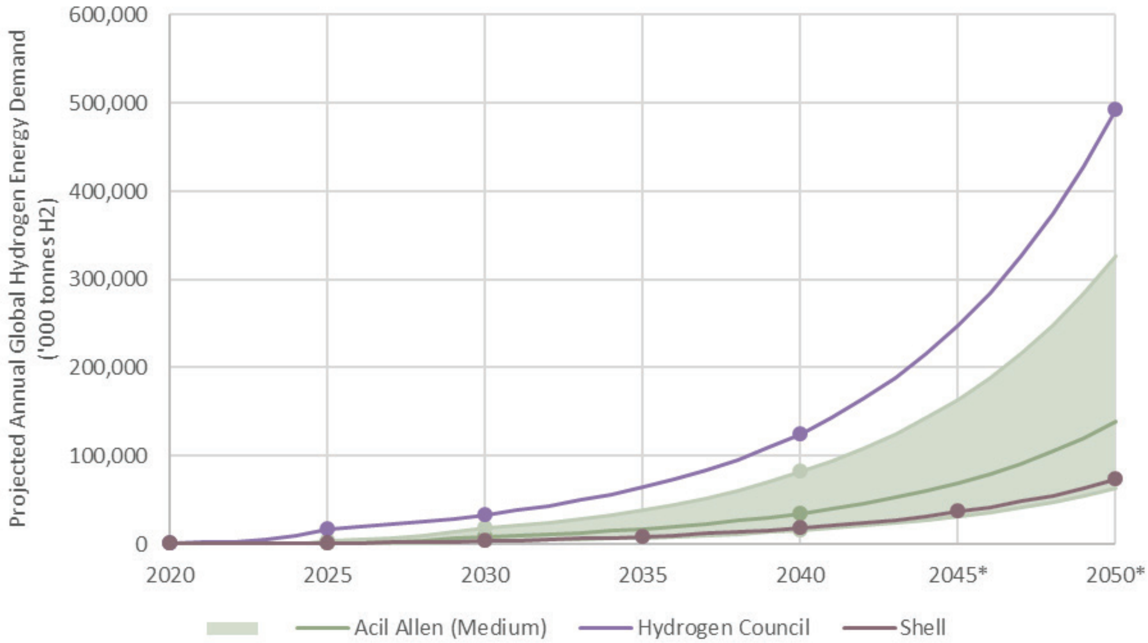
6.0 : Global Demand and Market Potential for Hydrogen

6.1 : Global Hydrogen Demand Projections to 2050

Hydrogen is expected to become increasingly important in the world's energy economy, though projections vary significantly based on assumptions around technology development and policy adoption. Figure 71 compares recent global hydrogen energy demand estimates from Acil Allen, the Hydrogen Council, and Shell.[144, 145, 146] Note that it does not include hydrogen use in industry.



**Acil Allen projections only provided to 2040. The 2050 values were estimated based on the year over year growth from the Hydrogen Council and Shell reports.*

Figure 71. Estimated Annual Global Hydrogen Demand (2020-2050).[144, 145, 146] Hydrogen consumption in industrial processes is not included.

144 Acil Allen Consulting. (2018). Opportunities for Australia from Hydrogen Exports. Retrieved from https://arena.gov.au/assets/2018/08/opportunities-for-australia-from-hydrogen-exports.pdf

145 The Hydrogen Council. (2017). Hydrogen Scaling Up: A Sustainable Pathway for the Global Energy Transition. Retrieved from http://hydrogencouncil.com/wp-content/uploads/2017/11/Hydrogen-scaling-up-Hydrogen-Council.pdf

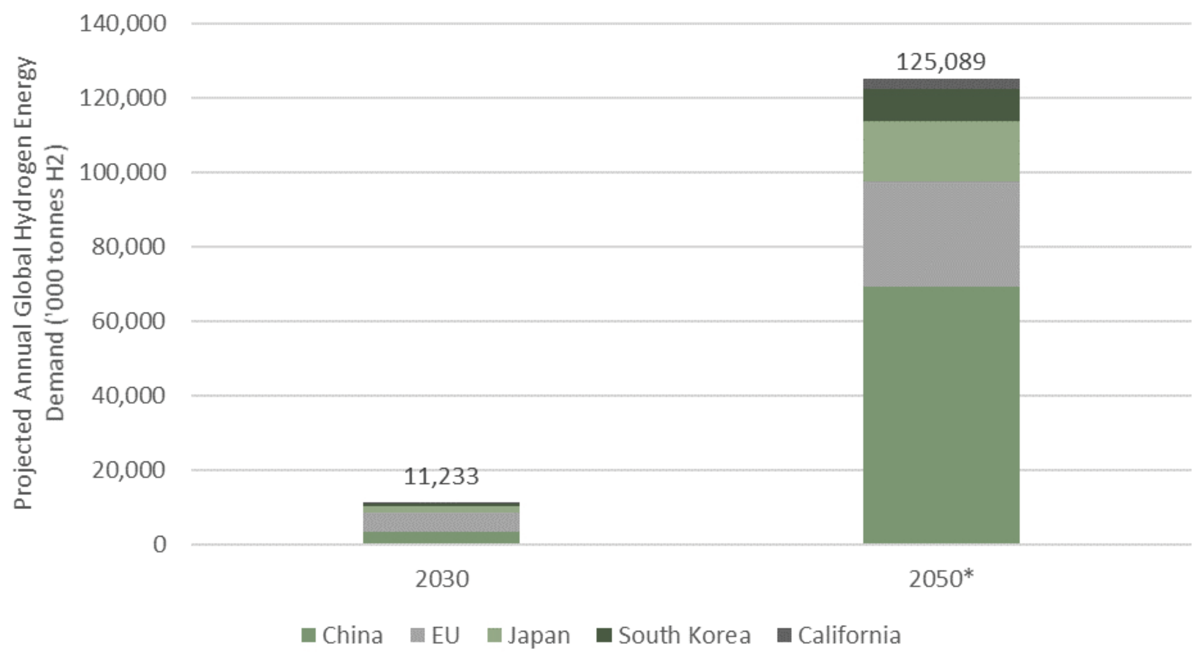
146 Shell. (2018). Shell Sky Scenario: Meeting the Goals of the Paris Agreement. Retrieved from https://www.shell.com/energy-and-innovation/the-energy-future/scenarios/shell-scenario-sky.html

Acil Allen provides low, medium, and high hydrogen uptake scenarios based on assumptions around the afore-mentioned technology development and policy adoption, as well as climate change and alternative fuel prices.[144] The Hydrogen Council projection is based on an ambitious vision in which hydrogen accounts for 18% of total energy demand in 2050.[145] Shell's Sky Scenario projects a slower uptake of hydrogen technologies, but still expects hydrogen to emerge as material energy carrier after 2040, resulting in 800 million tonnes of hydrogen demand for energy by 2070.[146]

Figure 72 shows the medium range estimate of hydrogen demand for regions which have placed the greatest emphasis on hydrogen technologies in 2030 and 2050. Figure 73 shows a range of estimates for each region individually. Demand projections for China, Japan and South Korea were based on Acil Allen.[144] EU projections were from FCH-JU[147] and California projections were from UC Irvine.[148]

Japan, China and South Korea – the world's three largest importers of liquefied natural gas (LNG) – have each embarked on ambitious hydrogen initiatives, which could explain the more aggressive projections. In California, the projections plateau around 2050 assuming hydrogen reaches its full market penetration potential.

Looking at these markets together, in 2030 and 2050 the total market size, based on the medium projection for each region, are 11.2 million tonnes per year and 125.1 million tonnes per year, respectively.



**Acil Allen projections only provided to 2040. The 2050 values were estimated based on the year over year growth from the Hydrogen Council and Shell reports.*

Figure 73. Estimated Annual Hydrogen Energy Demand of Selected Countries (2025-2050)

6.2 : Hydrogen Export Opportunity

As discussed in Section 3.0, BC has the potential to produce vast amounts of low-cost, low carbon hydrogen, leveraging the Province's abundant renewable electricity and natural gas resources.

BC's strategic advantages for producing hydrogen for export include:

- *Deepwater harbour accessible locations for the production and supply of large quantities of hydrogen to export markets, such as California, Japan, the Republic of Korea and China;*
- *An abundance of a very low carbon electricity with which to produce hydrogen through electrolysis;*
- *Large quantities of fresh water available for electrolysis; and*
- *An abundance of low-cost natural gas with which to produce hydrogen through SMR+CCS and pyrolysis.*

6.2.1 : Key Markets

Four key markets have been identified as viable export market for BC hydrogen: California, Japan, the Republic of Korea, and China. They are in closer proximity to BC than to other likely hydrogen exporters and have defined policies and programs to grow the development and use of clean hydrogen as an energy vector.

6.2.1.1 : California

California's projected hydrogen demand is expected to be as large as 1 to 4 million tonnes by 2050. The state is also a prime candidate to be an importer of renewable hydrogen in the future and has strong Governmental regulations and supportive funding for the initiation of a hydrogen supply infrastructure and deployment of fuel cell powered mobility.

6.2.1.2 : Japan

The Ministry of Economy, Trade and Industry (METI) from the Japanese Government developed the "Basic Hydrogen Strategy" (December 2017) for a plan of action until 2030, and, a future vision up to 2050. The prognosis for 2050 is for demand of between 5 to 35 million tonnes of hydrogen per year. The country is expected to be a very large importer of hydrogen and has already begun investigating supply options for importing large quantities of clean hydrogen in the future.

6.2.1.3 : The Republic of Korea

The Korean government has recently published its National Hydrogen Economy Roadmap. The prognosis for 2050 is for a demand of between 4 to 20 million tonnes per year.

6.2.1.4 : China

China is currently the leading region for the growth of renewable hydrogen and fuel cell market segments. The Chinese government is financially supporting these industries at the federal, provincial and municipal levels. The prognosis for 2050 is a demand of between 18 to 160 million tonnes per year.

6.2.2 : Storage and transport technologies

Hydrogen storage and transport from production hubs to users' sites will be one of the more challenging obstacles for the large-scale global adoption of hydrogen as a renewable energy vector. Liquefaction and chemical storage, in the form of chemical carriers, are treated in section 2.2.

6.2.3 : BC's Positioning

BC currently lacks a clear position on the importance of developing a hydrogen export market, in part because the demand for hydrogen is just starting to grow. In addition, BC has not currently developed any sources of hydrogen supply.

Australia would be a major competitor to BC in the Asian target markets identified above and has developed both a national roadmap and a strategy to guide development of a hydrogen export sector. It can also leverage decades of experience as an LNG exporter.

The size of the potential hydrogen export market for BC is significant. In 2030 and 2050, respectively, the total market size of the four combined target markets of China, Japan, Korea and California is expected to be $87 billion and $305 billion, respectively. If BC were to capture just 5% of these markets, this would represent export revenue potential of $4 billion in 2030 and $15 billion in 2050. Not only would this bring new export revenue to the Province, but it would stimulate local employment growth and would likely attract foreign capital investment.

The development of large-scale hydrogen export markets would create high enough production volumes that the cost of hydrogen in the Province would decrease. This would stimulate additional in-Province deployment, as lower cost hydrogen would improve the business case of switching from fossil fuels.

A SWOT (strengths / weaknesses / opportunities / threats) analysis is presented in Table 18 below.

STRENGTHS	WEAKNESSES
◆ *Abundance of renewable electricity for electrolytically produced hydrogen* ◆ *Relativley low-cost electricity for hydrogen production* ◆ *Abundance of water for electrolysis* ◆ *Close proximity to numerous large import markets via ocean freight* ◆ *Large source of natural gas supply for the production of clean hydrogen using SMR and CCS* ◆ *Export focused communities and sites along the BC West Coast* ◆ *Availability of deep water harbours to handle large ocean going vessels for export*	◆ *Clearly defined government policies, objectives and strategies to support and grow the clean hydrogen export markets* ◆ *The need to develop additional incentives to support the competitive production and supply of clean hydrogen to export markets* ◆ *Cost reductions in the production of clean hydrogen production technologies required to meet the various target prices for clean hydrogen in numerous global markets and related segments*
OPPORTUNITIES	**THREATS**
◆ *Business and job growth for local, remote communities and First Nations in BC* ◆ *Large future demand markets including California, Japan, Republic of Korea and China relatively close to BC* ◆ *The opportunity for multinationals involved in the clean energy economies to invest in BC* ◆ *Growth of the BC hydrogen related research and technology development* ◆ *The ability for BC to play a positive role in the reduction of GHG by producing and exporting large quantities of renewable hydrogen* ◆ *A large hydrogen export economy in BC will support low-cost domestic market needs*	◆ *Competition from Australia that has established a clear government-led strategy to produce and export large quantities of renewable hydrogen in the future* ◆ *Loss of the strong hydrogen and fuel cell resource base in BC to competitive regions around the globe*

Table 18. BC Hydrogen Export SWOT Analysis

7.0 : BC's Competitive Advantages and Disadvantages in Hydrogen and Fuel Cells

Canada's hydrogen and fuel cell sector is recognized as a global leader. In 2018, the industry generated revenue of $207 million and was responsible for 2,177 jobs. British Columbia, as the "cradle of the modern fuel cell industry", is home to Canada's largest hydrogen and fuel cell industry cluster as shown in Figure 74.

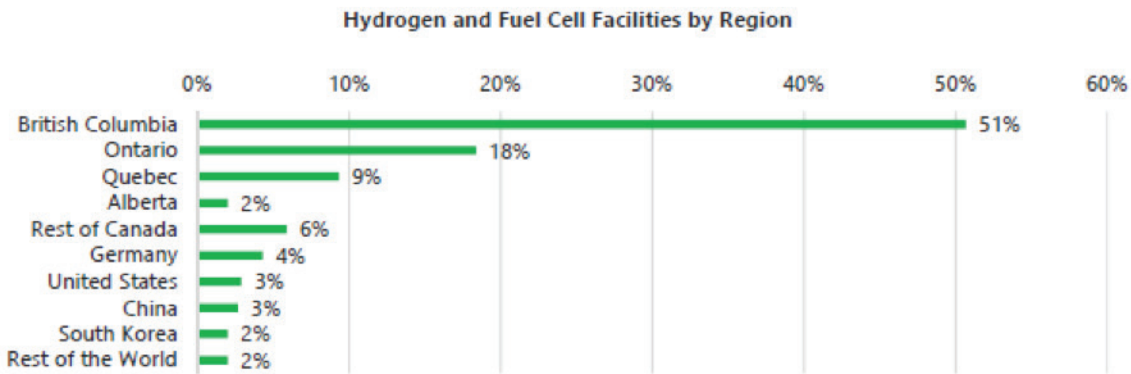

Figure 74. Hydrogen and Fuel Cell Facilities by Region[150]

BC's cluster has advanced technologies for hydrogen production and processing, equipment and systems testing, has undertaken world-leading research, development and commercialization, and has played a leading role in standards development. The Province is also home to world-class academic institutions supporting the clean tech sector. Centres of Excellence have been established at the University of British Columbia (UBC), the University of Victoria (UVic), Simon Fraser University (SFU) and the University of Northern British Columbia (UNBC).[149]

7.1 : Competitive Advantages and Recommendations

7.1.1 : Fuel Cells

BC is a global leader in the fuel cell sector, the industry cluster having been formed around Ballard Power Systems 40 years ago. Industry-academic collaborations and state of the art research and development facilities have created a recognized talent pool and recently led Austrian automotive consulting company AVL to establish its fuel cell research and development centre in Burnaby. Canadian companies such as Ballard Power Systems, Loop Energy, Hydrogen Technology and Energy Corporation (HTEC) and Powertech are also recognized as international leaders.

149 *UBC: Centre for Energy Systems Applications, Centre for Interactive Research on Sustainability and the Institute for Resources, Environment and Sustainability. SFU: School of Mechatronics. UVic: Institute for Integrated Energy Systems. The aforementioned and UNBC are all involved with the Pacific Institute for Climate Change Solutions.*

150 *CHFCA. (2018). Canadian Hydrogen and Fuel Cell Sector Profile. Retrieved from http://www.chfca.ca/media/CHFC%20Sector%20Profile%202018%20-%20Final%20Report.pdf*

7.1.2 : Potential Producer of Hydrogen – Natural Resources

BC is well positioned to become a bulk producer of hydrogen given its:

- *clean, renewable, low-cost hydroelectric resources;*
- *abundant, low-cost natural gas and supporting distribution network;*
- *proximity to major markets.*

The carbon intensity of BC Hydro's electricity generation is one of the lowest in North America, meaning hydrogen produced through electrolysis would have a very low carbon footprint.

As noted in prior sections, BC's low-cost natural gas can provide another path for supplying cost-competitive hydrogen, even when CCS costs are factored in.

Finally, BC's coastal access and relative proximity to leading markets such as California, Japan, South Korea and China put the Province in an excellent position to become an exporter of clean hydrogen. The Province's economy is heavily dependent on the export of natural resources, and hydrogen is a means by which BC can provide energy exports without emissions.

7.1.3 : Hydrogen Infrastructure

Vancouver is home to the first public hydrogen refueling station in Canada, part of a network of stations being built in the Metro Vancouver and Capital Region Districts. As demonstrated in California and elsewhere, fuel infrastructure leads the deployment of fuel cell electric vehicles, resolving the so-called "chicken-and-egg" dilemma. BC's investments in hydrogen fueling infrastructure provide a signal for auto manufacturers to make their FCEVs available for sale in this province.

7.1.4 : Recommendations

7.1.4.1 : Provincial Project Deployments

Products from BC's hydrogen and fuel cell industry cluster are deployed in the United States, Europe and Asia, but there are currently no deployments of BC hydrogen and fuel cell technology within the Province.

Local deployments of technology are key to maintaining employment, technical expertise and intellectual property in-province; ownership also tends to shift to where deployments occur. A recent case is that of BC's Corvus Energy, a pioneer in the use of battery energy storage systems for marine applications. Norway was home to many of its early product deployments, and by 2017 ownership stakes had been taken by Hydro and Statoil Technology Invest (both Norwegian) and BW Group (headquartered in both Norway and Singapore).[151]

It is strongly recommended that the Province deploy hydrogen and fuel cell technology from its own cluster, within-province. This would help root BC's sector expertise in British Columbia and would encourage international participants to locate themselves in-province as well. Deployments and pioneering lighthouse projects would strengthen the local cluster, provide additional opportunities for collaboration between industry and academia, and help BC businesses develop world-leading expertise they can export to slower-moving jurisdictions.

151 *Corvus Energy. (2017). Global Aluminum Supplier Makes Significant Investment in Corvus Energy. Retrieved from* https://corvusenergy.com/global-aluminum-supplier-makes-significant-investment-in-corvus-energy/

7.1.4.2 : Lead a Coordinated BC Cluster Strategy

Although BC is recognized as a centre of hydrogen and fuel cell expertise, companies involved in the sector operate very independently. At the federal level, the Canadian Hydrogen and Fuel Cell Association (CHFCA) provides a mechanism to pull companies in the sector together, but more is needed at the Provincial level to encourage and support stronger joint initiatives locally.

An organization similar to the California Fuel Cell Partnership (CaFCP) or Hydrogen Valley in Denmark could help coordinate industry and academia collaborations and work to ensure that companies are operating in step with each other as technology is brought to market. A provincial association could assist with initiatives to help Academia develop curriculum that will support talent development to grow the cluster. The association could also provide coordinated media efforts and outreach activities to educate the public about hydrogen and fuel cell initiatives occurring locally in our Province as well as abroad.

A Stream 5 Application through the Strategic Innovation Fund[152] could also be developed to support a coordinated cluster strategy for hydrogen and fuel cells.

7.2 : Competitive Disadvantages

7.2.1 : No Deployments in the Province

Despite being a leader in hydrogen and fuel cell R&D, there are no current technology deployments in the province. Local deployment of technology is key for BC companies to showcase their technology to attract investment, increase their scale of operations, improve their market readiness and support continued industry advancement.

Deployments of fuel cell buses, using world class fuel cell technology developed in BC, are well established in Europe, China and the US. Unfortunately, locally, there are no fuel cell bus deployments and no support from local transit authorities to consider fuel cell technology as a clean energy alternative. Support is needed to encourage technologies developed in BC to be demonstrated locally.

Without local project deployments, critical technical skill sets in manufacturing and operations, necessary for scaled up operations and commercialization, are not being developed. And although local academic institutions have supporting clean energy programs, relevant practical training, necessary for students to succeed in fuel cell sector jobs, is not being provided. An integrated project deployment with collaboration of industry and academia, could guide academia to develop appropriate curriculum to meet future skill set requirements in the sector. It would also ensure that knowledge and hands-on technical skills required to grow the sector beyond the R&D phase are created within the province.

The high cost of living in Vancouver also contributes to scarcity of technical personnel as it makes it difficult to both attract, and keep, skilled personnel.

152 *Innovation, Science and Economic Development Canada. (2019). Stream 5: National Ecosystems. Retrieved from https://www.ic.gc.ca/eic/site/125.nsf/eng/00017.html*

7.2.2 : Lack of Provincial R&D Funding

Investment is needed to maintain the province's leadership role in hydrogen and fuel cell R&D. Mid-TRL level projects are the most effective in developing technology and creating jobs, but currently in BC, there is no funding to support these types of projects.

Local organizations require access to funding that can be leveraged to access greater funds from outside entities. For example, a recent federally funded Ballard Power R&D project was moved from BC to Ontario because there was no provincial funding available in BC, which was required to access the federal funds.

NRCan no longer funds R&D and funding that is available, such as IRAP on a federal level, is spread thinly, with relatively modest sums. Funding can also be limited for larger companies or those with large parent companies. For example, AVL opened a fuel cell technology R&D centre in Vancouver because Vancouver has the largest cluster of fuel cell expertise in the world and can provide a solid base on which to further develop their fuel cell technology and commercialization plans. By locating in Vancouver, AVL creates additional jobs in the cluster and advances the technology, but because of its large parent company, is not eligible for funding.

Ballard has also hit the small to medium-sized enterprise (SME) limit on their eligibility to access local funding as their company size now exceeds 500 employees. As a result, Ballard is opening a Fuel Cell Centre of Excellence at their facility in Hobro, Denmark which will allow them to take advantage of $900 Million in funding available for European projects. Denmark will benefit from the jobs and technical skills developed at this CoE.

7.2.3 : Competitive Threat from China

China is investing heavily in hydrogen and fuel cell technologies and is preparing to deploy on a massive scale. It has aggressively pursued investment in foreign technology, and with its requirement for local content, foreign companies are establishing joint venture facilities in China.

Ultimately, China's large-scale development of fuel cell technology will drive down costs, benefitting the entire

BALLARD DEVELOPING NEXT-GEN FUEL CELL WITH ONTARIO UNIVERSITIES

The Canadian Urban Transit Research and Innovation Consortium (CUTRIC) is funding a collaborative project between industry, academia and government to develop low-cost, high performing durable fuel cells for next generation transit and automobile applications.

Project Partners: *University of Waterloo (Principal Investigator), Western University, Ballard Power Systems Inc.; and, StarPower ON Systems Inc.*

Funding: *CUTRIC, NSERC CRD, Industry Partners.*

BALLARD ESTABLISHING COE IN EUROPE

Ballard will establish a Marine Centre of Excellence (CoE) at its engineering, manufacturing and service facility in Hobro, Denmark.

The CoE will focus on development of next generation heavy-duty fuel cell module targeted for European marine applications with commercial launch planned for late 2019.

BALLARD-WEICHAI POWER COLLABORATION IN CHINA

Ballard has entered a strategic joint venture with Weichai which will see Ballard's next generation LCS fuel stack and fuel stack modules for buses and heavy-duty trucks manufactured in China.

industry, however, it comes at the expense of jobs and IP being created in China. As an example, Ballard is entering into a strategic joint venture with Weichai Power in China which will allow them to take advantage of the investment opportunities and enormous market size that China has to offer.

7.2.4 : Recommendations Moving Forward

(1) **Identify Hydrogen and Fuel Cells as a Priority Sector**

Despite its global leading status in fuel cell technology, this sector has not been explicitly identified as a priority by the Province. During discussions involving clean technology, such as zero emission vehicles, the focus is often entirely on BEVs, with FCEVs left out of the discussion altogether. As an example, the current Federal incentive cap of $45,000 for Zero Emission Vehicles eliminates fuel cell vehicles as an eligible option as the technology is still pre-commercial and no FCEVs fall within this threshold.

The Province needs to communicate strongly and consistently to the Federal Government that hydrogen and fuel cells are an important priority sector for BC.

(2) **Provincial R&D and Deployment Funding Support**

It is important for the Province to commit to research, development and deployment funding over the longer-term. Local organizations should have access to funding that can be combined with matching funds from the Federal government or leveraged to access greater funds from outside entities. Companies in the Province also struggle with reduced federal R&D funding, as NRCan has shifted its focus from R&D to infrastructure deployment.

The ARC program supports BC companies operating in the clean electric vehicle (CEV) sector and encourages international investment. The ARC fund could be expanded to support technologies beyond transportation and provide a base for matched federal funding.

(3) **Support for Maintaining Leadership**

It is recommended that the Province adopt an industrial policy of assisting BC companies in navigating the Chinese market. In the case of fuel cells, the BC sector would be advised to identify competitive advantages, such as the manufacturing of highly automated parts, that cannot be easily replicated by Chinese competition. Investment and policy support are necessary to keep the companies, jobs and technical knowledge in BC.

Canada has strong federal support organizations that may be able to assist in facilitating technology exchanges between China and BC. Establishing “sister province” initiatives with projects operating in parallel may provide a mechanism to overcome China’s strong preference to localize manufacturing.

7.3 : Opportunities for Innovation Leadership

The areas for BC innovation leadership can be divided into the categories of policy, investment and technology.

(1) **Policy**

BC can be a global leader by adopting policies that promote and support all sides of an emerging hydrogen economy including demand, supply and technology development. Any policy needs to maximize the GHG reduction impact, manage the cost issues associated with the change-over and allow the market to act in terms of technology selection. BC is rich in two key natural resources for the production of clean hydrogen: natural gas reserves and renewable hydroelectricity. Our policies should set BC as the global leader in hydrogen production from both of these assets with a clear understanding of how their inherent cost structure will drive market adoption. Specifically, decarbonized hydrogen from hydrocarbon sources will be cheaper and thereby adopted earlier, but at the same time, the policies should encourage the gradual transformation from the lower cost natural gas-sourced hydrogen to the more expensive fully renewable hydrogen as the finite hydrocarbon sources are depleted over time.

(2) **Investment**

BC can strongly drive innovation leadership by where and how it chooses to invest its capital. BC has had global innovation leadership over hydrogen and fuel cells in the past and there continues to be key innovation resources resident in BC to this day. However, because there has been only ad-hoc investment continuity, other areas in the world have largely taken over this innovation leadership position.

These competing regions include China – who have been actively hiring BC experts to bolster their own innovation leadership; Japan and Korea – countries who have declared their commitment to developing a hydrogen economy and are heavily investing in low-cost hydrogen production technologies, import systems, and hydrogen and fuel cell vehicles; the UK is conducting public trials of using hydrogen in NG networks; Germany is focussing on storing excess renewable energy using power-to-gas.

BC does well in the generation of large clean energy companies such as Ballard Power Systems, Carbon Engineering, InvenTys and General Fusion largely because of past investments in fuel cell and hydrogen through Ballard and other initiatives in the past. This had the effect of creating highly experienced, clean technology venture professionals who have spurred other innovation and venture creation. The Province can become a global leader in the development of hydrogen economy by investing in:

1) ***Revitalization of the Innovative Clean Energy (ICE) Fund***. The ICE fund plays an important role in the early stage infrastructure of BC's clean technology community and more funding will be essential to help foster the next generation of innovative clean energy companies.

2) ***Development of large H_2 infrastructure initiatives***. Large programs such as those being enacted in the UK and Japan will catalyze and concentrate the technology innovation required to execute these programs in sustainable techno-economic fashion. Examples of programs that could be enacted in BC are listed below. For each of these programs, there should be 'customer requirements' such as carbon intensity (CI) limits and cost targets established to which the sector must innovate.

    a. Build large decarbonized hydrogen production and CO_2 sequestration facilities in the Peace Region where BC can utilize its NG resources to provide decarbonized hydrogen into the NG grid for provincial or export use.

    b. Convert government fleets to fuel cells and hydrogen with stricter carbon intensity limits and cost criteria than the previous bus program in Whistler.

    c. Convert an entire community or area (such as UBC or a remote community) to hydrogen including production, storage, delivery and end use (vehicles, power, and heat) with a zero GHG emission target

    d. Build large LH_2 liquefier(s) in the province to help support low-cost transport of hydrogen fuel to market demand sites.

    e. Establish pilot facilities co-located at the Kitimat NG export terminal for the export of hydrogen produced in BC to the emerging global markets.

3) ***Tax incentives*** – Provide all investors in hydrogen and clean technologies with tax exempt status for their investments and create tax credits for business and individuals buying hydrogen and hydrogen related projects.

(3) **Technology Innovation**

a. ***Low-Cost Green and Blue Hydrogen Production***

Innovation is required to develop new production methods that can produce industrial quantities of hydrogen at a cost structure that is as low as current NG costs plus BC's CO_2 avoidance incentives. This means that the hydrogen will likely need to be under \$10/GJ (equivalent to \$1.20/kg H_2) to get industrial, commercial and residential consumers to take up the fuel without forcing regulations. In addition, if these costs can be achieved, the use of hydrogen as a vehicle fuel or as an input to the production of renewable synthetic fuels will become more widespread.

The specific areas of innovation include:

- *Low-cost NG pyrolysis technology to produce hydrogen and solid carbon from NG and other hydrocarbon feedstocks.*
- *Technologies and processes to utilize and monetize the emerging and plentiful carbon feedstocks to help offset costs of NG pyrolysis H_2 production methods.*
- *Lower cost and higher efficiency electrolysers including those that can operate at vehicle refueling pressures.*
- *Lower cost and less energy intensive technologies to convert renewable CO_2 and H_2O into H_2 and CO as feedstocks for renewable synthetic fuels.*

b. ***Hydrogen storage and delivery***

H_2 delivery and storage are key parts of any hydrogen economy. Hydrogen needs to be transported to the consumer as either a liquid or a gas. Areas of innovation include:

- ***Liquefaction*** *– Low-cost H_2 liquefaction will be essential for the delivery of H_2 to different customer sites, particularly refueling sites. Liquid hydrogen (LH_2) is transported and delivered at a much lower cost than compressed H_2 (CH_2). As BC develops a H_2 economy, it is possible that BC could become a net exporter of hydrogen to the world energy markets and would have further incentives to develop low-cost LH_2 liquefiers. Large baseload LNG plants are approaching ideal efficiencies but H_2 liquefaction costs are high and energy intensive – there is a long way to go. As well, technical innovation will be required on how to best recover LH_2 exergy since it is much higher than LNG due to lower liquefaction temperatures and ortho to para conversion. The Institute for Integrated Energy Systems at the University of Victoria (IESVic) has been researching novel hydrogen liquefaction and exergy recovery technologies since 1990 and is well suited to play a key role.*
- ***Pipelines*** *– A hydrogen economy will use as much of the sunk infrastructure as possible. In the case of the NG grid, BC already has a fully developed mature gaseous fuel distribution system. At present, BC can likely inject up to 10-15% of H_2 by volume in the NG grid without modification. To get to higher hydrogen utilization, the pipelines will either have to be replaced with pipelines made with hydrogen compatible materials or we will innovate a way to modify the existing pipelines in-situ in a cost-effective way.*
- ***Gas Separation*** *– The production and distribution of hydrogen requires separation of hydrogen with other gases. In typical cases, this can be accomplished with mature pressure swing absorption (PSA) technology. However, in certain production methods, H_2 will need to be separated from combusted gases and nitrogen which is not as straightforward. When H_2 is mixed with NG in the grid, there will likely be many instances where it will be advantageous to separate the H_2 at sites where demand is the highest and these sites are unlikely to correspond with pressure let down stations where PSA technology could be used. There needs to be innovation in low-cost hydrogen separation technologies such as membranes and electrochemical methods.*
- ***Other Hydrogen Storage*** *– LH_2 is an important way to store hydrogen but suffers from high capital costs. Other innovative storage technologies include cryo-compression, solid state storage, liquid organic storage, adsorbents, and non-carbon chemical carriers such as ammonia.*

c. ***Grid optimization using electrolysis hydrogen***

The electrolysis hydrogen production pathway offers unique opportunities to connect the electric grid and natural gas energy infrastructure in an optimized and efficient system. Innovative technology development includes grid monitoring and control systems, integration technologies that span the electrical and gas grid control systems, predictive Artificial Intelligence (AI) technologies that anticipate intermittent power production and storage variables.

d. ***Fuel cells***

BC still arguably holds an innovation edge in fuel cell technology. However, that hold is tenuous at best as other jurisdictions around the world ramp up their programs, particularly China. Increased R&D support for fuel cell materials, components, and systems is important for BC to maintain its position at the forefront of the industry.

e. ***Carbon and CO_2 sequestration***

The production of low-cost hydrogen from NG will produce either carbon or CO_2. Currently, CO_2 sequestration technology is mature. However, exploration of other sequestration sites in BC such as the off-coast sea beds will be important to create a network of sequestration sites that are closer to H_2 production sites. Innovation in carbon utilization methods will also be important. The amount of carbon created over the next decades will be substantial. Economic carbon use such as agriculture land applications, construction materials, and power production will require innovation. As well, further innovation for sequestration of solid carbon (Pyrogenic CCS[153]) without CO_2 production on land and in oceans is required.

f. ***Renewable synthetic gaseous and liquid fuels***

Renewable or decarbonized hydrogen and CO_2 from renewable resources are the most important feedstocks to renewable synthetic gaseous and liquid fuels. Currently, both of these feedstocks are too expensive. Opportunities for technology innovation leadership for these fuels are:

a. Low-cost decarbonized or renewable hydrogen (discussed above),

b. Low-cost environmental carbon dioxide capture from both the atmosphere and the oceans for CO synthesis,

c. Electrolysis, photo-electrolysis and other advanced methods for processing both water and renewable CO_2 together into H_2 and CO. Depending on the technology, the amount of hydrogen required for synthetic diesel for example could be reduced by up to 1/3 if the CO_2 reduction method can entirely avoid the reverse water-gas-shift reaction to produce the CO.

8.0 : Mid-term And Long-Term Hydrogen Cost Potential and Demand in BC

8.1 : Hydrogen Demand

As described in Section 4.0, hydrogen demand was estimated in the natural gas, transportation, industrial, and remote community sectors based on aggressive and conservative scenarios. Hydrogen used in the built environment was also considered, but the only significant use of hydrogen in the built environment is expected to be through injection in the natural gas grid. To avoid double counting, this hydrogen was attributed to the natural gas sector. The estimated demand in each sector should be considered a projection of what will occur in BC but represents what demand could be if certain policies are adopted and given certain rates of technology development.

Each sector was considered in isolation from the others, so the resulting demand is not necessarily additive. The most significant example of this is the interaction between industry and transportation. The estimated hydrogen demand in the industry sector is based on the production of synthetic fuel that will reduce the carbon intensity of liquid fuels to satisfy the Renewable & Low Carbon Fuels Program. In our analysis, the demand for liquid fuel remained constant from year to year. However, if hydrogen fuel cell and battery electric vehicles reach mass adoption, as predicted in the transportation sector in this analysis, liquid fuel demand in BC is likely to reduce significantly over time.

Figure 75 shows the estimated aggregate demand in the Province for the aggressive and conservative scenarios from 2020 to 2050. In the aggressive scenario in 2050, demand could reach as high as 1,445 kilotonnes/year annual demand. This number is less than half the estimated annual supply.

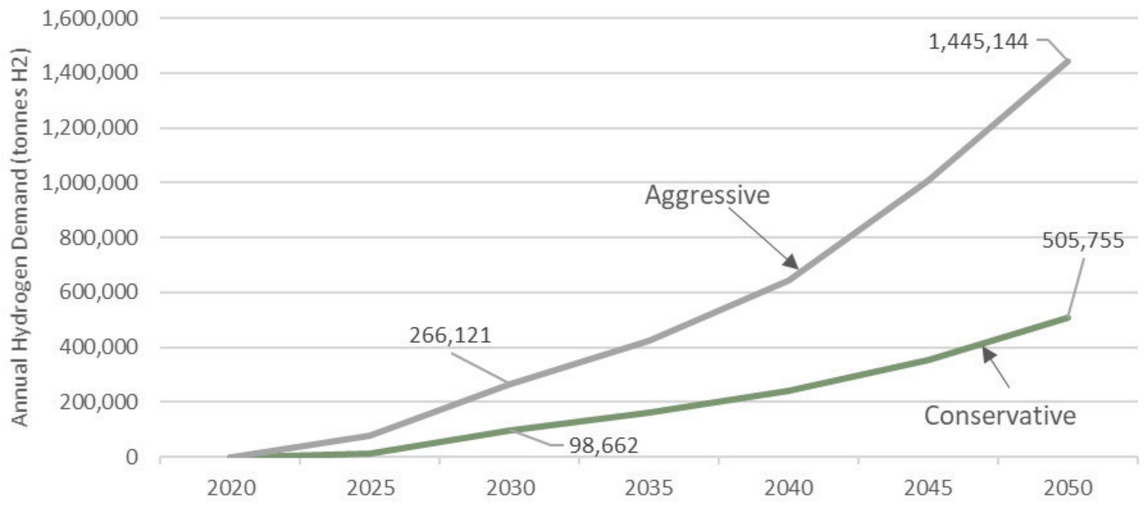

Figure 75. Aggregate Conservative and Aggressive Hydrogen Demand (2020-2050)

ZEN

Figure 76 and Figure 77 show the conservative and aggressive hydrogen demand scenarios from 2020 to 2050 by sector, and Figure 78 shows the detailed breakdown by sector in 2030 and 2050.

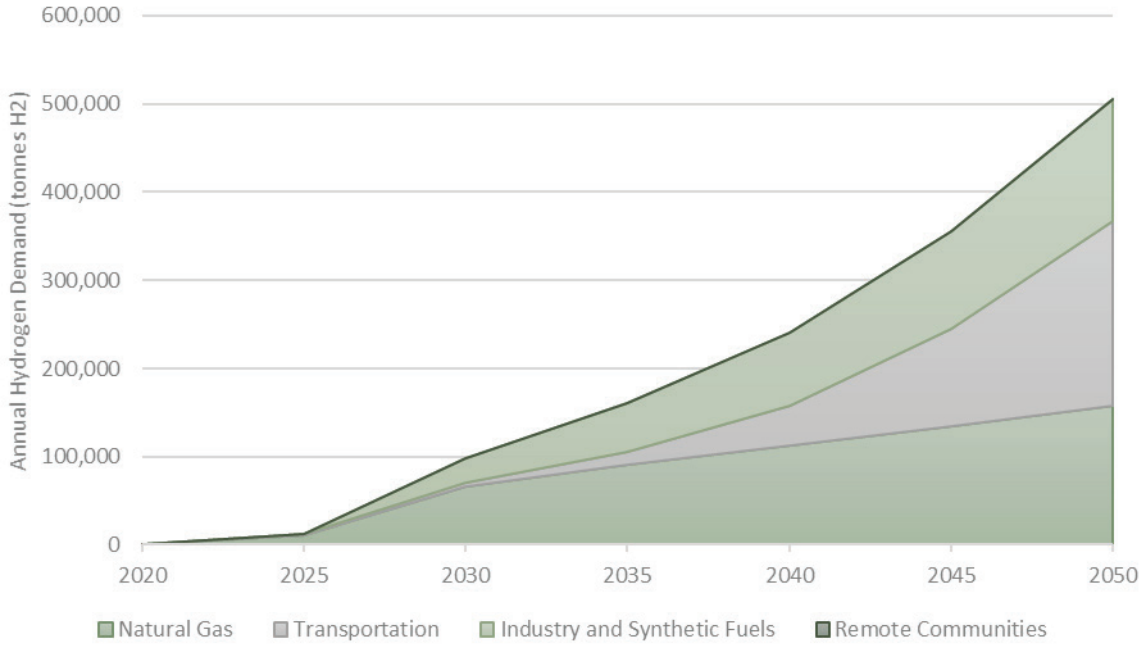

Figure 76. Conservative Aggregated Hydrogen Demand by Sector (2020-2050)

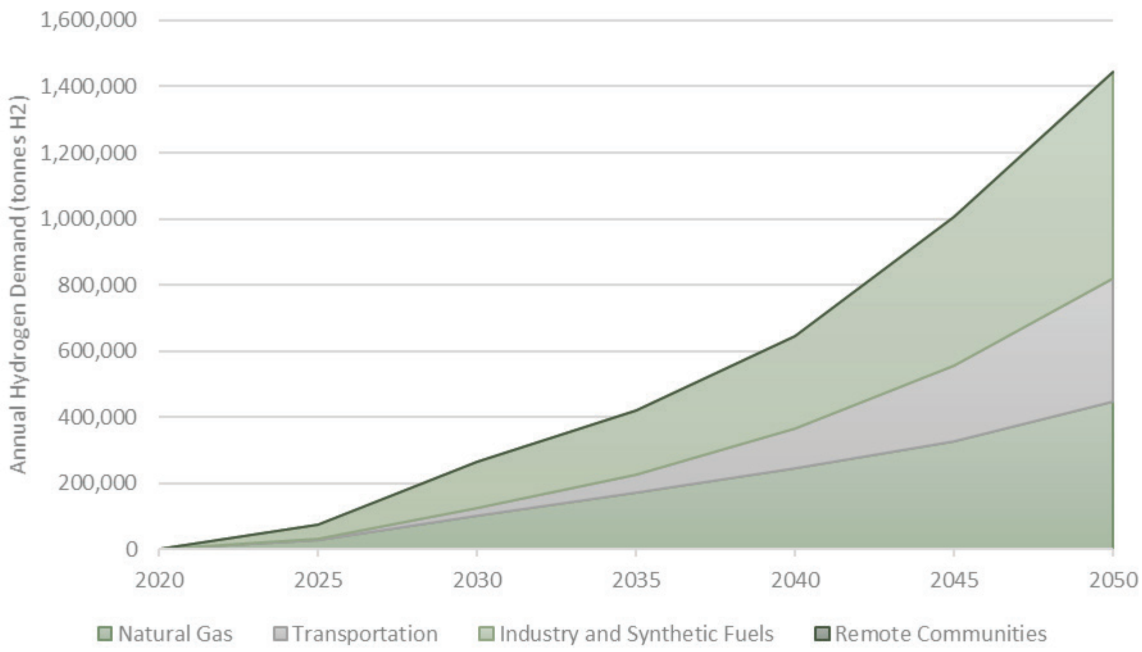

Figure 77. Aggregate Aggressive Hydrogen Demand by Sector (2020-2050)

Initially, the industry and natural gas sectors offer the greatest potential for hydrogen consumption, but by 2050, the transportation sector will play a significant role.

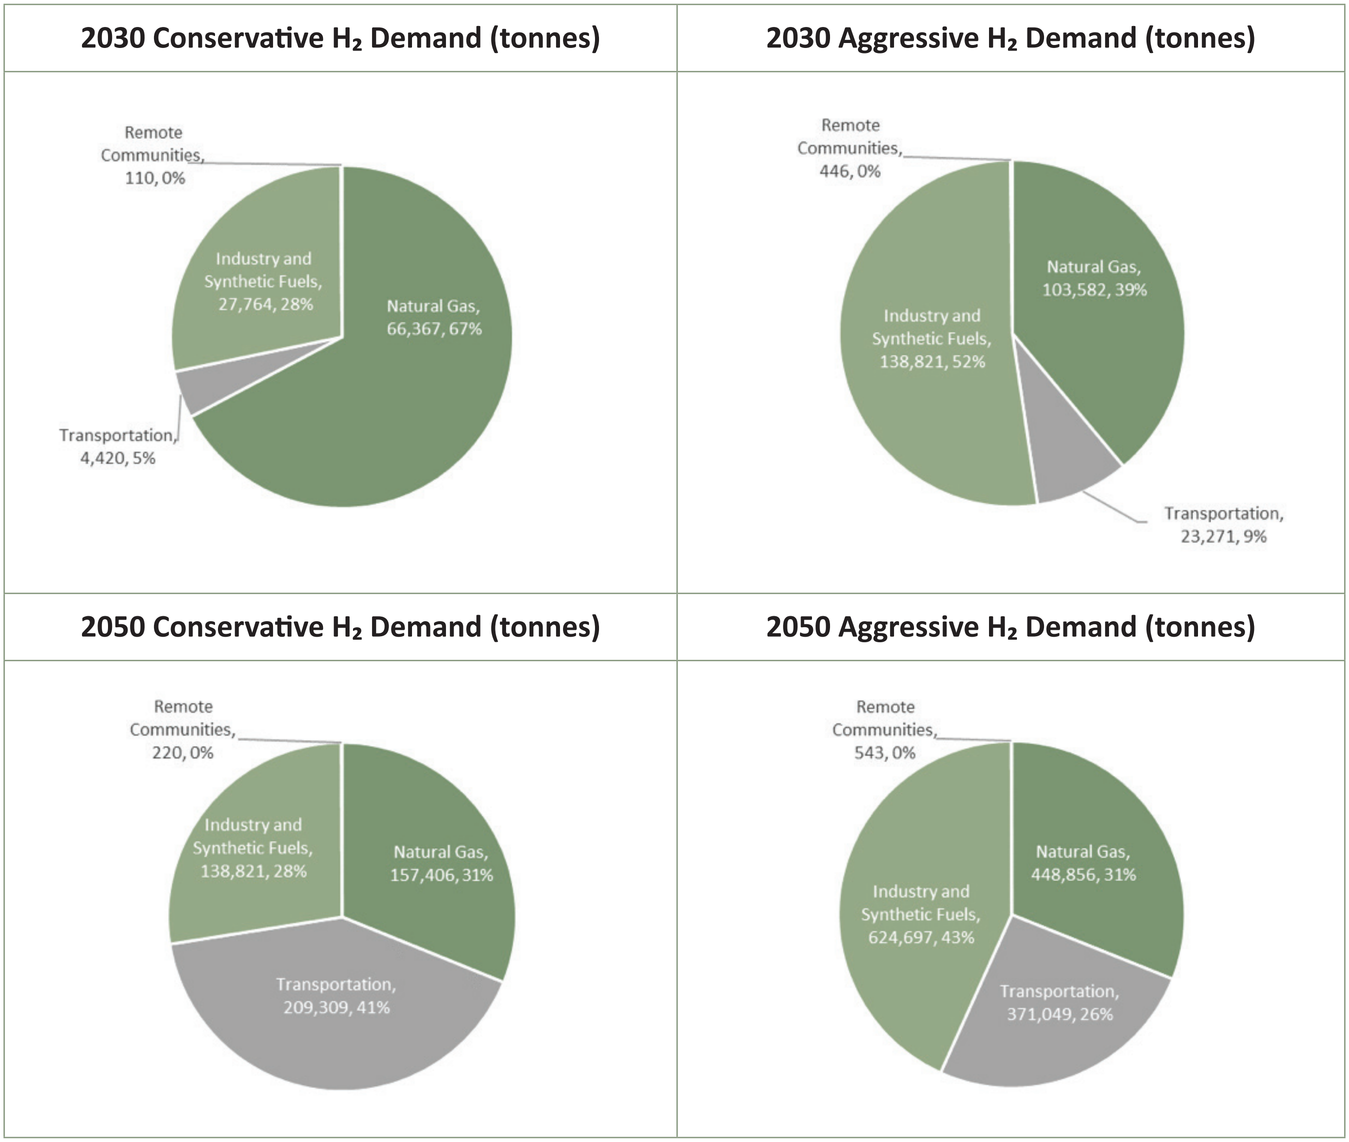

Figure 78. Conservative and Aggressive Aggregate Hydrogen Demand in tonnes by Sector (2030 & 2050)

8.2 : GHG Emissions Abatement

As described in detail in Section 4.0, hydrogen has the potential to reduce GHG emissions from each sector investigated in this study. Figure 79 shows the estimated aggregate GHG emissions that could be abated in the Province for the aggressive and conservative scenarios from 2020 to 2050. In the aggressive scenario in 2050, the reduction is 15.6 Mt CO_2e, which represents 31% of the Province's target to reduce emissions by 80% compared to a 2007 baseline. The conservative scenario estimates the reduction to be 7.2 Mt CO_2e, which represents 14% of the Province's target.

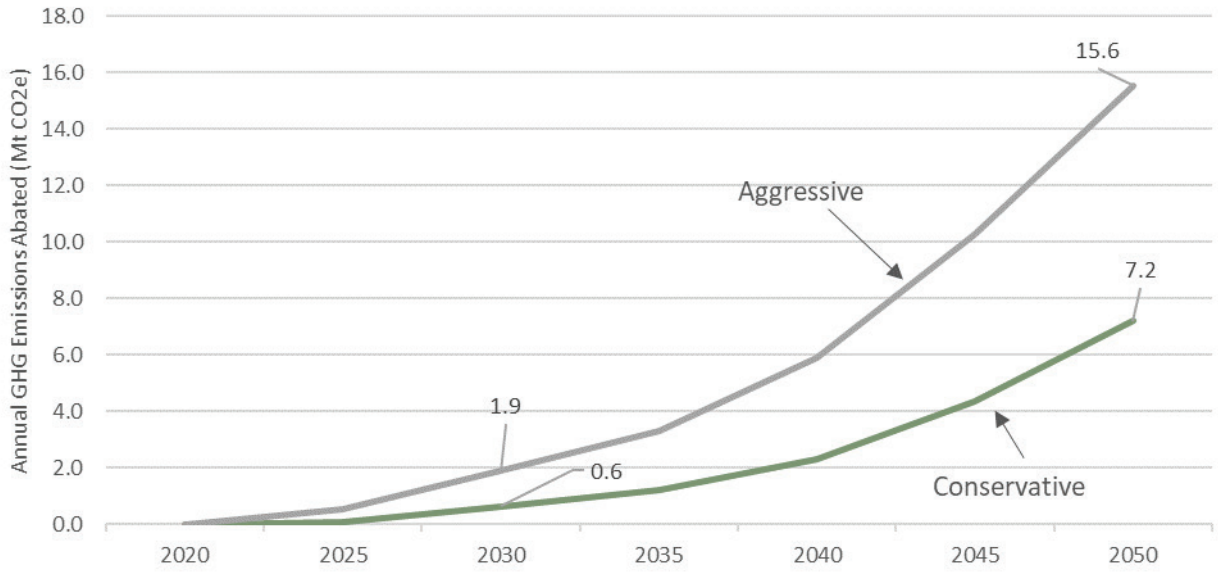

Figure 79. Aggregate Conservative and Aggressive GHG Emissions Reduction (2020-2050)

Figure 80 and Figure 81 show the conservative and aggressive GHG emissions reduction scenarios from 2020 to 2050 by sector, and Figure 82 shows the detailed breakdown by sector in 2030 and 2050.

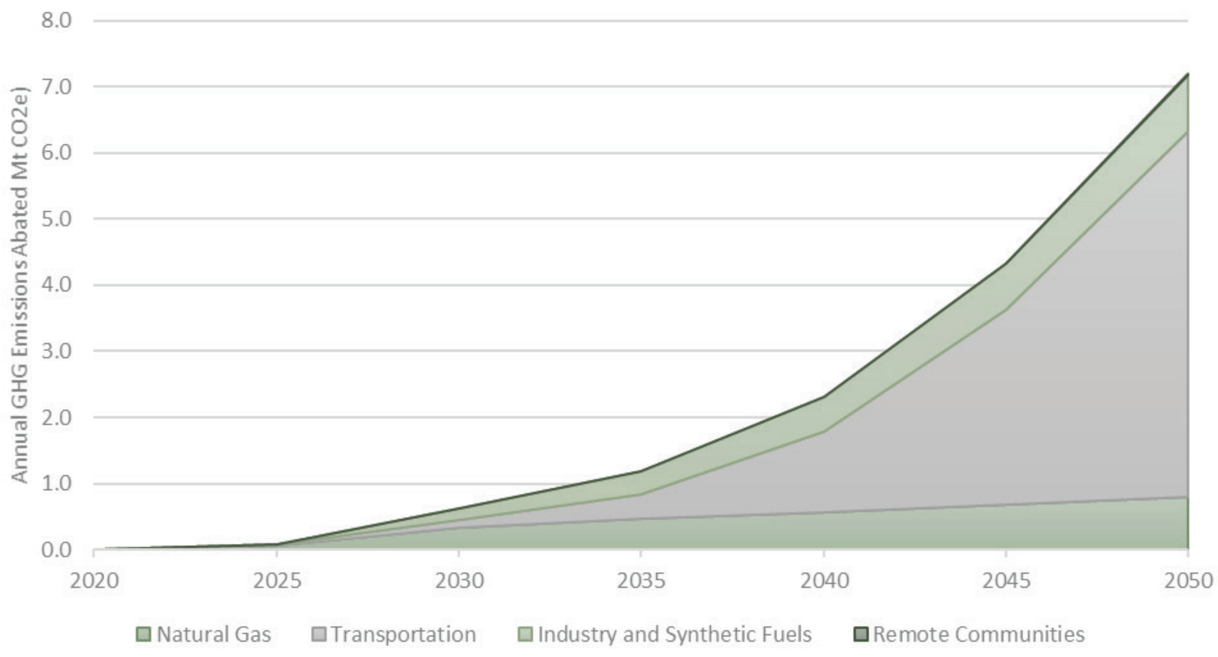

Figure 80. Conservative Aggregated GHG Emissions Reduction by Sector (2020-2050)

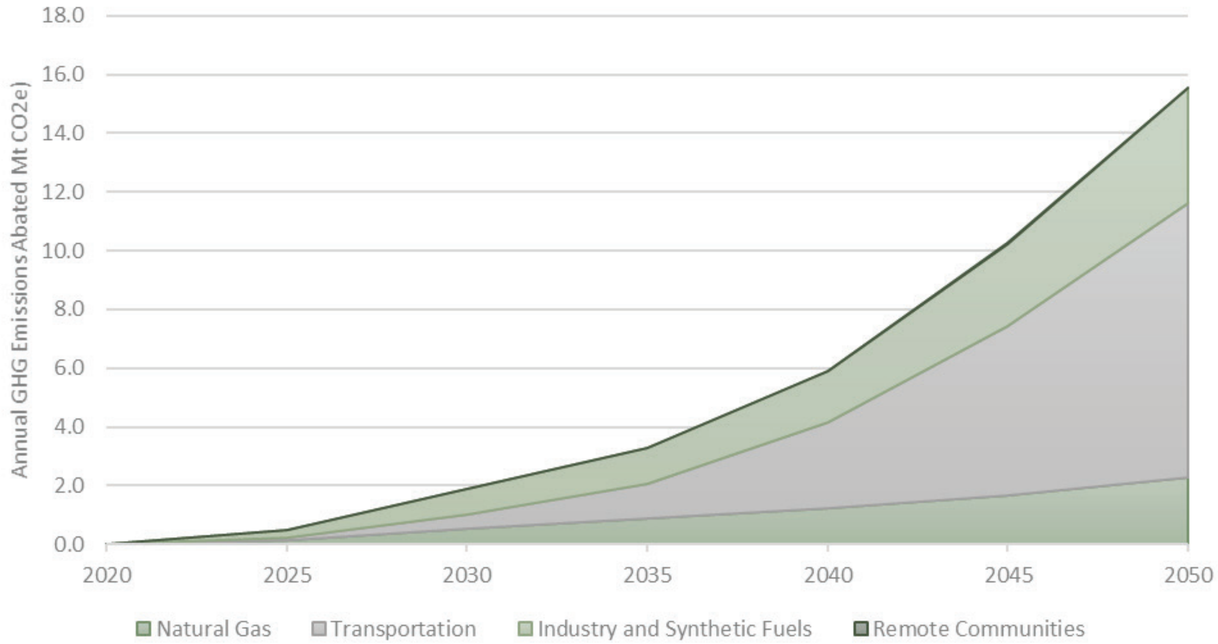

Figure 81. Aggressive Aggregated GHG Emissions Reduction by Sector (2020-2050)

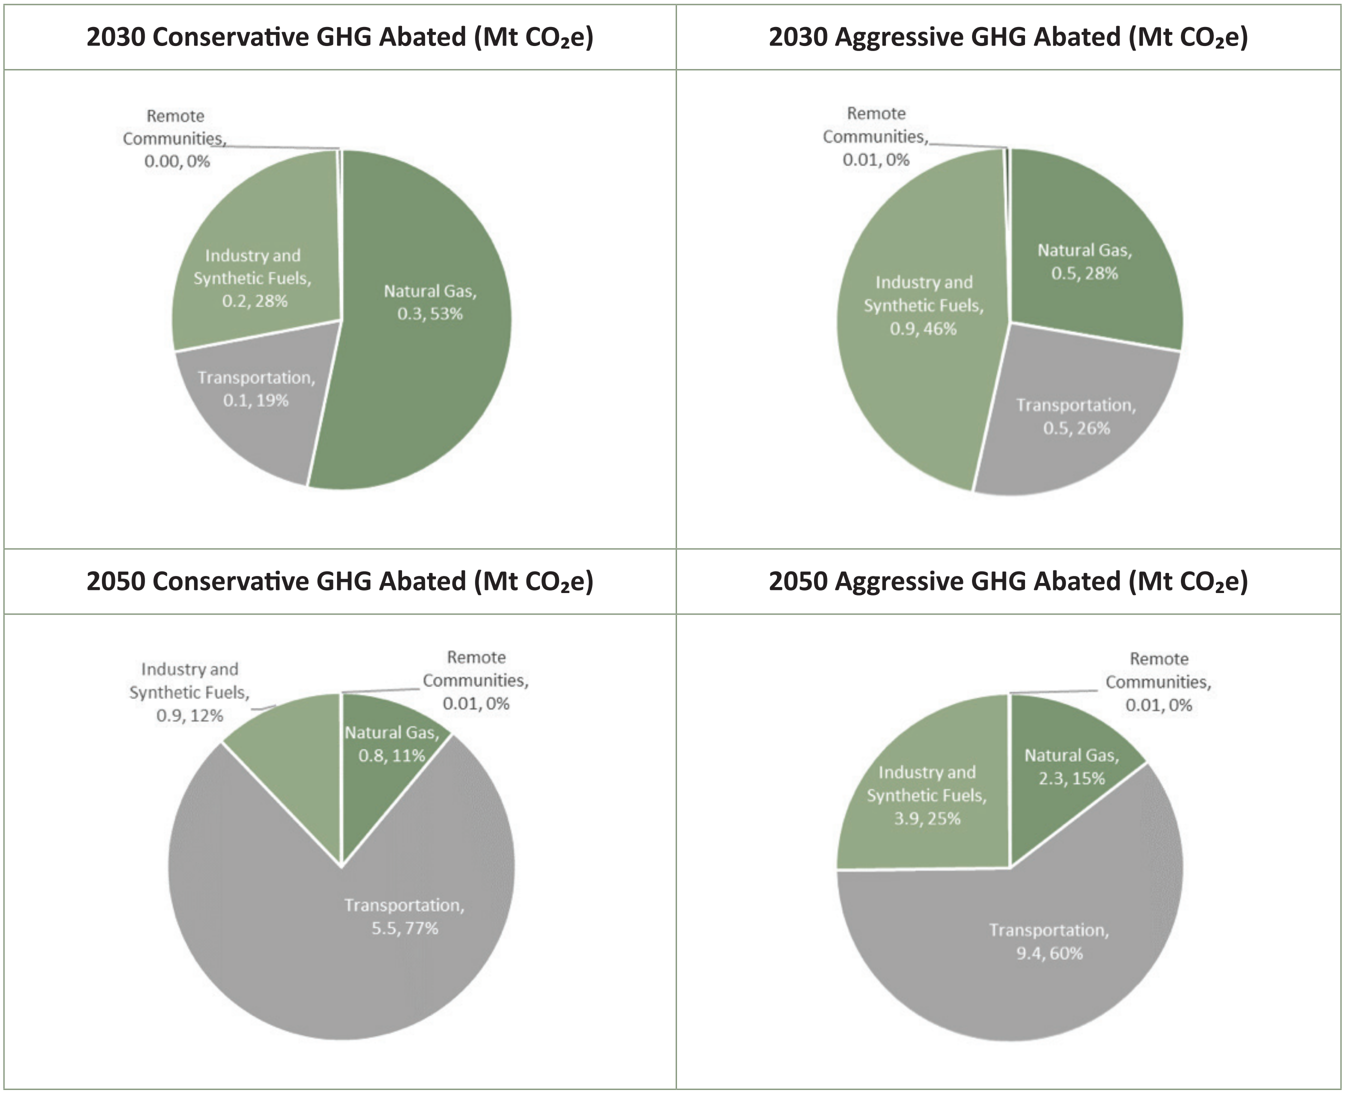

Figure 82. Conservative and Aggressive Aggregate Hydrogen Demand in tonnes by Sector (2030 & 2050)

Initially, natural gas offers the greatest potential for GHG emissions reduction, but by 2050 the transportation sector is expected to dominate savings. This occurs for two reasons. First, it will take time to build up the hydrogen transportation sector because of the large number of gasoline and diesel vehicles on the road and because of the time needed to develop the technology and scale up performance. In contrast, the natural gas grid can begin incorporating hydrogen immediately. Second, most transportation applications will be powered by fuel cells, which offer a significant efficiency improvement compared to burning the hydrogen. This analysis assumed the hydrogen injected into the natural gas grid will be burned directly, so the savings potential is greater in transportation applications.

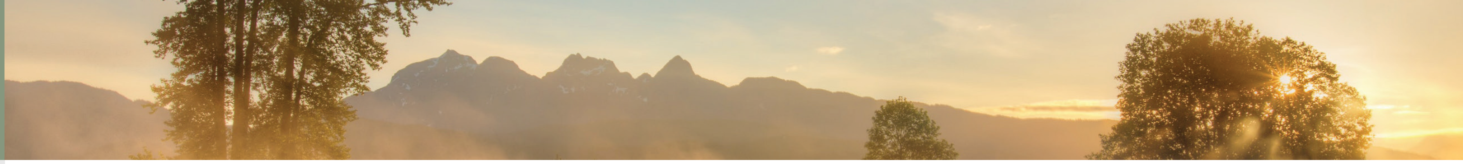
8.3 : Hydrogen Supply

In the near-term, the majority of hydrogen produced in the Province is expected to come from electrolysis. As described in Section 3.1.2, electrolysis can produce hydrogen at a cost of approximately $5 to $7 per kilogram. Facility design is highly scalable, allowing for distributed generation based on local demand. The capital expenditure to build an electrolysis facility is low relative to SMR, so it will be more palatable for investors while demand is low.

By-product hydrogen is expected to become available in the mid-term. This will be the lowest cost pathway for hydrogen production (less than $1 per kilogram as described in Section 3.1.1). However, the provincewide supply of by-product hydrogen is limited and localized to two regions: North Vancouver and Prince George. Industrial suppliers are also hesitant to provide the hydrogen at small scale, so it will not be available until sufficient demand exists.

In the mid-term, hydrogen can also be produced by decarbonizing natural gas through SMR with carbon capture and storage and pyrolysis. This approach leverages BC's abundant natural gas supply while reducing emissions and limiting the amount of new electrical generation capacity that would otherwise be needed to meet the Province's GHG emissions reduction targets. As described in Section 3.1.4, hydrogen produced in this way will be relatively low cost (approximately $2 per kilogram) and can be generated in large quantities. However, this hydrogen pathway is only viable at large scale. Building the infrastructure to produce and distribute the hydrogen will require significant investment and will take a minimum of three to five years to deploy, and therefore, a project would need to be initiated in the near-term to be available by 2025.

In the long-term, all three pathways are likely to continue. By-product hydrogen will reach its maximum capacity and continue at a consistent rate indefinitely. Hydrogen from natural gas will remain a major source as demand increases and new technologies, like pyrolysis, are commercialized. Electrolysis will likely continue to grow throughout the Province over this period as costs drop and regulation pushes towards renewable energy.



9.0 : Instruments and Policies to Develop Hydrogen Supply Chains in BC

9.1 : Jurisdictional Scan of Leading Markets

To inform the policy recommendations in this report, the project team conducted a review of jurisdictions leading the world in hydrogen technology development and deployment. Figure 83 summarizes hydrogen technology deployments in three key regions: North America, Europe, and Asia.[154]

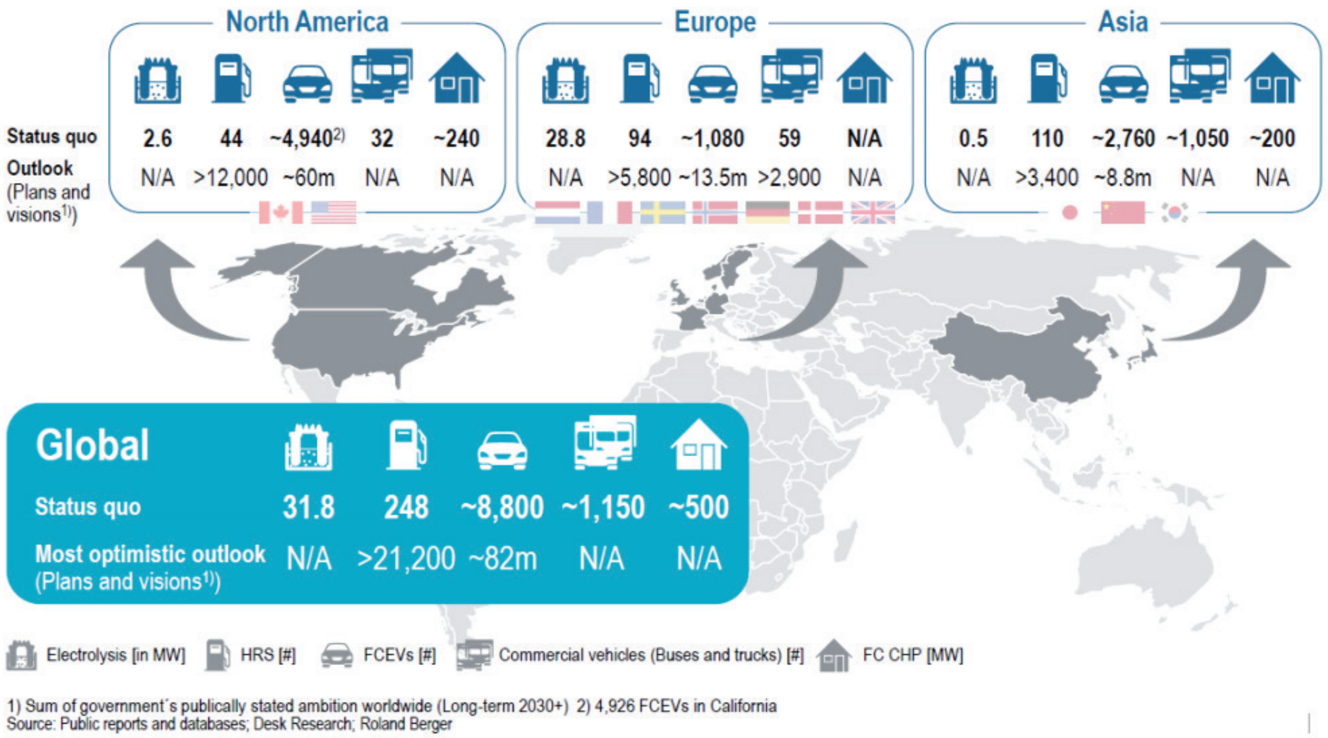


Figure 83. Status and Publicly Stated Plans of Hydrogen Technology Deployments by Continent. Source: Hydrogen Council.

Complementing the hydrogen deployment data, Figure 84 shows the International Energy Agency (IEA) summary of the number of countries offering policy support towards these deployments. IEA estimates that 10 to 15 countries already offer policy support for each of hydrogen fuel infrastructure, fuel cell passenger vehicles and buses. Some jurisdictions have also extended policy support towards the use of hydrogen in the built environment (building heat and power) and industry.

154 *The Hydrogen Council. (2019). Fostering Deployments – Next Steps. Retrieved from* https://www.iea.org/media/workshops/2019/2019hydrogen/Session4-3-FRANC.pdf

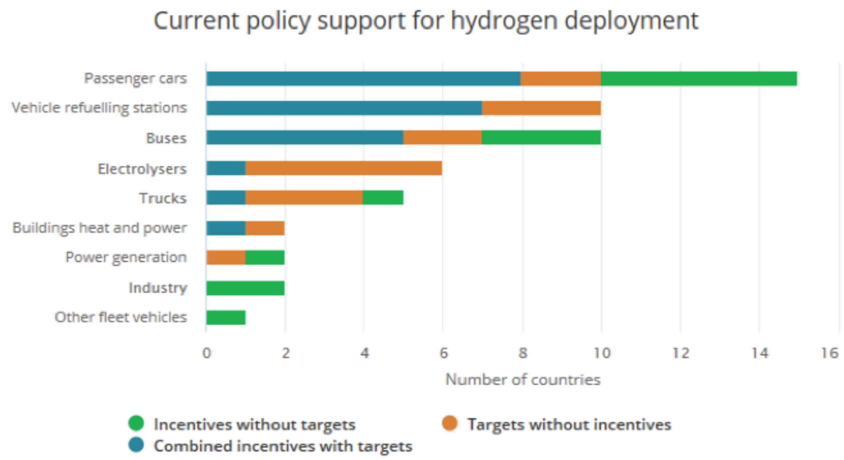

Figure 84. Number of Countries Offering Policy Support for Hydrogen Deployment. Source: International Energy Agency.

The review yielded several key insights:

- *Jurisdictions leading in hydrogen technology adoption have clearly laid out plans to incorporate hydrogen into their energy systems and well-defined targets to measure success.*
- *Jurisdictions are exploring hydrogen technologies to achieve different goals, such as energy security, local air quality, climate change mitigation, economic growth, and energy storage.*
- *Roughly 90% of hydrogen is currently produced from fossil fuels, but hydrogen combines well as an energy storage medium with variable power renewable sources. The carbon intensity of hydrogen production from fossil fuels could also be dramatically decreased through carbon capture and sequestration.*
- *Asia and California are expecting to dramatically increase hydrogen demand in the coming decade and will need to set up international supply chains to deliver clean hydrogen.*
- *Led by China, Asia is investing heavily in hydrogen fuel cell technology and is rapidly scaling up vehicle deployments, particularly in medium-duty trucks. Japan and the Republic of Korea are currently the only two countries producing light-duty fuel cell vehicles that are available for purchase in BC.*
- *Jurisdictions leading in light-duty fuel cell vehicle adoption have focused on building up fueling infrastructure, providing incentives (monetary and non-monetary), and tightening emissions standards. California, which leads adoption, also implemented a ZEV mandate.*
- *Europe has put the greatest emphasis on power-to-gas projects to better utilize intermittent renewable energy sources. Efforts there can be leveraged to inform safe levels of hydrogen injection and the most effective approach to improving the pipeline network.*

A series of one-page summaries outlining the current status of deployments in eight jurisdictions leading the world in adoption of hydrogen technologies is available in Appendix D: Jurisdictional Review summaries. These summaries include policies, incentives, and regulations in place in these jurisdictions.

Notable insights not featured in the one-page summaries included the following:

- *Switzerland's Lump-sum and Performance-based Heavy Vehicle Charges have greatly improved the competitiveness of zero emission trucking solutions. The Heavy Vehicle Charges apply to all vehicles with a permissible laden weight of more than 3.5 metric tonnes; certain vehicle types are exempted, including vehicles with electric drivetrains.*[155, 156] *They provide for the recovery of previously-externalized costs of diesel use based on the "polluter pays" principle*[157] *and are believed to have been pivotal in Hyundai's decision to deploy 1,600 hydrogen fuel cell-powered commercial trucks in the alpine country.*[158]
- *The United States has used tax credits to great effect in growing several clean energy technologies, including wind energy, solar photovoltaics, and fuel cells. US Federal incentives for the purchase of zero emission vehicles also take the form of tax credits instead of purchase subsidies. A key lesson from the US experience has been that long-term policy certainty is required for industries to benefit; among other factors, sales cycles can be lengthy. As shown in Figure 85, the American wind industry experienced several boom/bust cycles when its Production Tax Credit was allowed to repeatedly expire, then was repeatedly offered one-year extensions.*
- *Norway's spectacular success with ZEV adoption – plug-in electric vehicles accounted for 49% of passenger vehicle sales in calendar 2018 and accounted for 10% of the country's passenger vehicle stock – underscores the lesson of long-term policy commitments. Long before they were mass-produced in great numbers, ZEVs received exemptions from import taxes (1990), road tolls (1997), parking fees (1999), value-added tax (2001) and passenger ferry fees (2009). Other incentives included reduced annual registration taxes (1996) and nationwide bus lane access (2005). One insight could be to introduce policy measures before vehicles are sold in great numbers. While it is too late to do so for plug-in electric vehicles in British Columbia, there remains time to craft comprehensive incentives for hydrogen fuel cell vehicles.*
- *China's industrial policy, having established world leadership in batteries for battery electric vehicles, has shifted decisively in favour of hydrogen fuel cells.*[159] *While battery electric vehicle incentives are expected to end in 2020, hydrogen and fuel cell incentives remain generous: federal incentives amount to $40,000 CAD for fuel cell passenger vehicles and $100,000 CAD for heavy duty fuel cell vehicles, both of which can be supplemented by state or city incentives, covering up to 50% of the vehicle's purchase price. To offer a sense of scale of China's ambitions, BloombergNEF identified $17 billion USD in hydrogen and fuel cell investment commitments in China through 2023.*[160]

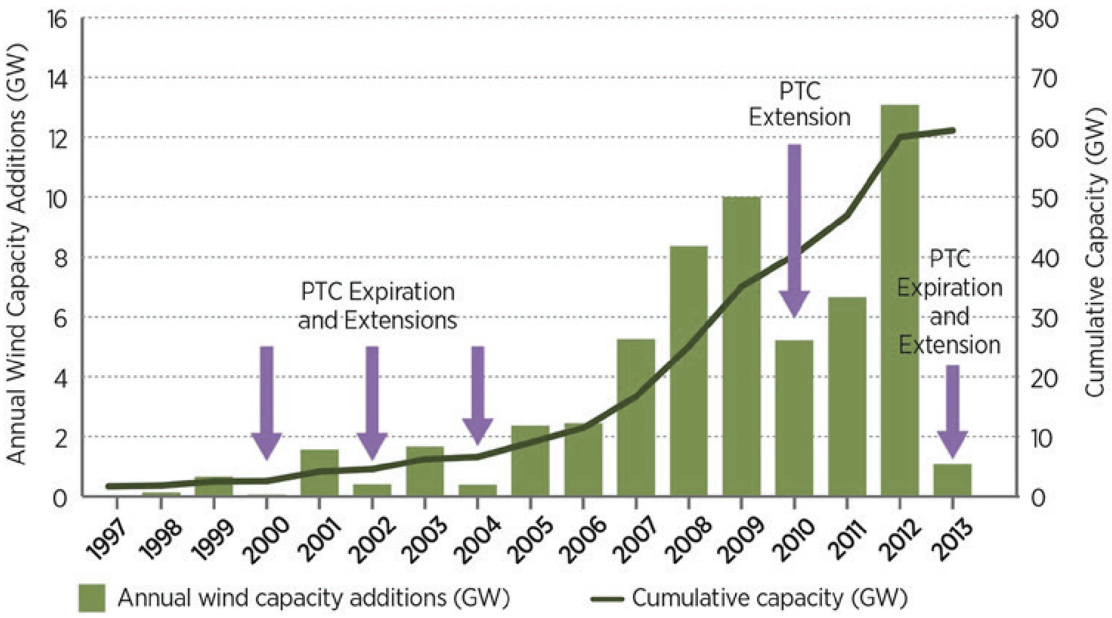

Figure 85. The Effect of Repeated Cycles of Production Tax Credit (PTC) Expiration and Extensions on US Wind Capacity Additions. Source: US Department of Energy.[161]

Based on the review, the project team assigned ratings from 0 to 4 to quantify the strength of each region in 5 categories: current adoption, future adoption, incentives, policy support, and financial commitment. The project team also assigned a rating of 0 to 4 indicating how great a priority the following 5 factors are for the jurisdiction: hydrogen exports, hydrogen imports, local power-to-gas adoption, local fuel cell vehicle adoption, and technology export. The results are summarized in Figure 86 and Figure 87.

9.2 : Recommended Instruments and Policies for BC

The following instrument and policy recommendations highlight critical actions in the 2020 – 2025 timeframe that will support the development of a hydrogen economy in BC. Supporting details and rationale are documented in relevant sections of the report and are summarized here for simplicity.

Hydrogen Production Pathways

1	Allow all sources of 'Clean Hydrogen' to qualify as 'Renewable Gas' under CleanBC goal for 15% Renewable Gas by 2030.

There is an immediate urgency to decarbonize BC's energy supply across all industry sectors. Hydrogen produced at scale from natural gas currently offers the lowest cost and highest availability of low carbon hydrogen when coupled with carbon capture and storage technology. Restricting to renewable sources of hydrogen would limit hydrogen production to electrolysis and biomass gasification pathways, which are currently higher cost and have limited supply in BC based on available resources. Restricting to renewable sources only would slow market penetration of hydrogen in BC.

BC's low carbon hydrogen production pathways include:

a. *'Green' hydrogen produced by electrolysis powered by renewable electricity sources such as hydro, wind, geothermal, or solar;*
b. *'Blue' hydrogen produced by steam methane reforming (SMR) with carbon capture and storage (CCS), biomass gasification with CO_2 sequestration, or hydrocarbon dissociation with solid carbon storage/utilization.*
c. *Hydrogen by-product from industry such as hydrogen produced in the chlor-alkali process.*

'Clean hydrogen' should be defined based on an overall carbon intensity value with clearly defined methodology for calculating the carbon intensity (CI). CI < 36.4 g CO_2e/MJ is the recommended threshold. For clarity, the term 'Renewable Gas' could potentially be modified to 'Low Carbon Gas' in the CleanBC goal and Greenhouse Gas Reduction Regulation.

The LCFR awards credits based on carbon reduction, and hence is already aligned with this recommendation.

2 Support longer-term transition to renewable hydrogen by setting required renewable content in CleanBC's 'Renewable Gas' target and providing incentives for renewable pathways in the LCFR.

Ultimately BC must transition to sustainable energy sources. While the Province has abundant natural gas reserves, these fossil fuel reserves are not sustainable energy sources given the timeframe to replenish these reserves is so great. If there is no required percentage of renewable content, it is possible that current economics could drive developers towards large SMR plants with CCS that could inhibit the development of renewable pathway projects with higher hydrogen production costs. The Province needs policy to drive adoption of multiple pathways in near and mid-term, as well as long-term, in order to ensure both decarbonization and ultimate sustainability goals are met.

It is recommended that the Province add a requirement to the 15% Renewable Gas goal that states that a certain percentage of the hydrogen (e.g. 33% in California) must come from renewable sources, where renewable sources include: electrolysis powered by hydro, wind, or solar; biomass gasification with CO_2 sequestration; and by-product hydrogen capture. It is recommended that the Province classify by-product hydrogen as renewable, given in BC the grid is 90% hydroelectric and is the original power source for this pathway. The LCFR is currently only focused on carbon intensity of the fuel and does not provide extra credit for renewable sources of fuel in relation to hydrogen used in transportation. It is recommended that the Province consider a mechanism to incentivize for the longer-term transition to renewable sources of transportation fuels by closing the gap on production costs between fossil based and renewable pathways. For example, the LCFR could provide base credits based on CI of pathway, with additional credits awarded for renewable sources.

3 Set a threshold for the CI of the hydrogen for all provincially funded projects and stipulate that there must be a transition plan for hydrogen to be produced within the province during the project.

In the past large demonstration projects like the Whistler bus fleet imported hydrogen to demonstrate end use applications. This resulted in negative public perception and did not drive the long-term build-out of hydrogen production infrastructure in the province which is critical to the growth of deployments following pilot demonstration periods. Where possible, it is recommended that projects use renewable pathways when demonstrating end used applications, and this should be reflected in project scoring criteria. In some cases, demonstration projects may need to use imported fuel for a period of time while local fuel supplies are developed for the project.

4 Work with BC Hydro and BCUC to develop rate tariffs that make hydrogen production via electrolysis more economically viable.

There are strategic benefits to encouraging the development of grid connected electrolysis projects in the Province. At the current industrial electricity rates of ~$60/MWh, the economics for electrolysis are challenging and development of projects will be limited. The existing rate structure does not reflect the benefits that electrolysis installations offer.

The electrolysis hydrogen production pathway offers unique opportunities to connect the electric grid and natural gas energy infrastructure in an optimized and efficient system. BC's natural gas infrastructure can be used simultaneously as a clean energy storage and transmission system for the electric system. Utilizing the gas system for electricity storage through power-to-gas conversion can improve electricity system efficiency and load factor, provide a mechanism for BC Hydro to offer dispatchable capacity by having large electrolysis demand loads that can be turned down on demand, minimize costs for end users, and create new delivery channels for low carbon fuels. Electrolysis also enables a distributed model of hydrogen production that is inherently scalable. The electrolysis pathway is currently the most expensive hydrogen production pathway for at-scale hydrogen production in the province. The big cost driver is electricity, making up approximately 70% of the levelized cost of hydrogen based on BC Hydro's current industrial electricity rates. There are a number of potential special rate structures that could support the economic viability of hydrogen production via electrolysis. It is therefore recommended that the Province work with BC Hydro and BCUC to evaluate potential rate tariffs that would reflect the benefits of electrolysis projects. Rate structures to be considered include:

- *Introduce a special rate for electrolysis plants. This could be accomplished by introducing a mechanism to put a value on carbon reduction when presenting proposed rate tariffs to BCUC.*
- *Support permanent adoption of the Freshet Rate Schedule (1892), which would enable higher capacity production and reduced costs during certain times of the year.*
- *Support development of rate programs for interruptible power demand, which fits well with electrolyzer load following capability.*
- *Reconsider BC Hydro's proposal for a Load Attraction rate but consider restricting this rate program to projects that support the Province's decarbonization goals.*
- *Consider a rate structure based on time of use charge, such that electrolyzers can be controlled to operate only in off-peak periods and reduce demand charges.*
- *Investigate the potential to offer retail access to power for electrolyzer operators. This could be limited to purchase of power within the province.*

5 Develop a special funding program to support hydrogen production projects that directly lead to decarbonization within the province.

This program could be either specific to electrolysis pathways and administered by BC Hydro (e.g. similar mechanism to Power Smart to fund a portion of project capital such as interconnection costs) or could be broader and less technology specific and administered by the Province. Program funding is a less restrictive way to make the economics for hydrogen production more commercially viable in the near-term.

6 Investigate the possibility of regulated utilities in the Province (e.g. BC Hydro, FortisBC, and PNG) having expanded mandate to include option to produce, distribute and sell hydrogen.

Electrolyzers present an opportunity to improve the load factor on power generation assets and provide a means by which energy systems can be highly optimized and integrated. Fleets of electrolyzers can provide a mechanism for BC Hydro to offer dispatchable capacity through large demand loads that can be turned down rapidly. If BC Hydro owns and operates the electrolysis infrastructure, it could enable greater optimization of the grid. This would require a mandate change for BC Hydro, and it is recommended this be explored first via a pilot demonstration project. Utilities in Washington state are now able to produce hydrogen through recently passed legislation.[162]

7 Support development of a hydrogen liquefaction plant and distribution assets in the Province, via a P3 arrangement.

A liquefaction plant is a strategic infrastructure asset in BC required to support the wider spread adoption of hydrogen and transport fuel cost effectively throughout the province. Transportation of gaseous hydrogen over long distances is expensive compared to transportation of volumetrically dense cryogenic liquid hydrogen. For example, transporting gaseous hydrogen over a 500 km distance will add approximately $10/kg to the cost of the fuel, versus $3/kg to transport liquid. A liquefaction plant would have to be located next to a large-scale hydrogen production plant with access to various modes of transportation including highway and rail. It is recommended that the initial plant be located in the metro Vancouver area if possible, to create an economical supply of hydrogen to support critical lighthouse projects and early deployments in the 2020-2025 timeframe.

8 Lighthouse project: Support a study to look at the potential for centralized hydrogen production and transport from the Peace region of BC, both through the NG pipeline and as liquid through liquefaction plant.

This region is very strategic for the Province in terms of potential to generate large volumes of low-cost hydrogen. The region is unique as it brings together key resources that could enable bulk centralized production of hydrogen that would support rollout in the Province. Strategic regional assets include:

- *BC Hydro Peace Canyon Project, which includes the Williston reservoir – 7th largest reservoir in world - powering the W.A.C. Bennett Dam and the associated Gordon M. Shrum Generating Station and the Peace Canyon Dam;*
- *Montney gas basin –enormous gas reserves and potential sites to inject and store sequestered carbon;*
- *Major transmission infrastructure for both electricity and natural gas; and*
- *Significant wind resources.*

Centralized large-scale hydrogen production and distribution infrastructure will be critical to enabling hydrogen to play a significant role in decarbonizing BC's industry sectors in the coming years. Government investment in this strategic infrastructure asset will be required to drive down hydrogen production costs in the Province and to de-risk private investment in large installed capacity while the markets are still developing. In the near-term, a plant in the Peace Region could focus on using the NG transmission system to store and transport hydrogen, and there is already demand from Fortis to meet the 15% RG target by 2030. As higher value markets emerge, economics will support alternative transport and delivery methods, such as liquid cryogenic hydrogen. In addition to supporting hydrogen rollout in the province, this project could support regional economic development in the Peace Region.

162 *See footnote 143.*

Natural Gas

9 **See Recommendation #1 and #2 above for hydrogen definition related to CleanBC Renewable Gas Target.**

10 **Lighthouse project: starting with a feasibility study, support a hydrogen community demonstration that shows the benefits and synergies of integrated hydrogen production, storage, and end use applications in a single region of the Province. The concept would evaluate conversion of a full community to hydrogen.**

There are two approaches to achieving the Province's 15% Renewable Gas target for the Province. One approach is to inject RG into the broad network and achieve this average throughout. A second concept is to target specific regions for a full conversion to RG, and focus efforts in concentrated areas to achieve the overall target goals. Other regions around the world are evaluating or moving forward with similar concepts. For example, H21 North of England is planning for the full conversion of the North of England to hydrogen over the 2028-2034 timeframe, starting with Leeds. It is recommended that the Province evaluate the pros and cons of fully converted hydrogen communities compared to bulk hydrogen adoption throughout the Province. A community such as Revelstoke, which runs an isolated grid on LPG, could be considered for such a concept.

11 **Develop standards that enable hydrogen injection into the NG grid: create a mandate for technical bodies to address hydrogen injection into the NG grid in relevant codes, standards, and protocols**

The current regulatory framework governing BC's gas production, transmission, and distribution sectors is not fit-to-purpose for the inclusion of hydrogen. The current mix of federal and provincial acts, regulations, statutory codes and standards do not specify the exact constituents of natural gas or renewable gas and their allocable percentages. The framework is spread over multiple layers of authority, including the National Energy Board, Canadian Standards Association, BC Oil and Gas Commission, the BC Utilities Commission, and Technical Safety BC. In order to introduce hydrogen into the natural gas pipeline system, a combination of code and regulatory changes will be required. It is recommended that the province take a leadership role to develop the required regulatory framework by convening the relevant agencies and driving progress.

12 **Consider changing provincial codes to ensure all future gaseous pipelines are compatible with 100% hydrogen, develop plans to transition other critical components to support increasing volumes of hydrogen in the grid.**

In order to enable a potential transition to 100% hydrogen in the NG distribution system, it is important to ensure materials are compatible. The incremental costs to make pipelines 100% H_2 compatible during new construction and/or planned replacement are relatively small compared to digging up and replacing.

Other components in the system will also have to transition to material and design compatibility for hydrogen. It will be important to signal the timeframe by which other components (valves, turbines, appliances) will need to be hydrogen compatible in order to ensure a smooth and timely transition.

13 Support innovation related to injection of hydrogen into the natural gas grid through establishing a specific and dedicated funding tranche.

Under the current regulatory framework, Fortis is unable to invest in precommercial activities related to technologies, including hydrogen, required to meet the 15% Renewable Gas target. There are still considerable technological and practical gaps to deploying hydrogen at scale in the natural gas network. Dedicated funding to support pilot projects, studies, and research initiatives will be critical to enabling hydrogen to reach its potential in the decarbonization of the NG system. Fortis is currently working to establish an innovation fund that would be funded through the multi-year rate application which would also complement the proposed provincial fund.

Pilot demonstrations that could be supported by this fund would help to identify and develop solutions for existing regulatory barriers and would help to accelerate hydrogen adoption.

Transportation (General)

14 Support and collaborate with progressive municipalities in the development of zero emission zones (e.g. regions with no combustion vehicles allowed by 2040).

Progressive municipalities could provide a focal point for hydrogen and fuel cell deployment at scale, similar to certain regions in China. Coordination of federal, provincial, and municipal government efforts in these regions would be critical. Cities with aggressive targets will help drive development and adoption of medium- and heavy-duty vehicles that are not covered by the light-duty ZEV mandate in BC.

15 Establish a prescriptive call for hydrogen infrastructure LCFR Part 3 Agreements to support the development of hydrogen infrastructure.

Similar to past prescriptive calls to develop infrastructure for emerging technologies, such as the call for E85 fueling stations, a prescriptive call focused on funding for hydrogen fueling infrastructure is a key enabler to support the expansion of the hydrogen fueling infrastructure to support vehicle deployments in the province. Regions such as California have learned through experience that the development of infrastructure must lead vehicle deployment for successful rollout of fuel cell electric vehicles. Station developers must currently compete with a wide range of other projects, and this uncertain funding environment makes it challenging for developers to plan expansion of the network.

16 Strengthen funding to support rollout of hydrogen infrastructure in the Province.

It is critical to support the deployment of hydrogen fueling stations in the Province in order to attract vehicles and support the business case for station owners. The CEV program has some existing funding mechanisms in place, but further funds will be required in order to support the projected station requirements. Better communication of existing funding sources is also recommended.

Transportation (Light-duty)

17 Implement a zero-emission vehicle mandate in the province for light-duty vehicles that recognizes the incremental value of longer-range passenger vehicles, with shorter fueling times. Make British Columbia the world leader in credit value for hydrogen fueled vehicles

The biggest impediment to the deployment of fuel cell electric passenger vehicles in the province over the near- to mid-term is the availability of supply. OEMs must choose between regulated markets when determining which jurisdictions to supply vehicles. Fuel cell electric vehicles are currently manufactured at a different scale than battery electric vehicles, therefore the marginal cost of deploying these vehicles in regulated markets is higher for OEMs seeking to demonstrate compliance with these vehicles.

Current credit schemes in California and Quebec provide higher credit values for longer range, which favours fuel cell vehicles. For example, a Toyota Mirai (FCEV) receives 3.6 credits (502 km range) while a Chevrolet Bolt (BEV) receives 2.9 credits (383 km range) and a Nissan Leaf (BEV) receives 1.3 credits (135 km range). Input from the OEMs indicate these credit "adders" are insufficient to make up the difference in cost. The Province should consider increasing the impact of range in determining the credits per vehicle and/or adding credits based on vehicle fueling/charging time. This would be more impactful than increased subsidies to the end users in the near- to mid-term.

18 Fund and foster a centralized platform for the exchange of information between FCEV OEMs, the provincial and federal governments, and hydrogen infrastructure providers.

Like the California Fuel Cell Partnership, this body would be the formal clearing house for determining vehicle supply for the Province from participating OEMs and tracking infrastructure roll out. Volumes could be aggregated to ensure confidentiality. This body could set clear targets for the deployment of light-duty fuel cell electric vehicles within the Province and drive and track progress toward the goal.

The Province would take the lead to support an independent modeling effort to strategically identify where hydrogen infrastructure should be deployed in the Province. The vehicle OEMs would provide market rollout projections, as well as insight into target customers and markets. An independent group would aggregate this data and build out an analytical model that would identify regions for infrastructure rollout to support the vehicle projections. Government solicitations would fund stations in specific regions, similar to how the California Energy Commission (CEC) deploys funds in line with the California Air Resources Board (CARB) modeled areas of focus.

19 Create incentives that provide operational benefits to ZEV drivers that encourage the adoption of FCEVs and BEVs.

Other jurisdictions, such as Norway, California, and China, have had success driving adoption of ZEVs through "soft" incentives that provide benefits to the driver beyond reducing the initial capital cost. In addition to allowing lone ZEV drivers to use the HOV lane, the Province could consider measures like reduced tolls and ferry travel benefits (discounted travel, free reservations, a percentage of reservation space only available to ZEV drivers, preferred loading, etc.). These types of incentives can be low cost to the Province while still impactful in the decision-making process for consumers.

20 **Extend CEV incentive to cover early rollout of FCEVs (5% of current annual sales) and initiate a program to incentivize purchase of second-hand FCEVs and BEVs.**

The Province's CEV incentive was designed to support early adoption of zero emission vehicles in the Province. To date that initiative has cost ~$60 million and has gone primarily to BEVs and PHEVs. Now that those technologies are in a more commercial stage, it is recommended the CEV vehicle incentive roll over to cover FCEVs in a similar total program amount to stimulate early adoption.

A common criticism of ZEV incentives is that they subsidize expensive cars for wealthy people. Bolstering the market for second-hand ZEVs would make it easier for low-income households to purchase them and drive demand away from older fossil fuel vehicles, which generate the greatest emissions. CEV incentives are currently limited to new vehicles purchased in BC.

Transportation (Medium-Duty)

21 **Create a Province-to-Province program with other jurisdictions (e.g. China, Japan, Korea) that facilitates the deployment of BC and foreign technology in both jurisdictions focused on medium-duty trucks for city use.**

Support homologation efforts to enable the import of medium-duty (delivery trucks) from China, or other jurisdictions, that will provide load for the BC hydrogen infrastructure, export opportunities for local industry (e.g. Ballard, Loop) and competition for North American OEMs that will drive costs down. This would include demonstration programs to validate vehicle performance in BC.

Transportation (Heavy-Duty)

22 **Implement a Transit Bus zero-emission fleet rule in the province similar to the Innovative Clean Transit rule in California.**

The creation of a zero-emission transit fleet rule would require TransLink and BC Transit to outline a plan and move beyond the testing phase for battery electric and fuel cell electric buses. Fuel cell electric buses are not competitive in comparison to other technologies in small-scale demonstrations, primarily due to the cost of the fueling infrastructure. For this reason, agencies tend to choose the easier pathway to demonstrate autonomous zero-emission operations to meet near-term board or policy objectives. The implementation of a zero-emission transit fleet rule would require these agencies confront the realities of scaling up the fueling infrastructure for both battery electric and fuel cell technologies.

23 Create a fuel cell electric coach pilot program in the Province, open to both private and public bus operators. This program should fund both rolling stock and fueling infrastructure.

Fuel cell electric coaches require an operating range that disqualifies battery electric buses for many/most routes. TransLink operates a limited number of coaches within its fleet and has indicated an interest in pursuing fuel cell electric buses for this application where funding for the incremental costs are available. The coach bus configuration is different than transit buses, in that the hydrogen cannot be stored on the roof due to centre of gravity. Funding support is required to develop and trial a first fleet of prototype units that could lead to significant rollout in the Province.

24 Develop a targeted voucher program to subsidize the incremental capital costs of zero-emission buses and fueling infrastructure.

Distribute these vouchers regionally to ensure that a diverse set of communities has access to zero-emission transit. Vary the value of the vouchers between technologies to address the cost differences proportionally. This is similar to CARB's Hybrid and Zero-Emission Truck and Bus Voucher Incentive Project (HVIP) voucher program which subsidizes technologies that are beyond the development stage but are not yet commercially viable due to cost and scale.

Fuel cell electric and battery electric transit buses are at a sufficient technology readiness level, with hundreds of vehicles deployed globally, that demonstration projects are no longer necessary to prove out the functionality. Cost is the primary impediment to adoption, and a targeted voucher program -in conjunction with a transit fleet rule -will drive the scale of deployments, providing the scale to reduce costs.

25 Create a large-scale, zero-emission heavy-duty vehicle program focused on Vancouver ports that includes both hydrogen and battery electric technology. This program should fund both rolling stock and fueling infrastructure for both technologies.

Hydrogen powered goods movement equipment such as drayage or yard trucks are still relatively immature. A large-scale (10+ vehicle) program will encourage consortia to form, creating new product configurations, with enough volume to spread the non-recurring engineering costs across multiple units. The hydrogen demand will also drive innovation on the production, distribution and dispensing systems and substantially scale the volume of fuel being produced for passenger vehicles.

26 Review the results of the pilot co-combustion vehicle study. If emissions reduction benefits warrant, remove the fuel cell specification of the Motor Tax and Low Carbon Fuel Standard.

Hydrogen co-combustion technology being developed in BC offers near-term potential for hydrogen in the heavy-duty sector and provides a path to retrofit existing vehicles. The technology and GHG reduction claims need to be validated before other incentives are considered. Given the near-term potential of this technology, it is recommended that any language that specifically excludes this technology be carefully considered and removed where warranted.

27 Support feasibility study for the use of hydrogen in marine, rail and off-road applications in BC.

In demand modeling discussion it was agreed that by 2030-2050 timeframe there should be some adoption in marine and rail based on international pilot projects underway. Other industries in BC, such as mining and forestry, use large diesel-powered off-road vehicles that are also well suited to conversion to hydrogen. Feasibility studies would be precursors to funding pilot demonstration projects for these applications.

Industry

28 Maintain strong and ongoing low carbon fuel standards to show project developers that investment in hydrogen production for these markets will be sustained over the long-term to justify the high up-front capital investment.

The low carbon fuel standard is driving the forecasted demand for hydrogen in synthetic fuel production and refining.

29 Support and encourage longer-term R&D projects and scaled up demonstration projects for synthetic fuel production utilizing low carbon hydrogen in the province.

This is an area of potential innovation leadership for the Province.

Built Environment

30 Focus hydrogen efforts for the built environment in the reduction of carbon emissions through injection of hydrogen in the NG grid for use in heating and domestic hot water.

Focusing hydrogen efforts for the built environment in this area will result in the strongest benefits. Hydrogen backup power systems or distributed power generation systems do not provide a compelling business case in the province given the low cost and carbon emissions profile of electricity.

31 Encourage new construction to select future proof appliances which allow for increasing hydrogen content with no or minor changes.

Remote Communities

32

For communities relying solely on trucked or barged in energy supply, encourage studying potential development of micro grids which utilize 100% hydrogen distribution grid and local combined heat and power (CHP) generation.

A Hydrogen supplied grid offers significant advantages over diesel generation to help remote communities. Benefits include: elimination of spill pollution and local air pollutants, lower transport weight (in the case of LH_2 supply), ability to self-generate a portion of energy demand via renewables to H2 technologies, and higher overall efficiencies. Moreover, remote communities are often completely reliant on imported fuels for their power generation and transportation, and transport costs make energy supply to these regions expensive. As such, remote communities provide an attractive costs basis for new competing renewable electricity and hydrogen technologies that can offset imported diesel and generate environmental benefits.

33

Provide information resources to remoted communities related to hydrogen options, and support education outreach in remote communities.

Every remote community is different and solutions for reducing diesel dependence will be community and site specific. Many communities do not have the human capacity with the technical know-how to even start the planning process, let alone develop and implement a project. Provide a 'hydrogen toolkit' including support to navigate funding opportunities, technical expertise for planning, implementation and operations, and a database with technical and cost details of successful clean energy projects involving hydrogen that can provide information for communities just starting the planning process.

Export

34

Support export market studies and pilot programs in BC, particularly where international investment can contribute to production capacity that also benefits the local market.

BC's natural resources, including low carbon renewable hydroelectric reserves, natural gas reserves, and fresh water supply, coupled with coastal access and relative proximity to leading markets such as California, Japan, and South Korea, uniquely position the region to be an exporter of clean hydrogen. While study stakeholders indicated that there is insufficient hydrogen supply in the Province to meet local demand and decarbonization objectives, international investment for large-scale hydrogen production has the potential to benefit local markets as well as generate significant revenue. BC's economy is heavily dependent on export of natural resources, and hydrogen fits as a future export resource that can support both local and international decarbonization efforts. A successful export market will likely rely on producing hydrogen from natural gas reserves coupled with CCS technology, as other pathways tend to be more expensive and in limited supply.

35 Support a thorough analysis of the carbon intensity of various BC pathways, and start lobbying / marketing efforts which target export markets, and California in particular.

California has been identified as the most viable export market on an economic and access basis in the near-term. Market development will in part be reliant on BC having hydrogen produced via electrolysis, either through hydro or wind, to be considered renewable hydrogen toward the state's 33% requirement. For project developers to be able to sell to California, it will likely be necessary to convince them that BC hydrogen made via electrolysis from Hydro should qualify as renewable and low carbon.

Sector support

36 Identify hydrogen and fuel cells as a priority sector for BC and communicate this clearly and consistently to Federal Government.

The importance of hydrogen in the Province must be elevated. Clear and consistent messaging about the role and strategic importance is critical for both internal alignment and prioritization at the provincial level, and for communicating and driving support at the federal level.

37 Support targeted outreach initiatives related to hydrogen technology deployment.

The recommended outreach initiative would be a collaborative effort with industry and government partners to lead outreach to groups such as municipalities, first responders, and community leaders in a coordinated and effective way, similar to the California Fuel Cell Partnership. This could be managed through a working group in an existing organization such as CHFCA.

38 Provide provincial R&D funding in support of hydrogen and fuel cell technology that can be combined with matching funds from the Federal Government or other nations.

Investment is needed to maintain the province's leadership role in hydrogen and fuel cell R&D. Local organizations should have access to funding that can be leveraged to access greater funds from outside entities. For example, a recent federally funded Ballard Power R&D project was moved from BC to Ontario because there was no provincial funding available in BC, which was required to access the federal funds. The ARC program could be expanded to meet this need, or a new fund formed that isn't tied specifically to clean energy vehicles.

9.3 : Investment Required

Government investment is needed to establish a hydrogen economy in BC and support the abovementioned recommendations. That investment will provide the necessary infrastructure and sector support to allow industry to establish a foundation from which to grow commercial deployments. Government investment will yield necessary decarbonization benefits for the Province, economic growth potential, and long-term diversity and security of our energy systems.

Our analysis recommends a total spend from the Province in the order of $176,000,000 over the next five years, which is approximately $35,200,000 per year. This funding would be focused primarily on supporting lighthouse projects and studies, funding critical infrastructure development, providing subsidies for the rollout of light-duty FCEVs, and supporting the sector through establishing dedicated R&D funding. It is anticipated that this Provincial funding would be leveraged with federal and industry match funding, thereby amplifying the benefits of this investment in the Province. A high-level estimate of funding is included in Table 19.

BC Investment Summary 2020-2025	R#	Amount
Lighthouse Projects and Studies		
Central Production Study - Peace Region	8	$ 250,000
Hydrogen Community Study	10	$ 250,000
Marine, Rail and Specialty Vehicle Study	28	$ 250,000
Coach Program with Heavy Duty Fueling Stations	24	$ 6,800,000
Port Program with Heavy Duty Fueling Stations	26	$ 13,300,000
Medium Duty Delivery Vehicle Program	22	$ 7,500,000
Infrastructure Deployment		
Modeling initiative for infrastructure deployment	19	$ 375,000
Liquefaction Plant	7	$ 5,000,000
Distributed Electrolysis Supply - Program Funding	5	$ 20,000,000
Light Duty and Medium Duty Fueling Stations	17	$ 22,500,000
Central Hydrogen Production Plant, Peace Region	8	$ 30,000,000
Vehicle Subsidies		
Extension of CEV for FCEVs, used vehicle incentive	21	$ 50,000,000
Voucher program for transit and intercity buses	25	$ -
Research and Development, Outreach		
Innovation support for hydrogen into NG grid	11, 13	$ 12,000,000
Hydrogen and fuel cell R&D funding	39	$ 2,500,000
Synthetic fuel, CCS R&D	30	$ 5,000,000
Support targeted outreach initiative	38	$ 275,000
Total		**$ 176,000,000**
Annual Spend, 2020-2025		$ 35,200,000

Appendix A-7

BUILDING A RESILIENT ENERGY FUTURE – GUIDEHOUSE STUDY FOR AGA

American Gas FOUNDATION

January 2021

Building a Resilient Energy Future:

How the Gas System Contributes to US Energy System Resilience

An American Gas Foundation Study Prepared by:

Guidehouse

Background and Methodology

This study was conducted to investigate the resilience of the US gas system and the ways in which the gas system contributes to the overall resilience of the US energy system. This work was directed to ask and answer four key questions:

- What are the characteristics of the US gas system that contribute to its resilience?
- How do those resilience characteristics allow the US gas system to contribute to the overall resilience of the US energy system?
- How can the US gas system be leveraged more effectively to strengthen the US energy system?
- What are the policy and regulatory changes that may help ensure that gas infrastructure can be maintained and developed to continue to support energy system resilience?

These questions were explored through a qualitative assessment conducted by Guidehouse, including discussions and interviews with many energy industry subject matter experts. Case studies and examples of resilience were identified as a part of these discussions. Guidehouse used these studies and examples to develop a framework for considering the resilience of the US gas system and to identify barriers and opportunities related to the gas system's role in supporting the resilience of the US energy system. The findings presented in this work identify issues that merit consideration and further exploration when developing future energy policy and regulation to ensure a resilient, reliable, and clean future energy system in all regions and jurisdictions.

Disclaimers

American Gas Foundation

Founded in 1989, the American Gas Foundation (AGF) is a 501(c)(3) organization focused on being an independent source of information research and programs on energy and environmental issues that affect public policy, with a particular emphasis on natural gas. When it comes to issues that impact public policy on energy, the AGF is committed to making sure the right questions are being asked and answered. With oversight from its board of trustees, the foundation funds independent, critical research that can be used by policy experts, government officials, the media and others to help formulate fact-based energy policies that will serve this country well in the future.

Guidehouse

Guidehouse is a leading global provider of consulting services to the public and commercial markets with broad capabilities in management, technology, and risk consulting. We help clients address their toughest challenges with a focus on markets and clients facing transformational change, technology-driven innovation and significant regulatory pressure. Across a range of advisory, consulting, outsourcing, and technology/analytics services, we help clients create scalable, innovative solutions that prepare them for future growth and success. Headquartered in Washington DC, the company has more than 7,000 professionals in more than 50 locations. Guidehouse is led by seasoned professionals with proven and diverse expertise in traditional and emerging technologies, markets and agenda-setting issues driving national and global economies. For more information, please visit: www.guidehouse.com

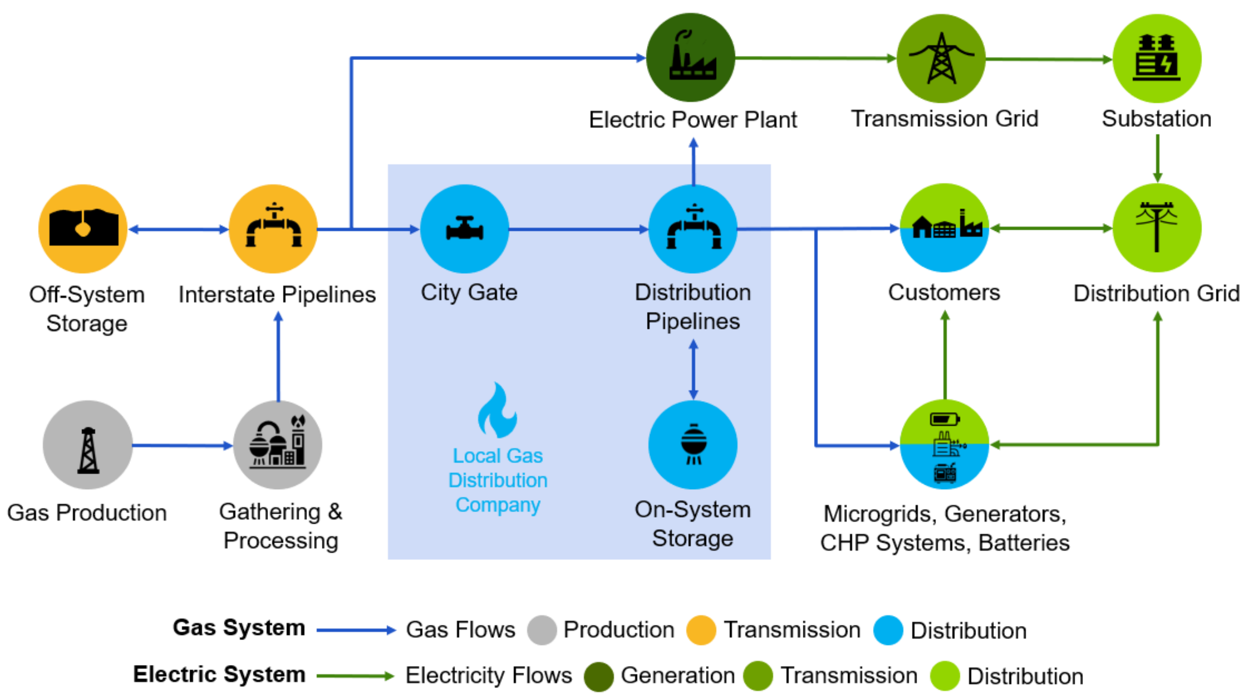
EXECUTIVE SUMMARY

A resilient energy system is essential to the operation of nearly every critical function and sector of the US economy as well as the communities that depend upon its services. Disruptions to the US energy system create widespread economic and social impacts, including losses in productivity, health and safety issues, and—in the most extreme cases—loss of life. As utilities, system operators, regulators, and policymakers deliberate the design and structure of the future energy infrastructure, they must consider the resilience of the entire energy system. As the transformation of the energy system accelerates, it is important for stakeholders to understand the increasing interdependence of gas and electric systems and their role in creating a more resilient future.

A Primer on the Energy System

An energy system is defined as the full range of components related to the production, conversion, delivery, and use of energy. Energy in the US can take many forms; this report focuses on the natural gas system, herein referred to as the gas system, and its interdependencies with the electric system (Figure 1).

Figure 1. Interdependencies Between the Gas and Electric Systems



Source: Guidehouse

What Is Resilience?

Resilience is defined as a system's ability to prevent, withstand, adapt to, and quickly recover from system damage or operational disruption. Resilience is defined in relation to a high-impact, low-likelihood events. The most common examples of these events are extreme weather events (which go beyond standard hot days or snowstorms) of a size and scale to cause significant operational disruption, system damage, and devastating societal impacts. Recent resilience events that affected the US energy system include the 2020 California heat waves, Hurricane Isaias, and the 2019 Polar Vortex.

> *Resilience and reliability are often referenced together, but they reflect critical differences in system design and operation. **Resilience** is defined as a system's ability to prevent, withstand, adapt to, and quickly recover from a high-impact, low-likelihood event such as a major disruption in a transmission pipeline. In comparison, **reliability** refers to a systems' ability to maintain energy delivery under standard operating conditions, such as the standard fluctuations in demand and supply.*

The increasing frequency and severity of climatic events amplifies the need to maintain the resilience of the US energy system. System resilience is gained through diversity and redundancy. The resilience of the US energy system is increased through evolving and holistic management of the gas and electric systems, valuing each of their unique characteristics. To ensure resilience, the energy system needs pipeline delivery infrastructure and storage capabilities meeting both short- and long-duration needs.

The nation's gas system is a critical resource for addressing resilience threats to the overall energy system. This report examines how the characteristics of the US natural gas system enable energy reliance today and opportunities to effectively use the gas system to achieve future energy resilience.

Resilience Characteristics of the Gas System

The gas system supports the overall resilience of the energy system through its inherent, physical, and operational capabilities (Figure 2) that enable it to meet the volatile demand profiles resulting from resilience events.

Figure 2. Resilience Characteristics of the Gas System

Inherent Resilience of Gas

Resilience in Action

Large, catastrophic failures of the energy system have been few and far between—the energy system has performed well, overcoming periods of high stress that have threatened its resilience. These high stress events are becoming more frequent due to the increase in the frequency and severity of extreme weather events associated with climate change. To successfully build for the future and invest in the right set of resilience solutions, it is important for stakeholders to understand how the energy system has performed under recent resilience events.

Recent climate events have revealed the US energy system's potential vulnerabilities. However, the multitude and diversity of resilience assets that already exist as part of the energy system have made the difference—facilitating energy flows to critical services and customers. As the following case studies illustrate, the resilience assets that are part of the gas system have supported the overall integrity of the energy system during these high stress periods.

2019 Polar Vortex

In 2019, the Midwest experienced record-breaking cold temperatures, which led to increased demand on the energy system to meet heating needs.

- CenterPoint Energy curtailed gas service to interruptible customers and pulled gas from every possible storage resource to maintain service to homes and businesses. In one day, CenterPoint delivered almost 50% more than a standard January day.
- On January 30, 2019, Peoples Gas, North Shore Gas, and Nicor Gas together delivered gas in an amount equivalent to more than 3.5 times

	the amount of energy that ComEd, the electric utility serving an overlapping territory has ever delivered in a single day. • The Consumers Energy's Ray Compressor Station fire on January 30 took a primary storage supply resource offline. Consumers leveraged several gas resilience characteristics (linepack, backup storage, and a highly networked gas system) to ensure that no critical, priority, or residential customer lost service.
2014 Polar Vortex	During early February 2014, a polar vortex brought extreme cold temperatures, snowfall, and high winds to Oregon. On February 6, during the system peak, NW Natural set a company record for natural gas sendouts, which still stands today. Nearly 50% of this peak demand was met by natural gas storage capacity. In combination with diligent planning and dedicated employees, this case study highlights the critical role that natural gas storage plays in meeting demand during extreme weather events.
2020 Hurricane Isaias	On August 4, 2020, Hurricane Isaias made landfall in North Carolina. It caused significant destruction as it moved north, triggering electric outages that affected more than 1 million New Jersey homes and businesses. Many customers experiencing electric outages turned on their natural gas backup generators, resulting in a massive increase in demand for New Jersey Natural Gas (NJNG). In 24 hours, NJNG experienced a 60% increase in daily demand on its gas system—the daily demand for this one day was higher than any other August day for the previous 10 years. Because of the built-in storage capacity (compressibility and on-system storage) and flexibility of the gas system, NJNG was able to ramp up service to customers with disrupted electricity supply.
2020 Heat, Drought, and Wildfires	In August 2020, California was in the middle of its hottest August on record,[1] a severe drought, and its worst wildfire season in modern history. Concurrent to increased demand on the electric system driven by increased cooling loads, California also experienced a decrease in renewable output (due to smoke from the fires)[2] and lower imports than had been anticipated by electric supply planners. To meet increased electric demand, system operators turned to gas-fired generation facilities. During the week of August 11, all of SoCalGas' system storage assets were employed to fill the gap between abnormally high electric demand and low renewable energy generation experienced in Southern California.

In all of these case studies, the gas system provided significant support to the energy system in maintaining resilience and ensuring that energy service was maintained to customers. To understand the gas system's contribution to resilience, it is important to differentiate between the pipeline infrastructure system and the natural gas molecules that flow through it. The gas pipeline system is defined as a series of physical assets that transport energy molecules from the source of production to end users, including residential, commercial, and industrial customers who use gas in their buildings and processes, and electric generators who use gas to

[1] NOAA. *National Climate Report*. August 2020.
[2] EIA. *Smoke from California Wildfires Decreases Solar Generation in CAISO*. September 30, 2020.

make electricity. Today, the gas system is used to transport mostly geologic natural gas, but it can be leveraged to transport low-carbon gases such as renewable natural gas (RNG) and potentially hydrogen in the future as utilities move to decarbonize the energy system.

The Growing Resilience Challenge

Driven by changes in the cost and availability of new technologies and increasing political and social pressure to decarbonize, our energy system is undergoing a transformation. This transformation exposes an issue of energy system resilience related to the interaction of the gas and electric systems.

> *As the percentage of electricity generation from intermittent renewable sources increases, the volume of natural gas used for electric power generation may decline; however, in responding to resilience events the necessity of the services provided by gas-fired electric generators may increase. As current compensation models for the gas system serving the power generation sector are tied to the volume of gas delivered to the facility, there becomes an increasing disconnect between the value of the services provided and associated remuneration for said services.*

To further highlight the need for energy system resilience as part of the current transformation, it is worth considering a recent review of the root cause of the California Independent System Operator (CAISO) electric outages during the August 2020 heatwave. One of the three factors identified was: "In transitioning to a reliable, clean and affordable resource mix, resource planning targets have not kept pace to lead to sufficient resources that can be relied upon to meet [electric] demand in the early evening hours. This makes balancing demand and supply more challenging. These challenges were amplified by the extreme heat storm."[3]

The current model for maintaining the resilience of our energy system was built to support a legacy view of how the energy system operates. As an example, natural gas infrastructure replacement and modernization programs were designed to enhance reliability and safety. As noted in this report they have also contributed to resilience. As the transition to the future energy system accelerates, it is important to understand how these programs complement future energy state resilience needs. The manner in which this energy system is regulated and managed is becoming outdated, and an update is necessary to maintain resilience of the evolving future energy system.

Ensuring a Resilient Future Energy System

The increasing frequency and intensity of climatic events combined with the transformation of the energy system to one increasingly powered by intermittent renewable sources establish the need for a new consideration of the resilience of the energy system. Utilities, system operators, regulators, and policymakers need to recognize that resilience will be achieved through a diverse set of integrated assets—for the foreseeable future, policies need to focus on optimizing the characteristics of both the gas and electric systems.

[3] CAISO. *Preliminary Root Cause Analysis: Mid-August 2020 Heat Storm*. 2020.

Achieving this is easier said than done. It will require a realignment of the valuation and cost recovery mechanisms that currently define the development of the US energy system:

- Energy system resilience must be defined as a measurable and observable set of metrics, similar to how reliability is considered.
- Resilience solutions must be developed considering all possible energy options and across utility jurisdictions, requiring electric, gas, and dual-fuel utilities to work together to determine optimal solutions.
- Methodologies need to be built to value resilience, such that it can be integrated into a standard cost-benefit analysis. Value should consider the avoided direct and indirect costs to the service provider, customers, and society.

The resilience of the current energy system is largely dependent on the gas system's ability to quickly respond to events and use its extensive long-duration storage resources to meet peak and seasonal demand. Ensuring future energy system resilience will require a careful assessment and recognition of the contributions provided by the gas system. Utilities, system operators, regulators, and policymakers need new frameworks to consider resilience impacts to ensure that resilience is not overlooked or jeopardized in the pursuit to achieve decarbonization goals.

1. Introduction

A resilient energy system is essential to the operation of nearly every critical function and sector of the US economy—and the need for energy system resilience is only increasing as emergency services, communications, transportation, banking, healthcare, water supply, and other critical systems become more interconnected than ever. Disruptions to the US energy system can have widespread economic and social impacts, including losses in economic productivity, health and safety issues, and—in the most extreme cases—loss of life.

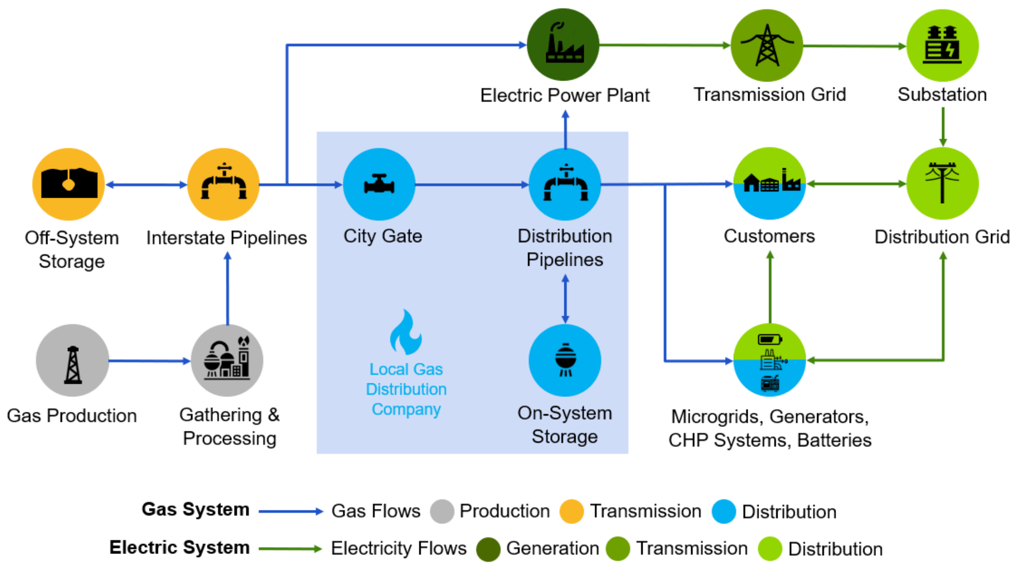
This report examines the resilience of the current gas system with a focus on the part of the system that is under the operational control of the gas local distribution company (LDC). It also examines how the gas system contributes to the resilience of the overall energy system. The work was directed to ask and answer four key questions:

1. What are the characteristics of the US gas system that contribute to its resilience?
2. How do those resilience characteristics allow the US gas system to contribute to the overall resilience of the US energy system?
3. How can the US gas system be leveraged more effectively to strengthen the US energy system?
4. What are the policy and regulatory changes needed to ensure that gas infrastructure can be maintained and developed to continue to support energy system resilience?

1.1 A Primer on the Energy System

An energy system is defined as the full range of components related to the production, conversion, delivery, and use of energy. Energy takes many forms; this report focuses on the natural gas system, herein referred to as the gas system, and its interdependencies with the electric system (Figure 1-1).

Figure 1-1. Interdependencies Between the Gas and Electric Systems

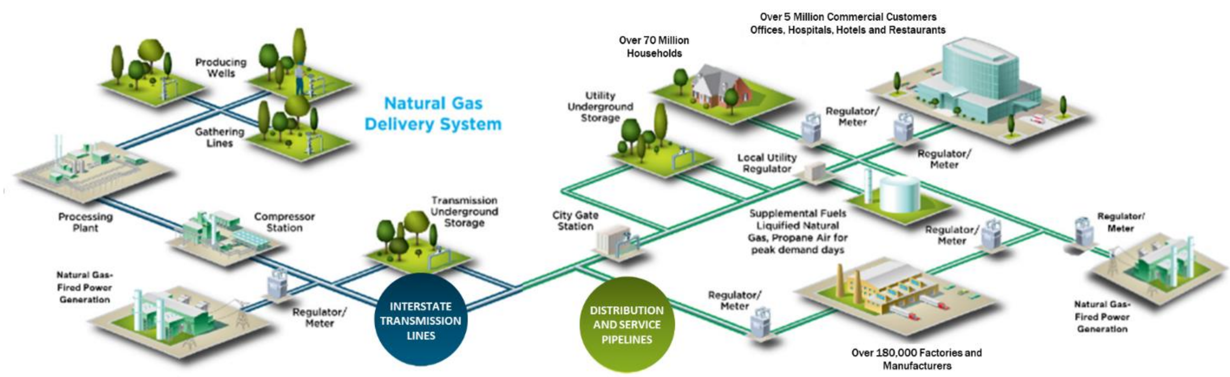


Source: Guidehouse

The gas system is the series of assets that transport energy molecules from the source of production to the site of consumption. The customers served by this system include residential, commercial, and industrial buildings and processes; gas-fired electric generation facilities; transportation fuel providers; and natural gas exporters.

Today, the gas system is used to transport mostly geologic natural gas and small amounts of renewable natural gas (RNG). In the future, the gas system can be leveraged, with only small upgrades, to transport a low carbon fuel supply including RNG, hydrogen, and synthetic methane.

Figure 1-2. Overview of the Gas System



Source: American Gas Association

The gas system can generally be divided into three sections (Appendix A presents further details):

1. **Production and Processing:** Encompasses the process of gathering the gas and treating it to remove impurities.
    - Wells extract natural gas primarily from geologic shale formations.
    - Gathering pipelines transport gas to processing facilities where impurities are removed.
    - Compressors move the gas through midstream pipelines to the connection with interstate transmission pipelines.

2. **Transmission:** Includes the network of high-pressure transmission lines that transport gas from supply basins to market demand centers and, in some cases, across local gas LDC systems.
    - Compressor stations are located approximately every 50 to 60 miles along long-haul transmission pipelines and within gas systems to regulate pressure and keep gas moving.
    - Storage assets connected to the transmission system (defined as off-system storage) exist along these transmission pipelines enabling operators to adjust flow to meet daily and seasonal demand requirements. Storage assets are either underground (i.e., depleted gas reservoirs, aquifers, or salt caverns) or aboveground (where gas is stored as LNG or CNG).

3. **Distribution:** Under the operational control of the LDC, the gas distribution system is primarily comprised of regulator stations, gas pipeline mainlines, and gas pipeline service lines that collectively reduce pressure and move gas from the transmission system to customers.

    - In many cases, gas passes through a city-gate where custody is transferred from the interstate transmission system to the LDC. At this point, gas volumes are measured, typically odorized, and pressure is reduced.
    - LDCs may have LNG, CNG, or underground storage assets on the distribution system (defined as on-system storage), allowing the LDC to maintain reliability and meet short-term demand increases.

1.2 A Primer on Resilience

Resilience is defined as a system's ability to prevent, withstand, adapt to, and quickly recover from system damage or operational disruption. The term is defined in relation to a high-impact, low-likelihood event. The most common examples of these events are extreme weather events (which go beyond standard hot days or snowstorms) of a size and scale to cause significant operation disruption, system damage, and devastating human health impacts. Common threats that test the durability of the energy system include extreme weather events (e.g., hurricanes, wildfires, and extreme heat/cold), cyberattacks (e.g., malware and cyber intrusions), and accidents.

Recent examples of resilience events that affected the US energy system include the 2020 California heat waves, Hurricane Isaias, and the 2019 Polar Vortex; each of which are explored in greater detail in Section 3. Other recent resilience events that have exposed the value of the gas system in maintaining energy system delivery include the 2017 Bomb Cyclone,[4] the 2017 Californian wildfires and landslides, Hurricane Irma, and Hurricane Harvey.[5]

Resilience and reliability are often referenced in tandem, but there is a critical difference between the terms and their impact on the design and operation of energy systems. Reliability is defined in relation to a low-impact, high-likelihood event. The US energy system manages reliability daily—in the standard fluctuations in energy supply and demand. Figure 1-3 illustrates resilience and reliability events, along with typical energy system responses and associated outcomes.

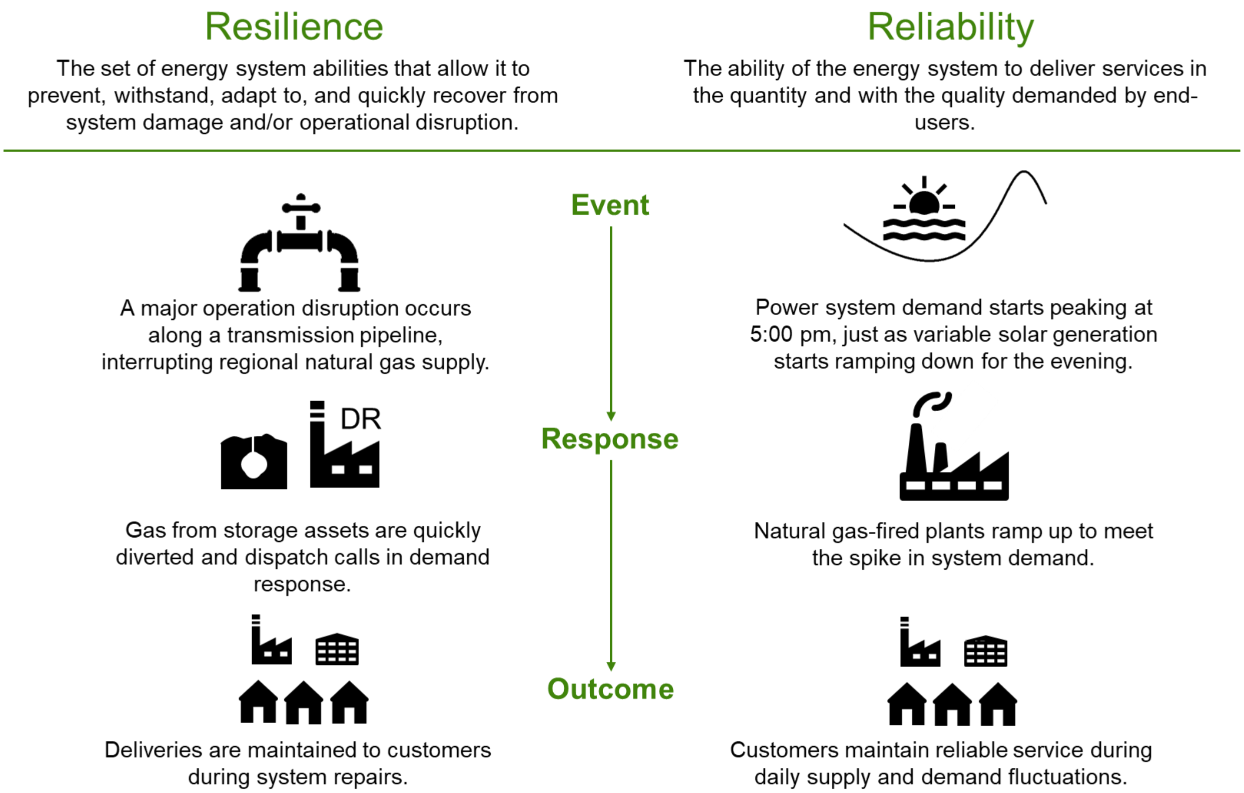
[5] ICF. 2018. *Case Studies of Natural Gas Sector Resilience Following Four Climate-Related Disasters in 2017*.

Figure 1-3. Comparison of Resilience and Reliability

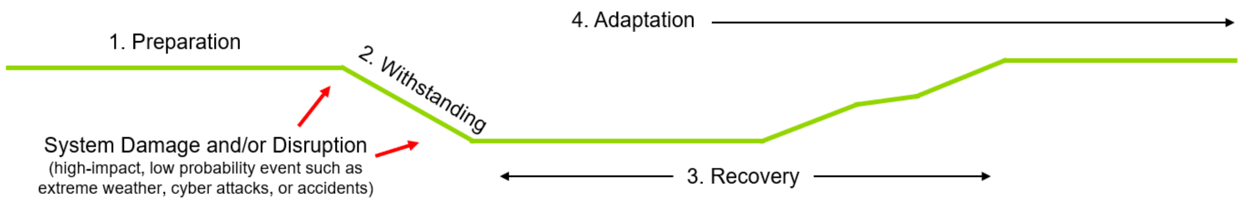


Source: Guidehouse

One way to conceptualize a resilience event is to separate it into distinct phases, where each phase is defined by a time period in relation to the event's onset. Figure 1-4. illustrates this approach with a resilience curve. Table 1-1Table 1-1. defines the four phases of this curve: preparation, withstanding, recovery, and adaptation.

The resilience curve provides a framework for understanding how an energy system's resilience can be strengthened. It is used in Section 2 to classify the resilience characteristics of the gas system.

Figure 1-4. The Energy System Resilience Curve



Source: Guidehouse

Table 1-1. Definition of the Phases of Resilience

Phase	Resilience Characteristics	Timeframe
1. Preparation	The ability to prepare for and prevent initial system disruption	Leading up to the disruption event

Phase	Resilience Characteristics	Timeframe
2. Withstanding	The ability to withstand, mitigate, and manage system disruption	During the disruption event
3. Recovery	The ability to quickly recover normal operations and repair system damage	Following the end of the disruption, until system functions are fully restored
4. Adaptation	The ability to adapt and take action to strengthen the energy system in face of future disruption events	Throughout, but especially during and following the recovery phase

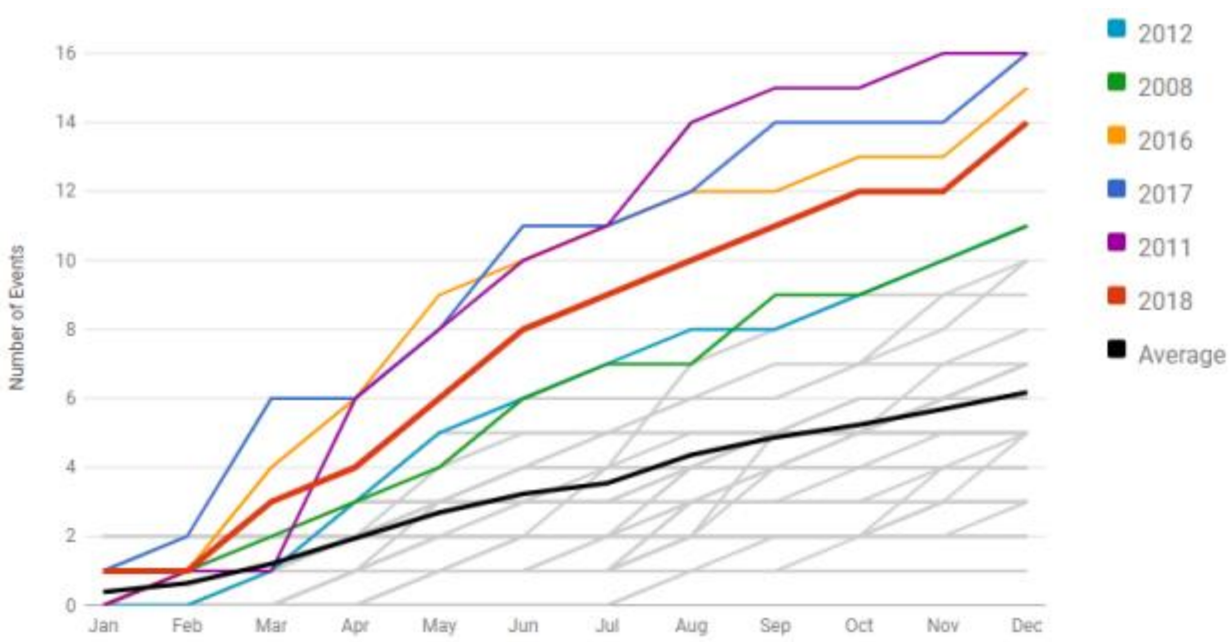
Source: Guidehouse

1.2.1 The Increasing Importance of Resilience

The increased frequency and severity of extreme weather events increasingly put the US energy system at risk. Over the last 50 years, much of the US has experienced increasingly extreme weather including prolonged periods of excessively high temperatures, heavy downpours, flooding, droughts, and severe storm activity.[6]

In the last decade, the US has experienced historic numbers of inflation-adjusted billion-dollar disasters. From 2016-2018 there were 15 billion-dollar disasters per year, up from an average of 6.2 billion-dollar disasters per year since 1980.[7] Figure 1-5. illustrates this trend and shows the cumulative inflation-adjusted billion-dollar disasters on an annual basis since 1980.

Figure 1-5. 1980-2018 Year-to-Date US Billion-Dollar Disaster Event Frequency (CPI-Adjusted, Events Statistics are Added According to the End Date)



Source: NOAA, [2018's Billion Dollar-Disasters in Context]

[6] NOAA. 2014. *Fourth National Climate Assessment*.
[7] NOAA. 2019. *2018's Billion Dollar Disasters in Context*.

To further highlight the importance of placing focus on the resilience of the energy system, consider California in August 2020. California was in the middle of its hottest August (record warmest in 126 years),[8] a severe drought, and its worst wildfire season in modern history. These weather events resulted in increased demand on the electric system, driven by increased cooling load. Concurrently, the state was experiencing a decrease in the anticipated electricity supply from hydroelectricity imports and solar electric generation due to smoke from the wildfires.[9] The coincidence of these events resulted in a significant gap between electricity demand and supply on the California system that led to rolling blackouts on August 14 and 15.[10]

As explored in Case Study 3, in Section 3, because the gas system filled a considerable portion of the gap between abnormally high electric demand and low renewable energy generation, Southern California avoided catastrophic failure.

The increasing frequency and severity of climate events amplify the need to maintain and strengthen the resilience of the US energy system. The energy system needs redundancy and storage capabilities to respond to dramatic shifts in supply and demand quickly.

1.3 An Orientation to this Report

The remaining content in this report is separated into five major sections.

- *Section 2 The Resilience of the Gas System* describes the various inherent, physical, and operational characteristics of the gas system that contribute to the resilience of the US energy system.

- *Section 3 Proving It: Resilience in Action* details five case studies that demonstrate how gas distribution companies across the country have demonstrated gas system resilience through real-world examples.

- *Section 4 Current Regulatory, Policy, and Market Structure* summarizes how current regulatory, policy, and market structures create challenges for building gas resilience assets.

- *Section 5 Ensuring A Resilient Future* explores how decarbonization-driven changes to the electric system may present challenges for future resilience and lessons learned from other economic sectors.

- *Section 6 Conclusions* presents a call to action for how the findings in this report can be used and their implications for policymakers and regulators.

2. The Resilience of the Gas System

This section explores the fundamental resilience characteristics of the gas value chain and describes how it provides resilience services to customers. These characteristics are detailed further in Section 3 in case studies that demonstrate gas system resilience through real-world examples.

2.1 Fundamental Resilience Characteristics of the Gas System

Guidehouse examines the fundamental inherent, physical, and operational characteristics of the gas system in relation to their contribution along the resilience curve phases, i.e. how they help the gas system prepare for, withstand, recover from, and adapt to a resilience event. Table 2-1 outlines the key questions considered in evaluating these characteristics within the gas value chain.

Table 2-1. Key Questions Used to Identify Resilience Characteristics

Resilience Phase	Key Identifying Questions
1. Preparation	• Does it help the system prepare for or prevent threats? • Does it reduce the physical exposure of system infrastructure to the threat?
2. Withstanding	• Does it help minimize system impacts or sensitivity to potential disruptions? • Does it help prevent the occurrence of cascading failures? • Does it help the system maintain functioning if a disruption occurs?
3. Recovery	• Does it assist in restoring or repairing lost functionality?
4. Adaptation	• Does it help the system adjust to changing climate or operating conditions? • Does it facilitate learning and resilience investments to prevent future threats?

Source: Guidehouse

Gas system characteristics that contribute to energy system resilience are highlighted in Figure 2-1. they are also discussed in greater detail throughout this section.

2.2 Inherent Characteristics of Gas Resilience

As a molecular form of energy storage, natural gas molecules have several inherent characteristics that contribute to the resilience of the gas system. Chief among these characteristics is its compressibility, which allows additional volumes of gas to be packed into the pipeline or under- and above-ground storage. Natural gas supply is also abundant and geographically diverse, allowing it to meet current energy needs even in the event of a supply chain disruption. The inherent characteristics also hold true for low carbon forms of gas supply which may replace natural gas in the future gas system. Table 2-2 summarizes the inherent characteristics of gas resilience, which are also discussed further in this section.

Table 2-2. Inherent Resilience Across the Phases of Resilience

<tr><td>Abundance and Diversity of Supply</td><td></td><td colspan="2">Maintains production in the event of a regionally isolated supply-side disruption</td><td>Low carbon options for a future energy system</td></tr>
</table>

Source: Guidehouse

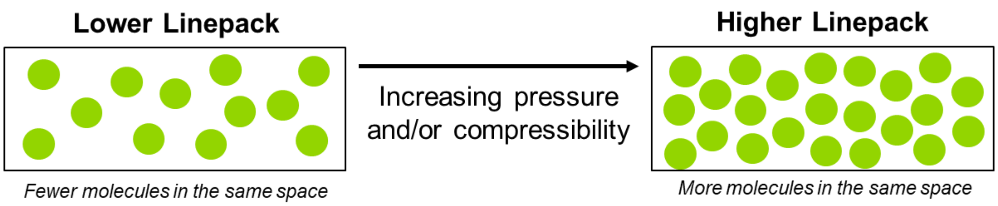
2.2.1 Compressibility

Natural gas is made up of inherently stable and compressible molecules, making it a desirable energy storage carrier and pipeline system buffer.

- **Storage** – Long-duration gas storage is frequently used to meet seasonal demand patterns and can be used as a complement to the electric system in meeting demand during low-likelihood, high-impact resilience events. Natural gas can be compressed and stored underground in geological formations (e.g., in depleted gas reservoirs, aquifers, or salt caverns) or aboveground in tanks (as LNG or CNG). As LNG, the volume of natural gas is about 600 times smaller than its gaseous form at atmospheric pressure; whereas, as CNG, it is 100 times smaller.

- **Linepack** – Excess natural gas molecules, i.e. more than what would be needed to meet customer demand can be compressed and stored within pipelines, acting as a buffer to minimize the impact of short-term hourly supply and demand fluctuations on the gas system (Figure 2-2).[11] Gas system operators, including LDCs, can control the amount of linepack in the pipes, allowing them to meet rapid, intraday changes in demand even if upstream supply is insufficient.

Figure 2-2. Linepack and Compressibility of Gas



Source: Guidehouse

Figure 2-2 provides a clear example of how linepack and storage can be used in tandem to prevent and mitigate the effects of a major gas system disruption. These characteristics are different from the electricity grid where disruptions can immediately impact all connected gas systems and increase the risk of cascading failures. Electric supply and demand must be balanced across the electric system near instantaneously and electricity can only be stored in specified storage assets, such as batteries.

2.2.2 Abundance and Diversity of Supply

Natural gas is supplied from a variety of sources across North America, including:

- **Conventional production:** Currently, natural gas is primarily produced from shale plays and formations; it is also produced in smaller quantities from conventional gas reservoirs, tight sands, carbonates, and coal-bed methane. Figure 2-3 highlights the geographic diversity of US shale plays and formations. Additionally, an evaluation by the Potential Gas Committee at year-end 2018 indicated that the US possesses a technically recoverable resource base of natural gas of nearly 3,400 trillion cubic feet (Tcf).[12] The US Energy Information Administration additionally reported that US proved

---

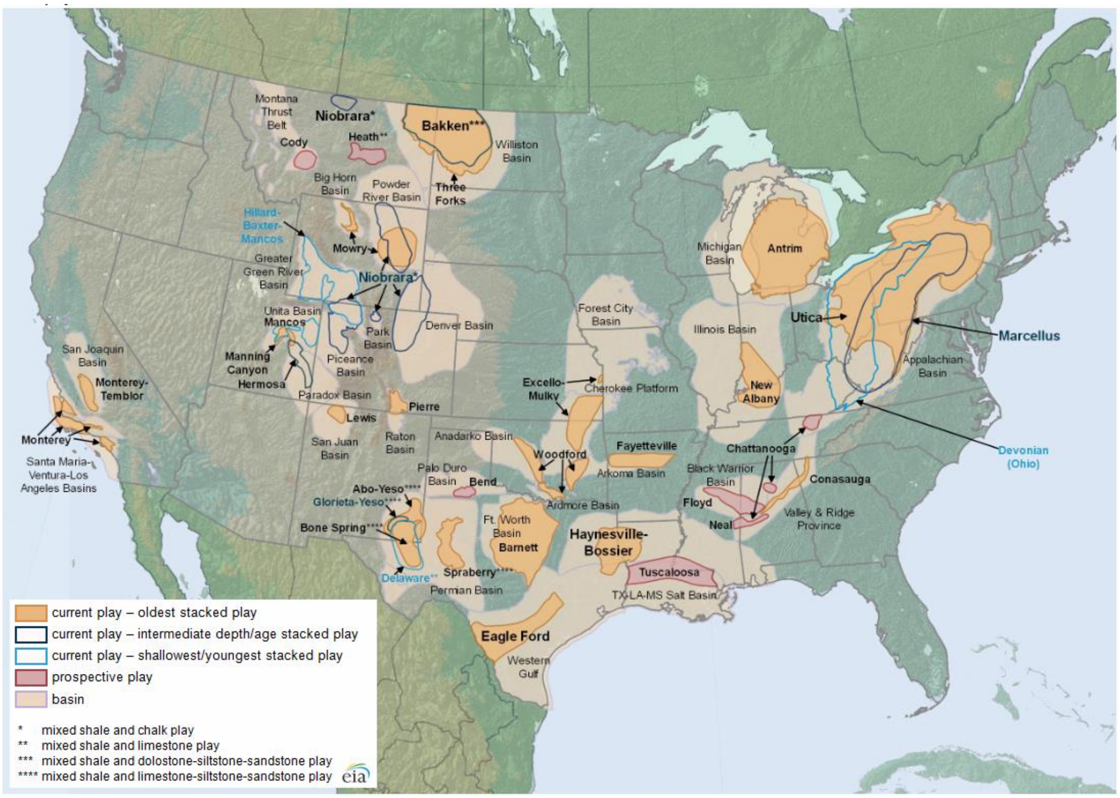
[11] Natural Gas Council. 2019. *Natural Gas: Reliable and Resilient.*

[12] Potential Gas Committee. 2019. *Potential Supply of Natural Gas in the United States.* Accessed November 2020.

reserves stood at 504.5 Tcf as of 2018. The combination of these supplies suggests a future gas supply resource enough to meet over 100 years of consumption at current levels.[13]

This abundance and diversity of natural gas supply ensures that natural gas can continue to meet customer demand even during regionally isolated supply-side disruptions such as a major storm event. For example, limited supply interruptions during recent hurricanes demonstrates the value of shifting natural gas production from the Gulf of Mexico to geographically diverse shale plays and formations.

Figure 2-3. US Shale Plays and Formations



Source: US Energy Information Administration

- **Low Carbon Production:** The abundance and diversity of resources transportable through the gas system will increase as RNG and hydrogen become increasingly commercially viable. Though it is only a small portion of current US gas supply, RNG supply is growing dramatically--produced from a variety of waste feedstocks from the sewage, agriculture, food, and forestry sectors, as detailed in Appendix B. Hydrogen is projected to serve a larger portion of future US gas demand, but it is earlier in the process of developing commercial viability in the US, though it is already flowing through the pipes in Europe as discussed in Appendix B.

[13] Natural Resources Canada. 2020. *Natural Gas Facts.* Accessed October 2020.

- **Pipeline Imports:** Natural gas is also imported via pipeline from Canada, and from elsewhere as LNG. These are critical supply sources during peak periods and lend to greater gas system flexibility.

2.3 Physical Characteristics of Gas System Resilience

The gas system's physical characteristics lend themselves to providing stability to the energy system. Most pipeline infrastructure is underground and looped, creating flexibility in a delivery system that is shielded from many major disruptive events. Much of the gas delivery system also runs on its own supply, making it self-reliant. The ability to store gas further strengthens the self-reliant attributes of the gas system, enabling it to respond to disruption or an extreme peak caused by unprecedented demand or upstream disruption. Table 2-3 summarizes these physical characteristics of gas resilience, which this section also discusses.

Table 2-3. Physical Resilience Across the Phases of Resilience

Source: Guidehouse

2.3.1 Underground Infrastructure

Natural gas is one of the few energy resources predominantly delivered to customers by pipeline. In contrast, other common energy forms, such as electricity, are mostly delivered by aboveground wires. Although each delivery method has advantages, the underground gas delivery system has significantly reduced exposure to disruptive events from extreme weather such as hurricanes and snowstorms. Because of this, significant weather events rarely disrupt localized segments of the network and damage is typically limited to aboveground facilities where pipeline assets may be exposed.[14]

[14] EIA. *Natural Gas Explained: Natural Gas Pipelines*. Accessed October 2020.

2.3.2 Looped and Parallel Transmission and Distribution Network

The gas system is extensively interconnected with multiple pathways for rerouting deliveries. This interconnectivity enables the sourcing of natural gas from various production centers across the country. Additionally, distribution mains are typically interconnected in multiple grid patterns with strategically located shut-off valves. These valves allow operators the ability to isolate segments of a gas system, which minimizes customer service disruptions. To reinforce the resilience of gas delivery, the valves are paired with on-system storage and mobile pipeline solutions.

> *A 2019 study by the Rhodium Group on natural gas system reliability indicated that, "the US natural gas system typically deals with a handful of disruptions every month that last a day or more. Despite these disruptions, deliverability to end-use sectors, including electric power generators, is rarely impacted because of the redundancy built into the system."[15] While this study focused on reliability, it highlights the system redundancy that is available to respond to higher-impact resilience events.*

In addition to the interconnectivity of the gas system design, pipeline capacity is often increased by installing two or more parallel pipelines in the same right-of-way (called pipeline loops), making it possible to shut off one loop while keeping the other in service. Further, in the event of one or more equipment failures, gas pipelines can continue to operate at pressures necessary to maintain deliveries to pipeline customers, at least outside the affected segment. Considering customer impacts of individual equipment failures in the design of gas pipelines and facilities to determine where investment in redundant infrastructure is prudent, is part of the gas utility risk management process.

2.3.3 Self-Reliant Gas-Fired Equipment

Much of the equipment used on the gas system, including compressors, dehydration equipment, pressure regulators, and heaters, are usually powered by the gas that flows through the pipes they serve. Powering equipment by the gas in the system limits the gas system's reliance on external supply chains. If gas continues to flow through the pipes—which has demonstrated to be a resilient supply chain itself—the gas system will continue to operate, and gas will flow to customers.

In some cases, the pursuit of decarbonization goals has resulted in the replacement of gas compressors with electric compressors. While electric compressors are not yet widespread, their use does reduce this resilient aspect of gas system operation.

2.3.4 Distributed Customer Generation

The US Department of Energy has documented how combined-heat and power (CHP) systems serve as a resilience solution, with specific case studies on how CHP has provided resilience for critical facilities during major weather events, giving them the flexibility to produce thermal energy and electricity onsite.[16] Example 1 highlights one such case study. CHP systems at

---

[15] Rhodium Group. 2019. *Natural Gas Supply Disruption: An Unlikely Threat to Electric Reliability*.

[16] US Department of Energy. 2018. "CHP Technology Fact Sheet Series."

these facilities are largely dependent on the resilience of the US gas system and its ability to continue delivering natural gas during resilience events.

At the end of 2019, there were 3,186 commercial and industrial (C&I) CHP sites fueled by natural gas with a total capacity of 58,140 MW.[17] This distributed generation is equivalent to over 5% of total US electric power generation capacity. Distributed CHP systems exemplify how the gas system supports the resilience of end-use customers by giving them alternative options to generate heat and electricity in the case of unplanned energy system disruptions. The costs and inconvenience of a power outage can be substantial, including losses in productivity, product, revenue, and customers. Gas-fired standby generators also provide a resilience benefit by helping to avoid the impact of a power outage. This benefit is discussed further in Case Study 5.

Example 1. CHP and Distributed Generation Support Critical Infrastructure During Extreme Weather Events[18]

Hurricanes. In 2008, Hurricane Ike flooded over 1 million square feet of the University of Texas Medical Branch (UTMB) in Galveston, Texas. The hurricane interrupted utility services and resulted in the complete loss of UTMB's underground steam distribution system. Learning from this experience, the UTMB installed a 15 MW CHP facility (11 MW fueled by natural gas) to improve resilience and allow for an immediate return of hospital and clinical operations.

This resilience solution was tested during Hurricane Harvey in 2017 when the campus lost power. In circumstances that would have otherwise caused a blackout, the CHP system continued to operate during and after the storm, allowing the hospital to maintain regular operations. As a co-benefit, the CHP system saves UTMB approximately $2 million per year in utility costs and reduces campus emissions by 16,476 tons of CO_2 per year.

2.3.5 Gas System Storage Capacity

The ability to store large quantities of energy supply is a fundamental strength of the gas system allowing it to respond to, prepare for, withstand, and recover from disruption. In addition, gas storage facilities offer further geographic supply diversity to the gas system, as these storage assets can often maintain supply if disruptions are experienced on the system. Gas system storage capacity is built as a result of long-term planning in response to forecasted seasonal and peak demand. Gas system storage can be classified by where it is connected to the gas value chain.

- **On-System Storage:** This storage is operated and controlled by the LDC, allowing it to respond quickly to peak demand requirements and emergency situations. On-system storage is often aboveground, and in some situations underground. One advantage of on-system storage is that it can be sited at specific locations on the gas distribution system to best provide a resilience benefit (both supply and pressure support) in the event of an upstream disruption. This benefit is exemplified in Case Study 4.

[17] U.S. Department of Energy. 2019. *U.S. Department of Energy Combined Heat and Power Installation Database*. Accessed October 2020.

[18] Southcentral CHP Technical Assistance Partnerships. 2019. *Project Profile: University of Texas Medical Branch 15 MW CHP System*. Accessed October 2020.

- **Off-System Storage:** This storage is connected to a transmission line and is not directly tied to an LDC's distribution system. In most cases, off-system storage is underground, which makes it resilient to many climate-driven disruptions.
- **Mobile Storage:** Stored as LNG or CNG, natural gas can be moved via truck to serve short duration needs such as providing temporary supply for emergency response, pipeline maintenance, and construction and peak shaving.

The gas system's storage capacity is critical to its ability to respond to disruption. For example, the gas system storage capacity allows the gas system to respond to extreme heat and cold events when large amounts of gas are drawn in a short period. In addition, system storage provides a supply buffer allowing the LDC vital time to respond to unplanned delivery constraints in the pipeline and distribution network, resulting from gas system disruptions. The capacity of US gas storage and the associated value of that storage is further explored in Example Box 2.

Example 2. The Value of Gas Storage

In 2019, the US consumed approximately 31 trillion cubic feet of natural gas. If this natural gas was consumed in the same amount every day, the US would consume approximately 85 Bcf per day (Bcfd). But natural gas usage is seasonal – in January 2019, the US consumed nearly 110 Bcfd on average compared to approximately 71 Bcfd in June.[19]

With seasonal fluctuations in use and additional fluctuations in daily consumption, gas storage plays a vital role in balancing supply and demand. The US has nearly 400 underground storage facilities in the lower 48 states with a total storage capacity of more than 4,000 Bcf. In 2019, approximately 2,300 Bcf of natural gas supply was delivered from storage facilities, roughly the energy equivalent of 700 million megawatt-hours (MWh).[20]

NW Natural operates the Mist underground storage facility in Oregon. Its 20.1 Bcf of gas storage capacity is equivalent to 6 million MWh. Installing a battery of equivalent size on the electric system would cost approximately $2 trillion in 2020 dollars.[21]

Storage assets are additionally well positioned to support future state resilience demands and are capable of using low carbon commodities. These long-lived assets can be re-missioned to meet evolving energy system resilience requirements.

2.4 Operational Characteristics of Gas System Resilience

The industry has several operational tools at its disposal to prepare for, withstand, recover from, and adapt to disruptions. The gas system has robust management practices for the flows of gas on the system and there are several opportunities to provide flexibility in delivery and to manage demand. Table 2-4 summarizes these operational characteristics of gas resilience, which are also discussed further in this section.

2.4.1 Robust Management Practices

The gas industry maintains safe and resilient operations using a variety of tools including long-term resource planning, emergency response planning, standard operating procedures, and incident-response protocols. The industry also has a well-established Mutual Aid Program that allows utilities to provide and receive aid from other utility members in the event of disaster or emergency situations.[22] Pipeline operators are trained per the US Department of Transportation's pipeline safety requirements.

Gas utilities also follow robust cybersecurity protocols,[23] and align their cybersecurity programs to several key frameworks and standards including the NIST Cybersecurity Framework, the ISA/IEC 62443 Series of Standards on Industrial Automation and Control Systems (IACS) Security, ISO 27000, NIST 800-82, the TSA Pipeline Security Guidelines, and API Standard 1164.[24] Gas assets are also designed with manual override and manual backups in case of cyber disruption.

2.4.2 Flexible Delivery

In addition to on-system storage, some LDCs use mobile pipeline solutions. These non-pipeline solutions are frequently LNG or CNG tanker trucks that deliver needed supplies directly to an injection point on the distribution system in the event of a gas system disruption. The ability to deliver through multiple pathways is a valuable characteristic of the gas system.

Example 3. Operational Management Helps Prepare for and Withstand Extreme Weather Events

During the January 2019 polar vortex, a severe wave of cold weather swept over the midwestern US, bringing temperatures to well below -20°F in several states. Minnesota experienced its lowest air temperatures since 1996, reaching a low of -56°F and wind chills below -60°F in some areas.[25]

Leading up to the event, CenterPoint Energy used gas system modeling and SCADA to predict how its gas system would react to the extreme cold temperatures. Based on this data, CenterPoint Energy deployed two CNG trailers to strategic locations where additional supply might be needed and placed field crews on standby across the state. Engineering, operations, and gas control were in constant communication, as is standard practice for most cold-weather events. Though CenterPoint Energy's gas system met demand during record temperatures without the need of the CNG trailers, this example highlights how gas LDCs use robust management practices to prepare for and withstand extreme weather events.[26] CenterPoint Energy's response to the 2019 polar vortex is highlighted further in Case Study 1 in Section 3.

2.4.3 Demand Side Management and Energy Efficiency

Gas system operators have a robust toolbox to safely, effectively, and efficiently accommodate demand. Many gas utilities offer demand side management (DSM) and energy efficiency programs to support their customers in managing their gas consumption, while some are also piloting demand response (DR) programs that can include controllable devices such as connected thermostats. Implementation of these programs frequently results in resilience benefits. For example:

- Residential customers participating in weatherization programs to reduce their energy use associated with heating and cooling will enjoy a home that is more efficient and can better maintain comfortable indoor temperatures. These residents will be better able to shelter in place if they experience disruptions in their energy supply.
- Participation in energy efficiency programs in general will result in more efficient energy usage and lower annual spend on energy.
- DSM and DR programs offer grid operators the opportunity to improve the efficiency and stability of the power system by reducing the severity of demand spikes. Although these programs are often developed to increase reliability, they also offer significant resilience benefits in allowing grid operators the ability to adjust the demand side of the equation when a significant disruption is experienced.

2.4.4 Large Customer Contract Design

Gas system operators contract with large-volume customers in a way that mitigates potential physical constraints around deliverability. Large-volume customers voluntarily enter into either a firm contract (i.e., they are contractually guaranteed an agreed amount of supply, regardless of potential gas system capacity constraint issues) or an interruptible contract (i.e., their service can be interrupted if the gas system is experiencing capacity constraint issues) with the gas system. This means that gas system operators have the flexibility to contractually curtail delivery to large-volume interruptible customers in the event of disruption, a form of demand response, which is one reason why the gas system rarely experiences service disruptions.

---

[25] Minnesota Department of Natural Resources. 2019. *Cold Outbreak: January 27-31, 2019.* Accessed October 2020.
[26] CenterPoint Energy, Interview. October 2020.

The definitions of firm and interruptible customers may need further clarification as the gas system sees more large-volume users with dramatic swings in their maximum and minimum usage throughout a day. However, the gas system's ability to contract differently with users that use the gas system differently is a resilience characteristic that must be recognized.

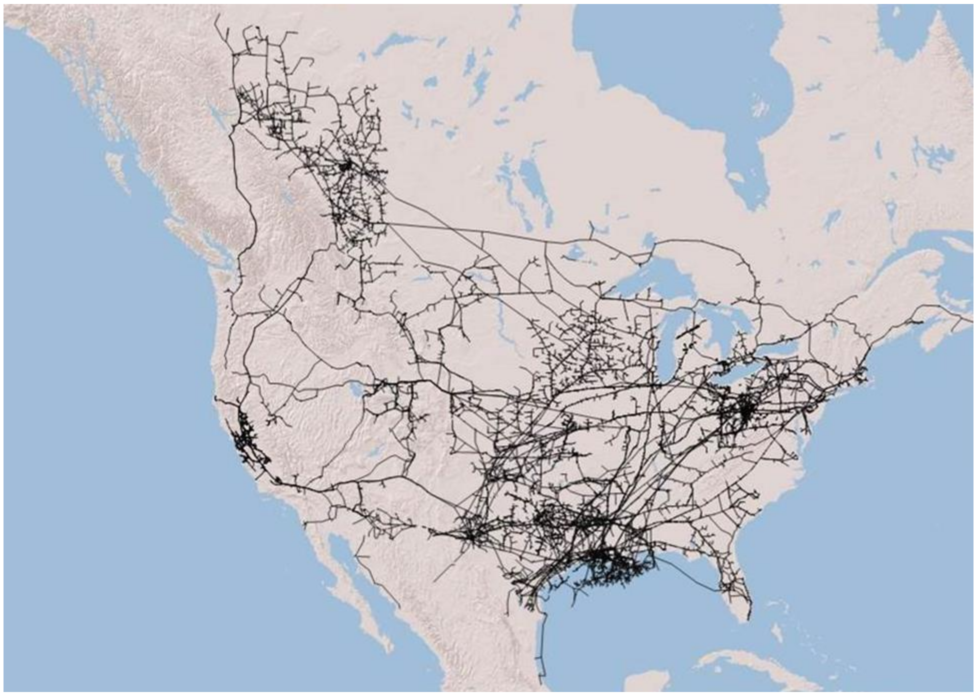
2.5 Resilience Limitations

The overall US gas system's network contributes to its stability but the degree of interconnectedness on the network can vary across LDCs based on the following two primary factors:

- The availability of operational capacity on upstream pipelines and storage
- The physical location of the LDC service territory in relation to pipelines and storage facilities

As Figure 2-4 illustrates, some US regions have more access to the transmission system than others. For example, the Pacific Northwest is supplied by fewer pipelines compared to the Upper Midwest and the Gulf Coast. A gas utility or geographic region with limited access to multiple transmission pipelines will need to leverage other resilience solutions to develop transportation and supply diversity, such as storage.

Figure 2-4. Major North American Natural Gas Pipelines



Source: S&P Global Market Intelligence

3. Proving It: Resilience in Action

The inherent, physical, and operational capabilities of the gas system—from receipt of supply from the upstream pipelines to the ability to provide short-notice storage withdrawal and injection rates—enable it to meet the volatile demand profiles resulting from resilience events. This section includes six case studies that exemplify how the gas system contributes to the resilience of the US energy system.

It is a testimony to the preparedness and true resilience of the industry that there are so few case studies of extra measures ever needing to be taken to respond to periods of extraordinarily high demand.

Polar Vortex (January 2019)

- In Case Study 1, the use of a diverse mix of gas resilience assets (upstream pipelines, storage, LNG and propane storage, flexible non-pipeline assets) allowed the gas system to meet record peak demand resulting from extreme cold temperatures.

- In Case Study 2, the integral role the gas system plays in supporting the space heating needs of customers in colder climates is explored. The case study also demonstrates that during a peak event, the gas system currently delivers substantially more energy than the electric system is built to deliver.

- In Case Study 3, the resilience attributes of the gas system were put to the test when a fire caused a failure on a critical gas compression and storage facility. Despite losing almost one-third of its on-system storage, the gas utility withstood this failure during a period of peak demand without involuntary loss to a single residential customer.

Polar Vortex (February 2014)

- In Case Study 4, the role of natural gas storage, both underground and aboveground, as a critical resilience solution to meet record gas demand is demonstrated.

Hurricane Isaias (August 2020)

- In Case Study 5, natural gas was used as a backup power source to ensure essential power functions could continue to be met for residential and commercial customers in the middle of a hurricane.

Heat, Drought, and Wildfires (August 2020)

- Case Study 6, storage capacity resources were used to meet the supply needs of gas-fired generation plants when the California electric system experienced high demand from a record-breaking heatwave and unplanned reductions in other sources of generation.

Case Study 1: Meeting Record Peak Demand (Minnesota)

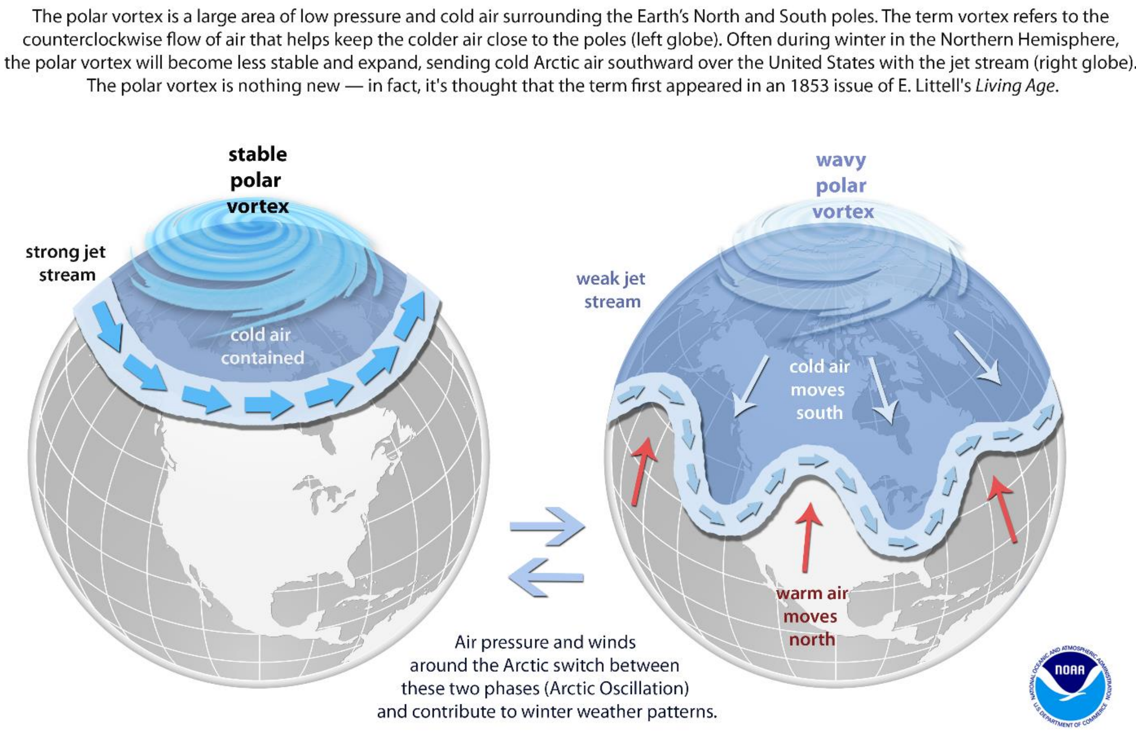
Key Finding

CenterPoint Energy used a diverse mix of gas resilience assets (upstream pipelines, storage, LNG and propane storage, flexible non-pipeline assets) to meet record peak demand resulting from extreme cold temperatures across the Midwest.

Introduction

The first three case studies pertain to the January 2019 Polar Vortex, when a weakened jet stream resulted in the coldest temperatures in over 20 years to most affected regions across the US and Canada (Figure 3-1). The event resulted in at least 22 deaths and grounded around 2,700 flights across the Midwest and Northeast.

Figure 3-1. The Science Behind the Polar Vortex



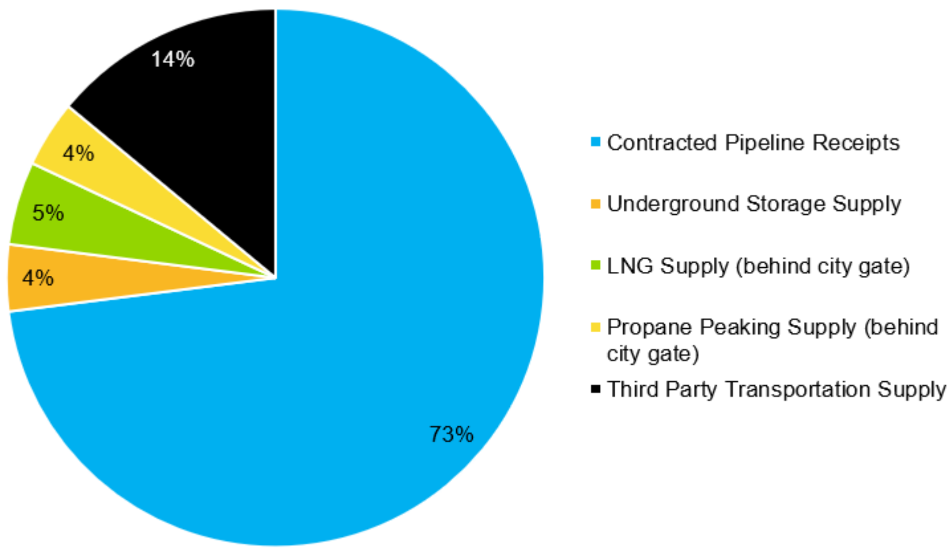
Source: National Oceanic and Atmospheric Administration

Overview

During the January 2019 Polar Vortex, in Minneapolis, Minnesota, the average temperature was -19°F from January 29 to 30. The coldest hour occurred at 6:00 a.m. on January 30 when the temperature was -30°F (before wind chill). On these days, CenterPoint Energy (which serves 870,000 customers in the greater Minneapolis region) experienced record daily delivery of natural gas of 1,495,000 Dth on January 29 and 1,448,000 Dth on January 30. This compares to 1,000,000 Dth of daily sendout in a typical January day, or a 49% and 44.8% increase over average for January 29 and 30, respectively.

Because the demand for gas was so high on CenterPoint's gas system on January 29 and 30, interruptible customers and interruptible transportation service deliveries were curtailed to maintain distribution system integrity for firm demand customers. Even after curtailing these customers, CenterPoint Energy needed to pull gas supply from every available source, as Figure 3-2 illustrates. Approximately 13% of the gas delivered to CenterPoint's customers in Minneapolis on these very cold days was supplied by storage, including LNG and propane assets, which played a critical role in providing additional supply and pressure to maintain gas system integrity.

Figure 3-2. Gas Supply by Source, CenterPoint Energy, Minneapolis, Minnesota, January 29-30, 2020



Source: Guidehouse, CenterPoint Energy

Like many gas utilities, this planning consists of a thorough review of gas supply plans and monitoring of distribution system performance in addition to heightened staffing to be prepared for quick response to issues.

Table 3-1. CenterPoint Energy Actions to Maintain Gas System Viability During the 2019 Polar Vortex

Phase of Resilience	CenterPoint Actions to Maintain Gas System Deliveries in Response to the 2019 Polar Vortex
1. Preparation	• Daily review of supply plans by gas supply, gas control, peak shaving, and engineering. • Daily preparation and execution of cold weather engineering plans. • Daily staging of operations technicians in critical locations to monitor/react. • Daily staffing of engineering personnel in the cold weather ops center to support system operations and gas control. • Dispatch Center: Extra staff added to coordinate with field operations. • Field operations: Implementation of cold-weather operating plans.

Phase of Resilience	CenterPoint Actions to Maintain Gas System Deliveries in Response to the 2019 Polar Vortex
	• The areas requiring CNG trailer deployment were identified using system modeling and SCADA to help predict how the system would react during the cold event. • Two CNG trailers were deployed and on standby. These flexible non-pipeline solutions provided just in time delivery to reinforce system operations
2. Withstanding	• Aside from the CNG locations, CenterPoint Energy positioned several field crews at different locations throughout its service territory on standby to be responsive should an unexpected issue arise. In addition, critical groups, including engineering, operations, and gas control were in constant communication to monitor the system.
3. Recovery	• The system did not incur any damage or major disruptions, so there was no recovery phase for this event.
4. Adaptation	• System reinforcements were identified and later completed for the areas where CNG trailer were deployed. • Regular review of distribution system performance as cold weather occurs. • Adjustments are made if needed and as possible. • Testing and operation of stations and equipment.

Source: Guidehouse, CenterPoint Energy

Conclusion

CenterPoint Energy’s use of a diverse mix of gas system resilience assets to meet record peak demand from a climate event exemplifies how the gas system contributes to the energy system’s overall stability. Upstream pipelines, storage, LNG and propane storage, and flexible non-pipeline assets were deployed for addressing unplanned or unforeseen events within the integrated energy system.

Case Study 2: The Role of Natural Gas (Illinois)

Key Finding

During the 2019 Polar Vortex, Nicor Gas, Peoples Gas, and North Shores Gas' daily distributions of natural gas (7.32 Bcf) were equivalent to 90GW of electricity—more than 3.5 times the amount of electricity that ComEd, the electric utility serving a similar territory has delivered in a single day. The gas system provides value in the volume of energy that can be delivered during peak events, which will require significant infrastructure buildout to be replaced.

Introduction

During the record-breaking cold weather that occurred January 30 and 31, 2019, Nicor Gas, the LDC serving 2.2 million customers in Illinois delivered more than 4.88 Bcf of natural gas per day. This is more than double the natural gas delivered on a typical day in January day. In terms of energy delivery, this amount of gas, an average of 0.20 Bcf per hour, compares to approximately 61 GW of electricity.[27] This is the single largest delivery of natural gas in the company's history—surpassing previous records set when 4.5 Bcf was delivered between January 6 and 7, 2014.

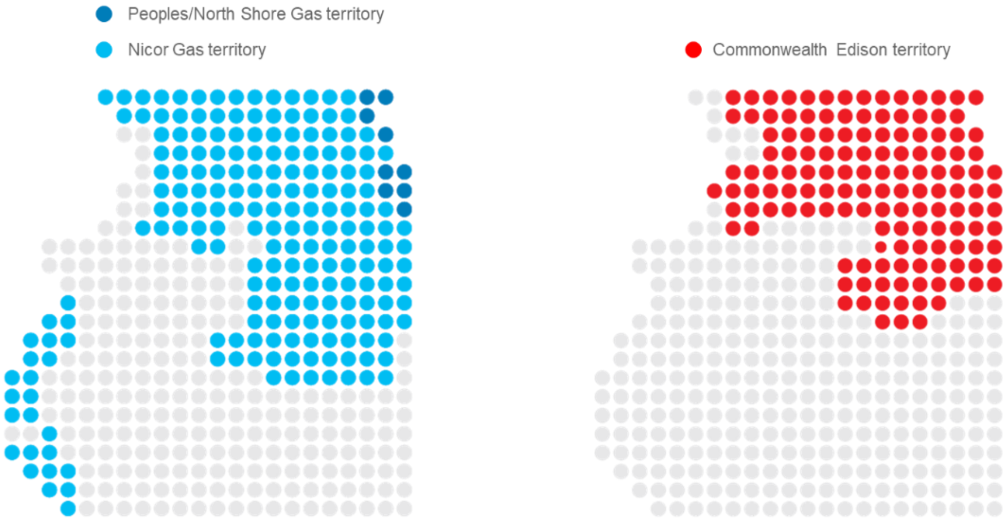
Nicor Gas employees worked around-the-clock during this cold weather to monitor the distribution system to ensure the safe performance and reliability of the infrastructure. More than 7,000 customer calls were received at the customer contact center and field operations responded to nearly 1,500 emergency calls for service during the two days. There were no major service outages during the weather event.

Overview

On January 30, 2019, together Peoples Gas, North Shore Gas, and Nicor Gas distributed more than 7.32 Bcf of natural gas—this is comparable to approximately 90 GW of electricity and represents more than 3.5 times the amount of electricity that ComEd, the electric utility serving northern Illinois, has ever delivered in single day (Figure 3-3). Even on a typical day, the Nicor Gas system alone delivers an amount of energy that is approximately equal to the maximum amount of energy that ComEd has ever delivered on a single day. The historic peak delivery day for the ComEd system is 24.8 GW, which occurred on July 20, 2011.

[27] Calculation: 4.88bcf/24 hours*10^9 scf* 1,020 Btu/scf * 1 kWh/3,412 Btu = 60, 785, 463 kW (or 60.8 GW)

Figure 3-3. Energy Distribution by Northern Illinois Utility



Utility	Peak demand (gas)	Peak demand (electricity)
Peoples Gas/North Shore Gas	~2.44 Bcf	~30.4 GW*
Nicor Gas	4.88 Bcf	~60.8 GW*
ComEd Historic Peak Demand on July 20,2011		24.8 GW

Source: Nicor Gas Company

There are several takeaways for regulators and policymakers that emerge from this case study. First off, it is critical to understand the implications of electrification on infrastructure investment, not just for a typical day, but for a peak event.

The gas system plays an integral role in supporting the space heating needs of customers in colder climates. Moreover, in the wintertime, space heating requirements typically begin to increase in the early morning and late afternoon hours; these are times when intermittent, renewable resources may not be available. Without the gas system, battery storage with significant duration and capacity capabilities would be required to bridge the gap between generation from intermittent, renewable resources and heating demands.

The gas system provides value in the volume of energy that can be delivered during peak events, which will require significant infrastructure buildout to be replaced.

Case Study 3: Ray Compressor Station Fire (Michigan)

Key Finding

Despite the loss of availability of the largest storage facility on its gas system, Consumers Energy was able to serve all of its customers without any involuntary disruption during a period of record cold temperature and peak demand.

Introduction

As the CenterPoint Energy and Nicor Gas case studies demonstrate, the Polar Vortex of January 2019 placed enormous stress on the gas delivery system under record-setting conditions. When extreme cold weather hit Michigan from January 29 to February 1, Consumers Energy was prepared to fulfill demand utilizing gas storage and pipeline supply as the primary supply sources. Consumers Energy had 61.9 Bcf of working natural gas inventory, above its target of 61.4 Bcf during a typical winter.

Gas storage fields play a critical role in enabling Consumers Energy to serve its customers during times of peak demand. They are used to meet demand at various levels:

- **Baseload demand:** Along with pipeline supply, baseload storage fields run daily during the winter to meet a foundation level of demand.
- **Intermediate demand:** Intermediate storage fields run during longer periods of higher demand.
- **Peak demand:** Peaker (and needle peaker) storage fields run during the extreme hours and days when demand changes quickly, typically in the early morning when customers start their day and their gas appliances.

Consumers Energy operates 15 storage fields with a total working capacity of 149 Bcf. The largest, the Ray Peaker field, has a capacity of 47.52 Bcf, or almost one-third of Consumers Energy's working storage capacity. The Ray facility is a combination compressor station and adjacent storage field.

Consumers Energy planned to fulfill demand during this cold period using baseload production storage fields, Ray field, and pipeline supply as the primary sources. Its other peaker fields were in reserve to support gas system packing and address any potential interruptions in pipeline supply, baseload fields, and compressor stations.

Incident

At approximately 10:30 a.m. on January 30, a fire occurred at the Ray Natural Gas Compressor Station. The fire reduced the amount of natural gas Consumers Energy could deliver to customers from underground storage in the Ray field near the compressor station. The damage to its largest storage and delivery system, which occurred during historically high natural gas demand due to cold temperatures, prompted Consumers Energy to take steps to ensure gas deliveries to its customers continued uninterrupted.

Response

Consumers used a variety of inherent, physical, and operational resilience characteristics to respond to the supply disruption during historic cold temperatures. Throughout the entire event, not a single critical, priority, or residential customer lost service involuntarily.

Table 3-2. Summary of Resilience Characteristics Used by Consumers Energy

Date	Key Resilience Characteristics
2018	• Consumers Energy held a training exercise in 2018 with a scenario involving a fire at Ray Compressor Station. This prepared employees by providing an opportunity to **rehearse emergency response** roles and responsibilities.
January 24, 2019	• In preparation of forecasted extreme cold temperatures, notice was given to **interruptible customers** that interruptible service would not be available beginning January 25.
January 30, 2019	• System **linepack** provides immediate buffer to sudden loss of storage supply from approximately 10:30 a.m. to 8:00 p.m. • At 10:45 a.m., Consumers Energy leveraged its **networked system** by calling five major interconnected pipelines that agreed to provide supply on a best effort basis. • **Peaker storage fields** were dispatched and began flowing at approximately 11 a.m., reducing sole reliance on linepack. • At 1 p.m., Consumers Energy began requests for **voluntary load reductions** from 104 of its highest volume customers. • Procurement of additional supply. • Formal **curtailment** for large transport customers began at approximately 3 p.m. • At 8 p.m., Consumers Energy worked with the governor to use the **Emergency Broadcast system** to ask residential customers for voluntary natural gas reductions. • Near 11 p.m., some of the Ray facilities supply capabilities were returned to service.
January 31, 2019	• Continued curtailment enables additional 40,000 Mcf of demand reduction.
February 1, 2019	• Announcement of cessation of curtailment at 8:22 a.m.

Source: Guidehouse, Consumers Energy

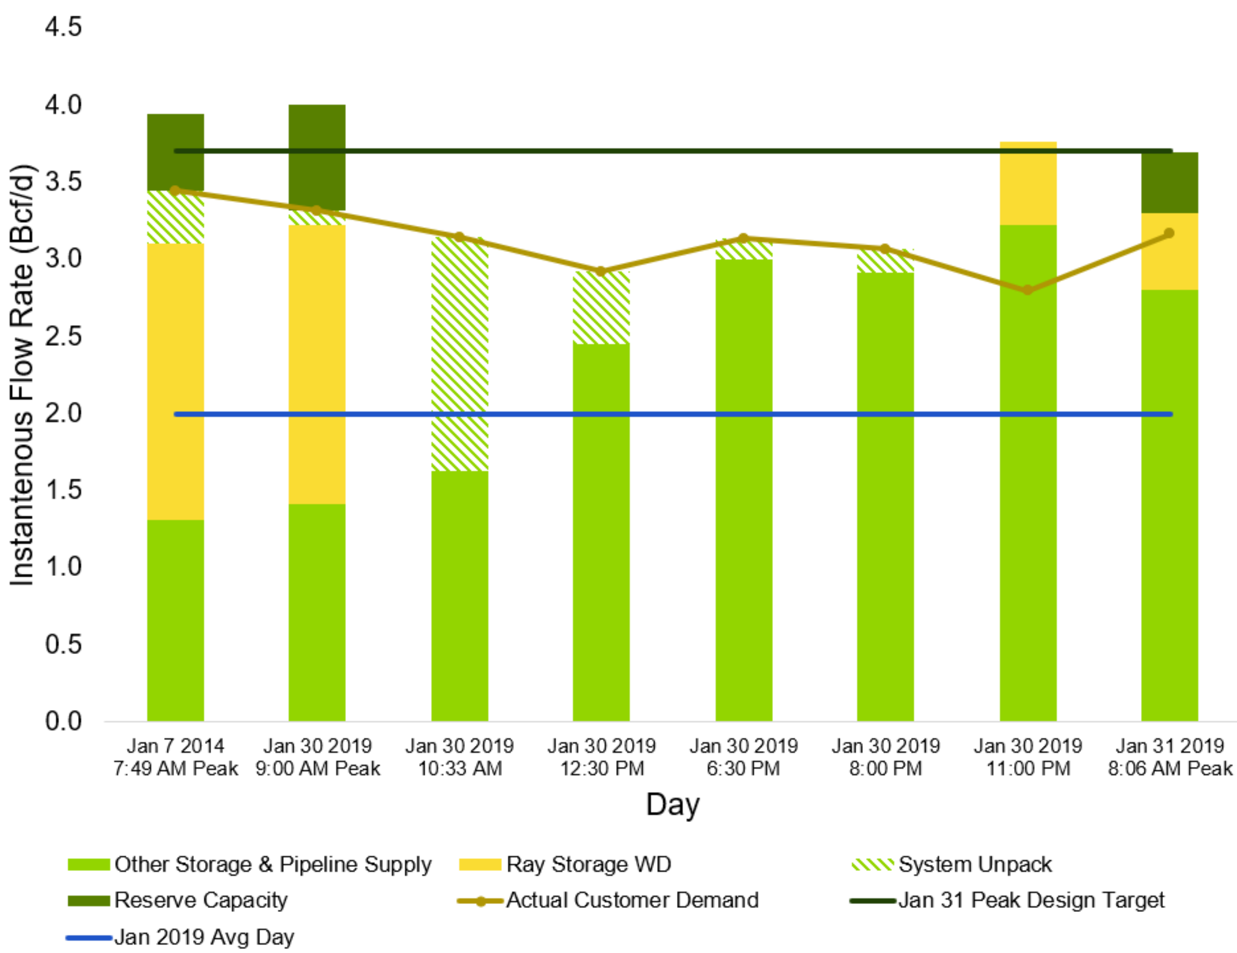
As Figure 3-4 shows, the loss of gas supply from the Ray facility caused the gas system to begin unpacking at an excessive rate. Unpacking means the amount of gas and the available pressure in the pipeline are decreasing and it occurs when the rate of total supply is lower than the rate of total delivery to customers. Figure 3-4 depicts the status of supply, demand, rate of gas system unpack,[28] and Ray Field flow on January 7, prior to the event. It also shows several points including the peak hour of January 30 at 11:00 p.m. and the peak hour of the next day at

[28] Unpack refers to the system's use of linepack.

8:06 a.m. on January 31. The loss of Ray and the rate at which the pipeline system was unpacking caused key gas system pressures to decline at excessive rates.

Shortly after the fire-gate alarm was received, Consumers Energy Gas Control adjusted the storage field rate orders to dispatch all peaking storage fields at maximum flow rates including those fields on standby. The peaking storage fields added approximately 975 MMcf/day of supply. The dispatch of the peaking fields maximized the total amount of storage supply delivered and reduced the gas system unpack rate. In addition, additional supplies provided by neighboring pipelines helped to mitigate the loss of supply from the Ray storage field (shown in light green in Figure 3-4 and the corresponding reduction in gas system unpack is shown in light green cross-hatching).

Figure 3-4. Consumers Energy System Supply, Demand, and Reserve Capacity January 30-31, 2019



Source: Guidehouse, Consumers Energy

Consumers Energy took several steps to mitigate the impact of the loss of access to the Ray storage field. These steps included requests for voluntary reductions in gas usage of all customers. Consumers Energy also implemented an Operational Flow Order (OFO) for the first time in its history for natural gas transportation customers, which required those customers to match their natural gas deliveries to Consumers Energy's system to their usages. When the requests for voluntary actions and the OFO did not result in the reductions in gas usage necessary to stabilize the gas system, Consumers Energy implemented a mandatory curtailment of gas deliveries to large business customers for the first time in its history, which required a reduction in their natural gas usage down to minimum loads required to protect equipment. In cooperation with Governor Whitmer, Consumers Energy also requested all-natural gas customers in Michigan to conserve natural gas by dialing down their thermostats. On Thursday, January 31, Consumers Energy announced that the appeal for assistance would end at 12:00 a.m. on February 1 for all customers—commercial, industrial, and residential.

Conclusion

This Ray Compressor fire event and the subsequent recovery by Consumers Energy is a unique story of the resilience characteristics of the gas system. Despite the loss of availability of the largest storage facility, not a single critical, priority, or residential customer lost service involuntarily during a peak of record cold temperature throughout the region, due to the fire-gate event.

Consumers Energy was able to withstand, recover, and adapt due to diligent advanced preparation and execution of its emergency response plan during the event. Access to physical assets is a key contributor to resilience. The ability to use alternate flow paths within facilities enables the recovery of the gas system and the return to customer's ability to use gas normally. Consumers Energy's ability to use existing storage assets as a first response demonstrates this opportunity. However, practice, preparation, and planning are also critical contributors to resilience, as demonstrated by Consumers Energy's response.

The company's capabilities in emergency management, including the use of an Incident Command System (ICS), enabled it to respond rapidly and organize into an ICS structure that included both a command post and an Emergency Operations Center (EOC). The well-defined chain of command, incident objectives, and tactics allowed for effective internal coordination of resources. It also enabled fast, complete, and transparent engagement with the MPSC, State Emergency Operations Center (SEOC), and the Governor's office throughout the event. Furthermore, it provided an organized approach to protect life and safety, to stabilize the incident, and to protect property and the environment.

Case Study 4: The Role of Winter Gas Storage (Oregon)

Key Finding

Storage assets, in combination with diligent planning and dedicated employees, play a critical role in providing natural gas during periods of critical demand in response to cold weather events.

Introduction

Northwest Natural (NW Natural) provides service to approximately 2.5 million people in Oregon and southwest Washington state (Figure 3-5). The Portland metro area represents the largest portion of NW Natural's customer demand, and its weather is characterized by a temperate oceanic climate with warm, dry summers and mildly cold, wet winters.

Figure 3-5. NW Natural Service Territory

Source: NW Natural

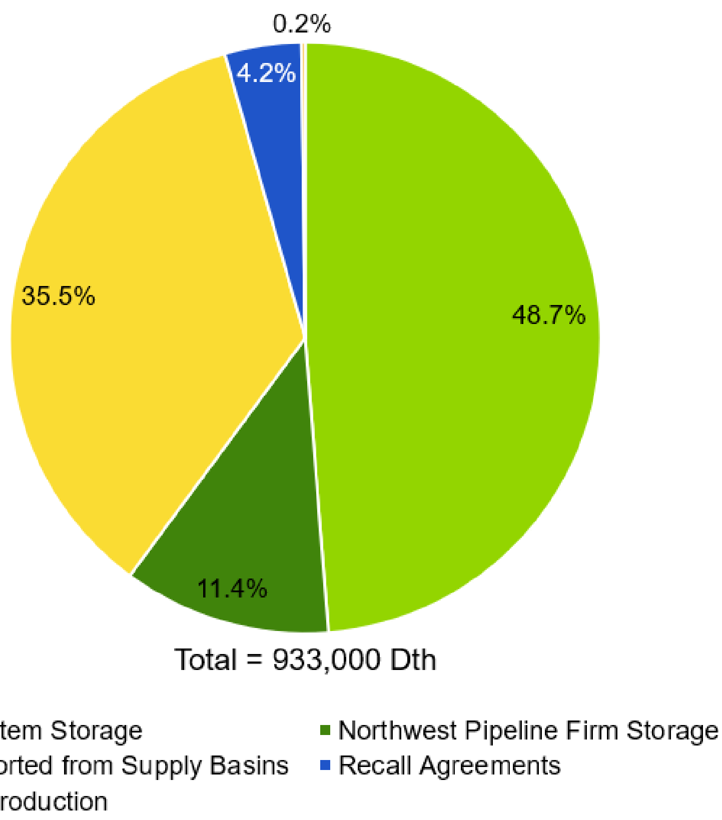
NW Natural personnel oversee the safe operation of 14,000 miles of transmission and distribution mains, monitor deliveries at over 40 interconnections with the upstream interstate pipeline system, and coordinate the usage of three on-system storage facilities (one underground storage and two LNG plants) along with off-system storage. The Gas Control department, as an example, is responsible for forecasting near-term loads, monitoring pressures, flows and other conditions using telemetry data fed from field devices, electronically controlling certain field equipment, and determining the usage rates of the on-system storage facilities, all on a 24/7 basis.

NW Natural's resource planning is designed to meet customer needs during an extreme cold weather event, occurring in late January or early February. One such event occurred in February 2014.

The Winter of 2013-2014

Extreme cold weather in early December 2013 set the stage for a challenging winter. Storage facilities are usually full at the start of the heating season, and large quantities can be withdrawn to meet sudden surges in sales. Stored gas is akin to a large battery, representing energy reserves that can be held indefinitely while remaining ready at short notice to satisfy customer requirements. On extremely cold days, stored gas is expected to supply approximately 60% of NW Natural's firm sales load (Figure 3-6). On February 6, 2014, total sendout set a record of 900,000 Dth that still stands today. NW Natural's prior record was 890,000 Dth, set on January 5, 2004. Stored gas played a critical role in meeting this record demand and provided nearly 50% of total sendout on this day.

Figure 3-6. NW Natural Peak Day Firm Resources, as of Nov 1, 2013



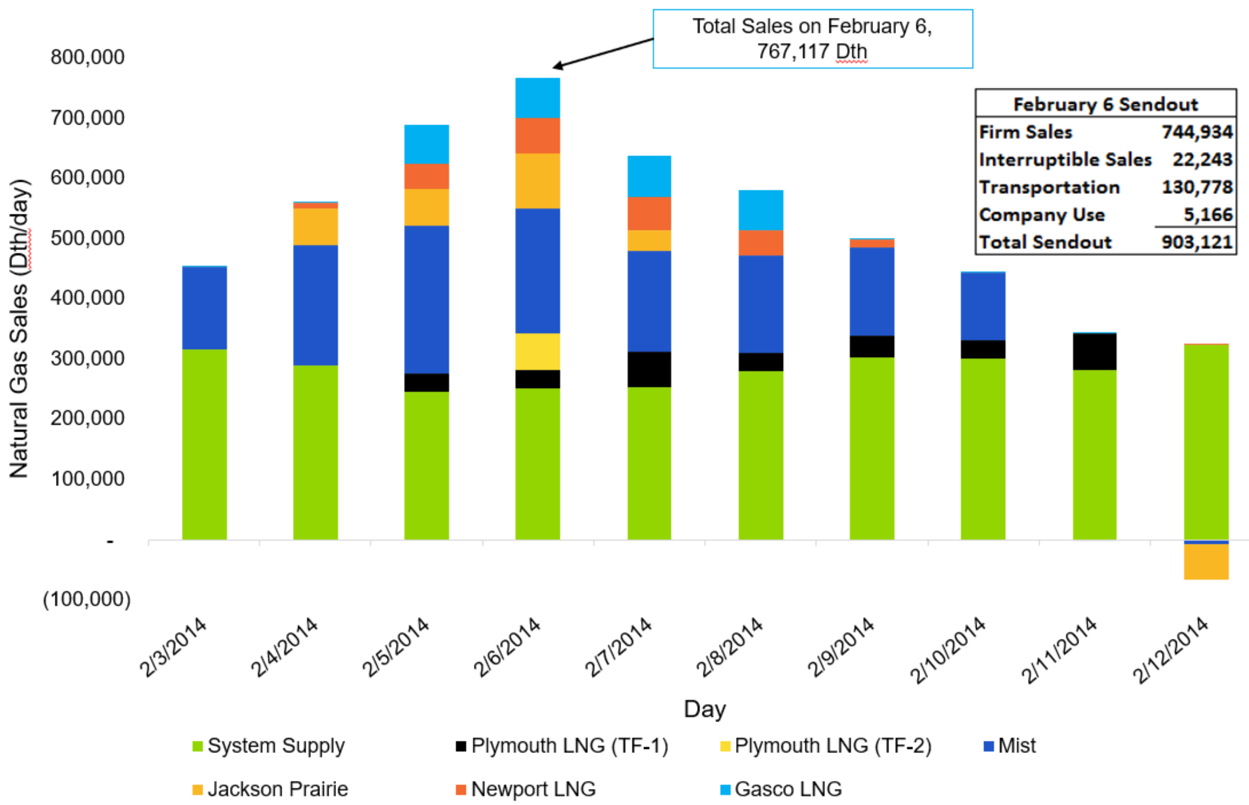
Source: Guidehouse, NW Natural

Stored gas, once withdrawn, will likely not be replenished until the following summer. Also, deliverability from storage can decrease as volumes are withdrawn, so the decision was made in December to procure additional supplies in the market in order to conserve the usage of storage gas. This planning proved extremely valuable later in the season.

The Peak Event

During early February, cold temperatures were accompanied by about a foot of snow and freezing rain. While this winter storm episode was not quite as long and cold as that experienced in the December event, a very high wind chill factor increased customer demand by an estimated 10 percent over what would be normal based on cold temperatures alone. During this period, storage resources were relied on heavily for both economic and delivery resilience reasons, growing to over 50% of daily sales requirements and then subsiding within a week's time (storage resources are all non-green colors in Figure 3-7).

Figure 3-7. NW Natural Resource Utilization During Cold Weather Event, February 3-12, 2014



Source: Guidehouse, NW Natural

Similar to the December event, in February, NW Natural had employees monitoring and controlling gas pressures at specific locations in North and East Vancouver (Washington), Southwest Salem, and South Eugene. The company also rotated two CNG trailers to support the morning peak demand in an isolated area of Northwest Vancouver, Washington.

Employee dedication and resourcefulness during the peak event included field crews manually controlling pressure regulators to ensure the maximum amount of gas could move through the pipes, storage operators working around the clock to maximize gas availability, Gas Control working with the upstream interstate pipeline to increase gate station throughput, and service technicians responding to four times the normal volume of customer calls.

Snow and ice took their toll on the gas system, requiring exceptional emergency response. For example, trees burdened by snow fell onto buildings and gas meters, some members of the public lost control of their vehicles and ran into gas meters, and parts of buildings collapsed onto gas meters. Some employees had to carry chainsaws in order to remove fallen trees blocking their way.

Aftermath

Several parts of NW Natural's service territory had seen significant customer growth over the prior two decades, and experience gained during the 2013-14 winter confirmed the need to reinforce the supply system to these areas. Besides reports of a handful of isolated customer outages, the only significant distribution system problem was in Clark County, Washington, where service had to be curtailed to four industrial interruptible customers during the morning burn hours.

Curtailment of service to interruptible sales and interruptible transportation customers is an explicit feature of NW Natural's resource planning. During the winter of 2013-14, interruptible customer curtailments were minimal because supplies were abundant, capacity was relatively unconstrained, and the gas system showed its resilience during weather conditions that tested but did not reach the extremes of the company's resource planning standards.

Case Study 5: Hurricane Response (New Jersey)

Key Finding

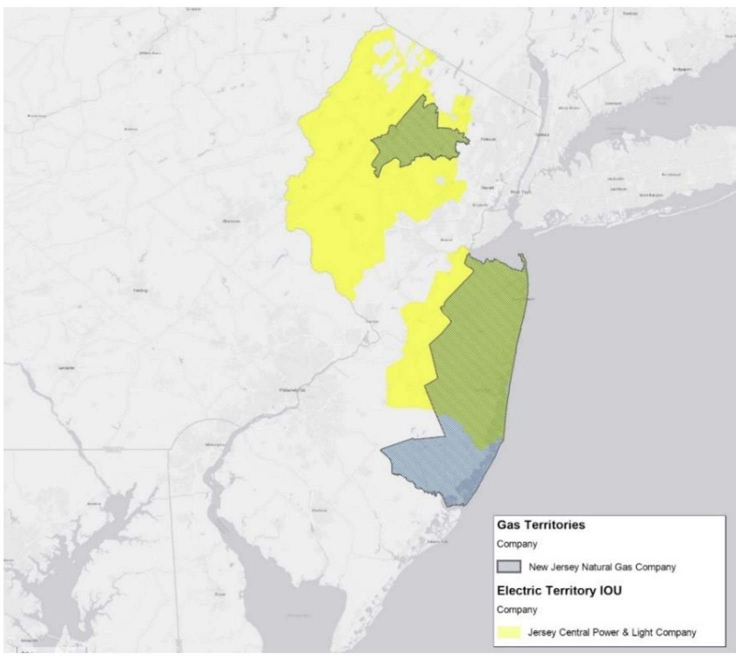
New Jersey Natural Gas Company delivered significantly more gas than normal in a short period to support backup electric power generation for residential and commercial customers in the middle of a hurricane.

Introduction

Hurricane Isaias was a destructive Category 1 hurricane that caused extensive damage across the Caribbean and the US East Coast. The hurricane made landfall near Ocean Isle Beach, North Carolina on August 4, 2020. Shortly after landfall, it was downgraded to a tropical storm.[29] When the storm reached the New Jersey region, it caused extensive damage and caused power outages that affected more than 1 million New Jersey homes and businesses.

Of the +1 million homes and businesses that lost power during Hurricane Isais, 788,000 were customers of Jersey Central Power & Light. As these customers saw an outage in their electric service, many turned to their natural gas generators to meet their power needs. New Jersey Natural Gas (NJNG), the gas provider for much of Jersey Central Power & Light's territory (Figure 3-8), experienced a massive increase in gas demand as these gas generators turned on.

Figure 3-8. Service Territories for Jersey Central Power & Light Company and New Jersey Natural Gas Company



Source: S&P Global Market Intelligence

[29] Len Melisurgo. August 8, 2020. "As bad as Tropical Storm Isaias was, here's why experts say N.J. dodged a bullet." *NJ.com*.

Overview

On Monday, August 3, the day before Hurricane Isaias caused the power outages, NJNG supplied 54,000 Dth to customers. On Tuesday, in response to the significant electric outages, NJNG supplied 84,536 Dth to customers, an almost 60% growth in daily demand in 24 hours. By the end of the week after most of the power was restored, the daily gas supplied by NJNG had dropped back to 58,394 Dth, in line with pre-storm sendout. Table 3-3 details the natural gas supplied by NJNG between August 3 and August 9, 2020.

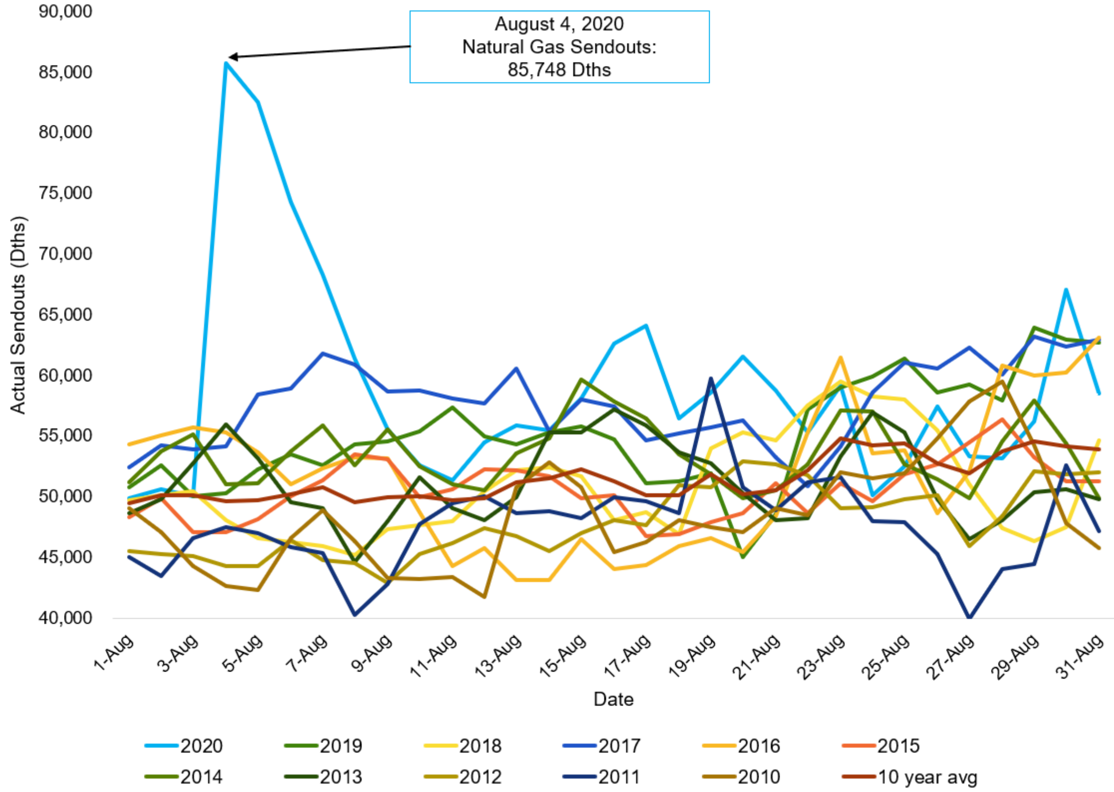
Table 3-3. NJNG Load Sendout: August 3, 2020 through August 9, 2020

Day	Date	Base Load Sendout (Dth)	Notes
Monday	8/3/2020	54,000	Pre-Storm Baseline
Tuesday	8/4/2020	85,536	Storm Hit 788,000 JCPL customers impacted
Wednesday	8/5/2020	84,198	Widespread Power Outages
Thursday	8/6/2020	78,688	Widespread Power Outages
Friday	8/7/2020	71,497	Widespread Power Outages
Saturday	8/8/2020	62,945	Majority of Power Restored
Sunday	8/9/2020	58,394	Majority of Power Restored

Source: Guidehouse, New Jersey Natural Gas

The daily natural gas output supplied by NJNG from August 4 through August 7, 2020 was higher than the daily output of any other August day for the previous 10 years. Figure 3-9 shows the 10-year average sendout from NJNG, the sendout from NJNG for the month of August 2020 identifying the dramatic peak from August 4 through 7, and the actual sendout from NJNG for August 2010-2019.

Figure 3-9. NJNG Comparison of August Actual Sendouts (Firm)



Source: Guidehouse, New Jersey Natural Gas

NJNG accredits most of the 30,000 Dth to 35,000 Dth increase in natural gas sendout during the storm to powering whole house generators, which served as backup power for customers who lost their electric supply. This load increase is estimated by NJNG to correlate with approximately 4,200, 20 kW generators running at full load (calculated using the assumptions in Table 3-4), or likely a larger number of natural gas generators running at partial load.

Table 3-4. Home Natural Gas Generator Assumptions

Generator Size (kW)	therms/ hour	dth/ hour	dth/ day	At 30,000dth/day number of 20 kW generators
20	3.00	0.30	7.20	Approximately 4,200

Source: Guidehouse, New Jersey Natural Gas

Conclusion

In August 2020, NJNG was not only able to withstand the hurricane, but it was also able to ramp up natural gas sendout quickly by relying on storage, allowing thousands of homes and businesses across New Jersey to keep their gas systems in operation when electric service was disrupted. Because of the built-in flexibility and dispatchable nature of the gas system, the gas system can complement the broader energy system as it responds to extreme climate events and keeps power flowing.

Case Study 6: Gas-to-Power Interface (California)

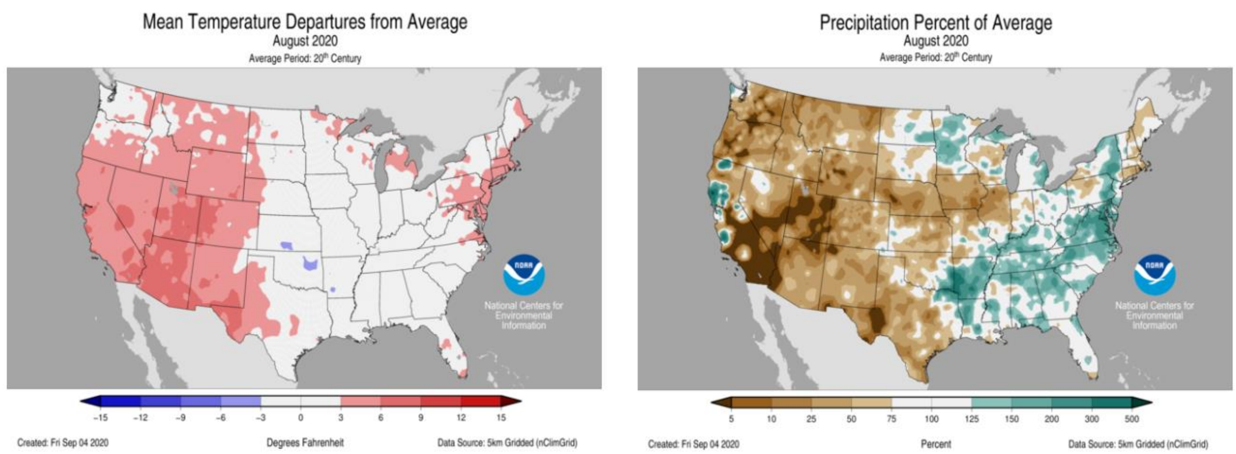
Key Finding

SoCalGas used storage capacity resources to meet the supply needs of gas-fired generation plants when the California electric system was experiencing multiple days of high demand from a record-breaking heatwave and unplanned decreases in other sources of electric generation.

Introduction

In August 2020, California was in the middle of its hottest August (record warmest in 126 years),[30] a severe drought (Figure 3-10), and its worst wildfire season in modern history. While California experienced increased demand on the electric system driven by increased cooling loads, it also experienced a decrease in the renewable output (due to smoke from the fires)[31] and imports than had been anticipated by electric supply planners. During these severe multi-day climate events, the gas system provided the flexible support required to ensure the broader energy system could provide power and prevented more extensive power outages.

Figure 3-10. August 2020 Mean Temperature and Precipitation, Departure from Average



Source: National Oceanic and Atmospheric Administration

On a standard summer day, California's electric grid is supplied by a wide variety of electric generation, renewables, natural gas, hydro, nuclear, coal, and imports from other regions. July 12, 2020 exemplifies a standard summer day in California (while the state was starting to experience a severe drought in July, average temperatures were within the normal range).[32]

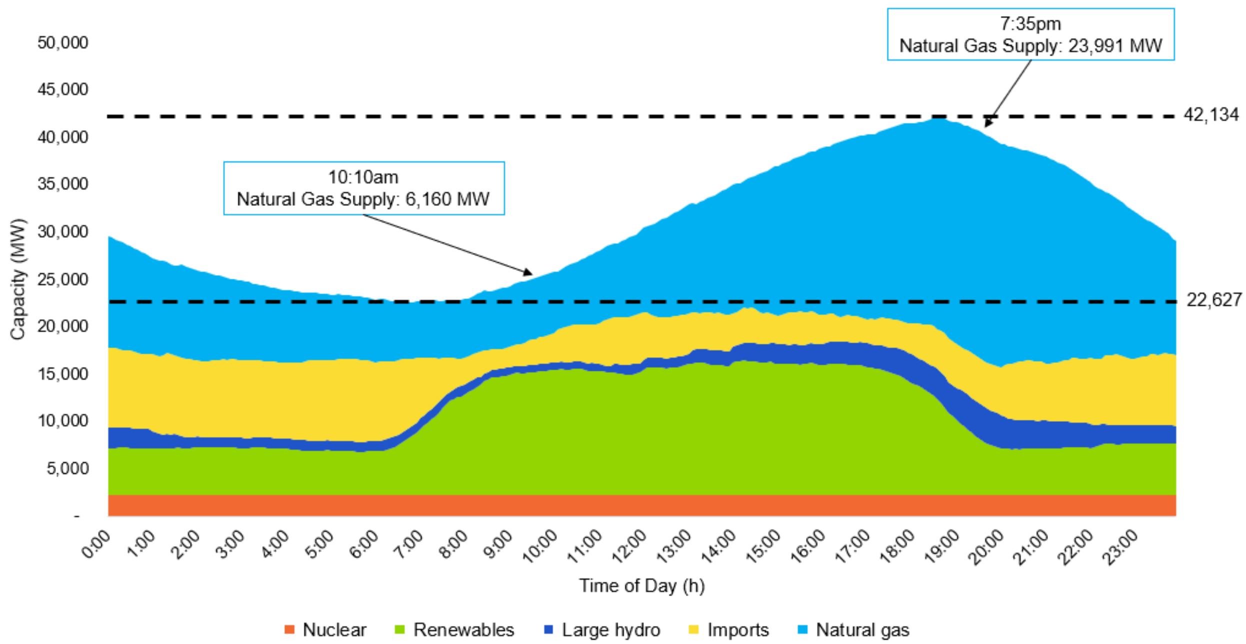
[31] EIA. *Smoke from California Wildfires Decreases Solar Generation in CAISO.* September 30, 2020. https://www.eia.gov/todayinenergy/detail.php?id=45336

[32] NOAA. National Climate Report – July 2020. https://www.ncdc.noaa.gov/sotc/national/202007

Overview

As Figure 3-11 shows, on July 12, 2020 renewable generation began to increase at around 06:30 hrs and remained relatively steady until approximately 17:00 hrs, driven primarily by solar generation during sunlit hours. By 08:00 hrs renewables provide 50% of the state's electric power generation, natural gas provides 25%, and the other sources provide the remaining 25%. As the day continues, gas-fired generation ramps up. By 20:00 hrs natural gas provides 60% of the electric power generation required to meet the peak load.

Figure 3-11. CAISO Supply Trend to Meet Electric Demand, July 12, 2020[33]



Source: Guidehouse, California Independent System Operator

Gas generation plants ramp up to meet peak demand, but the fuel demand of the generation plants is not ratable. Ratable is generally described as levelized demand where deliveries are made evenly throughout a delivery day. The hourly demand for gas to supply these generation plants often exceeds supply receipts, as arranged by the power plants, into the gas system. To overcome the imbalance between supply and use and to respond to the volatile demand needed to maintain the integrity of the electric system, underground storage plays a vital role.

Storage capacity and the stored commodity are contracted for in advance. Underground gas storage is expected to be used to maintain grid load balance and operation on high heat summer days (a hallmark of grid resilience). However, reliance on gas storage systems and the dispatchable nature of gas generation when the energy system is under higher stress (experiencing a resilience event), as seen in August 2020, requires a more significant drawdown of underground storage assets.

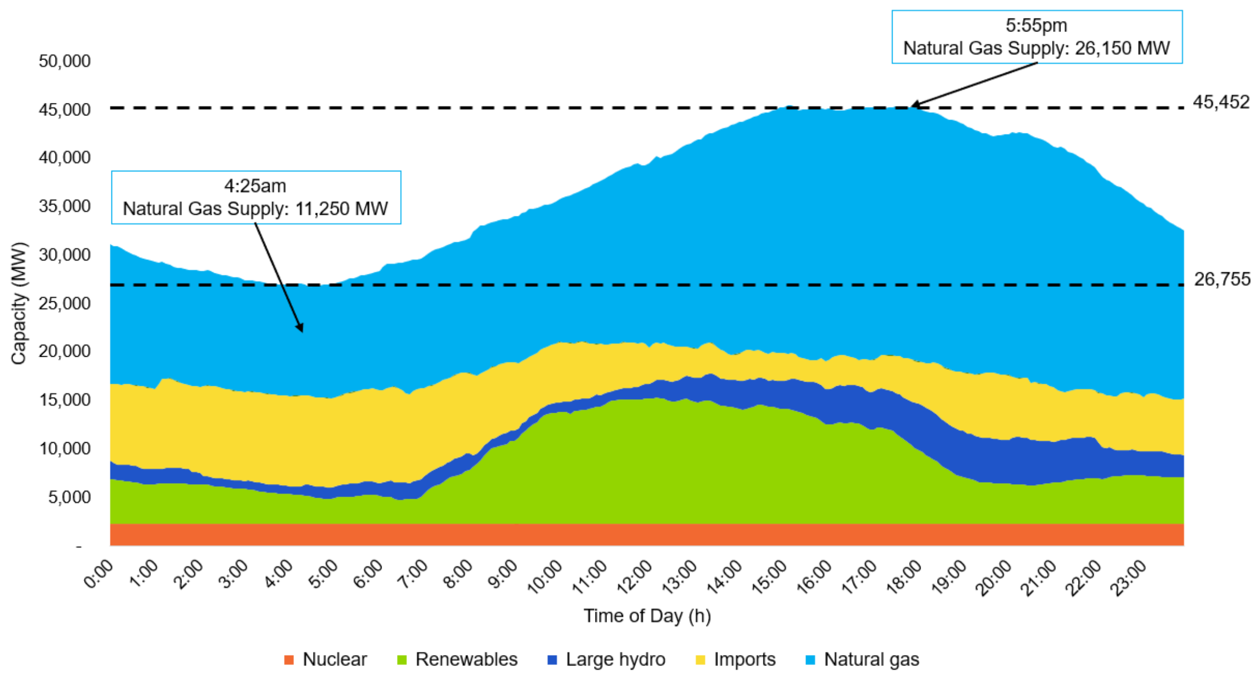
> *During the hours of highest electricity demand, gas generation provides the bulk of California's electric power generation.[34]*

[33] Batteries and coal contribute negligible amounts (± 50 MW) and are not shown within the figure.
[34] CAISO. 2020. "Supply and renewables."

The week of August 11, 2020 is a prime example of the California electric grid under a resilience event—coinciding extreme heat, drought, and wildfires. During this week, California experienced severe climatic events and associated higher electric consumption. Renewable output was also more variable and diminished due to heat, clouds, and wildfires, and power imports were lower than expected, since the entire western half of the US was experiencing the same heatwave as California.

Figure 3-12 illustrates the resources that contributed to CAISO's electric generation on August 17, 2020. Renewable generation supplied less electricity on August 17 compared to July 12 (peaking at around 13,000 MW at 12:00 hrs compared to over 14,000 MW at 14:00 hrs). Peak load was 45,452 MW on August 17, while on July 12 peak load was 42,134 MW. To meet the higher peak load and make up for the lower renewable generation, on August 17, gas-fired generation made up a higher percentage of CAISO's electric power generation capacity.

Figure 3-12. CAISO Supply Trend to Meet Electric Demand, August 17, 2020[35]



Source: Guidehouse, California Independent System Operator

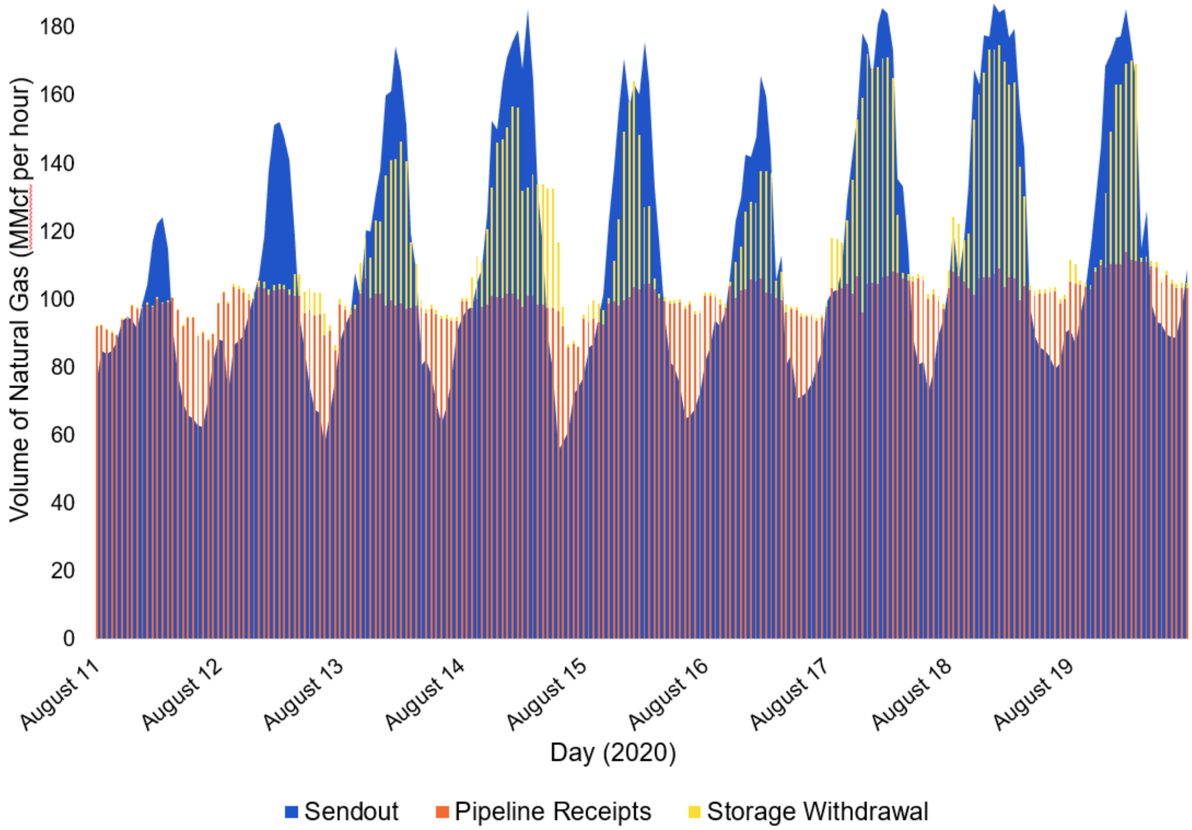
To meet the pressure on the CAISO system during the week of August 11, electric system operators turned to gas-fired generation facilities. To ensure that these generation plants had the natural gas supply to maintain the integrity of the electric grid, SoCalGas had to draw significantly on its gas system storage assets.

Figure 3-13 provides an hourly view of pipeline receipts into the SoCalGas distribution system, sendout, and withdrawals from storage. The blue vertical bars illustrate the hourly demand and sendout from the SoCalGas system. The orange vertical bars depict the quantities that were received into the system, which is generally received in steady hourly quantities over the course of the day. The yellow vertical bars above the receipts illustrate the volumes required to be withdrawn from storage on an hourly basis to meet the far more variable and changing intraday needs of electric generators, which exceeded the gas supplies arranged for delivery into the

[35] Batteries and coal contribute negligible amounts (± 100 MW) and are not shown within the figure.

SoCalGas system each day. The imbalance between daily pipeline receipts and sendout (mostly to serve the load of electric generators) was most significant on August 17 and 18, when sendout for each day was ~3.1 Bcf, while receipts were 2.5 Bcf, resulting in a deficit of ~0.6 Bcf daily, which was required to be made up by on-system storage.

Figure 3-13. Hourly Supply and Demand on the SoCalGas System



Source: Guidehouse, SoCalGas

From August 11 to 19, pipeline receipts on the SoCalGas system were approximately 100 MMcf per hour (2.4 Bcf per day/24 hours). In this same period, deliveries to SoCalGas customers exceeded 100 MMcf per hour during approximately 110 of 168 hours, or 65% of the time. August 11 was the only day SoCalGas was able to meet the peak delivery in excess of pipeline receipts through utilization of linepack (i.e., no storage withdrawal). On all following days, withdrawals from underground storage played a critical role when hourly consumption exceeded pipeline receipts.

Hourly withdrawals in excess of the equivalent of 800 MMcfd were experienced more than a dozen times between August 15 and 19. Those withdrawal rates were only possible with withdrawals from all SoCalGas' storage fields, including Aliso Canyon. The week of August 11, 2020, the totality of SoCalGas' system assets were employed to address the shortfall between abnormally high electric demand and low renewable energy generation experienced in Southern California.

Conclusion

Due to COVID-19-related impacts, C&I demand during this period was lower than normal. Although storage was critical to filling the gap between supply and demand, SoCalGas estimates that—had C&I demand been closer to average historic levels—it is likely that the capacity of the SoCalGas transmission and storage system would have been exceeded, which could have resulted in curtailment of electric generation. This is due to SoCalGas' planning standards and priority of services that are primarily focused on core customers, the SoCalGas tariff deprioritizes service to electric generators and allows curtailment during constrained/high demand periods. This situation is not unique to California, in other jurisdictions, electric generation, in the event of a curtailment, is given a lower level of prioritization compared to residential customers.

> *If the gas system was not able to fill the gap between abnormally high electric demand and low renewable energy generation to support the overall resilience of the electric system, Southern California would likely have experienced severe power outages during the system resilience event experienced in August 2020.*

The gas system fosters electric system reliability and serves as a resource that is capable of readily addressing unplanned or unforeseen events within the integrated energy system. When these resilience events occur, electric generators can experience large intraday swings in their need for gas supplies, often with little to no notice. In regions where the intermittent use of the gas system for electric power generation is a significant portion of total gas use on the system, this unpredictable non-ratable flow can stress the physical gas delivery system. Although the physical infrastructure including pipeline transportation and storage assets are in place and able to accommodate this type of intermittent usage, the underlying market framework and regulatory structure were not designed to provide this type of support service to the overall energy system. In general, the regulatory structure does not provide a means to construct and operate investments that provide resilience protection. That the gas system can provide this service demonstrates how resilience is a byproduct of the engineered reliability features of gas delivery system. The result being that the gas system and the gas LDC ratepayers provide this resilience service to the overall energy system without receiving compensation commensurate to its value.

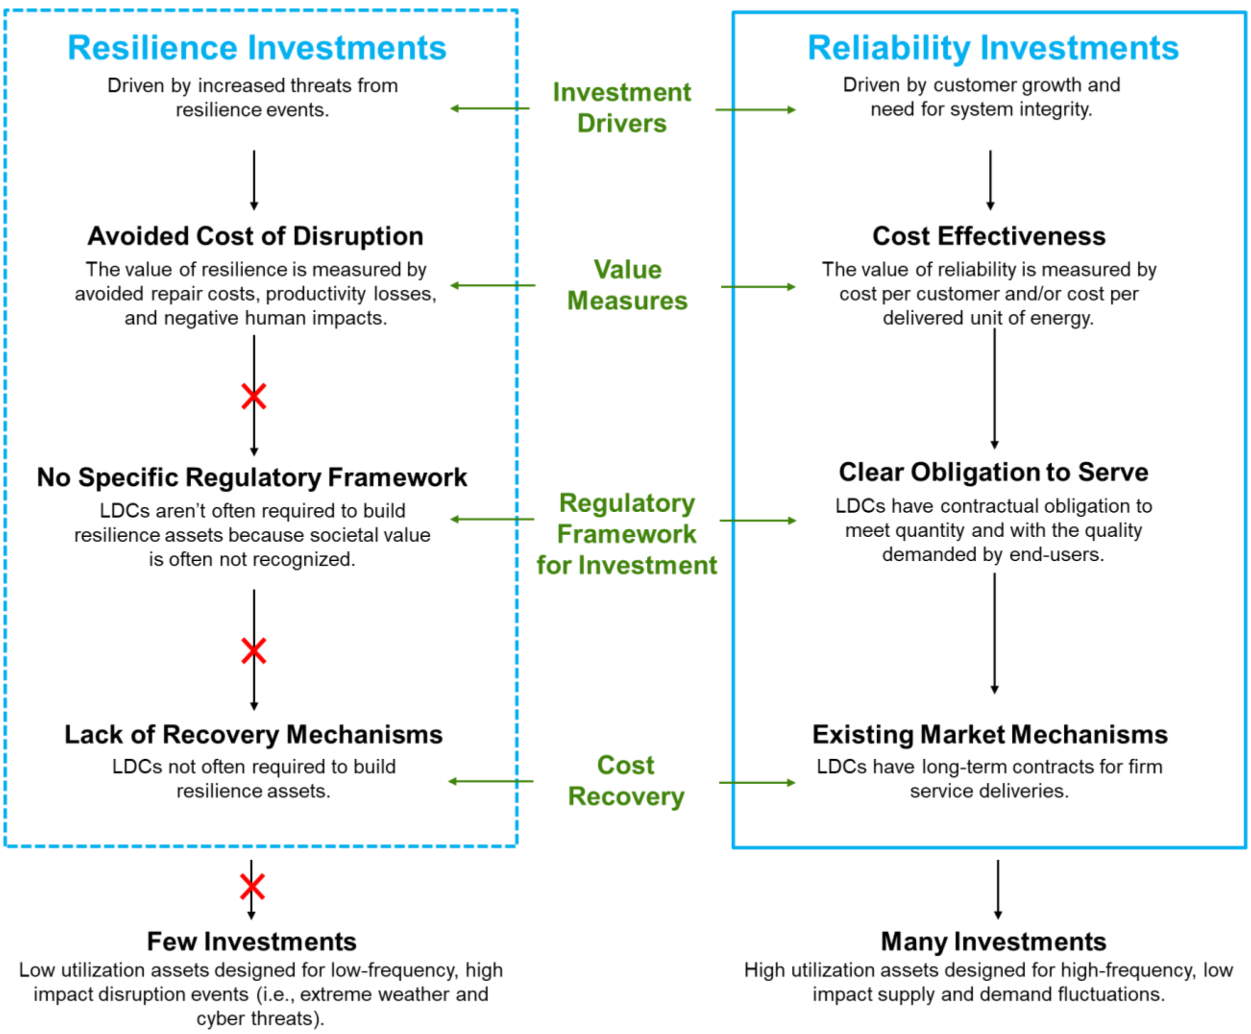
4. Current Regulatory, Policy, and Market Structures

The first half of this report established that the gas system provides resilience to the US energy system. The second half focuses on the regulatory, policy, and market structures that underpin the US energy market. This section explores the current state, including how these structures have developed and the challenges they create. Section 5 considers forward-looking considerations to ensure future energy system resilience.

4.1 The Difference Between Resilience and Reliability Investments

The current market economic framework is designed to support the development of physical assets with high utilization or those backed by long-term contracts. These assets provide reliability services to the energy system. Reliability assets often contribute to the resilience of the energy system as a byproduct, but they are not designed to meet the full needs of a resilience event. Figure 4-1 explores the differences between resilience and reliability investments.

Figure 4-1. Comparison of Resilience and Reliability Investments



Source: Guidehouse

4.2 Historical Context of Gas System Development

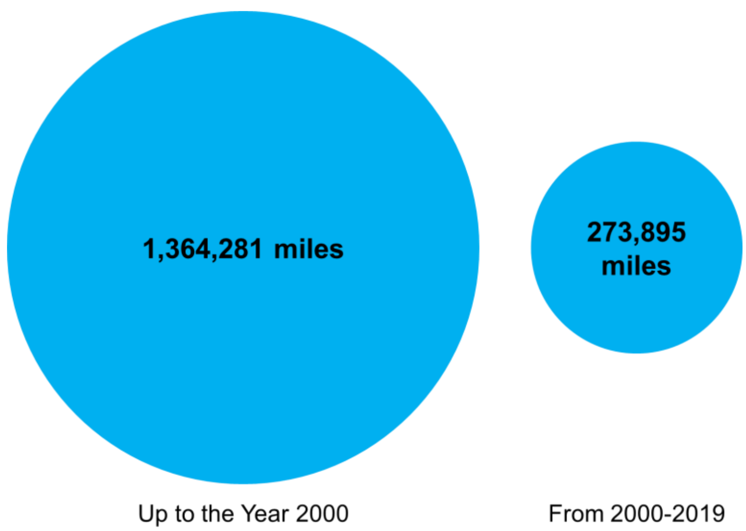
To fully understand some of the challenges in regulatory, policy, and market structures around the development and support for the use of natural gas as a resilience asset, it is necessary to understand the historical context around how these frameworks have developed. In this section, we consider the historical context of the development of the gas system and what implications that has had on the structure and the gas system's current support of energy system resilience.

Natural gas was first used in the early 1820s. However, lacking efficient transportation options, its usage was limited to powering light sources, usually close to natural gas wells. In the late 1890s, gas pipeline construction began and partnered with technological advances, this more efficient transportation of the resource fueled the growth of the US pipeline and connected natural gas wells to users—homes, businesses, and heavy industry. It was not until the late 1990s (really after 2000) that natural gas became a significant source of US electric power generation.

4.2.1 Residential, Commercial, Industrial Load (Pre-2000)

The majority of US natural gas gathering, transmission, and distribution pipeline infrastructure that exists today (approximately 83%) was built out prior to 2000, as Figure 4-2 shows. This infrastructure was built based on a paradigm of predictable and relatively stable demand from residential, commercial, and industrial loads—and stable investor returns. There are several mechanisms that pipeline companies and LDCs use to maintain the integrity of their systems in accordance with Federal law. Across the US, state utility commissions have approved infrastructure modernization programs and pipeline replacement programs to address aging infrastructure. A total of 41 states and the District of Columbia have adopted an approach to support the prioritization, financing, and execution of gas infrastructure upgrades. These programs not only increase the safety of the energy system, but also enhance the future resilience of the energy system.[36]

Figure 4-2. Incremental US Natural Gas Pipeline Additions

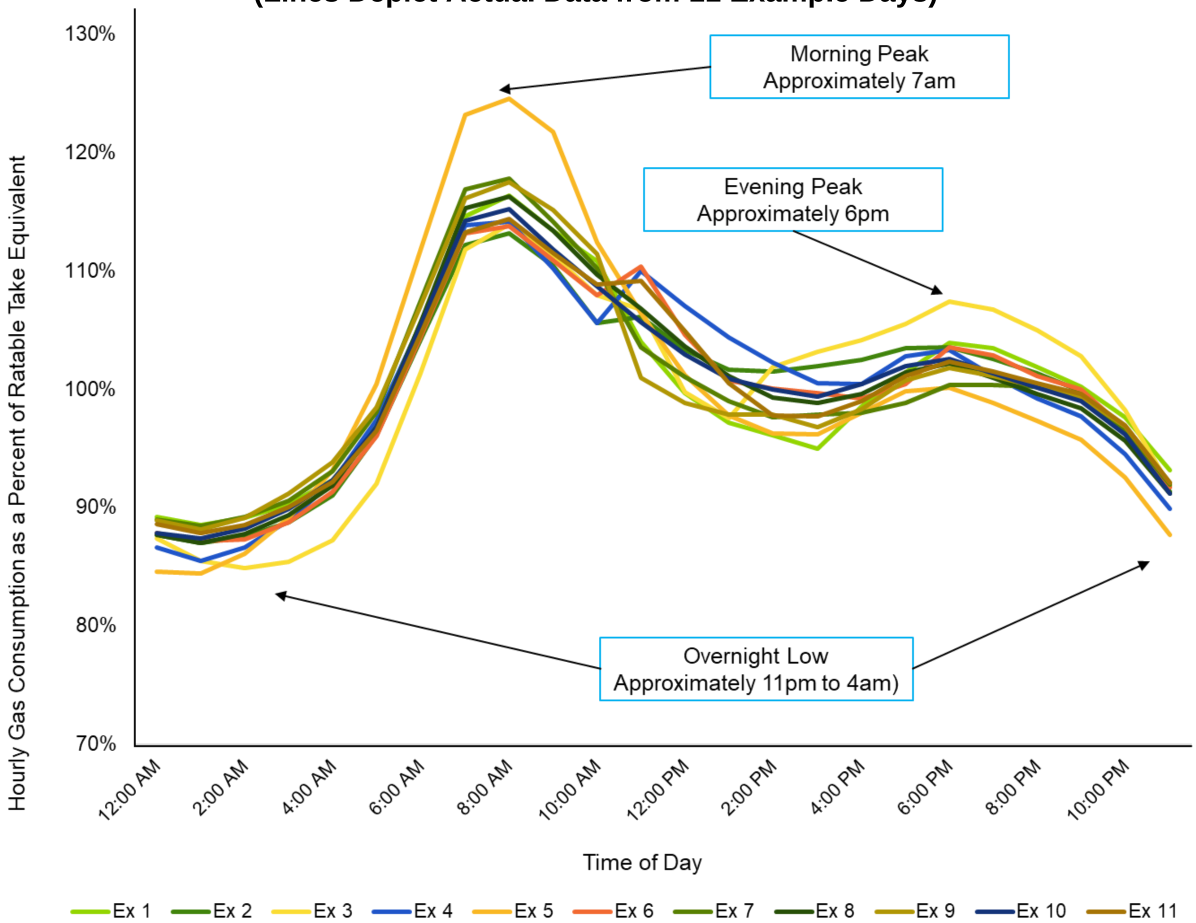


Source: Guidehouse, US Bureau of Transportation Statistics

[36] NARUC, January 2020. Natural Gas Distribution Infrastructure Replacement and Modernization.

The aggregate daily gas demand to serve residential, commercial, and industrial customers is predictable and relatively stable. Gas usage for these customers increases significantly in the morning before slowly decreasing over the course of the day. There is an additional, relatively minor, increase in the evening around dinner time before gas usage drops over the night. Figure 4-3 presents the aggregate load profile for these customers. The figure's y-axis indicates percent variation in hourly gas consumption as a percent of ratable take equivalent[37] and the minimum and maximum peaks only vary -16% to +25% from that daily average.

Figure 4-3. Aggregate Daily Natural Gas Load Profiles, for Residential, Small Commercial, and Industrial Customers (Lines Depict Actual Data from 11 Example Days) *



*Source: Guidehouse, Consumers Energy**

The gas usage pattern is predictable for these customer groups, even in varying climatic conditions. In colder conditions, the usage pattern features less volatility as demand for space heating is more constant throughout a cold day. In warmer conditions, the peaks and troughs widen, and the total daily usage is lower. The predictability of this trend enables gas LDCs to construct and operate the gas system and build new assets with a high degree of confidence in the use of those assets.

---

[37] *Ratable take equivalent* refers to the comparable amount of gas consumed in one day on a levelized basis over a 24-hour period, i.e., in even 1/24th increments. This is further discussed in Appendix A, Section A.3.1.

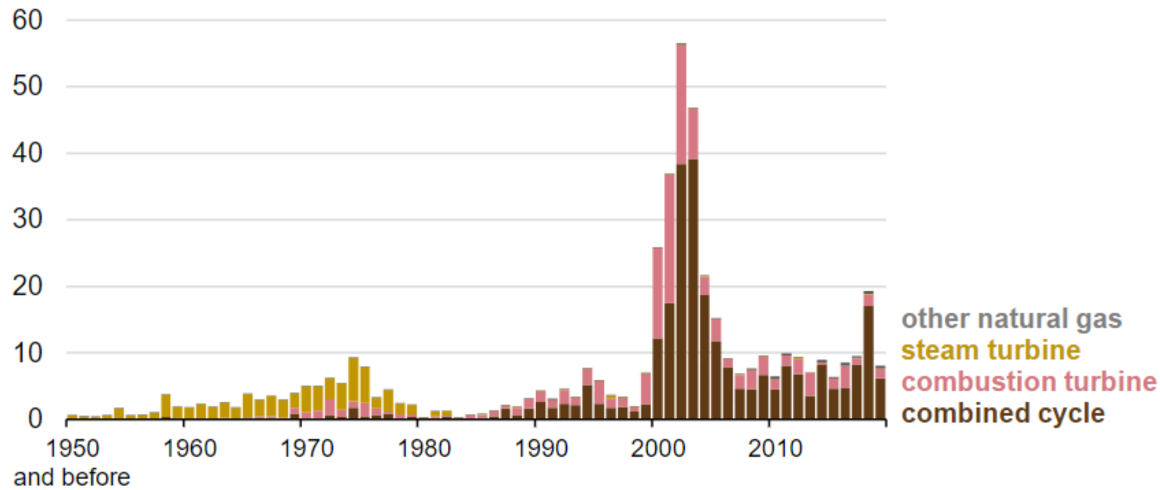
> *The gas system that serves the US today was built to serve the residential, commercial, and industrial sectors, where the relative predictability of usage over the course of a day (ratable takes) and throughout the year for these customer segments enabled LDCs to design, construct, and operate the gas system with a high degree of confidence in how the gas system would be used to serve demand.*

The entirety of the gas value chain's economic and operational framework is underpinned by this ratable system of supply and demand.

4.2.2 Gas-Fired Electric Generation (Post-2000)

When much of the current gas system was designed, the electric sector was a small component of overall demand. Between 1949 and 2000, gas-fired generation provided an average of just 16% of total electric power generation in the US on an annual basis. Since 2000, this has increased significantly. In 2019, natural gas accounted for 38% of US electric power generation and provided 43% of operating US electric power generating capacity.[38] Figure 4-4 explores this trend and shows that most of the growth in gas-fired generation capacity occurred between 2000 and 2020. More information on the role of natural gas in the electric power generation sector can be found in Appendix B.

Figure 4-4. US Gas-Fired Electric Power Generation



Source: US Energy Information Administration

4.3 Natural Gas in Electric Power Generation

There are critical differences in the way that gas-fired generation interacts with the gas system. This section explores those differences. In general, gas-fired generation plants fall into one of two classifications:

1. **High-capacity factor generation:** These low-heat rate/high-efficiency plants support electric power generation by operating often at close to full capacity 24/7.

[38] EIA. 2020. Electricity: Current Issues and Trends.

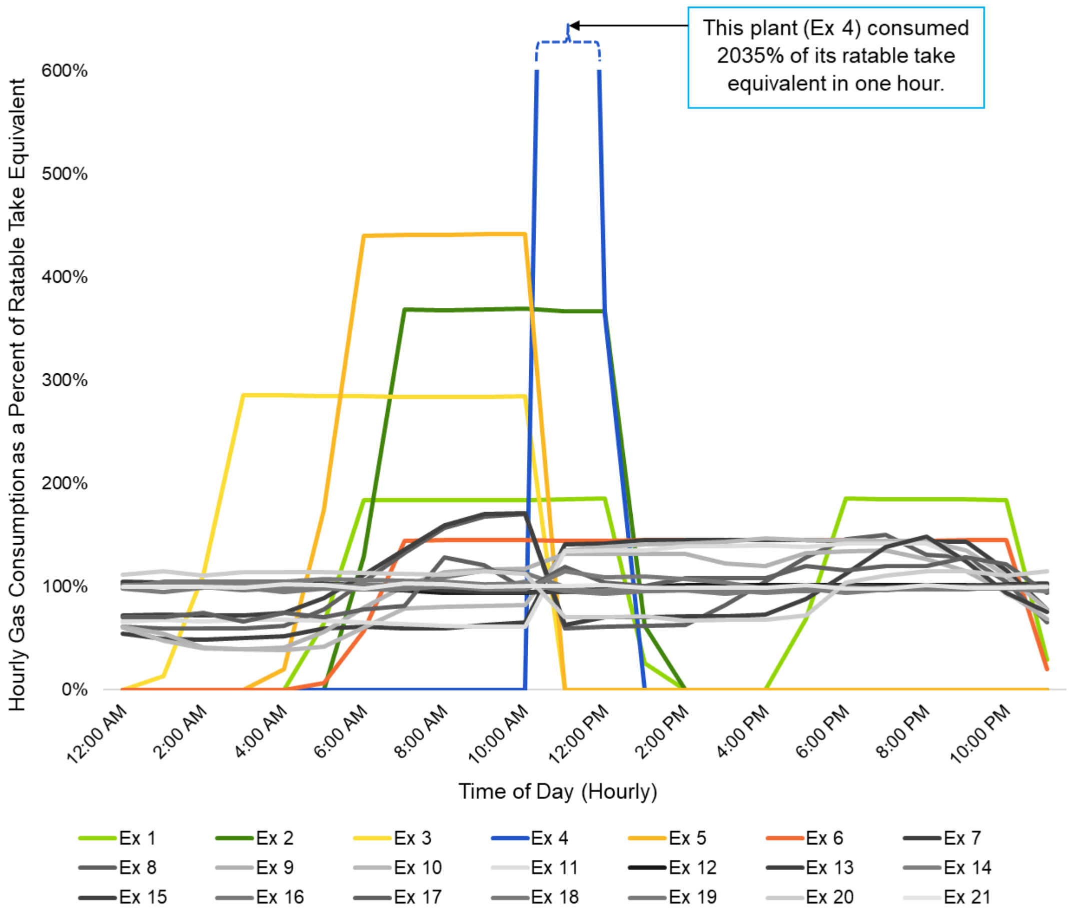
2. **Intermittent generation:** These plants serve as dispatchable resources for electric system operators, ramping their generation up and down quickly to fill the gaps between intermittent generation sources (such as renewable sources) and consumer demand.

4.3.1 Gas-Fired Electric Power Generation Load Profiles

Figure 4-5 illustrates the load profiles of six different gas-fired electric power generation plants over a period of 21 days. Gas load profiles of gas-fired electric power generation plants exhibit far more variance on a daily and hourly basis than the load profiles of residential, commercial, and industrial customers. In Figure 4-5, high-capacity factor generation plants are identified generally in gray (Ex 7 through Ex 21) and those serving intermittent generation capabilities are identified with varying colors (Ex 1 through Ex 6).

The load profile for high-capacity factor gas-fired plants (Ex 7 through Ex 21 in Figure 4-5) generally features a morning and evening peak, and the variation between the highest hour of usage and the lowest hour of usage from ratable take equivalent is 71% to -61%, similar in pattern to the load profiles for residential, commercial, and industrial customers but the magnitude of the swings are larger.

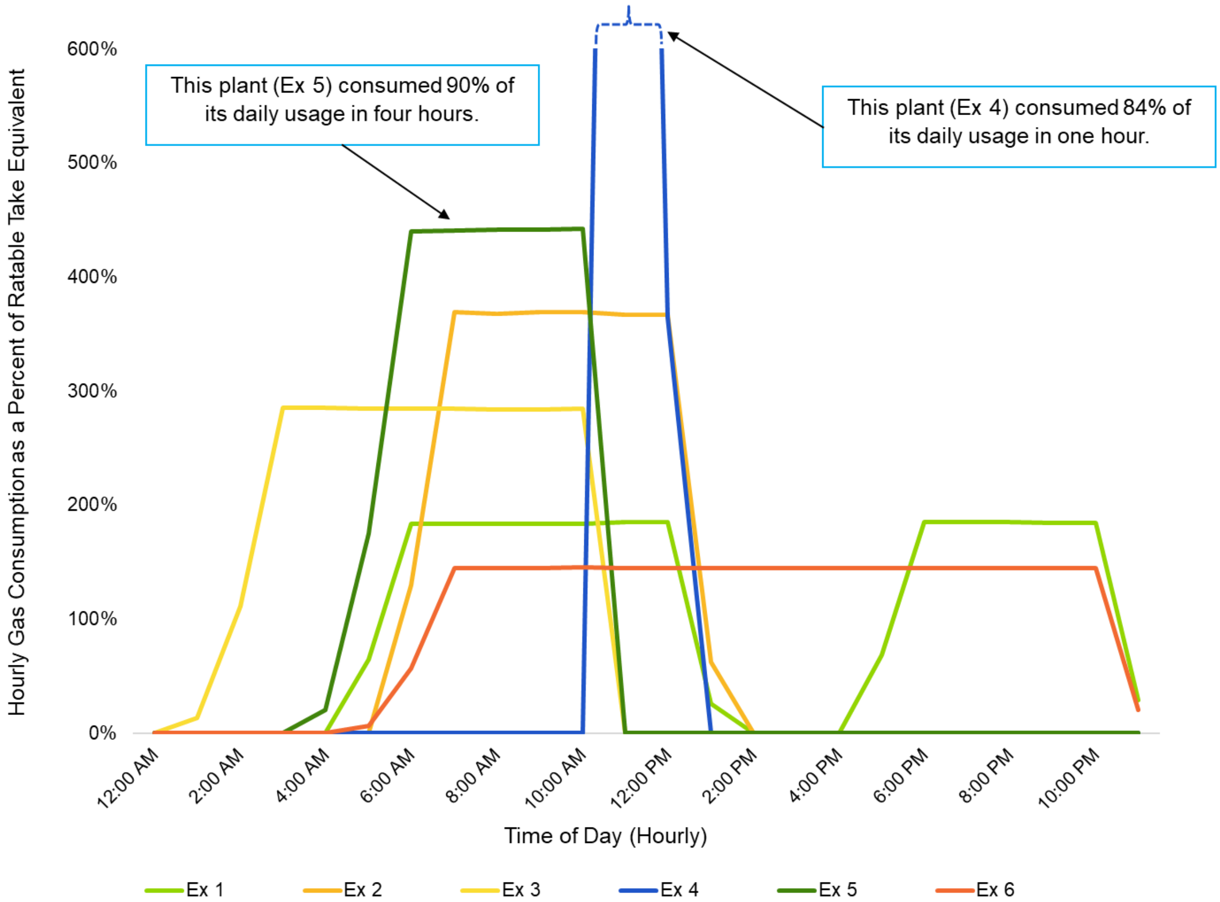
Figure 4-5. Daily Natural Gas Load Profiles for Gas-Fired Electric Power Generation (Lines Depict Actual Data for 21 Example Days, Data is Inclusive of Six Facilities)



Source: Guidehouse, Consumers Energy

Gas-fired plants that run intermittently exhibit a different load profile from the relatively predictable daily variation of high-capacity factor plants. In Figure 4-6, the high-capacity factor generation daily load profiles were removed to focus on the load profiles of intermittent gas-fired plants. The load profiles associated with these plants exhibit a high level of variability and intraday swings, as the plants quickly ramp up and down from their peak rates.

Figure 4-6. Daily Natural Gas Load Profile for Intermittent Gas-Fired Plants (Lines Depict Actual Data for Six Example Days, Data is Inclusive of Six Facilities)



Source: Guidehouse, Consumers Energy

The gas supply required by intermittent gas-fired plants is characterized by large volumes of fuel that are subject to a level of variability and intraday demand swings that are vastly different from how the residential, commercial, and industrial sectors consume gas over the course of a 24-hour period.

> *Intermittent gas-fired plants are primarily used to fill gaps between other intermittent generation sources (such as renewables) and customer demand for electricity. They are only capable of fulfilling this role because the gas delivery system enables the delivery of supply to serve the swings needed to provide such a quick-start response. Although the gas system fulfills these needs, the physical delivery system and the supporting market mechanisms and commercial terms that govern day-to-day operations were not designed for this type of usage*

4.3.2 Implications for the Gas Delivery System

Upstream pipeline deliveries to the gas distribution system occur at relatively steady hourly quantities throughout a day, but gas is not consumed in even hourly increments over the course of a day. Gas distributors have a variety of tools including linepack, storage, and mobile delivery capabilities to accommodate this intraday swing in demand and enable deliverability and respond to increases and decreases in consumption.

The gas transmission system is designed to accommodate the delivery needs of the predictable and low variability patterns required of residential, commercial, and industrial customers. Meeting the variable delivery needs of high capacity factor and intermittent gas-fired plants is a greater challenge as the gas consumption of these plants is much more variable, especially for intermittent gas-fired plants. Gas system operators supplement hourly pipeline receipts with linepack and storage withdrawals to maintain integrity and meet the needs of intermittent plants.

The gas distribution system's ability to provide this intermittent deliverability service is highly dependent on the amount of gas in the pipeline, the inventory levels in storage, the inventory in other storage assets, and contractual obligations to other customers. Providing service to gas-fired generators, particularly intermittent gas-fired generators requires coordinated planning from operators of the gas and electric systems.

4.4 The Regulatory Context

This section discusses how the current regulatory structures hinder the construction, utilization, and operation of new gas assets to serve resilience needs. Often, current regulatory structures tie the development of interstate pipeline and storage assets strictly to the needs of customers (producers, gas utilities, and other end users) willing to execute long-term firm service contracts. These do not easily support the construction, utilization, and operation of resilience assets that, by their nature, will be used infrequently to support low likelihood, high impact events. As a result, gas systems may not be appropriately compensated for the resilience services they provide.

Two critical principles often underlie the regulatory approval of infrastructure development:

- **Alignment between who benefits and who pays:** The ability to demonstrate how an asset provides a benefit to those who pay for its development is a standard principal of utility ratemaking.
- **The business case hinges on high utilization:** The construction and operation of most gas assets are founded upon the willingness to execute long-term firm service contracts; higher utilization translates to lower cost per unit.

This framework begins to break down when asset development activities or business model economics are not aligned with these principles. Applying these regulatory principals to the consideration of the construction, utilization, and operation of gas assets for resilience purposes, two key challenges are exposed:

- Current gas system resilience is a byproduct of reliability investments
- Gas systems may not be appropriately compensated for the resilience service they provide

The remainder of this section discusses these two challenges.

4.4.1 Current Regulatory Framework for Infrastructure Approval

To construct a new energy system asset, a gas utility must receive approval from its regulator, typically a state-level public utility commission. The investment is typically approved if the gas utility demonstrates the investment is prudent and serves the needs of its customers.

The principle of alignment between who benefits and who pays is applicable to regulating the expansion or new construction of interstate pipeline and storage infrastructure. A utility is responsible for the burden of proof of necessity on behalf of its customers. For interstate pipeline and storage assets, the burden of proof is on the market need demonstrated by customers who have executed precedent agreements.

The Federal Energy Regulatory Commission (FERC) regulates interstate pipeline and storage markets. Pipeline and storage operators seeking regulatory approval to construct or expand an asset must provide FERC with a demonstration of market interest to receive approval. FERC grants approval if this market interest can be demonstrated. Due to the long life of pipeline and storage assets, the regulators seek to balance the interests of customers with landowners and the public around environmental concerns,[39] as well as the financial viability of the project. Market interest is demonstrated in the form of customer execution of long-term firm service contracts, where firm service entails a right to a predetermined amount of capacity on the pipeline during the agreement period.

Natural gas utilities are regulated by state public utility commissions (PUCs). PUCs approve infrastructure investments based on the concept that the investment provides utility service and supports the utility's obligation to serve. Gas utilities enter long-term firm capacity contracts because they are required to fulfill an obligation to serve their customers, particularly during periods of peak usage. For example, a gas utility with a significant winter peaking load will subscribe to a long-term contract to serve that load even if its firm rights to pipeline capacity will be underutilized in the summer—resulting from the utility's obligation to serve.

> *A fundamental underpinning of regulatory approval for interstate pipeline and storage construction is the demonstration of market need, as supported by customer willingness to enter long-term contracts for firm capacity.*

When pipeline or storage customers are not willing to enter long-term firm contracts, the market structure creates barriers to obtain the right to a predetermined capacity that is not subject to a prior claim from another customer. This is an issue for certain gas-fired electric power generators. Electric power generators profit if their cost of producing power (fuel plus operations and maintenance) is lower than the average price they sell electricity. Given most gas-fired powered generators are unable to store fuel onsite, they must rely on quick response delivery of natural gas, resulting in two unequal options:

- **Sign a long-term firm contract.** While an option, it is not typical because it could increase the cost such that it is not competitive with other sources of generation, i.e. coal and fuel-oil plants that can store fuel onsite, and solar and wind power that do not require fuel input.
- **Sign a secondary or interruptible contract.** Most gas generators take this action because the economics are more favorable. Interruptible capacity refers to pipeline transportation capacity that is available when the holder of the firm right to this capacity

[39] FERC. 2020. "The Natural Gas Pipeline Application Process at FERC."

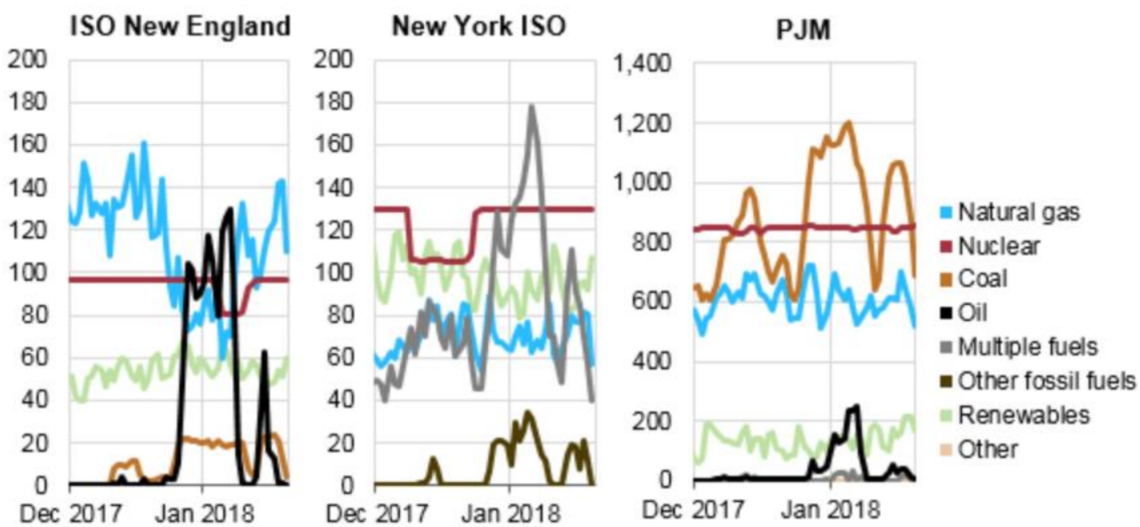
is not using it. The risk is that the pipeline or storage capacity may not be available when it is needed.

4.4.2 Regulatory Framework and Implications to Resilience

In periods of peak usage (e.g., during periods of high use), holders of firm pipeline transportation are likely to use their full allotment of capacity, leaving little to no capacity to secondary or interruptible contract holders. In these periods, gas-fired generators without firm capacity will likely be constrained. During periods of high use, a constrained gas pipeline can create economic or operational conditions that lead to increased fuel switching to oil-fired or dual-fuel generation. This has caused and can cause risk that electric generators lose the ability to serve peak electric load when customer demand for gas supply is also at its peak. This constraint is further illustrated in Figure 4-7.

Figure 4-7 details fuel switching in three electricity markets in the northeast (New England, New York, and PJM) during the January 2018 bomb cyclone. In early January, as the Northeast experienced the cold weather related to the bomb cyclone event, demand for electric power generators increased as natural gas transportation was constrained.

Figure 4-7. Comparison of Electric Power Generation During the January 2018 Bomb Cyclone[40]



Source: US Energy Information Administration

- In ISO New England (ISO-NE), oil generation jumped from almost nothing to a high of 36% of the daily generation mix. In comparison, gas-fired generation decreased from approximately 50% to less than 20% of supply.
- On New York ISO's (NYISO's) system, the output of dual-fuel generators, mostly gas-fired generators that can switch to fuel oil, and other fossil fuel generators rose significantly.
- In PJM, oil and coal generation increased while gas-fired generation remained consistent.

[40] EIA. 2018. Northeastern Winter Energy Alert.

Gas-fired generation did not make up the required increase in demand to meet the increased electric power generation needs during the 2018 bomb cyclone event. The structure of the underlying electricity markets, specifically the reliance on unused pipeline capacity for fuel delivery for gas-fired generation to maintain competitiveness, poses a challenge to investments in gas infrastructure in the electricity markets such as ISO-NE, NYISO, and PJM.

4.4.3 Current Gas System Resilience Is a Byproduct of Reliability

The current model for developing gas infrastructure supports construction of assets that support reliability of service and that can be underpinned by long-term contracts. This model has been supportive for maintaining the resilience of the gas system, but it must be recognized that the model does not reflect how the gas system will be operated in the future. It also does not support construction of assets that support resilience requirements.

As demonstrated by the case studies, gas infrastructure provides resilience benefits to the entire energy system. However, the strength of the current gas system is a byproduct of an outdated regulatory system, optimized around daily reliability instead of long-term resilience. Fortunately, the overlap between the two outcomes is considerable enough that the energy system currently experiences a reasonable level of resilience. However, the current regulatory structure does not provide a means to construct and operate investments primarily for resilience. As the transformation of the energy system continues, we anticipate the need for more resilience and a changing mix of assets required to provide that service. The manner in which this energy system is regulated and managed is becoming outdated; thus, an update is necessary to maintain resilience in the evolving future energy system.

4.4.4 Gas Systems Are Not Appropriately Compensated for Resilience Services

From a regulatory perspective, LDCs have an obligation to serve and must develop supply and transportation plans to provide gas reliably at the lowest sustainable cost. Typically, gas distribution utilities do not procure more gas supply than necessary for a given day and instead use storage and linepack to balance intraday supply and demand. In most cases, LDCs cannot secure regulatory recovery to procure and store additional gas supply for low likelihood, extreme climate events beyond that incorporated in reserve margin planning. When a customer draws significantly more gas from the gas system than its average demand, this additional supply comes from gas stored that is already allocated to another customer.

> *Any incremental supply that is available to serve electric power generation on short-notice will be gas that has been reallocated from other customers unless the pipeline or LDC offers a no-notice service.*[41]

Some interstate pipelines and gas distribution companies offer no-notice service on a firm basis by dedicating pipeline and storage infrastructure to support the delivery of gas on short notice—no-notice service is typically supported via interstate pipeline tariffs. An electric power generator may pay the cost of expansion of pipeline or storage assets to support the maximum volume consumed. Example 4 (page 57) is a good illustration of this scenario.

In other cases, providing gas supply on short notice to serve resilience events is limited by several features of the gas delivery system. From a physical perspective, the incremental supply

[41] No-notice service refers to the delivery of natural gas on as-needed basis, without the need to precisely specify the delivery quantity in advance (quantities within contract entitlements).

consumed on an intraday basis needs to be in the pipeline at the moment the electric power generator requires delivery throughout the period that the electric generator is producing power. The accommodation of non-ratable flows in the gas system depends on how other shippers use their contracted entitlement in the pipeline and the operational flexibility of the pipeline (e.g., line pack and storage availability). If the pipeline is already full, extreme spikes in demand from non-ratable users may not be met.

The LDC delivery system was not designed to provide large volumes of no-notice service to the electric power generation sector. However, in many circumstances, LDCs provide non-ratable service when capacity is available and when it does not threaten operations. In these cases, the gas system supports the energy system's overall resilience but is not adequately compensated for its service. This lapse in compensation occurs because an additional service is being provided with assets that were not designed for the circumstances.

4.5 Impacts on Consumers

This section considers the varying level of the impact of the findings on the current state on gas ratepayers and electric ratepayers. At a high level, gas ratepayers are more closely aligned with gas system resilience investments than electric ratepayers, as there is no misalignment around who benefits and who pays. Electric system ratepayers, who benefit from the gas system through gas-fired generation have greater misalignment with the development of gas system resilience investments.

4.5.1 Gas System Resilience to Benefit Gas Ratepayers

LDC customers benefit from the resilience provided by assets that are built to provide reliability. Assets are built to serve gas ratepayers. There is a disconnect between who benefits and who pays. The resilience byproduct of these assets benefits these customers. Construction of an asset that is primarily designed for resilience is problematic, because:

- **Lack of a Regulatory Framework:** Resilience of the gas system is not a current regulatory requirement.
- **Lack of Metrics:** Unlike reliability, which can be measured, resilience does not lend itself easily to quantification. For example, value of avoiding the socioeconomic consequences and costs of a prolonged disruption is difficult to measure.

The lack of a regulatory framework and the difficulty of measuring the value complicates the prudency review and cost-effectiveness evaluation of an asset whose business purpose is resilience. As such, reliability drives investment in gas infrastructure. Assets are designed and approved to meet reliability requirements driven by projected gas supply needs and delivery requirements for peak day usage based on historical data. A specific regulatory mechanism to support cost recovery for gas assets whose primary service is to serve resilience events does not exist and needs to be developed.

4.5.2 Gas System Resilience for Electric Ratepayers

There is a larger disconnect between current market structures and the development of resilience assets when the beneficiaries of gas system reliance are not direct gas system customers, such as electric market customers.

- **Difficulty to recover costs across complementary energy markets:** While there is a connection between the resilience of the gas and electric systems, there is no mechanism for electric market participants to collect revenue or provide cost recovery for investments in gas system resilience.

The gas delivery system was not constructed to handle the increasing frequency of large intraday swings in service demand by gas-fired generators that serve intermittent load. As discussed in Section 4.3.2 and as described in Case Study 6, the gas system accommodates the non-ratable flow of the electric sector on a best-efforts basis. In many cases, pipeline transportation arrangements, tariffs, and coordination efforts exist between an LDC and specific electric power generators. However, these are generally workarounds that do not address the core issue: the current state market framework was designed to promote reliability and does not support the construction of assets whose primary function is to serve resilience, especially when the beneficiaries of that resilience are outside of the gas infrastructure-ratepayer ecosystem (i.e., the electric sectors' customers), nor does it fairly compensate the LDCs as the provider of these resilience services.

To further highlight the cost associated with the development of resilience assets, in Example 4 we discuss a gas infrastructure project specifically designed to serve the resilience needs of the electric sector. This example illustrates the benefits that the gas system can provide to the overall energy system when there is alignment between who pays and who benefits and there is a long-term contract to support development.

Example 4. Gas-to-Power Coordination

Portland General Electric (PGE), an electric utility in Oregon, has traditionally relied on hydroelectric generation resources to provide electric system flexibility. However, it sought new ways to achieve flexibility to meet the expansion of solar and wind generation capacity. PGE needed an efficient technology capable of quick-starting, as well as fast ramp-up and ramp-down rates to fulfil the grid's need for flexibility. PGE constructed a 220 MW electric power plant to provide intermittent power during winter and summer periods, as well as load following and renewable integration throughout the year. The plant can ramp to full load in less than 10 minutes.

To assure deliverability of natural gas to accommodate this quick start-up time, PGE partnered with NW Natural, an Oregon-based LDC, to contract for no-notice storage service. To provide this service, NW Natural embarked on a $149 million project that included a 13-mile gas pipeline, a compressor station, and a 4.1 Bcf expansion of the NW Natural' North Mist natural gas storage reservoir. Through this storage service, PGE can draw on its natural gas resources from NW Natural's facilities in Mist, Oregon to meet its fueling needs and rapidly respond to peak demand and variability of wind, hydro, and solar generation. The facility is contracted for an initial 30-year period with a renewal option of up to 50 years beyond that.

Currently, no specific compensation mechanism exists for the resilience services that gas-fired electric power generation provides the electric sector. In the future, as the percentage of electricity generation from intermittent renewable sources increases, the volume of natural gas used for electric power generation may decline; however, in responding to resilience events the necessity of the services provided by gas-fired electric generators may increase. As current compensation models for the gas system serving the power generation sector are tied to the volume of gas delivered to the facility, there becomes an increasing disconnect between the value of the services provided and associated remuneration for said services.

> *Reliability assets are designed and economically justified based upon historical averages and relatively stable utilization. Resilience assets are essential to operation under infrequent and extreme conditions. The benefits of their existence often extend beyond the energy system for which they were designed, i.e., resulting in a greater socioeconomic benefit such as reduced economic loss resulting from an extreme event.*

5. Ensuring A Resilient Future

The energy system of today will not be the energy system of tomorrow. Decreases in the cost of technologies and increasing pressures to decarbonize the energy system are manifesting in increasing levels of renewable generation, a more distributed generation profile, and a less carbon intensive energy supply—there is some indication that certain versions of this future may have negative impacts on energy system resilience.

In a recent review of the root cause of CAISO outages during the August 2020 heatwave, one of the three factors identified was:

> "*In transitioning to a reliable, clean and affordable resource mix, resource planning targets have not kept pace to lead to sufficient resources that can be relied upon to meet demand in the early evening hours. This makes balancing demand and supply more challenging. These challenges were amplified by the extreme heat storm.*"[42]

As the resilience of the gas system grows in importance, cost recovery mechanisms need to be developed to support investments in assets that strengthen resilience. These cost recovery mechanisms should define the resilience requirement for both gas and electric ratepayers.

5.1 Lessons from Others

This section details key lessons learned from recent regulatory and legislative activities governing resilience in the electric, water, and healthcare sectors. These lessons highlight some opportunities that may exist to develop regulatory structures to support gas resilience investments.

5.1.1 FERC Order 841, Electric Storage Participation in Markets Operated by Regional Transmission Organizations and Independent System Operators

FERC Order 841,[43] issued in February 2018, directed regional grid operators to remove barriers to the participation of electric storage in wholesale markets. The order creates a legal framework for storage resources to operate in all wholesale electric markets and expands the universe of solutions that can compete to meet electric system needs. Order 841 was upheld in a federal appeals court decision in July 2020 that declared FERC has jurisdiction over how energy storage interacts with the interstate transmission markets it regulates, even if those energy systems are interconnected with state-regulated electric distribution grids.

> *By directing regional grid operators to establish rules that open capacity, energy, and ancillary services markets to energy storage, Order 841 affirms that storage resources must be compensated for all services provided and moves toward leveling the playing field for storage with other energy resources.*

A key component of the ruling is that "many participation models were designed for traditional generation resources—resulting in limitations or barriers to participation, which constrain competition,"[44] because novel resources technically capable of participating are precluded from doing so as they are forced to operate under participation models designed for existing

[42] CAISO. 2020. Preliminary Root Cause Analysis Mid-August 2020 Heat Storm.
[43] FERC. 2018. Order 841.
[44] US Court of Appeals. 2020. On Petitions for Review of Orders of the Federal Energy Regulatory Commission.

technologies. Energy storage resources (ESRs) such as batteries are especially affected by participation barriers because they have “unique physical and operational characteristics” distinct from traditional resources: ESRs can “both inject energy into the grid and receive energy from it.”

Although this order has limited direct applicability to the natural gas market, it does provide evidence that there are avenues to adapt the current market framework for valuable emerging technologies. Moreover, FERC Order 841 recognizes that the energy system is being used in a different way today than the current regulatory framework envisioned. The acknowledgment that the regulatory framework needs to be reconsidered to remove participation barriers supports the durability of the electric system.

5.1.2 FERC: ISO-NE, Cost-Recovery for Critical Infrastructure Protection (CIP)

Recent FERC orders approving cost recovery for CIP in the electric system showcase how the appropriate cost recovery mechanism can be designed. Federally mandated CIP requirements for electric systems assign protection standards at the low, medium, and high level, with higher standards carrying higher compliance costs. Left unresolved, however, was how generators in wholesale markets would recover the costs of compliance that cannot be competitively offered into the energy and capacity markets. This is because more stringent CIP requirements that result in higher compliance costs provide a disadvantage to a generator that is competing with a generator with lower compliance costs. In May 2020, FERC issued an order approving a proposal submitted by ISO-NE[45] to permit the recovery of incremental costs incurred when low-impact energy systems are reclassified as medium impact energy systems. The order permitted ISO-NE to allocate and collect those costs from transmission customers and disburse the funds to the pertinent facilities.

The concept behind CIP provides several lessons for the consideration of creating cost-recovery mechanisms to support resilience in the natural gas sector. The first is that there are examples in energy markets where resilience is legally mandated. Second, although these mandates can be a source of economic disadvantage to market participants in deregulated energy markets, FERC has approved RTO designed cost recovery mechanisms that socialize the costs.

FERC has mandated a set of protections for critical infrastructure in recognition of the vital role that the electric system plays in supporting the livelihoods of Americans and commerce in the US. The FERC CIP requirements can be viewed as a mandatory resilience requirement with a defined, measurable set of standards.

5.1.3 Energy Resilience in the Water Sector

Water utilities and their regulation offers key lessons on regulatory innovation and resilience. On September 13, 2008, Hurricane Ike made landfall on the upper Texas coast, causing significant damage. Millions of customers lost power, including 99% (more than 2.1 million) of CenterPoint Energy’s[46] customers. A critical pumping station that enables delivery of approximately 75% of Houston’s water supply was one of the casualties and was without power for approximately 10 days—Houston nearly had to declare a water emergency as a result.

[45] FERC. 2020. Docket No. ER20-739-002.
[46] CenterPoint Energy is the electric utility serving the Houston Area.

The Texas legislature enacted legislation[47] in 2015 mandating that water and wastewater treatment facilities have emergency backup power. The requirement also established a definition of resilience: duration at least equal to the longest power outage on record for the past 60 months, or at least 20 minutes, whichever is longer.

In addition, the America's Water Infrastructure Act (AWIA), passed by the US Congress in 2018 and reauthorized in May 2020, requires community water systems to conduct a risk and resilience assessment and develop an emergency response plan (ERP). The ERPs need to focus on more than merely being able to respond. They must include risk mitigation actions such as alternative source water, interconnections, redundancy improvements, asset hardening, and physical and cybersecurity countermeasures if and as justified through assessment. More specifically, the AWIA requires the following:

- Strategies and resources to improve the durability of the energy system, including physical security and cybersecurity.
- Plans and procedures that can be implemented, and identification of equipment that can be used, in the event of a malevolent act or natural hazard that threatens the ability of the community water system to deliver safe drinking water.
- Actions, procedures, and equipment that can obviate or significantly lessen the impact of a malevolent act or natural hazard on the public health and the safety and supply of drinking water provided to communities and individuals, including the development of alternative source water options, relocation of water intakes, and construction of flood protection barriers.
- Strategies that can be used to aid in the detection of malevolent acts or natural hazards that threaten the security or resilience of the energy system.

5.1.4 Energy Resilience in the Healthcare and Emergency Response Sectors

In 2012, Hurricane Sandy made landfall on the US coastline near Atlantic City, New Jersey, with winds upwards of 80 mph. The storm killed over 100 people, flooded coastal cities, destroyed structures, and tore down power lines. As the hurricane devastated the coast, 8.5 million people in 15 states lost power. The widespread power outages severely impacted medical facilities, leaving society's most vulnerable people in life-threatening situations.

Hospitals in New Jersey were forced to evacuate patients after floodwaters damaged backup generators needed to run elevators, lights, and ventilators. Transporting critically ill patients resulted in the loss of life and highlighted the need for more resilient solutions.[48] The total socioeconomic impact of Hurricane Sandy was also enormous, resulting in economic losses ranging from $27 billion to $52 billion.[49] According to the Executive Office of the President in

[47] Texas Administrative Code. 2015. Rule 217.63: Emergency Provisions for Lift Stations.

[48] Modern Healthcare. 2012. *Left in the dark: Seven years after Katrina, Sandy is teaching hospitals more lessons on how to survive nature's fury*.

[49] Executive Office of the President. 2013. *Economic Benefits of Increasing Electric Grid Resilience to Weather Outages*.

2012, "these costs of outages took various forms including lost output and wages, spoiled inventory, delayed production, inconvenience and damage to the electric grid."[50]

In response, legislation arose from the crisis. Assembly Bill 1561, the New Jersey Residents' Power Protection Act,[51] was passed in 2015, which requires "medical facilities, pharmacies, first aid squads, fire stations, gas stations,' and newly constructed grocery stores all have backup generators." These generators are expected to run for 96 hours in case of emergency. Additionally, generators must activate within 10 seconds and be inspected weekly. [52]

Senate Bill No 854 was also approved after the storm. It mandates healthcare facilities and retirement homes install emergency electric power generation should the need arise.

New Jersey's legislation focuses on investing in resilience and is impactful for the community and the economy. The legislation exemplifies the growing acceptance of the need for a resilient energy system. In the form of backup generation, the strength of the energy system can withstand shocks and protect vulnerable community members. It will mitigate the emergency costs hospitals face over time, "saving the economy billions of dollars and reducing the hardship experienced by millions of Americans when extreme weather strikes."[53]

5.2 Key Opportunities

Across the gas delivery value chain, the use of existing infrastructure assets is shifting. This shift in usage will undermine the current and future economics of how assets are compensated and limit the development of resilience-focused assets.

- **High-pressure intrastate and interstate pipelines** are developed based upon long-term agreements supported by shippers. Shippers are contract counterparties who provide the economic framework for development of pipeline infrastructure assets. These shippers have historically derived economic value from projects using high load factor ratable forecasts. In the past decade, most material projects were supported by a combination of electric power generation projects or increasing demand from LDCs. Primarily, these have been FERC regulated assets and regulatory approval is based upon a demonstration of demand by the referenced shippers. As utilization of gas-fired generation shifts due to the advent of more renewables and utility demand moderates under decarbonization pressure, forecasted utilization is likely to be significantly lower. As the use of the gas system changes, the way gas service is charged needs to change as well.
- **Storage assets** provide significant resilience benefits. Some utilities have the benefit of on-system storage due to the geologic formations being within the operating jurisdiction or they use aboveground storage assets. Other utilities subscribe to services from storage owners and operators upstream of city gates. Historically, the economic drivers for storage were seasonal pricing differentials and balancing services provided to the integrated gas infrastructure system. In the future state, these assets will continue to provide seasonal and long-duration supply services. Storage is an important resilience asset and will continue to be essential to an integrated energy system. The economics of legacy seasonal pricing

[50] Executive Office of the President. 2013. *Economic Benefits of Increasing Electric Grid Resilience to Weather Outages*.

[51] State of New Jersey. 2014. *Assembly Bill No. 1561.*

[52] Facilities Net. 2013. *NFPA 110's Fuel Requirements Can Help Guide Backup Power Plan For Hospitals*.

[53] Executive Office of the President. 2013. *Economic Benefits of Increasing Electric Grid Resilience to Weather Outages*.

differentials and balancing services may not provide sufficient revenue to encourage continued development and maintenance of these critical assets. If storage owners and developers were provided revenue for providing resilience benefits, however, the economic framework would sustain the availability of these necessary assets.

- **Distribution systems** have special duty assets including peak shaving storage, LNG storage, and non-pipeline solutions that provide resilience benefits. These assets historically have been designed to meet design day peak demand based upon historical heating degree days. However, as noted in the case studies, climate events create operating stress on existing gas systems. Like the interstate gas systems, the high frequency, high utilization economic framework that was used to justify investments in these legacy assets is not fit for stimulating future investments in a mix of assets that is becoming more intermittent.

The gas system is highly resilient and plays a critical role in supporting the stability of the overall energy system. Current regulatory, economic, and policy frameworks are not conducive to creating the vibrant energy system of the future. The gas and electric sectors are fortunate that the energy system designed to provide reliability has provided resilience benefits. However, the resilience benefits currently enjoyed are a regulatory byproduct and will not serve the needs of the future energy state.

6. Conclusions

The transformation of our energy system is well underway, driven by changes in the cost and availability of new technologies and increasing political and social pressure to decarbonize. The way energy is generated and used is changing rapidly, moving from a one-way power from centralized generation to end customers to a multidirectional network supporting two-way energy flows. As the energy system migrates to one increasingly powered by intermittent renewable sources, it also experiences increasingly frequent and intense climatic events—together these fundamental drivers are creating ever increasing operating stress on the energy system.

As discussed throughout this paper, the gas system is currently providing resilience benefits to the entire energy system. But, the strength of the current resilience is a byproduct of a regulatory environment that has valued investment in a reliable, ratable, and safe set of assets designed around a legacy demand forecast and historical heating degree day planning. As the transformation of the energy system continues, we anticipate a need to place a greater focus on resilience and a re-evaluation of the diversity of assets providing that service.

Full utilization of resilience assets is infrequent by nature. Yet, when a resilience service is demanded it is an essential product of the energy system and key to mitigating catastrophic risk and limiting socioeconomic costs to customers and communities. Utilities, system operators, regulators, and policymakers must make informed decisions to identify an economic framework to incent investments in resilience assets required to support a vibrant and strong future energy system. Resilience should be an energy system requirement like safety and not a byproduct of the existing framework.

6.1 Implications for Policymakers and Regulators

Looking into the future, evolving technology and the speed of transformation of the energy system will require a different economic and regulatory framework to support the appropriate mix of assets and fair compensation for continued investment. Achieving this is easier said than done. It will require a realignment of the valuation and cost recovery mechanisms that currently define the development of the US energy system.

Energy system resilience needs to be defined as a measurable and observable set of metrics, similar to how reliability is considered. To design a truly resilient system requires an ability to measure, evaluate, and optimize the benefit. Resilience needs to be considered as another dimension of system planning, similar to the way that reliability is considered today.

Resilience solutions must be considered from a fuel-neutral perspective and across utility jurisdictions, requiring electric, gas, and dual-fuel utilities to work together to determine optimal solutions. As this paper clearly illustrates through the case studies, when low likelihood, high impact events impact our energy system—the energy system responds through integrated responses that rely on fundamental characteristics of a diversity of assets. Energy system resilience solutions cannot be engineered through a siloed approach that considers only a portion of the energy system, they must consider the opportunity and value that can be brought to the energy system across a diversity of assets.

Methodologies need to be built for valuing resilience, such that it can be integrated into a standard cost-benefit analysis. Value must consider the avoided direct and indirect costs

to the service provider, customers, and society. LDCs and other pipeline infrastructure providers are not fully compensated for the true value of resilience services they provide to the overall energy system. Because the resilience of the gas system is largely a function of the reliability of the gas system, the true cost of resilience (i.e., return of and return on capital invested in physical infrastructure) is treated as a sunk cost. In other words, ratepayers are paying for reliability and enjoying resilience as a benefit—a disconnect that will become increasingly evident as extreme events become more frequent and the share of intermittent renewable generation increases.

In addition to the legacy evaluation criteria that determine cost-effectiveness, policymakers and regulators need to consider ways to evaluate the socioeconomic benefits and avoided costs to the communities resulting from a resilient energy system.

- What is the cost to the community of catastrophic loss of service during a climate event?
- If energy is not available to essential services can this value this be considered by analysis that primarily focuses on the costs per MMBtu or kWh?
- What level of insurance would these communities be willing to pay to have a future energy system that is robust enough to recover quickly and vibrantly from man-made and climate-driven events?

> *Resilience assets mitigate exposure to catastrophic impacts to the communities they serve and should be viewed as an insurance policy to limit risk.*

Cost recovery should be spread over the entire energy system when considering endorsement of capital projects for resilience assets. Further, cost recovery stimulated by utilization is not an appropriate metric for low load factor usage associated with low likelihood, high impact future scenarios.

6.2 A Call to Action

The development of a new regulatory framework will require innovation and collaboration from utilities, system operators, regulators, and policymakers to identify workable solutions that are fit for purpose and tailored to the requirements of regional markets. Preparing the future state to respond effectively to the current transformation requires the communication, coordination, cooperation and collaboration with all industry partners and stakeholders to identify, develop, and implement solutions.

Any future actions undertaken by regulators and other stakeholders should be evidence-based, fuel neutral, and based on objective criteria that scrutinized by all stakeholders. FERC has left it to the RTOs to assess how to best enhance the resilience of the power system and recognizes that solutions to improve gas/power resilience will need to be resolved at the RTO level, however federal direction may also be needed to coordinate productive discussion and facilitate collaboration.

Recent FERC regulatory activity and RTO-led stakeholder planning engagements indicates a precedent for this type of cross-industry collaboration. This activity suggests that the innovation required to address shifting requirements for energy system resilience and facilitate cost recovery for resilience assets is not only possible but achievable.

State PUCs have a vital role to play as well. As the primary regulator of LDCs, PUCs are charged with ensuring customer protection, fostering competition, and promoting high-quality infrastructure. Moreover, solutions to the issues identified in this report will require locally identified solutions that are tailored to the unique needs and circumstances of individual LDCs and the regions they serve.

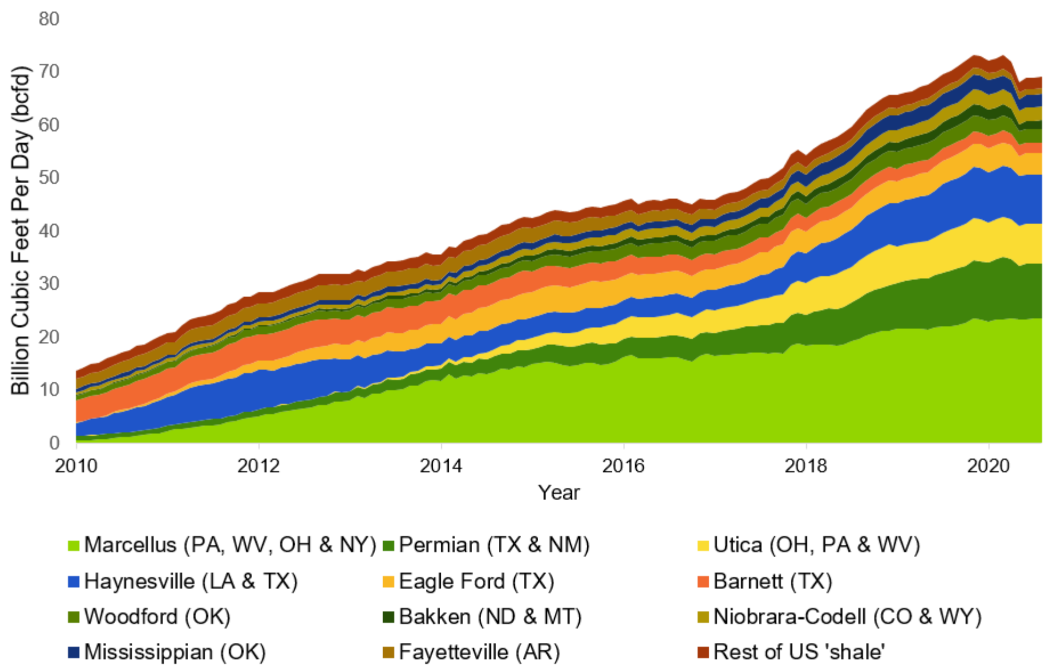
For energy system stakeholders at every level, resilience is not just a term that is currently in vogue, it is a characteristic that needs to be valued and engineered. Ensuring future energy system resilience will require careful assessments of all available solutions, maximizing the fundamental benefits of a diversity of assets. Utilities, system operators, regulators, and policymakers need new frameworks to consider resilience impacts as part of the energy system transformation, to ensure that resilience is not overlooked in the pursuit to achieve decarbonization goals.

Appendix A. The Natural Gas Value Chain

A.1 Production and Processing

Exploration and production companies explore, drill, and extract natural gas from geologic formations. In 2019, 81% of production came from shale.[66] Production from these formations has grown rapidly over the past decade, as Figure A-1 shows.

Figure A-1. US Dry Shale Gas Production, 2010-2020



Source: Guidehouse, US Energy Information Administration

Once produced and extracted, gathering pipelines transport natural gas to processing facilities where impurities are removed, resulting in pipeline-quality natural gas. Gathering systems use compressors to move gas through the midstream pipelines. Most compressors are fueled by natural gas from their own lines. This self-reliance increases resilience by allowing the movement of molecules without dependency on other fuel sources.

A.2 Transmission

From the gathering system, natural gas moves into the high-pressure transmission system for long-haul transportation to market centers. These pipelines efficiently move large amounts of natural gas thousands of miles.[54] In the US, there are approximately 3 million miles of mainline and other pipelines that connect gas production with consumption.[55] Over 30 companies in North America own and operate interstate pipelines, which the FERC regulates. Intrastate pipelines are generally owned by publicly traded entities and are regulated by the states in which they are located.

[54] American Gas Association. *How Does the Natural Gas Delivery System Work?*. Accessed October 2020.
[55] EIA. *Natural Gas Explained: Natural Gas Pipelines*. Accessed October 2020.

A.2.1 Compressor Stations

The pressure of gas in each section of the transmission system ranges from 200 psi to 1,500 psi, depending on where the pipeline operates. Compressor stations are located approximately every 50 to 60 miles along transmission pipelines to regulate pressure and keep gas moving.

A.2.2 Gas Storage

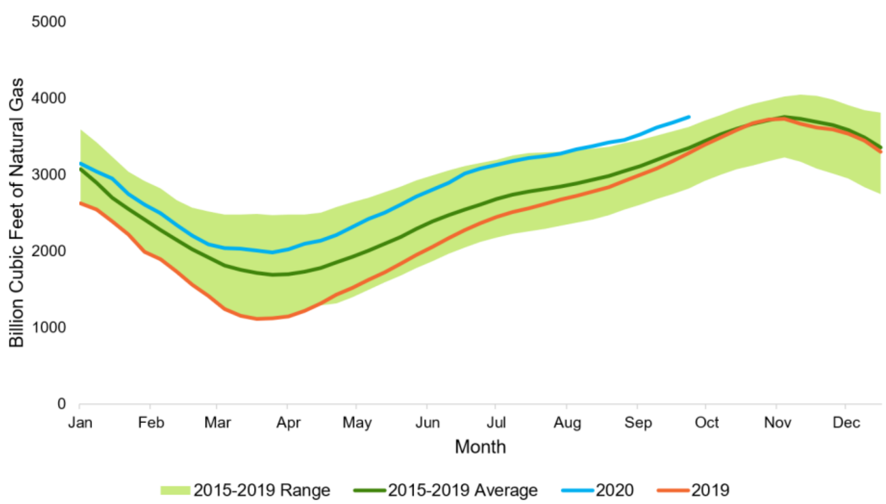
Storage capacity enables the delivery of reliable gas service to consumers and end-users throughout the year. While natural gas production remains relatively constant year-round, storage enables gas providers to adjust to daily and seasonal demand fluctuations (Figure A-2).

Storage can be owned or operated by natural gas transmission companies or LDCs. Off-system storage is not directly tied to a natural gas utility's distribution system, but that is accessible via the transmission system. Most off-system storage is underground; however, there are examples of aboveground off-system storage. Underground storage facilities can be developed from depleted gas reservoirs, aquifers, or salt caverns and are connected to one or more transmission pipelines; whereas aboveground storage is often provided through LNG or CNG.

In addition to offering storage services, some pipeline companies may provide a park and loan that enables shippers to borrow or lend gas. These services are typically used to balance daily or intraday markets. Some Pipelines also offer tariff-based delivery services called No Notice, which allows an LDC to receive gas at variable quantities throughout the day without placing nominations to the provider. These no-notice services are backed by storage and pipeline delivery assets.

In the lower 48 states, it is common for the gas system to have at least 2,000 Bcf to 3,000 Bcf of working natural gas in underground storage, as Figure A-2 shows. The entire US commercial sector consumed 3,500 Bcf in 2019. Base gas (or cushion gas) is the volume of natural gas intended as permanent inventory in a storage reservoir to maintain adequate pressure and deliverability rates throughout the withdrawal season. Working gas is the volume of gas in the reservoir above the level of base gas. Base gas inventories remain relatively steady at approximately 4,300 Bcf throughout the year.

Figure A-2. Working Gas in Underground Storage, Lower 48 States



Source: Guidehouse, US Energy Information Administration

A.2.3 City Gate Stations

Natural gas typically passes through a city gate to move from the transmission pipeline to the pipelines under operational control of LDCs. At the city gate, the pressure is reduced from transmission to distribution levels, an odorant is added, if not already provided by the upstream pipeline, and incoming flow is measured to ensure it matches the LDC's distribution requirements. Deliveries from transmission pipelines are normally scheduled a day or more prior to delivery and include the estimated total quantities for demand in the day forward. Some transmission systems provide operators the ability to make intraday changes to nominations in attempt to sync scheduled demand with actual demand.

In addition, pipeline midstream companies and inter-connection pipelines (i.e., LDC or other midstream pipeline companies) have OBAs in place in which parties agree to specified procedures for balancing between nominated levels of service and actual quantities transferred between the two pipelines.

A.3 Distribution

After leaving the city gate, natural gas moves into distribution pipelines. Each distribution system has sections that operate at different pressures, with mechanical regulators controlling the pressure to optimize efficiency. Generally, the closer natural gas gets to a customer, the lower the pressure.

Many distribution systems also feature on-system storage. This is typically aboveground and includes small-scale LNG or CNG storage that enables the distribution company to meet short-term requirements for increased gas demand and pressure balancing needs. Such facilities enable LDCs to supplement, or shave, the amount of natural gas needed from external suppliers through on-system resources. Some distribution systems also feature underground storage.

A.3.1 Customer Delivery

As gas travels through the main lines of the distribution system, it is routed to customers through smaller service lines. Flow meters and mechanical regulators reduce the pressure to under 0.25 psi, the normal pressure for gas within a household, equivalent to less pressure than a child blowing bubbles through a straw.

The types of customers served by the system include the following:

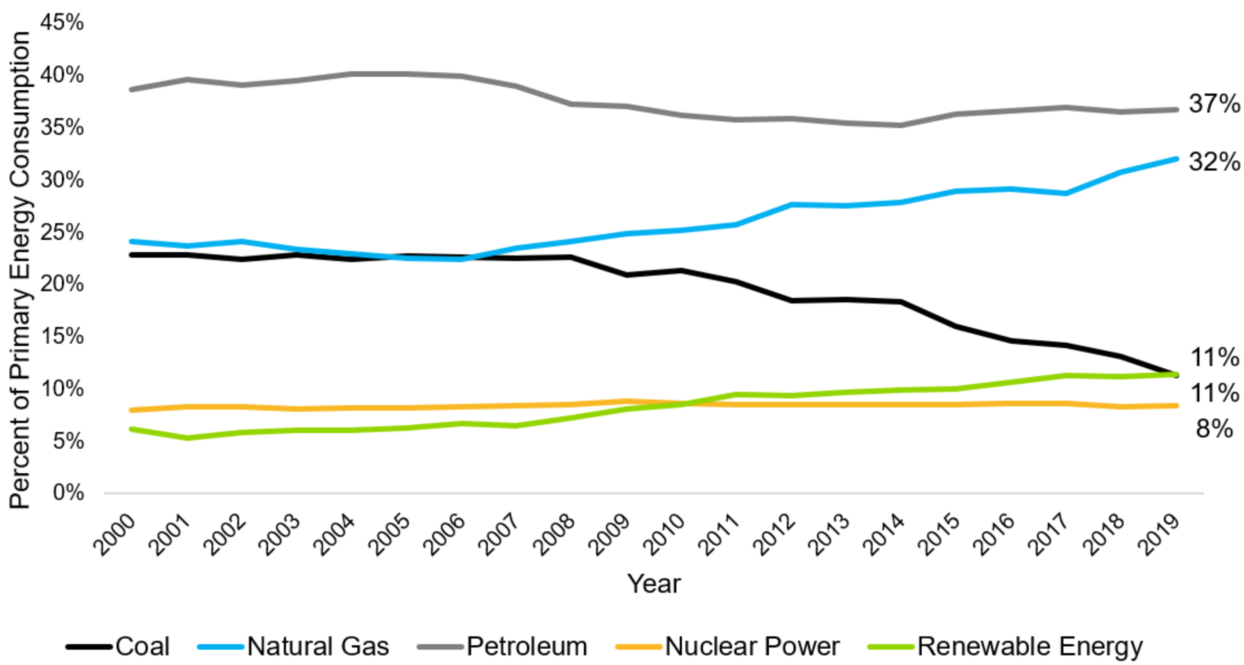
- **Interruptible vs. Firm Demand:** Interruptible customers are often large commercial or industrial customers that have selected to contract for natural gas service that can be interrupted when the delivery system is experiencing constraints. When a natural gas utility experiences a situation where gas consumption exceeds demand, such as during a peak heating day, system operators can curtail these interruptible customers while maintaining service to firm demand (or uninterruptible) customers.
- **Ratable vs Non-Ratable Flow:** Ratable flow refers to customers that will be delivered one-twenty-fourth of their nominated and scheduled daily quantity every hour—they receive the same amount of natural gas every hour of every day. Non-ratable flow refers to customers that receive uneven or varying consumption throughout the day.

Appendix B. The Current State of US Gas Consumption and Production

The US natural gas industry is larger today than ever before—gas consumption and production have grown since the 1950s and are currently at record levels. In 2019, the US consumed 31 trillion cubic feet of natural gas. Concurrently, the US produced approximately 33 trillion cubic feet of natural gas (dry production) in 2019.[56]

In 2019, natural gas accounted for 32% of US primary energy consumption.[57,58] Natural gas has been accounting for an increasing portion of the energy consumed in the US since 2000, as Figure B-1 illustrates.

Figure B-1. US Primary Energy Consumption by Source



Source: Guidehouse, US Energy Information Administration

B.1 Gas Consumption by Customer Segment

Natural gas is a significant energy source used to generate electricity in the electric sector and meet the end-use heating demands in the residential, commercial, and industrial sectors. It is also used in distributed electric power generation primarily through CHP in the industrial sector and as a transportation energy source.

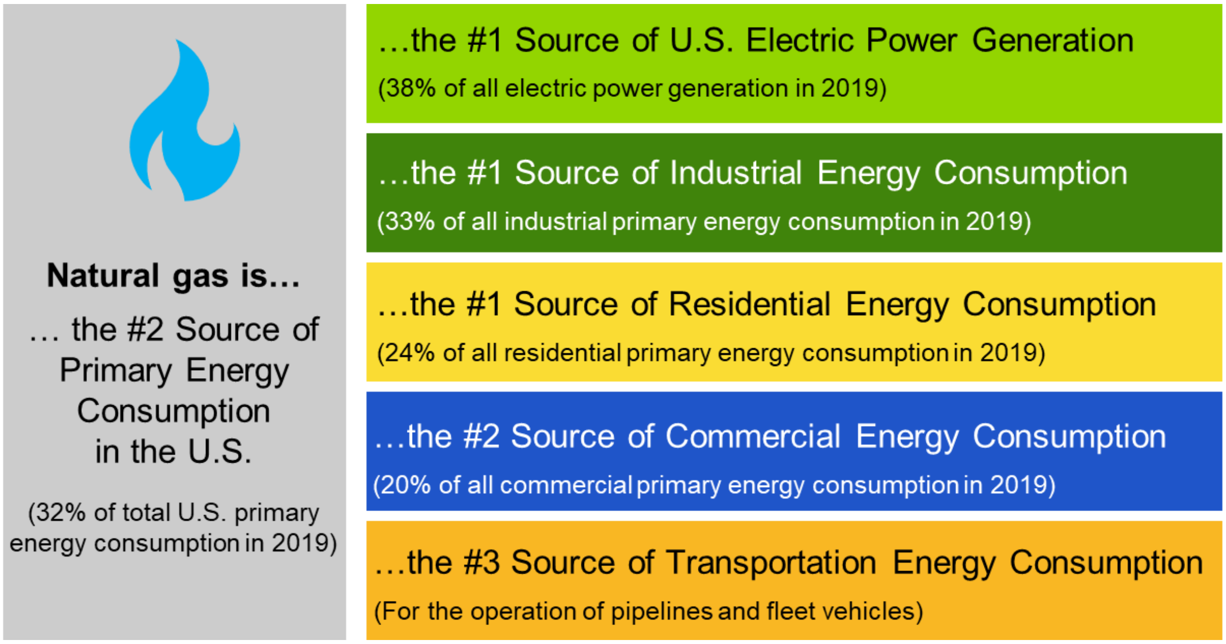
[56] EIA. 2020. *Annual Energy Outlook*.

[57] Primary energy consumption is a measure of total energy demand, covering the consumption of fossil fuels by end users like homes and businesses, the energy used to produce electricity, and losses during the transformation and distribution of energy.

[58] EIA. 2020. *Annual Energy Outlook*.

Figure B-2 illustrates the role that natural gas plays in powering each of these sectors. Natural gas supply is also detailed further throughout the remainder of this section.

Figure B-2. Natural Gas Deliveries and Consumption by Sector



Source: Guidehouse, US Energy Information Administration

B.1.1 Electric Power Generation

Growth in shale gas production has led to a decline in natural gas prices and has contributed to steady growth in the amount of electric power generated by natural gas (Figure B-3).

> *In 2019, 6,025 utility-scale gas generation facilities produced 38% of total US electricity, the largest share of any individual source. This is up from 5,722 gas generation facilities producing 33% of total US electricity in 2016.*[59]

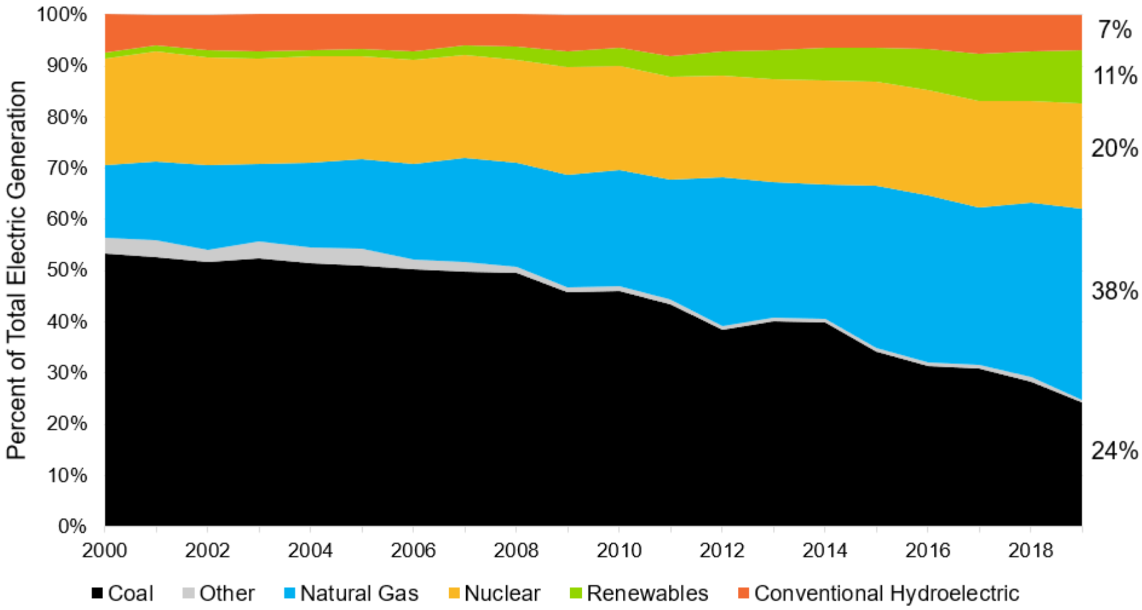
The price of natural gas is a key driver behind its growth as a source of electricity production. This trend continues today, with the 2025 EIA outlook for the levelized cost of electricity of next-generation coal plants hovering around \$76/MWh, and combined cycle natural gas plants around \$38/MWh. This is in-line with EIA projections for non-dispatchable technologies such as onshore wind (\$40/MWh) and solar PV (\$33/MWh), and cheaper than projections for offshore wind (\$122/MWh) and hydroelectric (\$53/MWh).[60]

Grid operators find value in gas-fired electric power generation because of its flexibility as an energy resource, serving as both high capacity factor baseload and dispatchable generation. The fast ramp-up and ramp-down times of natural gas generators are especially important in regions with a large share of renewables generation where natural gas plants are often required to balance the steep increase and decrease in generation capacity.

[59] EIA. 2020. *Preliminary Monthly Electric Generator Inventory, September 2020*.

[60] EIA. 2020. *Levelized Cost and Levelized Avoided Cost of New Generation Resources in the Annual Energy Outlook 2020.*

Figure B-3. Net Electric Power Generation by Source, 2000-2019



Source: Guidehouse, US Energy Information Administration

B.1.2 Industrial

Natural gas is critical to meeting the energy needs of the industrial sector. In 2019, the industrial sector accounted for 33% of total US natural gas consumption, which in turn accounted for 33% of the industrial sector's total energy consumption.[61]

Within the industrial sector, natural gas supports a wide range of uses including building heating, a feedstock for CHP, and as a feedstock for high energy-intense processes such as the production of chemicals, fertilizer, and steel.

B.1.3 Residential

In the US residential sector, natural gas is used to heat homes and water, cook, and dry clothes. Although the use of natural gas varies by geography (as Figure B-4 illustrates), about half of the homes in the US use it for space and water heating. In 2019, the residential sector accounted for approximately 16% of total US natural gas consumption, which translates to 24% of the residential sector's total primary energy consumption.[62]

B.1.4 Commercial

In the US commercial sector, natural gas is primarily used to heat buildings and water, to operate refrigeration and HVAC equipment, to cook, dry clothes, and provide outdoor lighting and heating. In 2019, the commercial sector accounted for approximately 11% of the total US natural gas consumption, which translates to 20% of the commercial sector's total primary energy consumption.[63]

B.1.5 Transportation

Natural gas plays a niche role in the US transportation sector, accounting for only 3% of the sector's total energy needs in 2019. Within the transportation sector, natural gas is used to operate compressors to move natural gas through pipelines and as a vehicle fuel in the form of CNG and LNG.

Most vehicles that use natural gas as a fuel are government and commercial fleet vehicles. CNG medium duty vehicles have gained increasing popularity over diesel due to lower prices and clean air benefits. In 2018, there were a total of 19,151 CNG public transit busses nationwide, compared to 32,671 diesel and 13,872 hybrid busses.[64] In 2020, there are 1,677

[63] EIA. 2020. *Levelized Cost and Levelized Avoided Cost of New Generation Resources in the Annual Energy Outlook 2020.*

[64] DOE. *Alternative Fuels Data Center, Transit Buses by Fuel Type*. Accessed October 2020.

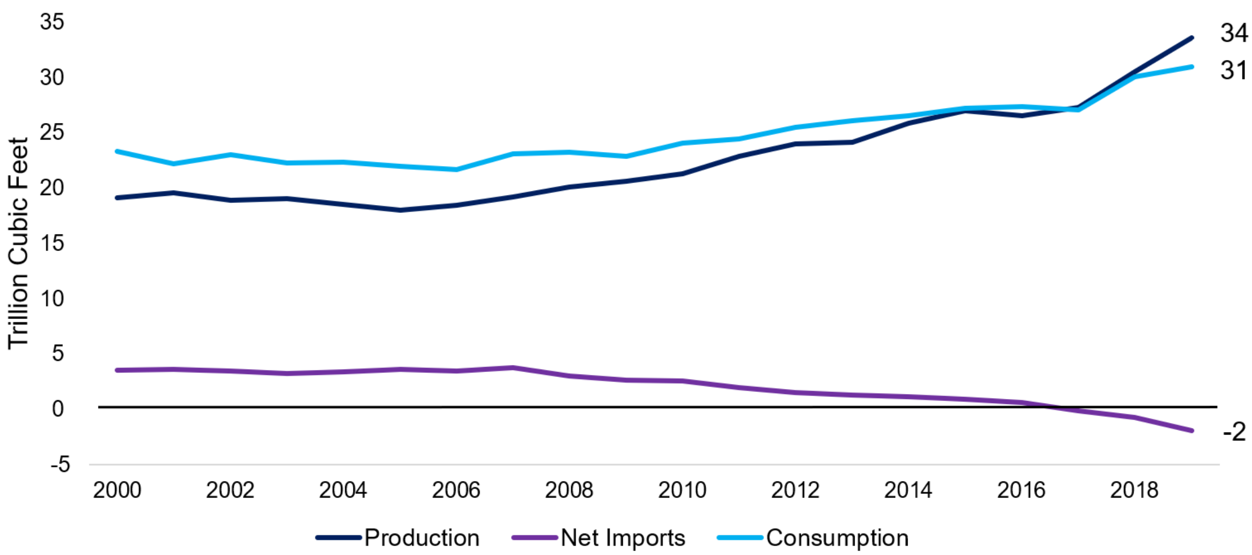
CNG and LNG refueling sites in the US compared to 29,738 EV stations. However, this infrastructure supports decarbonization of heavy and medium to light duty vehicles where EV infrastructure primarily supports light duty vehicles.[65]

B.2 US Gas Production

US natural gas production continues to grow; domestic production has exceeded consumption since 2017. The US now produces nearly all the gas it consumes, decreasing its reliance on imports from other countries. In large part due to accessible shale formations, most natural gas (97%) is produced onshore in a diversified base of over 30 states. Five states (Texas, Pennsylvania, Oklahoma, Louisiana, and Ohio) account for approximately 70% of the US total dry natural gas production.[66]

In 2019, 34 trillion cubic feet of natural gas was produced (Figure B-5).[67] Increased domestic production has contributed to a decline in prices, which has led to the significant increase in natural gas consumption across sectors, primarily in the electric power generation and industrial sectors.

Figure B-5. US Natural Gas Consumption, Dry Production, and Net Imports, 2000-2019



Source: Guidehouse, US Energy Information Administration

B.3 Low Carbon Gas Production

Since the early 2000s, US energy-related GHG emissions have been decreasing.[68] A significant driver of the emissions reduction has been a transition from higher-emissions fuels (e.g. coal) to natural gas. This transition is expected to continue, as natural gas supply is further decarbonized through the increase in low carbon gas production.

[68] EIA, *EIA Projects U.S. Energy-Related CO2 Emissions Will Remain Near Current Level Through 2050.*

Fueled by city and state commitments to decarbonize, investors are driving the capital necessary for companies to invest in the further research, development, and production of low carbon gases such as RNG, hydrogen-enriched natural gas, and hydrogen. Meanwhile, political and regulatory agencies are clearing the path for the growth of this low carbon gas development. Although low carbon gas production is nascent in the US, its growth potential provides a pathway for the natural gas industry to meet energy sector decarbonization goals. It also increases the resilience of the energy system by providing a locally sourced supply of clean energy.

B.3.1 Biogas

Biogas is produced primarily through landfill gas collection, thermal gasification, or anaerobic digestion of waste feedstocks from the sewage, agriculture, food, and forestry sectors. Biogas can be used to produce heat and electricity, or it can be further processed to remove impurities to meet the standards of conventional natural gas (defined as RNG) for distribution through the gas pipeline system, as Figure B-6 illustrates. Though most RNG produced is consumed onsite for electric power generation or heating, the American Gas Foundation found that there will be about 50 trillion Btu of RNG produced in the US for pipeline injection in 2020, a number that has grown at a compound annual growth rate (CAGR) of 30% over the past 5 years.[69]

> *The number of renewable natural gas (RNG) production facilities in North America grew by 145% from 2014 to 2019.*[70]

There are over 2,200 biogas production sites in the US. Investments into new biogas systems totaled $1 billion in 2018, a number that has been growing at a CAGR of 12%.[71] In 2019, the US produced approximately 230 billion cubic feet of biogas primarily from solid waste (83%), industrial (6%), wastewater (6.5%), and agricultural (4.5%) feedstocks.[72]

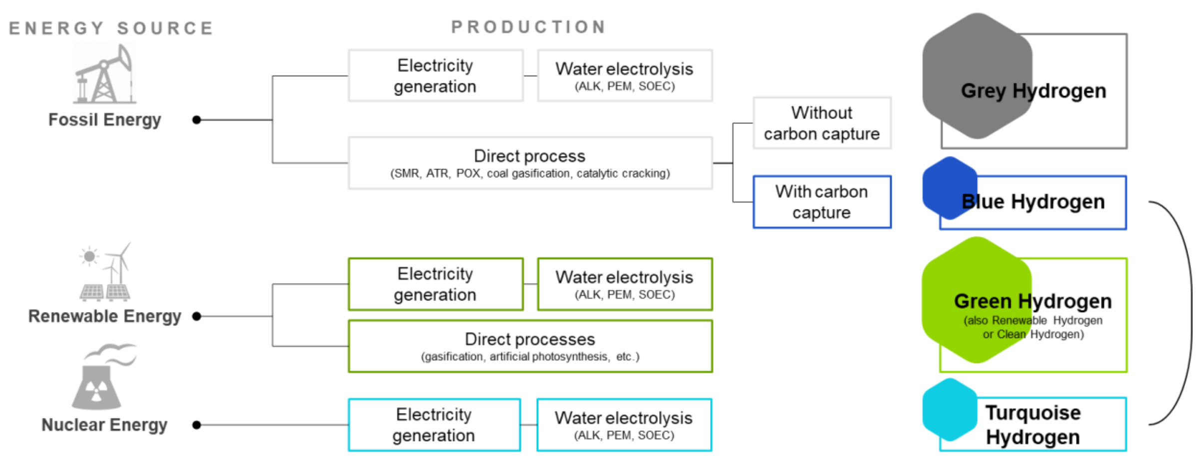
B.3.2 Hydrogen

Hydrogen is produced through electrolysis, a splitting of water atoms into their component parts of hydrogen and oxygen. Producing hydrogen requires an input of energy, the type of energy that is used defines the carbon intensity of the process and ultimately whether it is considered low carbon. Figure B-7 describes the various types of hydrogen across a color spectrum (grey, blue, green, and turquoise hydrogen).

Figure B-7. Hydrogen Production Technologies



Source: Guidehouse

Steam methane reforming is used to form most hydrogen production. Hydrogen is often produced for use alongside its two largest consuming sectors, petroleum refining and fertilizer production. There are1,600 miles of hydrogen pipeline in the US, and most states have a large hydrogen production facility producing approximately 10 million metric tons of hydrogen annually.[73] However, a recent California Energy Commission study estimates that with market and policy action to facilitate scale-up of production capacity, California alone could produce an excess of 2,000 metric tons per day by 2030.[74]

FEI'S STATEMENT OF INDIGENOUS PRINCIPLES

Our Statement of Indigenous Principles

Twenty years ago, we developed our formal Statement of Indigenous Principles with input, guidance and direction from several Indigenous leaders across BC.

FortisBC is committed to building effective Indigenous relationships and to ensuring we have the structure, resources and skills necessary to maintain these relationships. To meet this commitment, the actions of the company and its employees will be guided by the following principles:

- FortisBC companies acknowledge, respect and understand that Indigenous Peoples have unique histories, cultures, protocols, values, beliefs and governments.
- FortisBC supports fair and equal access to employment and business opportunities within FortisBC companies for Indigenous Peoples.
- FortisBC will develop fair, accessible employment practices and plans that ensure Indigenous Peoples are considered fairly for employment opportunities within FortisBC.
- FortisBC will strive to attract Indigenous employees, consultants and contractors and business partnerships.
- FortisBC is committed to dialogue through clear and open communication with Indigenous communities on an ongoing and timely basis for the mutual interest and benefit of both parties.

- FortisBC encourages awareness and understanding of Indigenous issues within its work force, industry and communities where it operates.
- To achieve better understanding and appreciation of Indigenous culture, values and beliefs, FortisBC is committed to educating its employees regarding Indigenous issues, interests and goals.
- FortisBC will ensure that when interacting with Indigenous Peoples, its employees, consultants and contractors demonstrate respect, and understanding of Indigenous Peoples' culture, values and beliefs.
- To give effect to these principles, each of FortisBC's business units will develop, in dialogue with Indigenous communities, plans specific to their circumstances.

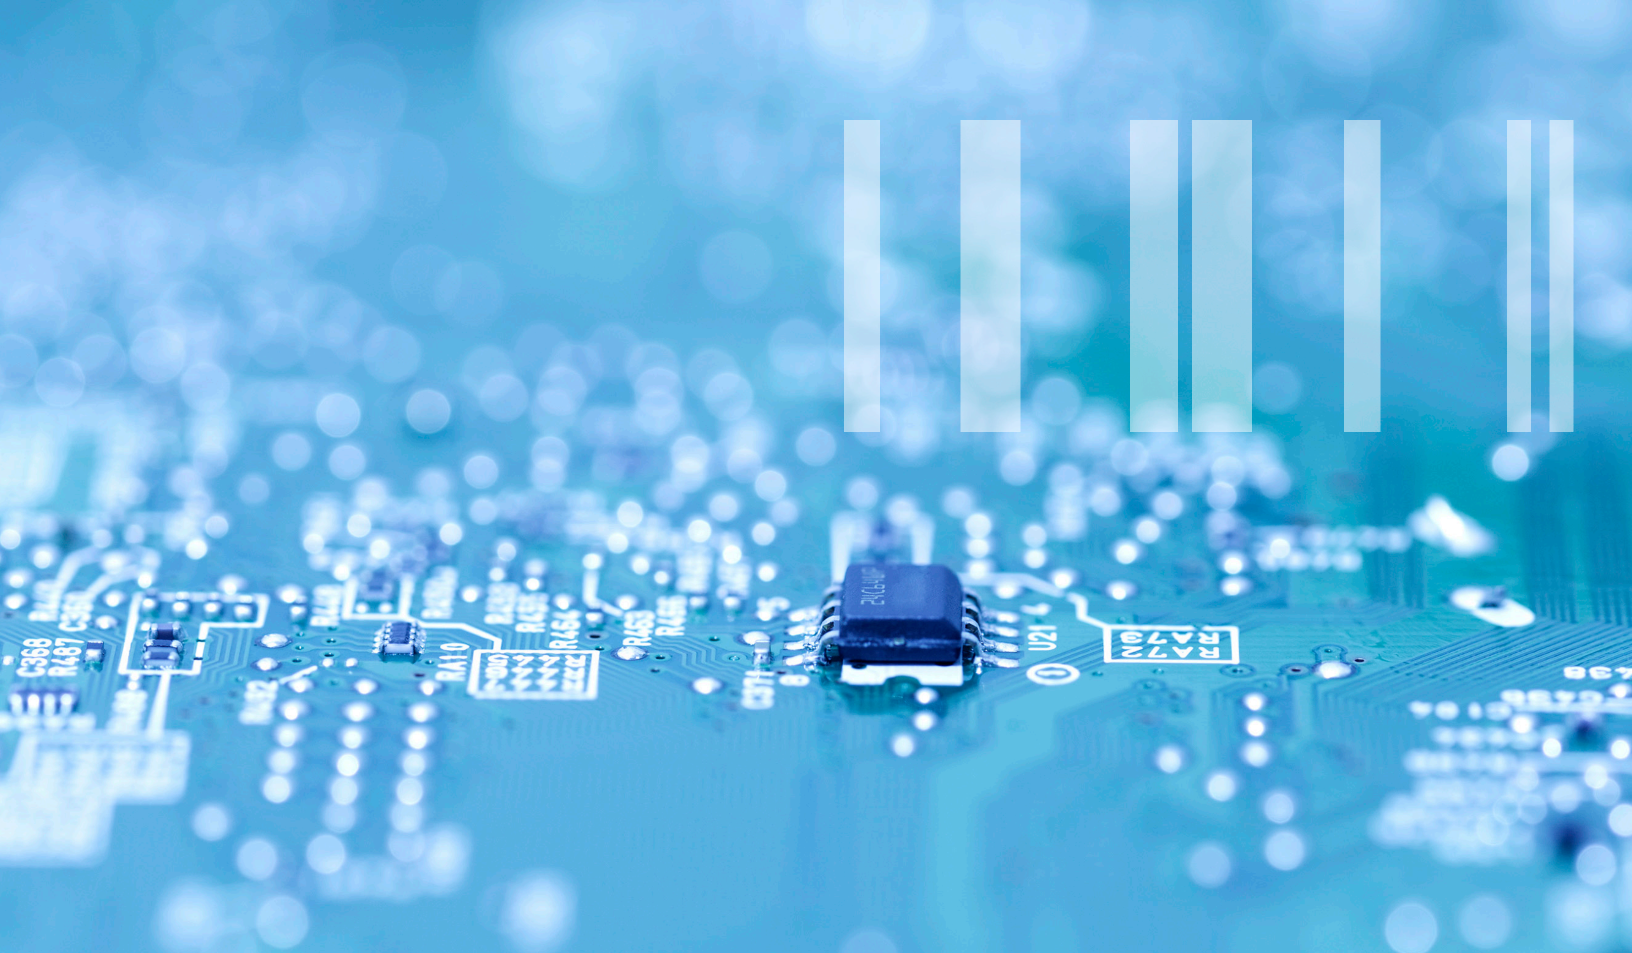
STUDIES SUPPORTING THE DIVERSIFIED PATHWAYS APPROACH



Implications of **Policy-Driven Electrification in Canada**

A Canadian Gas Association Study
Prepared by ICF

October 2019

ENERGY

IMPORTANT NOTICE:

This is a Canadian Gas Association (CGA) commissioned study prepared for the CGA by ICF. The CGA defined the cases to be evaluated, including major assumptions driving the timing and degree of electrification to be considered. The CGA also requested that ICF develop and use optimistic assumptions, based on third party sources related to the electrification technology costs and electric technology performance characteristics, to assess the impacts of electrification. ICF then analysed the implications and impacts of these in four scenarios. This scenario-based approach does not attempt to predict what is most likely to happen by 2050, but rather uses some boundary scenarios to highlight the impacts of different policy approaches. The Canadian Energy Regulator (CER) Energy Futures 2018 Reference Case, including energy prices and energy consumption trends, was used as the starting point for this analysis, and was combined with ICF's Integrated Planning Model (IPM®) for the analysis of electric generation capacity expansion.

This report and information and statements herein are based in whole or in part on information obtained from various sources. The study is based on public data on energy costs, costs of customer conversions to electricity, and technology cost trends, and ICF modeling and analysis tools to analyze the costs and emissions impacts of policy-driven electrification for each study scenario. Neither ICF nor CGA make any assurances as to the accuracy of any such information or any conclusions based thereon. Neither ICF nor CGA are responsible for typographical, pictorial or other editorial errors. The report is provided AS IS.

No warranty, whether express or implied, including the implied warranties of merchantability and fitness for a particular purpose is given or made by ICF or by CGA in connection with this report.

You use this report at your own risk. Neither ICF nor CGA are liable for any damages of any kind attributable to your use of this report.

FOREWORD ON STUDY ASSUMPTIONS

The goal of this study is to examine the impacts of a policy choice to replace natural gas and other fossil fuel use in Canada with electricity. Most of the assumptions pertain to those systems and their structures. In all cases these assumptions were deliberately ***'cost-conservative'*** meaning they were designed to not overstate the possible cost implications of such a policy choice.

The time frame under consideration is the period from 2020 to 2050. Electrification is assumed to begin in 2020 and to lead to near complete electrification of residential and commercial fossil fuel load by 2050, depending on the scenario being considered. The investments needed in the electricity system are assumed to proceed without delay with existing natural gas and electric end use equipment replaced at its normal usual end of life without any artificial acceleration that might make the transition to electricity appear more costly. The required additional electricity is assumed to come from a combination of renewable sources (wind and solar power) augmented and backed up with battery storage technologies to ensure the necessary 'dispatchability' for the electricity that will be needed.

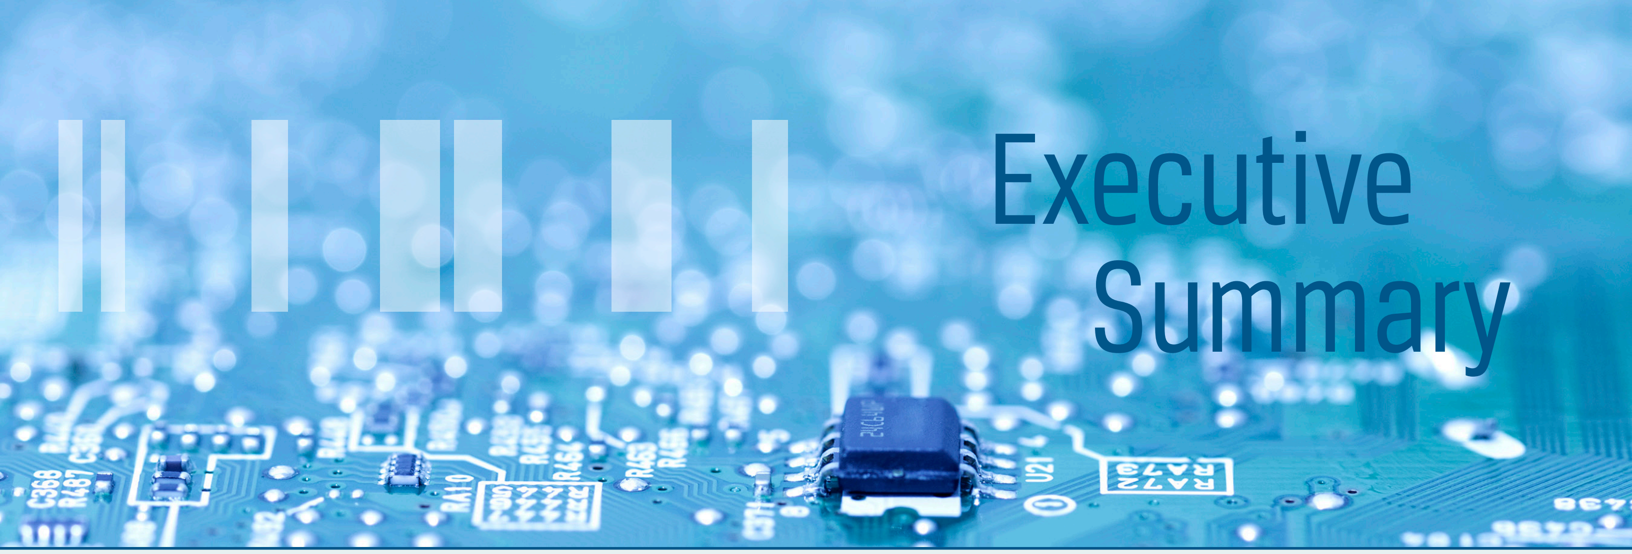
The starting reference case for the study is the Canadian Energy Regulator[1] 2018 Energy Futures Outlook. The study's scenarios then examine the impacts of a full move from natural gas and fossil fuels to electricity for residential use (e.g. space heating, water heating, cooking, etc.), for commercial use (in similar categories), for an assumed 50% of industrial natural gas and fossil fuel use that could most likely be electrified, and for significant electrification of motor vehicles. The study does not suggest this is a likely or even plausible future, it simply looks at the costs and requirements of a deliberate policy choice to electrify these elements of the natural gas and fossil fuel use.

These scenarios are based on aggressive assumptions regarding improvements in electric technology efficiency of performance and costs designed to hold down the costs of the electrification. To this end the National Renewable Energy Lab's (NREL) most aggressive outlook for the improved efficiencies of electric heat pump technologies was used. The NREL is a well-respected authority on future electrification technologies such as heat pumps. Heat pump technologies are assumed to improve from the current efficiency levels of 200-300% to achieve seasonal average efficiencies of 400-500% by 2050. Again, this is done to be deliberately cost-conservative as to the impacts on electricity requirements under a policy of electrification.

This study does not examine what the impacts or response from the natural gas and fossil fuel industry might be to an 'electrification policy'. Impacts on the natural gas systems' viability and its investors are not covered in this work. Similarly, the potential of new natural gas technologies, the impacts of electrification on the competitiveness of Canadian industry, the potential role of natural gas transmission and distribution infrastructure in enabling the future energy forms such as hydrogen, while important additional considerations, are not included within the scope of this analysis.

Certain costs have been 'excluded' from consideration in this study for cost-conservative reasons. The study did not consider the enhanced distribution system level infrastructure investment required to deliver incremental power load and assumes no change in price per unit of electricity. This approach means the resulting costs of electrification identified by this study are likely significantly understated, but a credible and comprehensive assessment of such added electricity distribution costs for the diverse regions of the country was not available at this time. Finally it is also important to note that the costs presented in this study are incremental to any costs embodied in the reference case.

[1] Formerly called the National Energy Board



Executive Summary

Moving away from an integrated multi-fuel, multi-grid energy system towards a fully electric single-grid system has been proposed in a number of jurisdictions as a pathway to significantly reduce Canada's greenhouse gas emissions. But, the viability of a policy of widespread electrification in Canada, in terms of the required new power infrastructure, the costs to households and businesses, and the relative cost and effectiveness of the GHG mitigation potential have not been comprehensively evaluated. With a goal of informing these aspects of this important discussion the Canadian Gas Association (CGA) engaged ICF to assess and illustrate the costs and benefits of several policy-driven electrification approaches in Canada.

Key Results from this Study:

- **A transition from current energy systems to high levels of mandated electrification will require a significant and costly expansion** of Canada's electrical infrastructure. Currently only 20% of Canada's energy requirements are met by electricity. Based on this analysis, replacing refined petroleum products and natural gas in homes, businesses, industry, and vehicles with electricity in Canada would require an expansion of generating capacity from 141 gigawatts (GW) today, to between 278 GW and 422 GW of capacity by 2050. This expansion, along with the associated incremental costs of added electric energy, electric technology adoption, new transmission infrastructure, and renewable natural gas (RNG), could increase national energy costs by between $580 billion to $1.4 trillion over the 30 year period between 2020 and 2050. These added requirements and their associated costs would be significantly higher were it not for the study's aggressive assumptions related to the improvement of electric end-use technologies (e.g., heat pumps) and assumed steep reductions in the heating load requirements of residential and commercial buildings.
- **Incremental costs associated with electrification will be driven by the need for the electricity system to meet a significantly increased peak load.** Critical energy infrastructure systems, including electricity and natural gas distribution systems are designed and implemented based on expected future demand and peak requirements. The design capacity of these systems is driven by the need to ensure reliability in extreme conditions. For example natural gas systems are typically designed to exceed the demand expected on the coldest day. It is understood that much of this infrastructure will rarely be required but must be in place for those extreme circumstances with the cost of that functionality being paid for by the energy end user. Replacing natural gas and fossil fuels in the transportation, residential, commercial, and industrial sectors of the Canadian economy via aggressive electrification is shown here to **increase peak electricity supply requirements to 287 GW by 2050 from 120 GW in the business as usual reference case.** This increase in energy demanded of the electric system and the significantly higher peak electric load requires significant additional electric system infrastructure to ensure reliable service at the peak design condition.
- **Not all types of electrification are equal.** If an electrification policy is not executed with consideration of the specific needs being met by each of the fuels it replaces, or the need for a reliable, sustainable, and affordable system, **the result could be an electrical system challenged to provide reliable service during the peak**

design condition at reasonable cost. This has led utilities and regulators to look for 'beneficial electrification'[2], that is electrification that saves consumers money over the longer term, reduces negative environmental impacts, and enables better grid management. Electrification is considered "beneficial" when it satisfies at least one of those conditions, without adversely affecting the other two.

Electrification initiatives need to be selective in their targets to meet these criteria. Consideration must be given to the pace of electrification, the amount of demand being converted to electricity, and the nature of local electrical infrastructure and supply. Some opportunities for electrification, such as in passenger commuter vehicles, could reduce operating and fuel costs, reduce GHG emissions, and have more limited impacts on system peak electric load (where utilities can stagger vehicle recharging). Conversely, other electrification opportunities, such as space heating, would only reduce GHG emissions in provinces with a sufficiently low emissions electric resource, and the cost of the added electric capacity required to reliably meet a new winter peaking load will be substantial.

- **GHG reduction policies that solely focus on electricity over gaseous fuels are more costly (\$289 / tCO_2) than approaches which allow for an integrated energy system to achieve GHG emission reductions (\$129 / tCO_2).** Canada's existing natural gas and low emitting electricity system and existing infrastructure combine effectively to serve different roles and together can be optimized for a reliable, affordable, low emissions solution. Natural gas infrastructure can continue to be leveraged for large peak loads on very cold days (when the efficiency of electric heating options drop), and in power generation to continue providing peak capacity. This integration enables lower cost use of intermittent renewables, drastically lowers the electric infrastructure requirements and costs compared to a scenario where gas is completely eliminated, and still achieves 90% of the GHG emission reductions seen in the significantly more costly electric-only scenario.

- **Local and regional context matters.** The costs and benefits of electrification vary considerably by province, and even by region within a province, making one-size fits all solutions ineffective and more expensive. Key regional factors must be considered when assessing whether or not electrification opportunities are 'beneficial' and ensure a reliable, affordable, and lower emitting energy system. These factors include local weather and climate, energy prices, local differences in the housing stock, the age and capacity of the existing electric generation, transmission, and distribution infrastructure, the GHG intensity of the electric grid, and the resource potential for non-emitting generation capacity.

Table 1: *Condensed Summary of Overall Impacts of Electrification*

	Scenario 1	Scenario 2	Scenario 3	Scenario 4
Scope of Electrification	Conversion of all residential and commercial space and water heating from natural gas and fossil fuels to electric heat pumps by 2050, all passenger vehicle sales to electric vehicles by 2040, and significant levels (50%) of electrification in the industrial sector.			Hybrid gas-electric heat pumps, only 25% industrial, and 10-15% RNG
Power Generation Impacts	252 GW of incremental capacity at cost of \$851 billion	232 GW of incremental capacity at cost of \$829 billion	169 GW of incremental capacity at cost of \$597 billion	108 GW of incremental capacity at cost of \$325 billion
Total Cost of Policy-Driven Electrification	Total energy costs increase by \$1.37 trillion	Total energy costs increase by \$1.33 trillion	Total energy costs increase by \$990 billion	Total energy costs increase by \$580 billion
GHG Emission Impacts	Annual CO_2 emissions reduced by 52% by 2050	Annual CO_2 emissions reduced by 47% by 2050	Annual CO_2 emissions reduced by 25% by 2050	Annual CO_2 emissions reduced by 47% by 2050
Cost of Emissions Reductions	\$289 per tonne of CO_2 reduction	\$291 per tonne of CO_2 reduction	\$411 per tonne of CO_2 reduction	\$129 per tonne of CO_2 reduction

TABLE OF CONTENTS

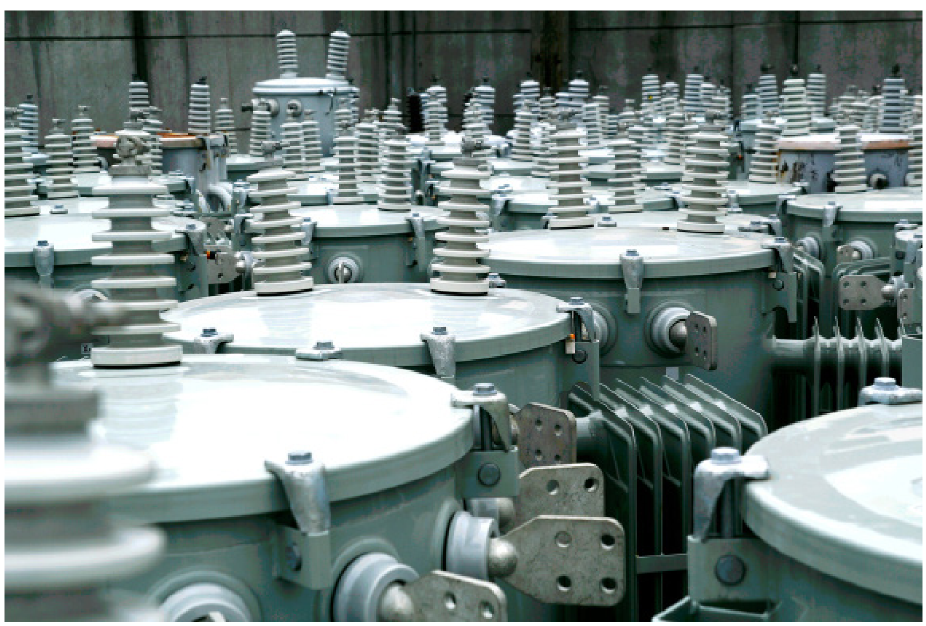
1 INTRODUCTION

Mitigation of greenhouse gas (GHG) emissions is a central tenet of most of the changes in Canadian energy policy currently under consideration. Much of this conversation has focused on the potential to transition away from natural gas and refined petroleum product use to just electricity. However the overall costs, benefits, and implications of potential policies for widespread electrification in Canada have not been comprehensively evaluated. The Canadian Gas Association (CGA) defined several policy-driven electrification scenarios and engaged ICF to assess and illustrate the costs and benefits, using optimistic assumptions for electric technology performance improvements. The study addresses three fundamental questions:

- What will be the impacts of policy-driven electrification on power sector infrastructure requirements?
- What will be the overall cost of policy-driven electrification?
- What would be the GHG emission impacts of policy-driven electrification?

This study's scenarios explore different combinations of technology options for customers on the demand side and different requirements for electricity generation on the supply side to achieve an overall reduction in GHG emissions. All of the scenarios are based on optimistic 'cost-conservative' assumptions regarding technology costs and performance for renewable power, power storage, electric heat pumps, and other electrification technologies considered.

This study does not attempt to predict what is most likely to happen by 2050, nor determine the lowest cost pathway to meet a specific GHG reduction target. Instead, the study compares several boundary scenarios to contrast the impacts resulting from a number of different technology pathways.



2 OVERVIEW OF THE CANADIAN ENERGY LANDSCAPE

In order to understand the impacts of an electrification policy for Canada, it is critical to understand what fuels Canada currently uses to meet its energy requirements. **Figure 1** below highlights the breakdown in 2018 end use energy consumption, based on the most recent Canadian Energy Regulator 2018 Energy Futures report. Electricity currently provides 19% of the country's energy needs – significantly less than natural gas (39%) and refined petroleum products, mainly gasoline & diesel (35%). This highlights the scale of transformation that widespread electrification of fossil fuels would require.

***Figure 1:** Breakdown of 2018 End Use Energy Consumption in Canada*[3]

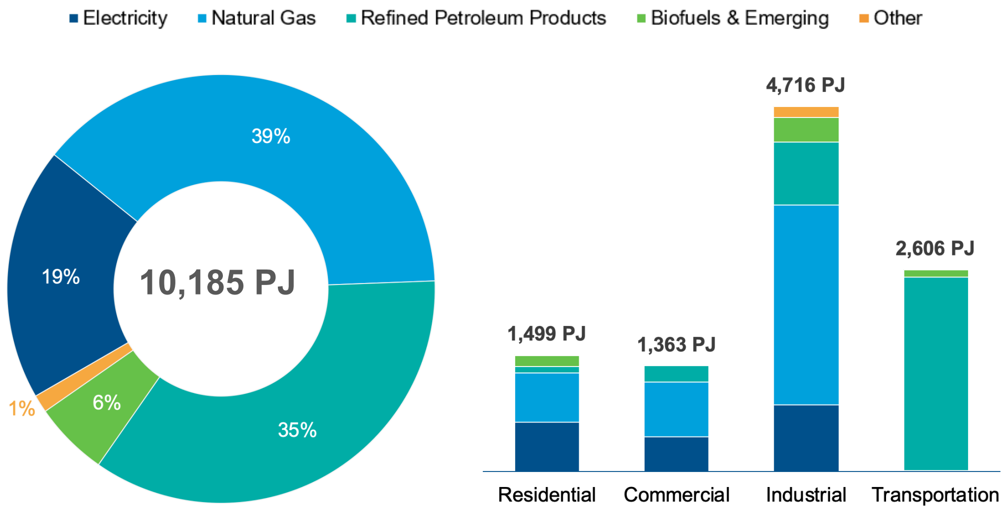


Figure 1 above also highlights the relative consumption of different fuel types in the major sectors of the Canadian economy, showing natural gas is the main source of energy in all sectors except transportation.

- **Residential:** Space heating represents most of the natural gas and refined petroleum products (RPPs) use in the residential sector, with about 7 million households[4] (~50%) in Canada using natural gas as their primary source of heat. Water heating and other uses like cooking also contribute to natural gas load.
- **Commercial:** Space heating represents the largest use of natural gas and RPPs in the commercial sector as well, followed by water heating and cooking.
- **Industrial:** Manufacturing and industrial processes are often energy intensive, with this sector using almost as much energy as the other three combined. 75% of industrial energy comes from fossil fuels, making this a critical area for GHG emission reductions.
- **Transportation:** Cars, trucks, trains, planes, and other forms of transportation represent the second largest energy consuming sector – and since 96% of this energy is derived from fossil fuels the transportation sector represents a major portion of Canada's GHG emissions.

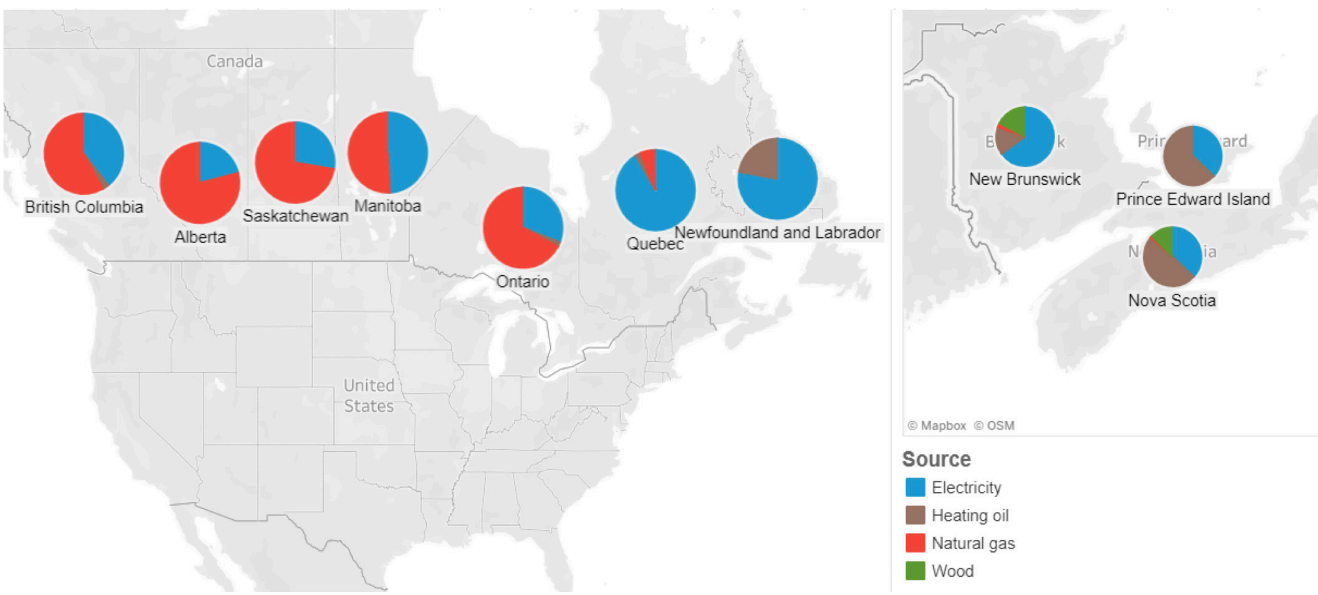
[3]Canada Energy Regulator (CER), "Canada's Energy Future 2018: Energy Supply and Demand Projections to 2040", https://www.cer-rec.gc.ca/nrg/ntgrtd/ftr/2018/index-eng.html - with 300PJ/year and 1,150 PJ/year of natural gas and RPPs, respectively, removed from the total to account for non-energy consumption of these fuels that is included in CER numbers.

[4]Natural Resources Canada (NRCan), "Comprehensive Energy Use Database – Residential Sector, Table 20", http://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/showTable.cfm?type=CP&sector=res&juris=ca&rn=20&page=0#footnotes

Energy use and energy sources also vary significantly by province. Provincial electricity and natural gas distribution grids each face very different circumstances. As such, though not reported here, a full analysis of potential electrification opportunities and impacts would need to be conducted at a provincial level to properly reflect these major differences – including differences in existing infrastructure levels, existing electricity and fossil fuel requirements, efficiency of buildings, energy prices, the GHG intensity of the province's electric grid, and the province's specific seasonal temperature levels.

Figure 2 highlights one such important difference by province, namely the type of fuel used for space heating in the residential sector. While natural gas is the primary source of space heating for homes in British Columbia, Alberta, Saskatchewan, and Ontario – in Quebec and New Brunswick the majority of households use electricity while fuel oil heating is the primary choice in Nova Scotia. These space heating differences have major impacts on the cost and opportunity for electrification in those provinces.

Figure 2: *Comparison of Primary Energy Source used for Residential Heating by Province*[5]



3 ELECTRIFICATION SCENARIOS IN THIS STUDY

Table 2 provides an overview of the four different 'electrification' scenarios compared to the 'business as usual" reference case. The scenarios all include a high level of electrification – converting all natural gas and fossil fuel residential and commercial space and water heating to electric heat pumps or hybrid heat pump gas furnaces by 2050, all passenger vehicle sales to electric vehicles (EVs) by 2040, and significant levels of electrification in the industrial sector.

[5]Canada Energy Regulator (CER), "What is in a Canadian residential natural gas bill?", Figure 1: Energy source used for heating – primary heating system by Province, available at: https://www.cer-rec.gc.ca/nrg/sttstc/ntrlgs/rprt/cndnrsdntlntrlgsbll/index-eng.html (the reproduction of this figure has not been produced in affiliation with, or with the endorsement of the CER)

Scenarios 1-3 involve the same level of electric load growth – but showcase the impact of three different policy scenarios for how the electricity generation requirements would be met.

Scenario 4 differs in that natural gas is maintained as a back-up fuel for heat pumps on cold days (thus limiting peak electric load growth), industrial electrification is more limited, natural gas vehicles supplement EVs, and renewable natural gas (RNG) is brought in to lower GHG emissions from natural gas use. By design **scenario 4** power generation emissions were capped to provide the same overall emissions reduction as **scenario 2.**

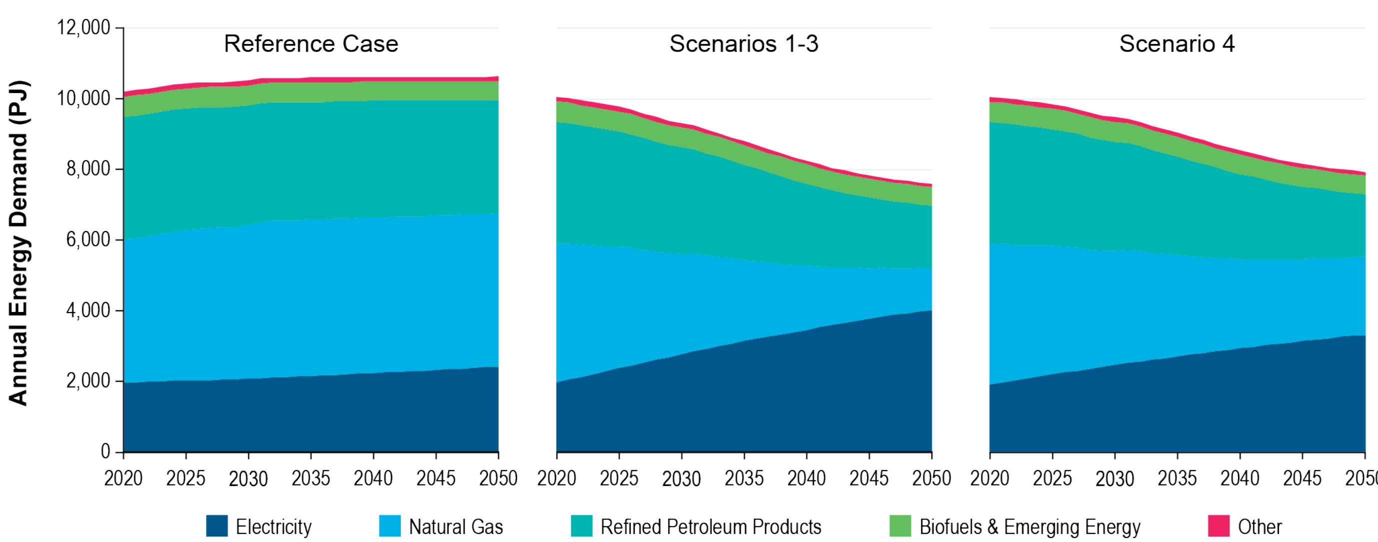
Table 2: *Scenario Descriptions*

Scenario 1 Renewables-Only	Scenario 2 Renewables & Existing Gas	Scenario 3 Market-Based Generation	Scenario 4 Integrated Energy Systems
Aggressive electrification & wind, solar, and battery storage replace all fossil fuel generation by 2050	Aggressive electrification & all new power generation capacity is wind, solar, and battery storage, but existing natural gas & oil power generation maintained	Aggressive electrification & all power generation expansion uses the most economic options	Alternative electrification approaches allowing fossil fuels to meet peak loads while driving GHG emission reductions

More details on each of the scenarios can be found in **Appendix A** and **Appendix C**. While the impacts of electrification were analyzed at a provincial level, the results are presented as an aggregate of the provinces covered in this study.[6]

Figure 3 illustrates the transition in Canada's energy consumption under each scenario. Whereas the reference case has modest growth in energy consumption to 2050, **scenarios 1-3 and 4** present a broad-based shift to the use of renewable electricity and electricity storage and an overall reduction in energy consumption. While electricity (dark blue) currently provides around 20% of energy requirements, widespread electrification nearly doubles the electricity needed in **scenarios 1-3** by 2050, even allowing for significant improvements in energy efficiency of electricity end uses.

Figure 3: *Change in Annual Energy Demand from 2020 to 2050*



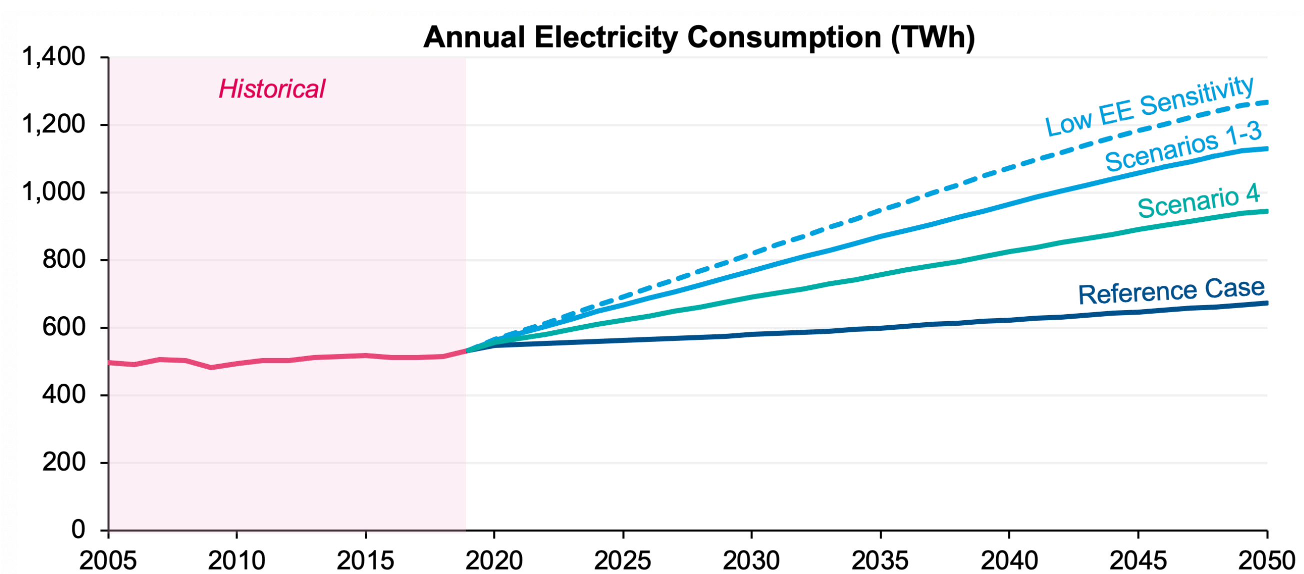
[6]Newfoundland and Labrador, Prince Edward Island, and the territories are not included in the results of this study – as natural gas distribution infrastructure is not present in these provinces.

4 GROWTH IN ANNUAL ELECTRICITY CONSUMPTION

Figure 4 illustrates historical levels of total electricity consumption as well as the growth in annual electricity consumption in each of the study's scenarios:

- Historically, from 2005 to 2018, annual electricity consumption was relatively stable.
- In the **reference case** annual electricity consumption increases at a modest pace, rising from 532 TWh in 2019 to 672 TWh in 2050.
- In **scenarios 1-3** annual electricity consumption rises to 1,130 TWh in 2050 – doubling from 2020, based on electrification in the residential, commercial, industrial, and transportation sectors.
- In **scenario 4** annual electricity consumption rises to 944 TWh in 2050, which is roughly 70% of the load growth seen in **scenarios 1-3**. This is because **scenario 4** assumes that Canadians install air-source heat pumps with natural gas (or other fossil fuels) as a back-up, and on average rely on this back-up fuel for 20% of heating needs. This reduction also reflects lower levels of industrial electrification in this scenario.
- In **scenarios 1-3** the growth in electricity consumption is held down by aggressive assumptions for the improvement in heat pump efficiency, rapid improvements in building shell efficiency, and the upgrade of inefficient electric resistance heating to heat pumps. The dashed blue **Low Energy Efficiency (EE) Sensitivity** line shows the change to **scenario 1-3** impacts without these 'electrification enabling' assumptions. Under these conditions annual electricity consumption rises to 1,266 TWh in 2050, or 12% higher.

Figure 4: Overall Annual Electricity Consumption



5
THE IMPORTANCE OF PEAK ELECTRIC LOAD

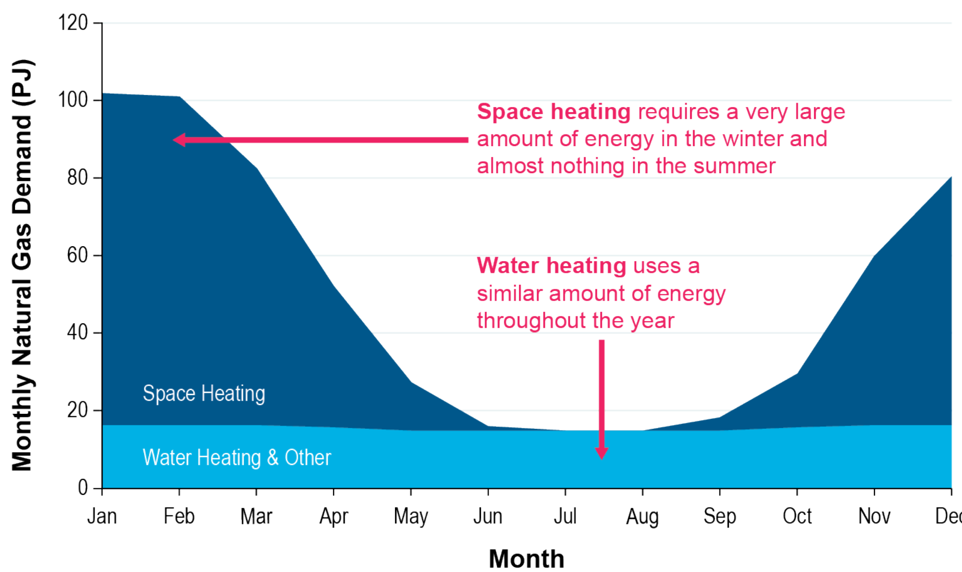
The challenge with electrification is meeting peak load, not just annual energy requirements, because it's peak load that drives infrastructure requirements and costs. In critical energy infrastructure systems, including our electricity and natural gas distribution systems, infrastructure costs are driven by the need to meet peak demand and ensure reliability in extreme conditions – for example, when temperatures drop to -40°C. Even though much of the required infrastructure might only be needed for a very short time, it needs to be in place to ensure system reliability and, in turn, consumer heating safety.

Electrification policy needs to be designed with consideration of the specific nature of the demand met by each of the fuels it seeks to replace, and with consideration of the need for a reliable, sustainable, and affordable system, or the result could be an ineffective electrical system unable to meet critical peak demands. Electrification initiatives need to be selective to avoid negatively impacting grid reliability.

Figure 5 highlights how some energy requirements, like space heating, are weather-driven and hence very concentrated in the few coldest months of the year. Electrifying these loads has a disproportionally large impact on peak electric load, relative to its annual consumption, because a tremendous amount of energy is required to meet space heating requirements when it is very cold. This addition of peak load to the grid makes it challenging for space heating electrification to meet the beneficial criteria.

In addition to the seasonal variation of the energy requirements, another important consideration is how 'manageable' the energy load is. If a utility can add new load without creating a new peak, or can 'shift load' to fill in the valleys between existing high demand periods, then it can better utilize its existing infrastructure and meet the incremental load without requiring major investments in new infrastructure. The ability for a utility to control the timing of load, for example ensuring electric vehicles charge at night when other electricity demands are low, could minimize increases to peak load without impacting system reliability.

***Figure 5:** Comparison of Monthly Natural Gas Consumption Patterns*



WHAT ARE HEAT PUMPS?

An air-source heat pump (ASHP) looks like an air-conditioning unit sitting in your backyard - but can both heat and cool your home.

ASHP efficiency varies based on the temperature outside – since the unit is extracting heat from that air.

ASHPs can be very efficient (300%-500%) in mild temperatures but rely on less efficient (100%) electric-resistance back-up when it gets very cold outside and the ASHP cannot pull in enough heat from that cold air.

Cold-climate ASHPs are designed to operate more efficiently at lower temperatures but will still rely on back-up heating below certain temperatures.

While demand response efforts that would enable load to be shifted to "off-peak" periods are being considered by both the power and natural gas industries, to date, there have been only limited options for reducing space heating load on peak days. The inherent 'peakiness' of space heating energy requirements make it more challenging to electrify without the need for additional infrastructure. After widespread electrification, there would be much larger spikes in load that would occur when temperatures hit extreme cold – a situation that natural gas distribution and storage infrastructure currently handles in many provinces. The magnitude of such peaks is highlighted by the distribution of heating load by temperature presented in **Figure 6.** This figure shows that while energy infrastructure is required to plan for temperatures as cold as -40°C in some provinces, infrastructure built for such situations will infrequently be required. Overall in Canada, temperatures below -25°C represent just 1.4% of the heat demand, while temperatures below -10°C represent around 20% of the heat demand.

While these percentages vary significantly by province, this forms part of the logic for using hybrid gas-electric heat pumps, that use natural gas for the coldest 20% of the heat demand allowing peak electric infrastructure to be designed to accommodate temperatures of just -10°C and not -40°C.

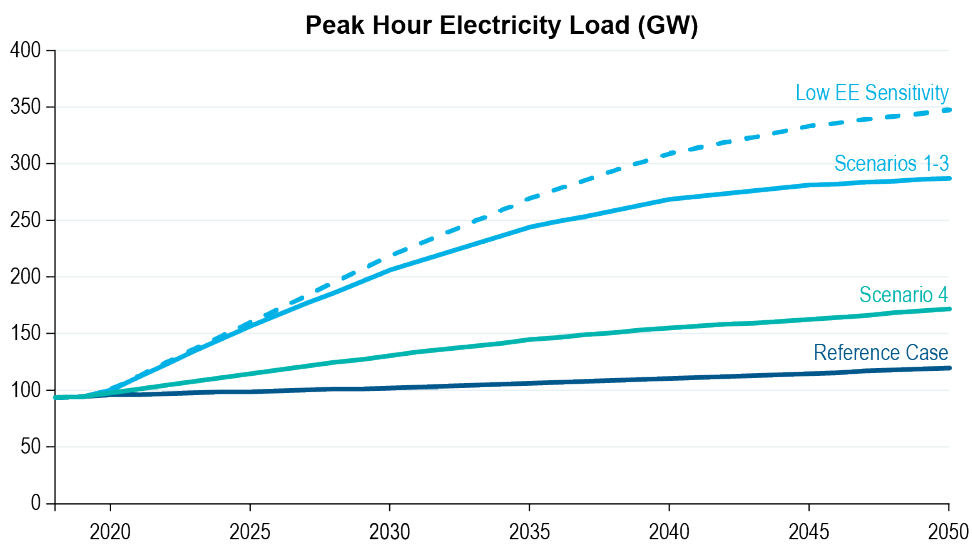
6
GROWTH IN PEAK ELECTRIC LOAD

Figure 7 shows the growth in peak electric load in each of the study's scenarios:

- In **scenarios 1-3** the total peak electricity load from the residential, commercial, industrial, and transportation sectors rises to 287 GW in 2050 – tripling from 91 GW in 2020. That growth occurs despite assuming that Canadian households and businesses install the most-efficient cold-climate air-source heat pumps available to them, whose efficiencies are assumed to improve rapidly over the study period through significant R&D developments[7], and the assumption of significant improvements to energy efficiency in the building stock.
- In **scenario 4** the incremental peak load growth is 56 GW, or roughly a third of the other scenarios. This is because this scenario assumes that Canadians install conventional air-source heat pumps but maintain natural gas (or other fossil fuels) as a back-up – allowing for electric heating most of the year, but relying on natural gas distribution infrastructure to continue dealing with spikes in heating requirements on cold days. This reduction also reflects lower levels of industrial electrification in this scenario.
- In **scenarios 1-3** the growth in electricity capacity requirements is held down by aggressive assumptions for the improvement in heat pump efficiency and rapid improvements in building shell efficiency. The dashed blue **Low Energy Efficiency (EE) Sensitivity** line shows the change to **scenario 1-3** impacts if energy efficiency was reduced and heat pump technology did not improve from the current performance levels of the top cold-climate air-source heat pumps. Under these conditions the peak electricity needs rise to 345 GW in 2050.

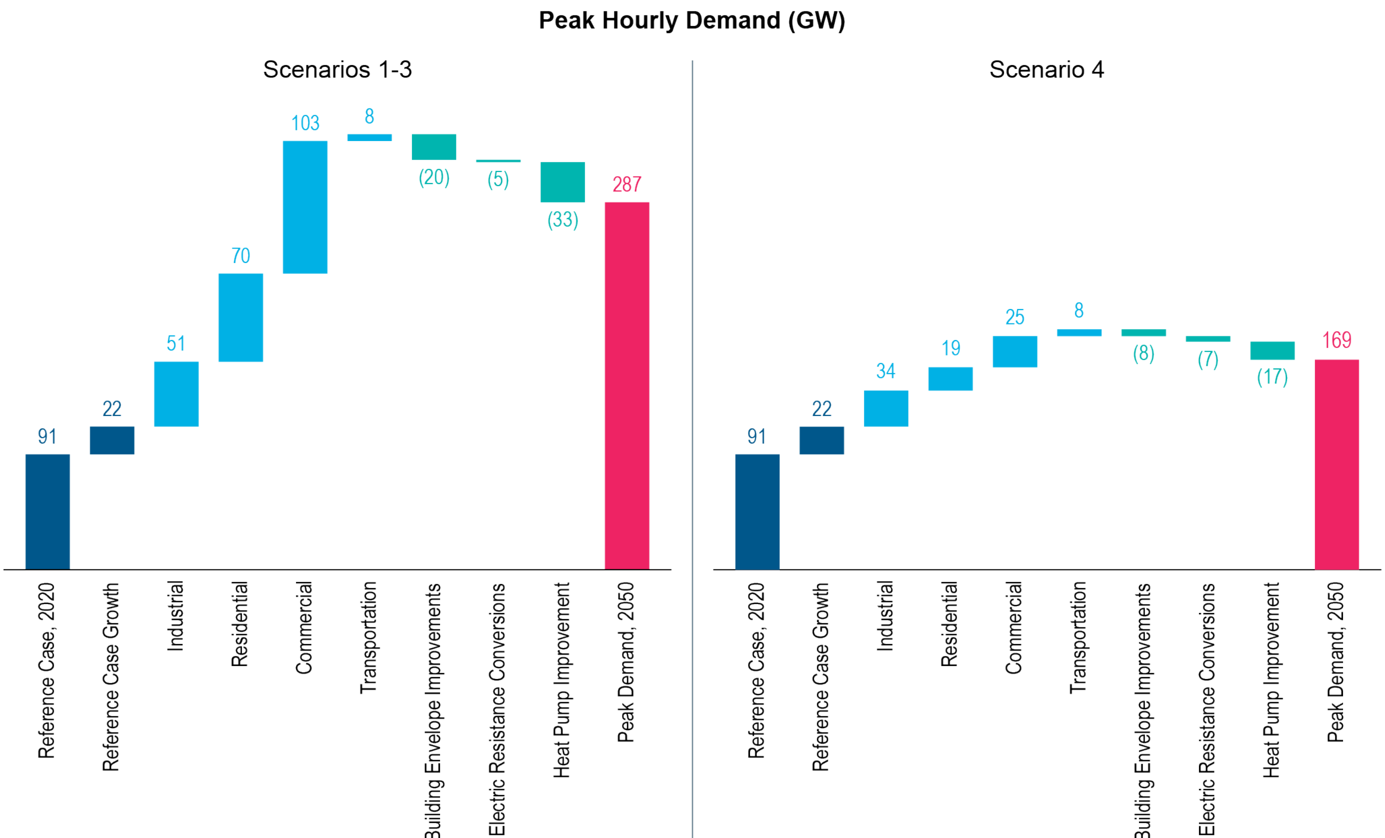
Figure 7: Overall Peak Hour Electricity Load



[7] For scenarios 1 through 3 in this study, cold-climate air-source heat pumps with major improvements in efficiency over time, were modeled to replace fossil fuel furnaces, as well as 75% of existing heat pumps and electric resistance heaters. The heat pump efficiency improvements made to 2050 are consistent with the 'rapid advancement' trajectory from NREL's 2017 Electrification Futures Study (https://www.nrel.gov/docs/fy18osti/70485.pdf).

The specific components of these peak load impacts are highlighted in **Figure 8** which compares the electricity requirements on the 2050 peak day in each scenario. Building on top of the reference case growth in electric demand (dark blue), the peak contributions of industrial, residential, commercial, and transportation electrification are stacked (light blue). The teal categories show the reductions in peak day requirements due to energy efficiency and technology improvements assumed to reduce the overall peak demand growth requirements in these scenarios.

***Figure 8:** Components of Incremental Peak Electricity Load*



Scenarios 1-3 on the left rely on **all electric heating, based primarily on highly efficient cold climate heat pumps**. Despite the significant improvement in heat pump performance assumed in this study (a near doubling of average seasonal efficiency by 2050), an all-electric space heating scenario would result in significantly higher peak loads for the residential and commercial sectors on the coldest days of the year, when even high-efficiency air-source heat pumps operate less efficiently.
